Sol. Here, put $x = \frac{1}{y}$ in $\lim_{x \to \infty} \left\{x - x^2 \cdot \log\left(1+\frac{1}{x}\right)\right\}$

$$= \lim_{y \to 0} \left\{\frac{1}{y} - \frac{\log(1+y)}{y^2}\right\}$$

$$= \lim_{y \to 0} \frac{y - \log(1+y)}{y^2}$$

$$= \lim_{y \to 0} \frac{y - \left\{y - \frac{y^2}{2} + \frac{y^3}{3} - \frac{y^4}{4} + \ldots\right\}}{y^2}$$

$$= \lim_{y \to 0} \frac{y^2\left\{\frac{1}{2} - \frac{y}{3} + \ldots\right\}}{y^2}$$

$$= \lim_{y \to 0} \left\{\frac{1}{2} - \frac{y}{3} + \ldots\right\} = \frac{1}{2}$$

Remark

If we solve above question as

$$\lim_{y \to 0} \left\{\frac{1}{y} - \frac{\log(1+y)}{y^2}\right\} = \lim_{y \to 0} \left\{\frac{1}{y} - \frac{\log(1+y)}{y} \cdot \frac{1}{y}\right\}$$

$$\left[\text{as } \lim_{y \to 0} \frac{\log(1+y)}{y} = 1\right]$$

$$= \lim_{y \to 0} \left(\frac{1}{y} - \frac{1}{y}\right) = 0, \text{ then it is not correct.}$$

Exponential Limits

There are two types of exponential limits discussed below

(i) Based on Series Expansion

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \ldots \infty$$

To evaluate the exponential limit, we use the following results.

(a) $\lim_{x \to 0} \frac{e^x - 1}{x} = 1$ **(b)** $\lim_{x \to 0} \frac{a^x - 1}{x} = \log_e a$

Example 34 Evaluate $\lim_{x \to 0} \frac{a^x - b^x}{x}$.

Sol. We have, $\lim_{x \to 0} \frac{a^x - b^x}{x} = \lim_{x \to 0} \frac{(a^x - 1) - (b^x - 1)}{x}$

$= \lim_{x \to 0} \frac{a^x - 1}{x} - \lim_{x \to 0} \frac{b^x - 1}{x} = \log a - \log b = \log (a / b)$

Example 35 Evaluate $\lim_{x \to 0} \frac{(ab)^x - a^x - b^x + 1}{x^2}$.

Sol. We have, $\lim_{x \to 0} \frac{(ab)^x - a^x - b^x + 1}{x^2} = \lim_{x \to 0} \frac{a^x b^x - a^x - b^x + 1}{x^2}$

$= \lim_{x \to 0} \frac{a^x (b^x - 1) - (b^x - 1)}{x^2}$

$= \lim_{x \to 0} \frac{(a^x - 1)}{x} \times \lim_{x \to 0} \frac{(b^x - 1)}{x} = \log a \times \log b$

$\left[\because \lim_{x \to 0} \frac{a^x - 1}{x} = \log_e a \right]$

Example 36 Evaluate $\lim_{x \to 0} \frac{e^{\tan x} - e^x}{\tan x - x}$.

Sol. We have, $\lim_{x \to 0} \frac{e^{\tan x} - e^x}{\tan x - x} = \lim_{x \to 0} \frac{e^x \times e^{(\tan x - x)} - e^x}{(\tan x - x)}$

$= \lim_{x \to 0} \frac{e^x \{e^{\tan x - x} - 1\}}{(\tan x - x)}$

$= e^0 \times 1$ [as $x \to 0, \tan x - x \to 0$]

$= 1 \times 1 = 1$

Example 37 Evaluate $\lim_{x \to 0} \frac{ae^x - b}{x} = 2$. Find a and b.

Sol. Given, $\lim_{x \to 0} \frac{ae^x - b}{x} = \lim_{x \to 0} \frac{a\left(1 + \frac{x}{1!} + \frac{x^2}{2!} + \ldots \infty\right) - b}{x} = 2$

$\Rightarrow \lim_{x \to 0} \frac{(a - b) + xa + \frac{ax^2}{2!} + \ldots \infty}{x} = 2$

Since, limit is finite, so $(a - b) = 0 \Rightarrow b = a$

$\therefore \lim_{x \to 0} \frac{xa + \frac{ax^2}{2!} + \ldots \infty}{x} = 2$

$\Rightarrow \lim_{x \to 0} a + \frac{ax}{2!} + \ldots \infty = 2 \Rightarrow a = 2$

$\therefore b = 2$

Example 38 Solve $\lim_{x \to 0} \frac{a \sin x - bx + cx^2 + x^3}{2x^2 \log (1 + x) - 2x^3 + x^4}$, if it exists and is finite, also find a, b and c.

Sol. Let $L = \lim_{x \to 0} \frac{a \sin x - bx + cx^2 + x^3}{2x^2 \log (1 + x) - 2x^3 + x^4}$

$= \lim_{x \to 0} \frac{a\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \ldots\right) - bx + cx^2 + x^3}{2x^2\left(x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \ldots\right) - 2x^3 + x^4}$

$= \lim_{x \to 0} \frac{(a - b)x + cx^2 + \left(1 - \frac{a}{3!}\right)x^3 + \frac{a}{5!}x^5 + \ldots}{\frac{2}{3}x^5 - \frac{1}{2}x^6 + \ldots}$

For finite limit, $a - b = 0, c = 0, 1 - \frac{a}{3!} = 0$, i.e. $a = b = 6, c = 0$]

$\therefore L = \lim_{x \to 0} \frac{\frac{a}{5!} + \text{higher powers of } x}{\frac{2}{3} - \frac{1}{2}x + \cdots}$

$= \frac{a}{5!} \cdot \frac{3}{2} = \frac{a}{80} = \frac{6}{80} = \frac{3}{40}$ [$\because a = 6$]

So, $\lim_{x \to 0} \frac{a \sin x - bx + cx^2 + x^3}{2x^2 \log (1 + x) - 2x^3 + x^4} = \frac{3}{40}$

Where, $a = 6 = b, c = 0$

Example 39 Find the values of a, b and c such that

$$\lim_{x \to 0} \frac{axe^x - b \log (1 + x) + cxe^{-x}}{x^2 \sin x} = 2.$$

Sol. We have, $\lim_{x \to 0} \frac{axe^x - b \log (1 + x) + c\, xe^{-x}}{x^2 \sin x} = 2$

Using the expansion, we have

$$\lim_{x \to 0} \frac{\left[ax\left(1 + x + \frac{x^2}{2!} + \ldots\right) - b\left(x - \frac{x^2}{2} + \frac{x^3}{3} - \ldots\right) + cx\left(1 - \frac{x}{1!} + \frac{x^2}{2!} - \frac{x^3}{3!} + \ldots\right) \right]}{x^2\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \ldots\right)} = 2$$

$$\lim_{x\to 0}\frac{x(a-b+c)-x^2\left(a+\frac{b}{2}-c\right)+x^3\left(\frac{a}{2}-\frac{b}{3}+\frac{c}{2}\right)+\ldots}{x^2\left(x-\frac{x^3}{3!}+\frac{x^5}{5!}-\ldots\right)}=2$$

Now, above limit would exist, if least power in numerator is greater than or equal to least power in denominator, i.e. Coefficient of x and x^2 must be zero and coefficient of x^3 should be 2.

i.e. $a-b+c=0, a+\frac{b}{2}-c=0, \quad \frac{a}{2}-\frac{b}{3}+\frac{c}{2}=2$

On solving, we get $a=3, b=12, c=9$.

(ii) Evaluation of Exponential Limits of the Form 1^∞

To evaluate the exponential limits of the form 1^∞, we use the following results.

If $\lim_{x\to a} f(x)=\lim_{x\to a} g(x)=0$,

then $\lim_{x\to a}\{1+f(x)\}^{1/g(x)}=e^{\lim_{x\to a}\frac{f(x)}{g(x)}}$

or when $\lim_{x\to a} f(x)=1$ and $\lim_{x\to a} g(x)=\infty$

Then, $\lim_{x\to a}\{f(x)\}^{g(x)}=\lim_{x\to a}[1+f(x)-1]^{g(x)}$

$$=e^{\lim_{x\to a}(f(x)-1)\,g(x)}$$

Particular Cases

(i) $\lim_{x\to 0}(1+x)^{1/x}=e$ (ii) $\lim_{x\to\infty}\left(1+\frac{1}{x}\right)^x=e$

(iii) $\lim_{x\to 0}(1+\lambda x)^{1/x}=e^\lambda$ (iv) $\lim_{x\to\infty}\left(1+\frac{\lambda}{x}\right)^x=e^\lambda$

Example 40 Evaluate $\lim_{x\to\infty}\left(1+\frac{2}{x}\right)^x$.

Sol. We have, $\lim_{x\to\infty}\left(1+\frac{2}{x}\right)^x=e^{\lim_{x\to\infty}\frac{2}{x}x}=e^2$ [1^∞ form]

Example 41 Evaluate $\lim_{x\to 1}(\log_3 3x)^{\log_x 3}$.

Sol. We have, $\lim_{x\to 1}(\log_3 3x)^{\log_x 3}=\lim_{x\to 1}(\log_3 3+\log_3 x)^{\log_x 3}$

$$=\lim_{x\to 1}(1+\log_3 x)^{1/\log_3 x}\qquad\left[\text{as }\log_b a=\frac{1}{\log_a b}\right]$$

$$=e^{\lim_{x\to 1}\log_3 x\times\frac{1}{\log_3 x}}$$

$$=e^1$$

Example 42 ***Evaluate*** $\lim_{x\to a}\left(2-\frac{a}{x}\right)^{\tan\frac{\pi x}{2a}}$.

Sol. We have, $\lim_{x\to a}\left(2-\frac{a}{x}\right)^{\tan\frac{\pi x}{2a}}$

$$=\lim_{x\to a}\left\{1+\left(1-\frac{a}{x}\right)\right\}^{\tan\frac{\pi x}{2a}}=e^{\lim_{x\to a}\left(1-\frac{a}{x}\right)\cdot\tan\frac{\pi x}{2a}}\qquad[1^\infty\text{ form}]$$

$$=e^{\lim_{x\to a}\left(\frac{x-a}{x}\right)\cdot\tan\frac{\pi x}{2a}}=e^{\lim_{x\to a}f(x)}\qquad\ldots(i)$$

Let $x-a=h$, we get

$$e^{\lim_{h\to 0}\left(\frac{h}{a+h}\right)\cdot\tan\frac{\pi}{2a}(a+h)}=e^{\lim_{h\to 0}\frac{h}{a+h}\cdot\tan\left(\frac{\pi}{2}+\frac{\pi h}{2a}\right)}$$

$$=e^{\lim_{h\to 0}\frac{h}{a+h}\left[-\cot\left(\frac{\pi h}{2a}\right)\right]}=e^{\lim_{h\to 0}\frac{-h}{(a+h)\tan(\pi h/2a)}\cdot\frac{\pi}{2a}\cdot\frac{1}{\pi/2a}}$$

$$=e^{\lim_{h\to 0}\frac{-2a}{\pi(a+h)}\cdot\frac{\pi h/2a}{\tan(\pi h/2a)}}=e^{\frac{-2a}{\pi(a)}}=e^{-2/\pi}\qquad\left[\text{as }\lim_{x\to 0}\frac{x}{\tan x}=1\right]$$

Example 43 Evaluate $\lim_{x\to\infty}\left(\frac{x+6}{x+1}\right)^{x+4}$.

Sol. We have, $\lim_{x\to\infty}\left(\frac{x+6}{x+1}\right)^{x+4}$

As $x\to\infty$, $\lim_{x\to\infty}\frac{x+6}{x+1}=1$ and $(x+4)\to\infty$ [1^∞ form]

$$\therefore\ \lim_{x\to\infty}\left(\frac{x+6}{x+1}\right)^{x+4}=\lim_{x\to\infty}\left[1+\left(\frac{x+6}{x+1}-1\right)\right]^{x+4}$$

$$=\lim_{x\to\infty}\left[1+\frac{5}{x+1}\right]^{x+4}=e^{\lim_{x\to\infty}\left(\frac{5}{x+1}\right)\cdot(x+4)}$$

$$=e^{\lim_{x\to\infty}5\cdot\frac{x+4}{x+1}}=e^{5\cdot(1)}=e^5\qquad\left[\text{as }x\to\infty;\ \lim_{x\to\infty}\frac{x+4}{x+1}=1\right]$$

Example 44 Evaluate $\lim_{x\to 0}(1+\tan^2\sqrt{x})^{\frac{1}{2x}}$.

Sol. We have, $\lim_{x\to 0}(1+\tan^2\sqrt{x})^{\frac{1}{2x}}=e^{\lim_{x\to 0}\tan^2\sqrt{x}\cdot\frac{1}{2x}}$

$$=e^{\frac{1}{2}\lim_{x\to 0}\left(\frac{\tan\sqrt{x}}{\sqrt{x}}\right)^2}=e^{1/2}\qquad\left[\text{as }\lim_{x\to 0}\frac{\tan x}{x}=1\right]$$

Example 45 ***Evaluate*** $\lim_{x\to 0}\left\{\tan\left(\frac{\pi}{4}+x\right)\right\}^{\frac{1}{x}}$.

[IIT JEE 1993]

Sol. We have, $\lim_{x\to 0}\left\{\tan\left(\frac{\pi}{4}+x\right)\right\}^{\frac{1}{x}}=\lim_{x\to 0}\left\{\frac{\tan\frac{\pi}{4}+\tan x}{1-\tan\frac{\pi}{4}\tan x}\right\}^{\frac{1}{x}}$

$$= \lim_{x\to 0}\left\{\frac{1+\tan x}{1-\tan x}\right\}^{\frac{1}{x}} = \lim_{x\to 0}\left\{1+\frac{2\tan x}{1-\tan x}\right\}^{\frac{1}{x}}$$

$$= e^{\lim_{x\to 0}\left(\frac{2\tan x}{1-\tan x}\right)\cdot\frac{1}{x}} = e^{\lim_{x\to 0} 2\cdot\frac{\tan x}{x}\cdot\frac{1}{1-\tan x}} = e^2$$

Example 46 Evaluate $\lim_{x\to 0}\left(\frac{1+5x^2}{1+3x^2}\right)^{1/x^2}$. *[IIT JEE 1996]*

Sol. We have, $\lim_{x\to 0}\left(\frac{1+5x^2}{1+3x^2}\right)^{1/x^2} = \lim_{x\to 0}\left(1+\frac{2x^2}{1+3x^2}\right)^{1/x^2}$ [1^∞ form]

$$= e^{\lim_{x\to 0}\left(\frac{2x^2}{1+3x^2}\right)\cdot\frac{1}{x^2}} = e^{\frac{2}{1+0}} = e^2$$

Example 47 ***Evaluate*** $\lim_{x\to\infty}\left(\frac{x-3}{x+2}\right)^x$. *[IIT JEE 2000]*

Sol. We have, $\lim_{x\to\infty}\left(\frac{x-3}{x+2}\right)^x = \lim_{x\to\infty}\left(1+\frac{(-5)}{x+2}\right)^x$

$$= e^{\lim_{x\to\infty}\left(\frac{-5}{x+2}\right)\cdot x} \qquad = e^{\lim_{x\to\infty}\frac{-5}{1+\frac{2}{x}}} = e^{-5}$$

Example 48 The value of

$$\lim_{x\to 0}\left\{\sin^2\left(\frac{\pi}{2-ax}\right)\right\}^{\sec^2\frac{\pi}{2-bx}}$$ is equal to

(a) $e^{-a/b}$ (b) e^{-a^2/b^2} (c) $a^{2a/b}$ (d) $e^{4a/b}$

Sol. Here, $\lim_{x\to 0}\left(\sin^2\left(\frac{\pi}{2-ax}\right)\right)^{\sec^2\left(\frac{\pi}{2-bx}\right)}$

$$= \lim_{x\to 0}\left\{1-\cos^2\left(\frac{\pi}{2-ax}\right)\right\}^{\sec^2\left(\frac{\pi}{2-bx}\right)}$$ [1^∞ form]

$$= e^{\lim_{x\to 0}-\left\{\cos^2\left(\frac{\pi}{2-ax}\right)\cdot\frac{1}{\cos^2\left(\frac{\pi}{2-bx}\right)}\right\}}$$

$$= e^{\lim_{x\to 0}-\left\{\frac{2\sin\left(\frac{\pi}{2-ax}\right)\cos\left(\frac{\pi}{2-ax}\right)}{2\sin\left(\frac{\pi}{2-bx}\right)\cos\left(\frac{\pi}{2-bx}\right)}\times\frac{\pi a}{(2-ax)^2}\cdot\frac{}{}\times\frac{\pi b}{(2-bx)^2}\right\}}$$

[using L'Hospital's rule]

$$= e^{-\lim_{x\to 0}\frac{\sin\left(\frac{2\pi}{2-ax}\right)}{\sin\left(\frac{2\pi}{2-bx}\right)}\cdot\frac{a}{b}\cdot\frac{(2-bx)^2}{(2-ax)^2}} = e^{-\lim_{x\to 0}\frac{a}{b}\cdot\frac{(2-bx)^3}{(2-ax)^3}} = e^{-\frac{a}{b}}$$

Hence, (a) is the correct answer.

Example 49 ***The value of*** $\lim_{x\to 7/2}(2x^2-9x+8)^{\cot(2x-7)}$ ***is equal to***

(a) $e^{5/2}$ (b) $e^{-5/2}$
(c) $e^{7/2}$ (d) $e^{3/2}$

Sol. Here, $\lim_{x\to 7/2}(2x^2-9x+8)^{\cot(2x-7)}$ [1^∞ form]

$$= \lim_{x\to 7/2}\{1+(2x^2-9x+7)\}^{\cot(2x-7)}$$

$$= e^{\lim_{x\to 7/2}(2x^2-9x+7)\cdot\cot(2x-7)}$$

$$= e^{\lim_{x\to 7/2}\frac{4x-9}{\sec^2(2x-7)\cdot 2}} = e^{5/2}$$

Hence, (a) is the correct answer.

Example 50 ***The value of*** $\lim_{x\to 1}\left(\tan\left(\frac{\pi}{4}+\log x\right)\right)^{\frac{1}{\log x}}$ ***is equal to***

(a) e (b) e^{-1}
(c) e^2 (d) e^{-2}

Sol. Here, $\lim_{x\to 1}\left(\tan\left(\frac{\pi}{4}+\log x\right)\right)^{\frac{1}{\log x}}$ [1^∞ form]

$$= \lim_{x\to 1}\left(1+\frac{2\tan(\log x)}{1-\tan(\log x)}\right)^{\frac{1}{\log x}} = e^{\lim_{x\to 1}\frac{2\tan(\log x)}{\{1-\tan(\log x)\}}\cdot\frac{1}{\log x}}$$

$$= e^{2\lim_{x\to 1}\frac{\tan(\log x)}{\log x}\cdot\frac{1}{1-\tan(\log x)}} = e^{2\cdot(1)} = e^2$$

[as $x\to 1,\ \log x\to 0$]

Hence, (c) is the correct answer.

Example 51 ***The value of*** $\lim_{x\to 0}\left(\sin\frac{x}{m}+\cos\frac{3x}{m}\right)^{\frac{2m}{x}}$ ***is equal to***

(a) e (b) 1 (c) e^{-1} (d) e^2

Sol. Here, $\lim_{x\to 0}\left(\sin\frac{x}{m}+\cos\frac{3x}{m}\right)^{\frac{2m}{x}}$

$$= \lim_{x\to 0}\left\{1+\left(\sin\frac{x}{m}+\cos\frac{3x}{m}-1\right)\right\}^{\frac{2m}{x}}$$ [1^∞ form]

$$= e^{\lim_{x\to 0}\frac{2m}{x}\left(\sin\frac{x}{m}+\cos\frac{3x}{m}-1\right)}$$

$$= e^{\lim_{x\to 0}\frac{2m\left(\frac{1}{m}\cos\left(\frac{x}{m}\right)-\frac{3}{m}\sin\frac{3x}{m}\right)}{1}} = e^{2m\left(\frac{1}{m}\right)} = e^2$$

Hence, (d) is the correct answer.

Example 52 The value of $\lim_{n\to\infty}\left(\frac{a-1+\sqrt[n]{b}}{a}\right)^n$ $(a>0, b>0)$ is equal to

(a) $\sqrt[q]{b}$ (b) $\sqrt[b]{a}$ (c) $\sqrt{b}$ (d) $\sqrt{a}$

Sol. Here, $\lim_{n\to\infty}\left(\frac{a-1+\sqrt[n]{b}}{a}\right)^n = \lim_{n\to\infty}\left(1+\frac{\sqrt[n]{b}-1}{a}\right)^n$

$= e^{\lim_{n\to\infty}\left(\frac{\sqrt[n]{b}-1}{a}\right)\cdot n}$ [1^∞ form]

$= e^{\lim_{n\to\infty}\frac{1}{a}\cdot\frac{b^{1/n}-1}{1/n}} = e^{\lim_{n\to\infty}\frac{1}{a}\cdot\frac{b^{1/n}\log b\left(\frac{-1}{n^2}\right)}{-1/n^2}}$

$= e^{\frac{1}{a}\log_e b} = e^{\log_e b^{1/a}} = b^{1/a}$

Hence, (a) is the correct answer.

Exercise for Session 3

1. The value of $\lim_{x\to 0}\frac{e^x - e^{x\cos x}}{x+\sin x}$ is

(a) 0 (b) 1 (c) −1 (d) None of these

2. The value of $\lim_{x\to y}\frac{x^y - y^x}{x^x - y^y}$ is

(a) $\frac{1-\log x}{1+\log x}$ (b) $\frac{1-\log y}{1+\log y}$ (c) $\frac{\log x - \log y}{\log x + \log y}$ (d) None of these

3. The value of $\lim_{x\to 0}\frac{p^x - q^x}{r^x - s^x}$ is

(a) $\frac{1-\log p}{1+\log p}$ (b) $\frac{\log p - \log q}{\log r - \log s}$ (c) $\frac{\log p\cdot\log q}{\log r\cdot\log s}$ (d) None of these

4. The value of $\lim_{x\to\infty}(x+2)\tan^{-1}(x+2) - (x\tan^{-1}x)$ is

(a) $\frac{\pi}{2}$ (b) Doesn't exist (c) $\frac{\pi}{4}$ (d) None of these

5. The value of $\lim_{x\to 4}\frac{(\cos\alpha)^x - (\sin\alpha)^x - \cos 2\alpha}{x-4}$, $\alpha\in\left(0,\frac{\pi}{2}\right)$ is

(a) $\log(\cos\alpha) + (\sin\alpha)^4\log(\sin\alpha)$ (b) $(\cos^4\alpha)\log(\cos\alpha) - (\sin\alpha)^4\log(\sin\alpha)$

(c) $(\cos^4\alpha)\log(\cos\alpha)$ (d) None of these

6. The value of $\lim_{x\to 0}\left(\frac{1^x + 2^x + 3^x + \ldots + n^x}{n}\right)^{a/x}$ is

(a) $(n!)^{a/n}$ (b) $n!$ (c) $a^{n!}$ (d) Doesn't exist

7. If $\lim_{x\to 0}(1+ax+bx^2)^{2/x} = e^3$, the values of a and b are

(a) $a=\frac{3}{2}, b\in R$ (b) $a=\frac{1}{2}, b\in R$ (c) $a\in R, b\in R$ (d) None of these

8. If α and β are roots of $ax^2+bx+c=0$, the value of $\lim_{x\to\alpha}(1+ax^2+bx+c)^{2/x-\alpha}$ is

(a) $e^{2a(\alpha-\beta)}$ (b) $e^{a(\alpha-\beta)}$ (c) $e^{\frac{2a}{3}(\alpha-\beta)}$ (d) None of these

9. The value of $\lim_{n\to\infty}((15)^n + [(1+0.0001)^{10000}]^n)^{1/n}$, where [·] denotes the greatest integer function, is

(a) 1 (b) $\frac{1}{2}$ (c) Doesn't exist (d) 2

10. The value of $\lim_{x\to 0}|x|^{[\cos x]}$, where $[\cdot]$ denotes the greatest integer function, is

(a) 0 (b) Doesn't exist (c) 1 (d) None of these

Session 4

Miscellaneous Forms

Miscellaneous Forms

(i) 0^0 Form

When $\lim_{x \to a} f(x) \neq 1$ but $f(x)$ is positive in the neighbourhood of $x = a$.

In this case, we write $\{f(x)\}^{g(x)} = e^{\log_e \{f(x)\}^{g(x)}}$

$$\Rightarrow \quad \lim_{x \to a} [f(x)]^{g(x)} = e^{\lim_{x \to a} g(x) \log_e f(x)}$$

Example 53 Evaluate $\lim_{x \to 0} |x|^{\sin x}$.

Sol. $\lim_{x \to 0} |x|^{\sin x} = \lim_{x \to 0} e^{\sin x \log_e |x|} = e^{\lim_{x \to 0} \frac{\log_e |x|}{\operatorname{cosec} x}}$ [0° form]

$= e^{\lim_{x \to 0} \frac{1/x}{-\operatorname{cosec} x \cot x}}$ [by L' Hospital's rule]

$= e^{\lim_{x \to 0} -\frac{\sin^2 x}{x \cos x}} = e^{\lim_{x \to 0} -\left(\frac{\sin x}{x}\right)^2 \cdot \left(\frac{x}{\cos x}\right)}$

$= e^{-(1)^2 \cdot (0)} = e^0 = 1$

Example 54 Evaluate $\lim_{n \to \infty} (\pi n)^{2/n}$.

Sol. Let $A = \lim_{n \to \infty} (\pi n)^{2/n}$ [∞^0 form]

$\therefore \quad \log A = \lim_{n \to \infty} \frac{2 \log (\pi n)}{n}$ $\left[\frac{\infty}{\infty} \text{ form}\right]$

$= \lim_{n \to \infty} \frac{2 \cdot \frac{1}{\pi n} \cdot \pi}{1}$ [by L'Hospital's rule]

$= \lim_{n \to \infty} \frac{2}{n} = 0$

$\therefore \quad \log_e A = 0 \Rightarrow A = 1$

Example 55 Evaluate $\lim_{n \to \infty} \left(\frac{e^n}{\pi}\right)^{1/n}$.

Sol. Let $A = \lim_{n \to \infty} \left(\frac{e^n}{\pi}\right)^{1/n}$ [∞^0 form]

$\therefore \quad \log A = \lim_{n \to \infty} \frac{1}{n} \log \left(\frac{e^n}{\pi}\right)$

$= \lim_{n \to \infty} \frac{n \log e - \log \pi}{n}$ $\left[\frac{\infty}{\infty} \text{ form}\right]$

$= \lim_{n \to \infty} \frac{\log e - 0}{1}$ [by L'Hospital's rule]

$\log A = 1$

$\Rightarrow \quad A = e^1$ or $\lim_{n \to \infty} \left(\frac{e^n}{\pi}\right)^{1/n} = e$

Example 56 ***Evaluate*** $\lim_{x \to 0} (\operatorname{cosec} x)^x$.

Sol. Let $A = \lim_{x \to 0} (\operatorname{cosec} x)^x$ [∞^0 form]

$\Rightarrow \quad \log A = \lim_{x \to 0} x \log (\operatorname{cosec} x)$

$= \lim_{x \to 0} \frac{\log (\operatorname{cosec} x)}{\frac{1}{x}}$ $\left[\frac{\infty}{\infty} \text{ form}\right]$

$= \lim_{x \to 0} \frac{\frac{1}{\operatorname{cosec} x} \cdot (-\operatorname{cosec} x \cot x)}{-\frac{1}{x^2}}$ [by L'Hospital's rule]

$= \lim_{x \to 0} \frac{x^2}{\tan x} = 0$

$\therefore \quad \log A = 0$ or $A = 1 \Rightarrow \lim_{x \to 0} (\operatorname{cosec} x)^x = 1$

(ii) 1^0 Form

Example 57 Solve $\lim_{x \to 0} \frac{(1+x)^{1/x} - e}{x}$.

Sol. Let $L = \lim_{x \to 0} \frac{(1+x)^{1/x} - e}{x}$

$= \lim_{x \to 0} \frac{e^{\log (1+x)^{1/x}} - e}{x} = \lim_{x \to 0} \frac{e\left\{e^{\frac{\log (1+x)}{x} - 1}\right\}}{x}$

$= \lim_{x \to 0} \frac{e\{e^M - 1\}}{M} \cdot \lim_{x \to 0} \frac{\log(1+x) - x}{x^2}$,

where $M = \frac{\log(1+x)}{x} - 1$

$\therefore \quad L = \lim_{M \to 0} \frac{e \cdot \{e^M - 1\}}{M} \cdot \lim_{x \to 0} \frac{\frac{1}{1+x} - 1}{2x}$

$= e \times 1 \times \lim_{x \to 0} \frac{-x}{2x(1+x)} = -\frac{e}{2}$ [as $x \to 0 \Rightarrow M \to 0$]

Exercise for Session 4

1. Evaluate $\lim_{x \to 0^+} (\sin x)^x$.

2. Evaluate $\lim_{x \to 0^+} (\sin x)^{\tan x}$.

3. Evaluate $\lim_{n \to \infty} \left(\frac{e^n}{\pi}\right)^{1/n}$.

4. The value of $\lim_{x \to 0} \frac{e - (1+x)^{1/x}}{\tan x}$ is

(a) e (b) $\frac{11e}{24}$ (c) $\frac{e}{2}$ (d) None of these

Session 5

Left Hand and Right Hand Limits

Left Hand and Right Hand Limits

Let $y = f(x)$ be a given function and $x = a$ is the point under consideration. Left tendency of $f(x)$ at $x = a$ is called its **left hand limit** and right tendency is called its **right hand limit.**

Left tendency (left hand limit) is denoted by $f(a-0)$ or $f(a-)$ and right tendency (right hand limit) is denoted by $f(a+0)$ or $f(a+)$ and are written as

$$\left.\begin{aligned} f(a-0) &= \lim_{h \to 0} f(a-h) \\ f(a+0) &= \lim_{h \to 0} f(a+h) \end{aligned}\right\}$$

where, h is a small positive number.

Thus, for the existence of the limit of $f(x)$ at $x = a$, it is necessary and sufficient that

$f(a-0) = f(a+0)$, if these are finite or $f(a-0)$ and $f(a+0)$ both should be either $+\infty$ or $-\infty$.

Example 58 ***Evaluate the right hand limit and left hand limit of the function***

$$f(x) = \begin{cases} \dfrac{|x-4|}{x-4}, & x \neq 4 \\ 0, & x = 4 \end{cases}.$$

Sol. Given, $f(x) = \begin{cases} \dfrac{|x-4|}{x-4}, & x \neq 4 \\ 0, & x = 4 \end{cases}$

Now, RHL of $f(x)$ at $x = 4$

$$= \lim_{x \to 4^+} f(x) = \lim_{h \to 0} f(4+h)$$

$$= \lim_{h \to 0} \frac{|4+h-4|}{4+h-4} = \lim_{h \to 0} \frac{|h|}{h} = 1$$

LHL of $f(x)$ at $x = 4$

$$= \lim_{x \to 4^-} f(x) = \lim_{h \to 0} f(4-h)$$

$$= \lim_{h \to 0} \frac{|4-h-4|}{4-h-4} = \lim_{h \to 0} \frac{|h|}{-h} = \lim_{h \to 0} \frac{h}{-h} = -1$$

Thus, RHL $\neq$ LHL. So, $\lim_{x \to 4} f(x)$ does not exist.

Example 59 If $f(x) = \begin{cases} 5x-4, & 0 < x \leq 1 \\ 4x^3 - 3x, & 1 < x < 2 \end{cases}$, show that $\lim_{x \to 1} f(x)$ exists.

Sol. We have, $f(x) = \begin{cases} 5x-4, & 0 < x \leq 1 \\ 4x^3 - 3x, & 1 < x < 2 \end{cases}$

LHL of $f(x)$ at $x = 1 = \lim_{x \to 1^-} f(x) = \lim_{h \to 0} f(1-h)$

$$= \lim_{h \to 0} 5(1-h) - 4 = \lim_{h \to 0} 1 - 5h = 1$$

RHL of $f(x)$ at $x = 1 = \lim_{x \to 1^+} f(x) = \lim_{h \to 0} f(1+h)$

$$= \lim_{h \to 0} 4(1+h)^3 - 3(1+h) = 4(1)^3 - 3(1) = 1$$

Thus, RHL = LHL = 1. So, $\lim_{x \to 1} f(x)$ exists and is equal to 1.

Example 60 ***Show that*** $\lim_{x\to 0}\dfrac{e^{1/x}-1}{e^{1/x}+1}$ ***does not exist.***

Sol. Let $f(x)=\dfrac{e^{1/x}-1}{e^{1/x}+1}$.

Then, $\text{LHL}=\lim_{x\to 0^-} f(x)=\lim_{h\to 0} f(0-h)$

$$=\lim_{h\to 0}\frac{e^{-1/h}-1}{e^{-1/h}+1}$$

$$=\lim_{h\to 0}\frac{(1/e^{1/h}-1)}{(1/e^{1/h}+1)}=\frac{0-1}{0+1}=-1$$

$[\text{as } h\to 0 \Rightarrow \frac{1}{h}\to\infty\Rightarrow e^{1/h}\to\infty \Rightarrow 1/e^{1/h}\to 0]$ ...(i)

$\text{RHL}=\lim_{x\to 0^+} f(x)=\lim_{h\to 0} f(0+h)$

$$=\lim_{h\to 0}\frac{e^{1/h}-1}{e^{1/h}+1}=\lim_{h\to 0}\frac{(1-1/e^{1/h})}{(1+1/e^{1/h})}$$

[dividing numerator and denominator both by $e^{1/h}$]

$$=\frac{1-0}{1+0}=1 \qquad \text{[using Eq. (i)]}$$

Clearly, $\lim_{x\to 0^-} f(x)\neq\lim_{x\to 0^+} f(x)$

Hence, $\lim_{x\to 0} f(x)$ doesn't exist.

Example 61 Evaluate $\lim_{x\to 1}\dfrac{\sqrt{1-\cos 2(x-1)}}{(x-1)}$.

[IIT JEE 1998]

Sol. We have, $\lim_{x\to 1}\dfrac{\sqrt{1-\cos 2(x-1)}}{(x-1)}$

$$=\lim_{x\to 1}\frac{\sqrt{2\sin^2(x-1)}}{(x-1)}=\lim_{x\to 1}\frac{\sqrt{2}|\sin(x-1)|}{(x-1)}$$

$\therefore\ \text{LHL}=\lim_{x\to 1^-}\dfrac{\sqrt{2}|\sin(x-1)|}{(x-1)}$

$$=\lim_{h\to 0}\frac{\sqrt{2}|\sin(-h)|}{(-h)}=\lim_{h\to 0}\frac{\sqrt{2}\sin h}{-h}=-\sqrt{2}$$

Again, $\text{RHL}=\lim_{x\to 1^+}\dfrac{\sqrt{2}|\sin(x-1)|}{(x-1)}$

$$=\lim_{h\to 0}\frac{\sqrt{2}|\sin(h)|}{h}$$

$$=\lim_{h\to 0}\frac{\sqrt{2}\sin h}{h}=\sqrt{2}$$

Clearly, $\lim_{x\to 1^+} f(x)\neq\lim_{x\to 1^-} f(x)$

Hence, $\lim_{x\to 1} f(x)$ doesn't exist.

Example 62 Solve (i) $\lim_{x\to 1}[\sin^{-1}x]$ (ii) $\lim_{x\to 0^+}\left[\dfrac{\sin x}{x}\right]$

(iii) $\lim_{x\to 0^-}\left[\dfrac{\sin x}{x}\right]$

(where $[\cdot]$ denotes greatest integer function.)

Sol. (i) Here, $L=\lim_{x\to 1}[\sin^{-1}x]$

Put $\sin^{-1}x=t$

$\therefore\quad x=\sin t$ and $t\to\dfrac{\pi}{2}$ as $x\to 1$

$\Rightarrow\quad L=\lim_{t\to\pi/2}[t]=\left[\dfrac{\pi}{2}\right]=1$

$\therefore\quad \lim_{x\to 1}[\sin^{-1}x]=1$

(ii) Here, $L=\lim_{x\to 0^+}\left[\dfrac{\sin x}{x}\right]$

Put $\dfrac{\sin x}{x}=t\Rightarrow t\to 1^-$ as $x\to 0^+$ and $[t]=0$

$\Rightarrow\quad L=\lim_{t\to 1^-}[t]=[1-h]=0$

$[\text{as } x\to 0+h\Rightarrow t\to 1-h]$

(iii) Here, $L=\lim_{x\to 0^-}\left[\dfrac{\sin x}{x}\right]$

Put $\dfrac{\sin x}{x}=t$

$\Rightarrow\ t\to 1^-$ as $x\to 0^-$

$\therefore\quad L=\lim_{t\to 1^-}[t]=[1-h]=0$

$[\text{as } x\to 0-h\Rightarrow t\to 1-h\ \therefore\ [t]=0]$

Example 63 Solve (i) $\lim_{x\to\infty}[\tan^{-1}x]$

(ii) $\lim_{x\to-\infty}[\tan^{-1}x]$

(where $[\cdot]$ denotes greatest integer function.)

Sol. (i) Here, $\lim_{x\to\infty}[\tan^{-1}x]$

Put $\tan^{-1}x=t\ \Rightarrow\ t\to\dfrac{\pi}{2}$ as $x\to\infty$

$\therefore\quad \lim_{t\to\pi/2}[t]=\left[\dfrac{\pi}{2}\right]=1$

(ii) Here, $\lim_{x\to-\infty}[\tan^{-1}x]$

Put $\tan^{-1}x=t\ \Rightarrow\ t\to-\dfrac{\pi}{2}$ as $x\to-\infty$

$\therefore\ \lim_{t\to-\pi/2}[t]=\left[-\dfrac{\pi}{2}\right]=[-1.57]=-2$

Example 64 Solve (i) $\lim_{x \to 0^+} \left[\frac{\tan x}{x}\right]$

(ii) $\lim_{x \to 0^-} \left[\frac{\tan x}{x}\right]$

(where $[\cdot]$ denotes greatest integer function.)

Sol. (i) Here, $\lim_{x \to 0^+} \left[\frac{\tan x}{x}\right]$

Put $\frac{\tan x}{x} = t \Rightarrow t \to 1^+$ as $x \to 0^+$

$\therefore \lim_{t \to 1^+} [t] = [1 + h] = 1 \qquad [\text{as } x \to 0 + h \Rightarrow t \to 1 + h]$

(ii) Here, $\lim_{x \to 0^-} \left[\frac{\tan x}{x}\right]$

Put $\frac{\tan x}{x} = t \Rightarrow t \to 1^+$ as $x \to 0^-$

$\therefore \lim_{t \to 1^+} [t] = [1 + h] = 1 \qquad [\text{as } x \to 0 - h \Rightarrow t \to 1 + h]$

Example 65 ***Solve***

(i) $\lim_{x \to 1^-} [\sin(\sin^{-1} x)]$ (ii) $\lim_{x \to \pi/2} [\sin^{-1}(\sin x)]$

(where $[\cdot]$ denotes greatest integer function.)

Sol. (i) Here, $\lim_{x \to 1^-} [\sin(\sin^{-1} x)]$

$= \lim_{x \to 1^-} [x] \quad [\text{as } \sin(\sin^{-1} x) = x, \text{if } -1 \le x \le 1]$

$= \lim_{h \to 0} [1 - h] \qquad [\text{as } x \to 1^- \Rightarrow x = 1 - h]$

$= 0$

$\therefore \lim_{x \to 1} [\sin(\sin^{-1} x)] = \lim_{x \to 1^-} [\sin(\sin^{-1} x)]$

and no need to check for $\lim_{x \to 1^+} [\sin(\sin^{-1} x)]$

(ii) $\lim_{x \to \frac{\pi}{2}} [\sin^{-1}(\sin x)] = \lim_{x \to \frac{\pi^-}{2}} [\sin^{-1}(\sin x)]$

$= \lim_{x \to \frac{\pi^-}{2}} [x] = \lim_{h \to 0} \left[\frac{\pi}{2} - h\right] = 1$

Remark

If $\lim_{x \to 1} [\sin(\sin^{-1} x)]$, it means you have to calculate only left hand limit and not right hand limit as for $x > 1$, $\sin(\sin^{-1} x)$ is not defined.

Example 66 Solve (i) $\lim_{x \to 0} [\cot x]$

(ii) $\lim_{x \to +\infty} [\cot^{-1} x]$

(where $[\cdot]$ denotes greatest integer function.)

Sol. (i) Here, $\lim_{x \to 0} [\cot x]$

Put $\cot x = t$, now as $x \to 0$; $\cot x$ exhibits two values for $x \to 0^+$ and $x \to 0^-$. i.e. $\cot x \to +\infty$ and $\cot x \to -\infty$, respectively.

$\therefore$ We should apply right hand and left hand limit;

i.e. $\lim_{x \to 0^+} [\cot x] = \lim_{t \to +\infty} [t] = \infty$

$[\because \cot x = t \Rightarrow t \to +\infty \text{ as } x \to 0^+]$

and $\lim_{x \to 0^-} [\cot x] = \lim_{t \to -\infty} [t] = -\infty$

$[\because \cot x = t \Rightarrow t \to -\infty \text{ as } x \to 0^-]$

$\therefore$ Limit doesn't exist.

(ii) Here, $\lim_{x \to +\infty} [\cot^{-1} x] = \lim_{t \to 0^+} [t]$

$[\because \cot^{-1} x = t \Rightarrow t \to 0^+ \text{ as } x \to +\infty]$

$= \lim_{h \to 0} [0 + h] = \lim_{h \to 0} 0 = 0$

Example 67 ***Solve*** $\lim_{x \to 0} \left[\sin \frac{|x|}{x}\right]$***, where*** $[\cdot]$ ***denotes greatest integer function.***

Sol. Here, $\lim_{x \to 0} \left[\sin \frac{|x|}{x}\right]$, since we have greatest integer function, we must define function.

Now, RHL (put $x = 0 + h$) $= \lim_{h \to 0} \left[\frac{\sin|0+h|}{0+h}\right]$

We know that, $\frac{\sin h}{h} \to 1$ as $h \to 0$ but less than 1.

$\therefore$ RHL $= \lim_{h \to 0} 0 = 0 \qquad \left[\because \left(\frac{\sin h}{h}\right) = 0 \text{ as } h \to 0\right]$

Again, LHL (put $x = 0 - h$) $= \lim_{h \to 0} \left[\sin \frac{|0-h|}{0-h}\right]$,

we know $\frac{\sin h}{-h} \to -1$ as $h \to 0$ but greater than -1.

$\therefore$ LHL $= \lim_{h \to 0} -1 = -1 \qquad \left[\because \left(\frac{\sin h}{h}\right) = -1 \text{ as } h \to 0\right]$

Thus, Limit doesn't exist, as RHL = 0 and LHL = -1.

Example 68 Solve $\lim_{x \to 0} \left[\frac{\sin|x|}{|x|}\right]$, where $[\cdot]$ denotes greatest integer function.

Sol. Here, $\lim_{x \to 0} \left[\frac{\sin|x|}{|x|}\right]$ ...(i)

We know that, $\frac{\sin x}{x} \to 1$ as $x \to 0$ or $\frac{\sin|x|}{|x|} \to 1$ as $x \to 0$ from right or left,

i.e. at $x = 0 + h$ or $x = 0 - h$, $\frac{\sin|x|}{|x|} \to 1^-$

$\therefore \quad \left[\frac{\sin|x|}{|x|}\right]=0 \text{ as } \frac{\sin|x|}{|x|}<1$

From Eq. (i) whether we find RHL or LHL

$\lim_{x\to 0}\left[\frac{\sin|x|}{|x|}\right] = \lim_{x\to 0} 0 = 0 \Rightarrow \lim_{x\to 0}\left[\frac{\sin|x|}{|x|}\right]$,

exists and is 0.

Example 69 $\lim_{x\to 0}\left[\frac{-2x}{\tan x}\right]$, where $[\cdot]$ denotes greatest integer function is

(a) -1 (b) 4
(c) 5 (d) None of these

Sol. We know, when $x \to 0$

$\Rightarrow \quad \frac{x}{\tan x}<1 \Rightarrow \frac{-x}{\tan x}>-1$

$\Rightarrow \quad \frac{-2x}{\tan x}>-2$

So, $\lim_{x\to 0}\left[\frac{-2x}{\tan x}\right]=-2$

Hence, (d) is the correct answer.

Exercise for Session 5

1. The value of $\lim_{x\to 1}\{1-x+[x-1]+[1-x]\}$ (where $[\cdot]$ denotes the greatest integral function) is

(a) -1 (b) Doesn't exist
(c) 1 (d) None of these

2. The value of $\lim_{x\to 0}\frac{\sin[x]}{[x]}$ (where $[\cdot]$ denotes the greatest integer function) is

(a) 1 (b) sin 1
(c) Doesn't exist (d) None of these

3. The value of $\lim_{x\to 0}\sin^{-1}\{x\}$ (where $\{\cdot\}$ denotes fractional part of x) is

(a) 0 (b) $\frac{\pi}{2}$
(c) Doesn't exist (d) None of these

4. The value of $\lim_{x\to 0}\left[\frac{x^2}{\sin x \tan x}\right]$ (where $[\cdot]$ denotes the greatest integer function) is

(a) 0 (b) 1
(c) Doesn't exist (d) None of these

Session 6

Use of Standard Theorems/Results, Use of Newton-Leibnitz's Formula in Evaluating the Limits, Summation of Series Using Definite Integral as the Limit

Use of Standard Theorems/Results

Theorem 1 : Sandwich/Squeeze Play Theorem

General The Squeeze principle is used on limit problems where the usual algebraic methods, factorisation or algebraic manipulation etc., are not effective. However, it requires to "squeeze" our problem in between two other simpler function, whose limits can be easily computed and equal. Use of Squeeze principle requires accurate analysis, indepth algebra skills and careful use of inequalities.

Statement If f, g and h are three functions such that $f(x) \le g(x) \le h(x)$ for all x in some interval containing the point $x = c$ and if

$$\lim_{x \to c} f(x) = \lim_{x \to c} h(x) = L$$

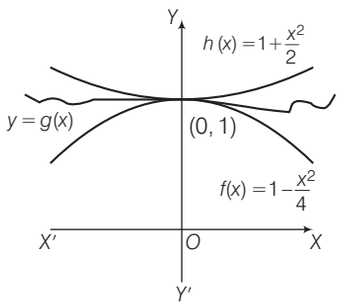

Figure 5.10

Then, $\lim_{x \to c} g(x) = L$

From the figure, note that $\lim_{x \to 0} g(x) = 1$.

Remark

The quantity c may be a finite number, $+\infty$ or $-\infty$. Similarly, L may also be finite number, $+\infty$ or $-\infty$.

Theorem 2 : Limits of Trigonometric Functions

If x is small and is measured in radians, then

$$\lim_{x \to 0} \frac{\sin x}{x} = 1 = \lim_{x \to 0} \frac{x}{\sin x}$$

$$= \lim_{x \to 0} x \operatorname{cosec} x = \lim_{x \to 0} \frac{\sin^{-1} x}{x} = \lim_{x \to 0} \frac{x}{\sin^{-1} x}$$

Proof Consider a circle with unit radius.

Area of $\Delta OAP <$ Area of sector $\overset{\frown}{OAP} <$ Area of ΔOAT

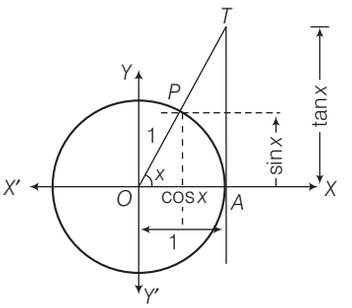

Figure 5.11

$$\frac{\sin x}{2} < \frac{x}{2} < \frac{\tan x}{2} \Rightarrow 1 < \frac{x}{\sin x} < \frac{1}{\cos x} \quad [\because 0 < x < \pi/2]$$

$$\Rightarrow \quad \cos x < \frac{\sin x}{x} < 1$$

Now, using Sandwich theorem,

$$\lim_{x \to 0} \cos x < \lim_{x \to 0^+} \frac{\sin x}{x} < 1$$

Obviously, we have $\lim_{x \to 0^+} \frac{\sin x}{x} = 1$

Put $x = -y$, $\lim_{y \to 0^-} \frac{\sin y}{y} = 1$

Hence, $\lim_{x \to 0} \frac{\sin x}{x} = 1$

Similarly, $\lim_{x\to 0}\frac{\sin x}{x}=1=\lim_{x\to 0}\frac{x}{\sin x}=\lim_{x\to 0}x\operatorname{cosec}x$

$$=\lim_{x\to 0}\frac{\sin^{-1}x}{x}=\lim_{x\to 0}\frac{x}{\sin^{-1}x} \quad ...(i)$$

Using Eq. (i), we can deduce

$$\lim_{x\to 0}\frac{\tan x}{x}=1=\lim_{x\to 0}\frac{x}{\tan x}=\lim_{x\to 0}x\cot x$$

$$=\lim_{x\to 0}\frac{\tan^{-1}x}{x}=\lim_{x\to 0}\frac{x}{\tan^{-1}x}$$

Important Results

The $\lim_{x\to 0}\frac{\sin x}{x}$ always approaches 1 from its left hand,

i.e. 0.9999....

$\Rightarrow \lim_{x\to 0}\left[\frac{\sin x}{x}\right]=0$, where $[\cdot]$ denotes step up function.

$$\left[\text{Note that } \left(\lim_{x\to 0}\frac{\sin x}{x}\right)=1\right]$$

Note that the $\lim_{x\to 0}\frac{\tan x}{x}$ approaches 1 from RHS.

$\Rightarrow \lim_{x\to 0}\left[\frac{\tan x}{x}\right]=1$, where $[\cdot]$ denotes step up function.

Example 70 Evaluate $\lim_{x\to 0}x^3\cos\frac{2}{x}$.

Sol. Here, $\lim_{x\to 0}x^3\cos\frac{2}{x}$

As, $-1\le\cos\frac{2}{x}\le 1\Rightarrow -x^3\le x^3\cos\frac{2}{x}\le x^3$ for $x>0$

and $x^3\le x^3\cos\frac{2}{x}\le -x^3$ for $x<0$,

Thus, $\lim_{x\to 0}x^3\cos\frac{2}{x}=0$, as in both the cases limit is zero.

Example 71 Evaluate $\lim_{x\to\infty}\frac{x^2(2+\sin^2 x)}{x+100}$.

Sol. We have, $\lim_{x\to\infty}\frac{x^2(2+\sin^2 x)}{x+100}$

Now, $\frac{2x^2}{x+100}\le\frac{x^2(2+\sin^2 x)}{x+100}\le\frac{3x^2}{x+100}$, as $0\le\sin^2 x\le 1$

$$\therefore \lim_{x\to\infty}\frac{2x^2}{x+100}\le\lim_{x\to 0}\frac{x^2(2+\sin^2 x)}{x+100}\le\lim_{x\to\infty}\frac{3x^2}{x+100}$$

$$\Rightarrow \lim_{x\to\infty}\frac{x^2(2+\sin^2 x)}{x+100}=\infty$$

$$\left[\because \lim_{x\to\infty}\frac{2x^2}{x+100}=\lim_{x\to\infty}\frac{3x^2}{x+100}=\infty\right]$$

Example 72 *Evaluate*

$$\lim_{n\to\infty}\left(\frac{n}{n^2+1}+\frac{n}{n^2+2}+\frac{n}{n^2+3}+\ldots+\frac{n}{n^2+n}\right).$$

Sol. Let $f(n)=\frac{n}{n^2+1}+\frac{n}{n^2+2}+\frac{n}{n^2+3}+\ldots+\frac{n}{n^2+n}$

Note that $f(n)$ has n terms which are decreasing.

Suppose

$$h(n)=\left(\frac{n}{n^2+1}+\frac{n}{n^2+1}+\frac{n}{n^2+1}+\ldots+\frac{n}{n^2+1}\right),\ n \text{ terms}$$

$$=\frac{n^2}{n^2+1} \qquad [\text{obviously } f(n)<h(n)]$$

and

$$g(n)=\left(\frac{n}{n^2+n}+\frac{n}{n^2+n}+\frac{n}{n^2+n}+\ldots+\frac{n}{n^2+n}\right),\ n \text{ terms}$$

$$=\frac{n^2}{n^2+n} \qquad [\text{obviously } g(n)<f(n)]$$

Hence, $\lim_{n\to\infty}g(n)<\lim_{n\to\infty}f(n)<\lim_{n\to\infty}h(n)$

Since, $\lim_{n\to\infty}g(n)=1=\lim_{n\to\infty}h(n)$

Hence, using Sandwich theorem, $\lim_{n\to\infty}f(n)=1$.

Example 73 The value of the $\lim_{x\to 0}\frac{x}{a}\left[\frac{b}{x}\right]$ $(a\ne 0)$

(where $[\cdot]$ denotes the greatest integer function) is

(a) a (b) b

(c) $\frac{b}{a}$ (d) $1-\frac{b}{a}$

Sol. Since, $\frac{b}{x}-1<\left[\frac{b}{x}\right]\le\frac{b}{x}$

Now, we have two cases depending upon the value of $\frac{x}{a}$.

***Case* I** For $\frac{x}{a}>0$

$$\Rightarrow \lim_{x\to 0}\left(\frac{b}{x}-1\right)\frac{x}{a}<\lim_{x\to 0}\left[\frac{b}{x}\right]\frac{x}{a}\le\lim_{x\to 0}\frac{b}{x}\cdot\frac{x}{a}$$

Using Squeeze play theorem, we have $=\lim_{x\to 0}\frac{x}{a}\left[\frac{b}{x}\right]=\frac{b}{a}$

***Case* II** For $\frac{x}{a}<0$

$$\Rightarrow \lim_{x\to 0}\left(\frac{b}{x}-1\right)\frac{x}{a}>\lim_{x\to 0}\left[\frac{b}{x}\right]\frac{x}{a}\ge\lim_{x\to 0}\frac{b}{x}\cdot\frac{x}{a}$$

Using Squeeze play theorem, we have

$$\lim_{x\to 0}\frac{x}{a}\left[\frac{b}{x}\right]=\frac{b}{a}$$

Hence, (c) is the correct answer.

Example 74 *Evaluate*

$$\lim_{n\to\infty}\frac{[x]+[2x]+[3x]+\ldots+[nx]}{n^2},$$

where $[\cdot]$ denotes the greatest integer function.

Sol. We know that, $x-1<[x]\le x$

$\Rightarrow$ $2x-1<[2x]\le 2x$

$\Rightarrow$ $3x-1<[3x]\le 3x$

.....

.....

$\Rightarrow$ $nx-1<[nx]\le nx$

$\therefore\ (x+2x+3x+\ldots+nx)-n<[x]+[2x]+\ldots+[nx]\le(x+2x+\ldots+nx)$

$$\Rightarrow\quad \frac{xn(n+1)}{2}-n<\sum_{r=1}^{n}[rx]\le\frac{x\cdot n(n+1)}{2}$$

Thus, $\lim_{n\to\infty}\dfrac{[x]+[2x]+\ldots+[nx]}{n^2}$

$$\Rightarrow\quad \lim_{n\to\infty}\frac{x}{2}\left(1+\frac{1}{n}\right)-\frac{1}{n}<\lim_{n\to\infty}\frac{[x]+[2x]+\ldots+[nx]}{n^2}\le\lim_{n\to\infty}\frac{x}{2}\left(1+\frac{1}{n}\right)$$

$$\Rightarrow\quad \frac{x}{2}<\lim_{n\to\infty}\frac{[x]+[2x]+\ldots+[nx]}{n^2}\le\frac{x}{2}$$

$$\therefore\quad \lim_{n\to\infty}\frac{[x]+[2x]+\ldots+[nx]}{n^2}=\frac{x}{2}$$

Aliter We know that, $[x]=x-\{x\}$

$$\sum_{r=1}^{n}rx=[x]+[2x]+\ldots+[nx]$$
$$=x-\{x\}+2x-\{2x\}+\ldots+nx-\{nx\}$$
$$=(x+2x+3x+\ldots+nx)-(\{x\}+\{2x\}+\ldots+\{nx\})$$
$$=\frac{xn(n+1)}{2}-(\{x\}+\{2x\}+\ldots+\{nx\})$$

$$\therefore\frac{1}{n^2}\sum_{r=1}^{n}[rn]=\frac{x}{2}\left(1+\frac{1}{n}\right)-\frac{\{x\}+\{2x\}+\ldots+\{nx\}}{n^2}$$

Since, $0\le\{rx\}<1$

$$\therefore\quad 0\le\sum_{r=1}^{n}\{rx\}<n$$

$$\Rightarrow\quad \lim_{n\to\infty}\frac{\sum_{r=1}^{n}\{rx\}}{n^2}=0$$

$$\therefore\quad \lim_{n\to\infty}\frac{\sum_{r=1}^{n}[rx]}{n^2}=\lim_{n\to\infty}\frac{x}{2}\left(1+\frac{1}{n}\right)-\lim_{n\to\infty}\frac{\sum_{r=1}^{n}\{rx\}}{n^2}$$

$$\Rightarrow\quad \lim_{n\to\infty}\frac{\sum_{r=1}^{n}[rx]}{n^2}=\frac{x}{2}$$

Use of Newton-Leibnitz's Formula in Evaluating the Limits

Let us consider the definite integral,

$$I(x)=\int_{\phi(x)}^{\psi(x)}f(t)\,dt$$

Newton-Leibnitz's formula states that,

$$\frac{d}{dx}\{I(x)\}=f\{\psi(x)\}\cdot\left\{\frac{d}{dx}\psi(x)\right\}-f\{\phi(x)\}\left\{\frac{d}{dx}\phi(x)\right\}$$

Example 75 *Evaluate*

$$\lim_{x\to0}\left(\frac{1}{x^5}\int_0^x e^{-t^2}\,dt-\frac{1}{x^4}+\frac{1}{3x^2}\right).$$

Sol We have, $\lim_{x\to0}\left(\dfrac{1}{x^5}\int_0^x e^{-t^2}dt-\dfrac{1}{x^4}+\dfrac{1}{3x^2}\right)$

$$=\lim_{x\to0}\frac{3\int_0^x e^{-t^2}\,dt-3x+x^3}{3x^5}\qquad\left[\frac{0}{0}\text{ form}\right]$$

$$=\lim_{x\to0}\frac{3\frac{d}{dx}\int_0^x e^{-t^2}\,dt-3+3x^2}{15x^4}\text{ [by L'Hospital's rule]}$$

Applying Newton-Leibnitz's formula,

$$\frac{d}{dx}\int_0^x e^{-t^2}\,dt=e^{-x^2}\cdot\frac{d}{dx}(x)-e^{-0}\frac{d}{dx}(0)=e^{-x^2}$$

$$\therefore\lim_{x\to0}\frac{3\frac{d}{dx}\int_0^x e^{-t^2}\,dt-3+3x^2}{15x^4}=\lim_{x\to0}\frac{3e^{-x^2}-3+3x^2}{15x^4}\qquad\left[\frac{0}{0}\text{ form}\right]$$

$$=\lim_{x\to0}\frac{-3(2x)e^{-x^2}+6x}{60x^3}\qquad\text{[again, apply L'Hospital's rule]}$$

$$=\lim_{x\to0}\frac{-6x(e^{-x^2}-1)}{60x^3}=\lim_{x\to0}\frac{-(e^{-x^2}-1)}{10x^2}=\frac{1}{10}\lim_{x\to0}\left(\frac{e^{-x^2}-1}{-x^2}\right)$$

$$=\frac{1}{10}\times1=\frac{1}{10}\qquad\left[\because\lim_{x\to0}\left(\frac{e^x-1}{x}\right)=1\right]$$

Example 76 Evaluate $\lim_{x\to0}\dfrac{x-\int_0^x\cos t^2\,dt}{x^3-6x}$.

Sol. Let $L=\lim_{x\to0}\dfrac{x-\int_0^x\cos t^2\,dt}{x^3-6x}\qquad\left[\dfrac{0}{0}\text{ form}\right]$

Applying L'Hospital's rule, we get

$$L=\lim_{x\to0}\frac{1-\frac{d}{dx}\int_0^x\cos t^2\,dt}{3x^2-6}$$

Applying Newton-Leibnitz's rule,

$$\frac{d}{dx}\int_0^x (\cos t^2)\,dt = \cos(x^2)\cdot 1 - 0 = \cos(x^2)$$

$$\therefore \quad L = \lim_{x\to 0}\frac{1-\frac{d}{dx}\int_0^x \cos t^2\,dt}{3x^2-6} = \lim_{x\to 0}\frac{1-\cos(x^2)}{3(x^2-2)}$$

$$= \frac{1-\cos 0}{3(0-2)} = \frac{1-1}{3(-2)} = \frac{0}{-6} = 0$$

Example 77 ***Evaluate*** $\lim_{x\to 0}\dfrac{\int_0^{x^2}\cos t^2\,dt}{x\sin x}$.

[IIT JEE 1997]

Sol. Applying Newton-Leibnitz's rule, followed by L' Hospital's rule, we get

$$\lim_{x\to 0}\frac{\cos(x^2)^2\cdot\{2x\}-0}{x\cos x+\sin x} = \lim_{x\to 0}\frac{2\cos x^4}{\cos x+\left(\frac{\sin x}{x}\right)}$$

$$= \frac{2\cos 0}{\cos 0+1} = \frac{2}{1+1} = 1$$

Summation of Series Using Definite Integral as the Limit

The expression of the form,

$$\lim_{n\to\infty}\frac{1}{n}\sum_{r=\phi(x)}^{\psi(x)} f\left(\frac{r}{n}\right) = \int_a^b f(x)\,dx$$

where, (i) Σ is replaced by $\int$,

(ii) $\dfrac{r}{n}$ is replaced by x,

(iii) $\dfrac{1}{n}$ is replaced by dx,

(iv) To obtain, $a = \lim_{n\to\infty}\dfrac{\phi(x)}{n}$ and $b = \lim_{n\to\infty}\dfrac{\psi(x)}{n}$

The value so obtained is the required sum of the given series.

Example 78 ***Evaluate*** $\lim_{n\to\infty}\dfrac{1}{n}\sum_{r=1}^{2n}\dfrac{r}{\sqrt{n^2+r^2}}$.

[IIT JEE 1997]

Sol. Let $L = \lim_{n\to\infty}\dfrac{1}{n}\sum_{r=1}^{2n}\dfrac{r}{\sqrt{n^2+r^2}}$ dividing numerator and denominator both by n, we get

$$L = \lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{2n}\frac{r/n}{\sqrt{1+(r/n)^2}}$$

Put $\dfrac{r}{n} = x; \dfrac{1}{n} = dx;\ \lim_{n\to\infty}\sum_{r=1}^{2n} = \int_a^b$

where, $a = \lim_{n\to\infty}\dfrac{1}{n} = 0$ and $b = \lim_{n\to\infty}\dfrac{2n}{n} = 2$

$$\therefore \quad L = \lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{2n}\frac{r/n}{\sqrt{1+(r/n)^2}} = \int_0^2\frac{x}{\sqrt{1+x^2}}\,dx$$

$$= \left(\sqrt{1+x^2}\right)_0^2 = \sqrt{5}-1$$

Example 79 Evaluate

$$\lim_{n\to\infty}\left(\frac{n}{n^2+1^2}+\frac{n}{n^2+2^2}+\ldots+\frac{n}{n^2+n^2}\right).$$

Sol. Let $S = \lim_{n\to\infty}\left(\dfrac{n}{n^2+1^2}+\dfrac{n}{n^2+2^2}+\ldots+\dfrac{n}{n^2+n^2}\right)$

$$= \lim_{n\to\infty}\sum_{r=1}^{n}\frac{n}{n^2+r^2} = \lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{n}\frac{n^2}{n^2+r^2}$$

[dividing numerator and denominator both by n]

$$= \lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{n}\frac{1}{1+(r/n)^2}$$

Replace $\dfrac{r}{n} = x; \dfrac{1}{n} = dx;\ \lim_{n\to\infty}\sum_{r=1}^{n} = \int_a^b$

where, $a = \lim_{n\to\infty}\dfrac{1}{n} = 0$ and $b = \lim_{x\to\infty}\dfrac{n}{n} = 1$

we get, $S = \lim_{n\to\infty}\dfrac{1}{n}\sum_{r=1}^{n}\dfrac{1}{1+(r/n)^2}$

$$= \int_0^1\frac{1}{1+x^2}\,dx = [\tan^{-1}x]_0^1 = \tan^{-1}(1)-\tan^{-1}(0) = \frac{\pi}{4}$$

Example 80 The value of $\lim_{n\to\infty}\left(\dfrac{n!}{n^n}\right)^{1/n}$ is equal to

(a) $\dfrac{1}{e}$ (b) e (c) e^2 (d) $\dfrac{1}{e^2}$

Sol. Let $A = \lim_{n\to\infty}\left(\dfrac{n!}{n^n}\right)^{1/n}$

$$\therefore \log A = \lim_{n\to\infty}\frac{1}{n}\log\left(\frac{n}{n}\cdot\frac{(n-1)}{n}\cdot\frac{(n-2)}{n}\cdots\frac{3}{n}\cdot\frac{2}{n}\cdot\frac{1}{n}\right)$$

$$= \lim_{n\to\infty}\frac{1}{n}\sum_{r=0}^{n-1}\log\left(\frac{n-r}{n}\right)$$

$$= \int_0^1 1\cdot\log(1-x)\,dx = -1$$

[replace $\dfrac{r}{n}$ by n and $\dfrac{1}{n}$ by dx $\lim_{n\to\infty}\sum_{r=0}^{n-1} = \int_a^b$, where $\dfrac{0}{n} = 0$, $a = \lim_{n\to\infty}, b = \lim_{n\to\infty}\dfrac{n-1}{n} = 1$]

$$\Rightarrow \quad \log_e A = -1 \quad \Rightarrow \quad A = e^{-1}$$

Hence, (a) is the correct answer.

Exercise for Session 6

1. The value of $\lim_{n\to\infty}\frac{1}{n^3}([1^2x+1^2]+[2^2x+2^2]+\ldots+[n^2x+n^2])$ (where $[\cdot]$ denotes the greatest integer function) is

(a) $\frac{x}{3}$ (b) $x+\frac{1}{3}$

(c) $\frac{x}{3}+\frac{1}{3}$ (d) None of these

2. The value of $\lim_{x\to\infty}\left\{\lim_{n\to\infty}\frac{[1^2(\sin x)^x]+[2^2(\sin x)^x]+\ldots+[n^2(\sin x)^x]}{n^3}\right\}$ (where $[\cdot]$ denotes the greatest integer function) is

(a) $\frac{x}{3}+\frac{\sin x}{3}$ (b) $\frac{x}{3}+(\sin x)^x$

(c) $\frac{1}{3}$ (d) 0

3. The value of $\lim_{x\to 1^+}\frac{\int_1^x |t-1|\,dt}{\sin(x-1)}$ is

(a) 0 (b) 1

(c) Doesn't exist (d) None of these

4. The value of $\lim_{n\to\infty}\sum_{K=1}^{n}\log\left(1+\frac{K}{n}\right)^{1/n}$ is

(a) $\log_e\left(\frac{e}{4}\right)$ (b) $\log_e\left(\frac{4}{e}\right)$

(c) $\log_e 4$ (d) None of these

5. The value of $\lim_{n\to\infty}\left(\frac{1}{na}+\frac{1}{na+1}+\frac{1}{na+2}+\ldots+\frac{1}{nb}\right)$ is

(a) $\log\left(\frac{a}{b}\right)$ (b) $\log\left(\frac{b}{a}\right)$

(c) $\log(ab)$ (d) None of these

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *The value of* $\lim_{x\to 0}\dfrac{x\sin(\sin x)-\sin^2 x}{x^6}$ *equals*

(a) $\frac{1}{6}$ (b) $\frac{1}{12}$

(c) $\frac{1}{18}$ (d) $\frac{1}{24}$

Sol. *(c)* Here, $\lim_{x\to 0}\dfrac{x\sin(\sin x)-\sin^2 x}{x^6}$

$= \lim_{t\to 0}\dfrac{\sin^{-1}(t)\cdot\sin t - t^2}{(\sin^{-1}t)^6}$ [put $\sin x = t$]

$= \lim_{t\to 0}\dfrac{\sin^{-1}(t)\cdot\sin t - t^2}{t^6}\cdot\dfrac{t^6}{(\sin^{-1}t)^6}$

$= \lim_{t\to 0}\dfrac{\left\{t+\frac{t^3}{6}+\frac{9t^5}{120}+\frac{5t^7}{112}+\ldots\right\}\cdot\left\{t-\frac{t^3}{3!}+\frac{t^5}{5!}-\ldots\right\}-t^2}{t^6}\times 1$

$= \lim_{t\to 0}\dfrac{t^6\left(\frac{1}{5!}-\frac{1}{6\cdot(3!)}+\frac{9}{120}\right)+\text{higher powers to } t}{t^6}$

$= \frac{1}{120}+\frac{9}{120}-\frac{1}{36}=\frac{1}{18}$

● **Ex. 2** *If* $\lim_{x\to 0}\dfrac{\log_e\cot\left(\frac{\pi}{4}-K_1x\right)}{\tan K_2x}=1$, *then*

(a) $K_1 = K_2$ (b) $2K_1 = K_2$

(c) $K_1 = 2K_2$ (d) $K_1 = 4K_2$

Sol. *(b)* Here, $\lim_{x\to 0}\dfrac{\log_e\left[\cot\left(\frac{\pi}{4}-K_1x\right)\right]}{\tan K_2x}=1$

$\Rightarrow \lim_{x\to 0}\dfrac{\log\left[\cot\left(\frac{\pi}{4}-K_1x\right)-1+1\right]}{\tan K_2x}=1$

$\Rightarrow \lim_{x\to 0}\dfrac{\log\left(1+\frac{2\tan K_1x}{1-\tan K_1x}\right)}{\tan K_2x}=1$

$\Rightarrow \lim_{x\to 0}\dfrac{\log\left(1+\frac{2\tan K_1x}{1-\tan K_1x}\right)}{\frac{2\tan K_1x}{1-\tan K_1x}}\cdot\dfrac{\frac{2\tan K_1x}{1-\tan K_1x}}{\tan K_2x}=1$

$\Rightarrow \lim_{x\to 0}\dfrac{2\tan K_1x}{\tan K_2x}=1 \Rightarrow \lim_{x\to 0}\dfrac{\frac{2\tan K_1x}{K_1x}\cdot K_1x}{\frac{\tan K_2x}{K_2x}\cdot K_2x}=1$

$\Rightarrow \dfrac{2K_1}{K_2}=1 \Rightarrow 2K_1 = K_2$

● **Ex. 3** *Let* $f(\theta)=\dfrac{1}{\tan^2\theta}\{(1+\tan\theta)^3+(2+\tan\theta)^3+\ldots+(10+\tan\theta)^3\}-10\tan\theta$.

Then, $\lim_{\theta\to\frac{\pi}{2}^-} f(\theta)$ *is equal to*

(a) 170 (b) 166 (c) 165 (d) None of these

Sol. *(c)* Here,

$\lim_{\theta\to\frac{\pi}{2}^-}\dfrac{(1+\tan\theta)^3}{\tan^2\theta}=\lim_{\theta\to\frac{\pi}{2}^-}\dfrac{1+3\tan\theta+3\tan^2\theta+\tan^3\theta}{\tan^2\theta}$

$[(a+b)^3=a^3+b^3+3a^2b+3ab^2]$

$=\lim_{\theta\to\frac{\pi}{2}^-}3+\tan\theta+\left(\dfrac{3\tan\theta+1}{\tan^2\theta}\right)=\lim_{\theta\to\frac{\pi}{2}^-}(3+\tan\theta)$

$\left[\text{as }\lim_{0\to\frac{\pi}{2}^-}\left(\dfrac{3\tan\theta+1}{\tan^2\theta}\right)=0\right]$

$\Rightarrow \lim_{\theta\to\frac{\pi}{2}^-} f(\theta)=\lim_{\theta\to\frac{\pi}{2}^-}[(3+\tan\theta)+(3(2)+\tan\theta)+\ldots+(3(10)+\tan\theta)]-10\lim_{\theta\to\frac{\pi}{2}^-}\tan\theta$

$=\lim_{\theta\to\frac{\pi}{2}^-}3(1+2+3+\ldots+10)+10\cdot\lim_{\theta\to\frac{\pi}{2}^-}(\tan\theta)-10\cdot\lim_{\theta\to\frac{\pi}{2}^-}(\tan\theta)$

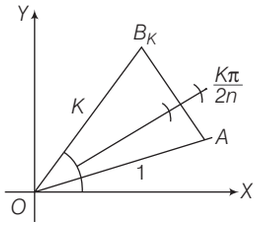
$=\dfrac{3\times 10\times 11}{2}=165$

● **Ex. 4** *For positive integers* $K=1,2,3,\ldots,n$. *Let* S_k *denotes the area of* ΔOAB_K *(where 'O' is the origin) such that* $\angle AOB_K=\dfrac{K\pi}{2n}$, $OA=1$ *and* $OB_K=K$. *The value of the* $\lim_{n\to\infty}\dfrac{1}{n^2}\cdot\sum_{K=1}^{n}S_K$ *is*

(a) $\frac{2}{\pi^2}$ (b) $\frac{4}{\pi^2}$ (c) $\frac{8}{\pi^2}$ (d) $\frac{1}{2\pi^2}$

Sol. *(a)* Here, $OB_K = K$ and $\angle AOB_K = \dfrac{K\pi}{2n}$

$\therefore \quad S_K = \dfrac{1}{2}\cdot(1)(K)\sin\left(\dfrac{K\pi}{2n}\right)$ $\left[\text{using, } \Delta = \dfrac{1}{2}ab\sin\theta\right]$



Then, $L = \lim\limits_{n\to\infty}\dfrac{1}{n^2}\cdot\dfrac{K}{2}\cdot\sin\left(\dfrac{K\pi}{2n}\right)$

$= \dfrac{1}{2n}\cdot\lim\limits_{n\to\infty}\dfrac{K}{n}\cdot\sin\left(\dfrac{\pi}{2}\cdot\dfrac{K}{n}\right) = \dfrac{1}{2}\cdot\int_0^1 x\cdot\sin\left(\dfrac{\pi}{2}x\right)dx$

$= \dfrac{1}{2}\left[\left(\underbrace{\dfrac{-2}{\pi}\cdot x\cdot\cos\dfrac{\pi x}{2}}_{0}\right)_0^1 + \dfrac{2}{\pi}\int_0^1\cos\dfrac{\pi x}{2}\cdot dx\right]$

$= \dfrac{1}{2}\left[\dfrac{2}{\pi}\cdot\dfrac{2}{\pi}\cdot\left(\sin\dfrac{\pi x}{2}\right)_0^1\right] = \dfrac{2}{\pi^2}$

● ***Ex. 5*** *If*

$S_n = \left(1-\tan^4\dfrac{\pi}{2^3}\right)\left(1-\tan^4\dfrac{\pi}{2^4}\right)\ldots\left(1-\tan^4\dfrac{\pi}{2^n}\right).$

The value of $\lim\limits_{n\to\infty} S_n$, *is*

(a) $\dfrac{\pi^3}{4}$ (b) $\dfrac{\pi^3}{16}$

(c) $\dfrac{\pi^3}{32}$ (d) $\dfrac{\pi^3}{256}$

Sol. *(c)* Here,

$$S_n = \left(1-\tan^4\frac{\pi}{2^3}\right)\left(1-\tan^4\frac{\pi}{2^4}\right)\ldots\left(1-\tan^4\frac{\pi}{2^n}\right)$$

$$\left(\cos^2\frac{\pi}{2^3}-\sin^2\frac{\pi}{2^3}\right)\left(\cos^2\frac{\pi}{2^4}-\sin^2\frac{\pi}{2^4}\right)$$

$$= \frac{\ldots\left(\cos^2\dfrac{\pi}{2^n}-\sin^2\dfrac{\pi}{2^n}\right)}{\left(\cos^4\dfrac{\pi}{2^3}\cdot\cos^4\dfrac{\pi}{2^4}\ldots\cos^4\dfrac{\pi}{2^n}\right)}$$

$$= \frac{\left(\cos\dfrac{\pi}{2^2}\right)\cdot\left(\cos\dfrac{\pi}{2^3}\right)\ldots\left(\cos\dfrac{\pi}{2^{n-1}}\right)}{\left(\cos^4\dfrac{\pi}{2^3}\cdot\cos^4\dfrac{\pi}{2^4}\ldots\cos^4\dfrac{\pi}{2^n}\right)}$$

$$= \frac{\dfrac{1}{\sqrt{2}}}{\left(\cos\dfrac{\pi}{2^3}\cdot\cos\dfrac{\pi}{2^3}\ldots\cos\dfrac{\pi}{2^{n-1}}\right)^3}\cdot\frac{1}{\cos^4\dfrac{\pi}{2^n}} \qquad \ldots(i)$$

Let $M = \cos\dfrac{\pi}{2^3}\cdot\cos\dfrac{\pi}{2^4}\ldots\cos\dfrac{\pi}{2^{n-1}}$

$$= \frac{\sin\left(2^{n-3}\cdot\dfrac{\pi}{2^{n-1}}\right)}{2^{n-3}\cdot\sin\left(\dfrac{\pi}{2^{n-1}}\right)} = \frac{\sin\left(\dfrac{\pi}{2^2}\right)}{2^{n-3}\cdot\sin\left(\dfrac{\pi}{2^{n-1}}\right)}$$

$\therefore \quad S_n = \lim\limits_{n\to\infty}\dfrac{\dfrac{1}{\sqrt{2}}}{\left(\dfrac{1}{\sqrt{2}}\right)^3}\times\left\{2^{n-3}\cdot\sin\dfrac{\pi}{2^{n-1}}\right\}^3\times\dfrac{1}{\cos^n\left(\dfrac{\pi}{2^n}\right)}$

$$= \lim_{n\to\infty} 2\cdot\left(\frac{\sin\dfrac{\pi}{2^{n-1}}}{\dfrac{\pi}{2^{n-1}}}\right)^3\cdot\left(\frac{\pi}{4}\right)^3\times\frac{1}{\cos^n\left(\dfrac{\pi}{2^n}\right)}$$

$$= 2\left(\frac{\pi}{4}\right)^3\cdot\frac{1}{1} = \frac{\pi^3}{32}$$

● ***Ex. 6*** *The value of* $\lim\limits_{x\to 2}\dfrac{\sqrt{x+7}-3\sqrt{2x-3}}{\sqrt[3]{x+6}-2\sqrt[3]{3x-5}}$ *is*

(a) $\dfrac{33}{23}$ (b) $\dfrac{34}{23}$ (c) $\dfrac{54}{25}$ (d) None of these

Sol. *(b)* We have, $L = \lim\limits_{x\to 2}\dfrac{\sqrt{x+7}-3\sqrt{2x-3}}{\sqrt[3]{x+6}-2\sqrt[3]{3x-5}}$ $\left[\dfrac{0}{0}\text{ form}\right]$

Let $x-2 = t$, such that $x\to 2 \implies t\to 0$

$\therefore \quad L = \lim\limits_{t\to 0}\dfrac{(t+9)^{1/2}-3(2t+1)^{1/2}}{(t+8)^{1/3}-2(3t+1)^{1/3}}$

$$= \frac{3}{2}\cdot\lim_{t\to 0}\frac{(1+t/9)^{1/2}-(2t+1)^{1/2}}{\left(1+\dfrac{t}{8}\right)^{1/3}-(1+3t)^{1/3}} \qquad \left[\frac{0}{0}\text{ form}\right]$$

$$= \frac{3}{2}\cdot\lim_{t\to 0}\frac{\left(1+\dfrac{1}{2}\cdot\dfrac{t}{9}\right)-\left(1+\dfrac{1}{2}\cdot(2t)\right)}{\left(1+\dfrac{1}{3}\cdot\dfrac{t}{8}\right)-\left(1+\dfrac{1}{3}\cdot(3t)\right)};$$

$[\text{using } (1+x)^n = 1+nx, \text{ as } x\to 0]$

$$= \frac{3}{2}\cdot\lim_{t\to 0}\frac{\dfrac{t}{18}-t}{\dfrac{t}{24}-t} = \frac{3}{2}\cdot\frac{\left(\dfrac{1}{18}-1\right)}{\left(\dfrac{1}{24}-1\right)} = \frac{34}{23}$$

● ***Ex. 7*** *Let* $\Delta(x) = \begin{vmatrix} f(x+\alpha) & f(x+2\alpha) & f(x+3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}$ *for some real values differential function* f *and constant* α, $\lim\limits_{x\to 0}\dfrac{\Delta(x)}{x}$ *is equal to*

(a) 0 (b) 1 (c) 2 (d) 3

Sol. *(a)* Here, $\Delta(0)=\begin{vmatrix} f(\alpha) & f(2\alpha) & f(3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}$

Thus, $\lim_{x\to 0}\frac{\Delta(x)}{x}$ $\left[\frac{0}{0}\text{ form}\right]$

$=\lim_{x\to 0}\frac{\Delta'(x)}{1}=\Delta'(0)$ [applying L'Hospital's rule]

$\therefore \lim_{x\to 0}\frac{\Delta(x)}{x}=\Delta'(0)$ ...(i)

Given, $\Delta(x)=\begin{vmatrix} f(x+\alpha) & f(x+2\alpha) & f(x+3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}$

Using definition of differentiation of determinant,

$$\Delta'(x)=\begin{vmatrix} f'(x+\alpha) & f'(x+2\alpha) & f'(x+3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}+\begin{vmatrix} f(x+\alpha) & f(x+2\alpha) & f(x+3\alpha) \\ 0 & 0 & 0 \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}+\begin{vmatrix} f(x+\alpha) & f(x+2\alpha) & f(x+3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ 0 & 0 & 0 \end{vmatrix}$$

[as α is constant $\Rightarrow \frac{d}{dx}(\alpha)=0$]

$\therefore\ \Delta'(x)=\begin{vmatrix} f'(x+\alpha) & f'(x+2\alpha) & f'(x+3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}$

or $\Delta'(0)=\begin{vmatrix} f'(\alpha) & f'(2\alpha) & f'(3\alpha) \\ f(\alpha) & f(2\alpha) & f(3\alpha) \\ f'(\alpha) & f'(2\alpha) & f'(3\alpha) \end{vmatrix}=0$

[$\because R_1$ and R_3 are identical]

Hence, $\lim_{x\to 0}\frac{\Delta(x)}{x}=\Delta'(0)=0$

● ***Ex. 8*** *Let* $\lim_{x\to 1}\frac{x^a-ax+a-1}{(x-1)^2}=f(a)$. *The value of* $f(101)$ *equals*

(a) 5050
(b) 5151
(c) 4950
(d) 101

Sol. *(a)* We have, $\lim_{x\to 1}\frac{x^a-ax+a-1}{(x-1)^2}$

Put $x=1+h$, we have

$$\lim_{h\to 0}\frac{(1+h)^a-a(1+h)+a-1}{h^2}$$

$$=\lim_{h\to 0}\frac{\left(1+ah+\frac{a(a-1)}{2!}h^2+\ldots\right)-a-ah+a-1}{h^2}$$

$\therefore f(a)=\frac{a(a-1)}{2}$; $f(101)=5050$

● ***Ex. 9*** $\lim_{x\to 1}\frac{nx^{n+1}-(n+1)x^n+1}{(e^x-e)\sin\pi x}$, *where* $n=100$ *is equal to*

(a) $\frac{5050}{\pi e}$ (b) $\frac{100}{\pi e}$ (c) $-\frac{5050}{\pi e}$ (d) $-\frac{4950}{\pi e}$

Sol. *(c)* Let $l=\lim_{x\to 1}\frac{nx^n(x-1)-(x^n-1)}{(e^x-e)\sin\pi x}$

Put $x=1+h$, so that as $x\to 1, h\to 0$

$\therefore\ l=-\lim_{h\to 0}\frac{h\cdot n(1+h)^n-\{(1+h)^n-1\}}{e\,(e^h-1)\sin\pi h}$

$$\Rightarrow\ l=-\lim_{x\to 1}\frac{n\cdot h(1+{}^nC_1h+{}^nC_2h^2+{}^nC_3h^3+\ldots)-(1+{}^nC_1h+{}^nC_2h^2+{}^nC_3h^3+\ldots-1)}{\pi e(h^2)\left(\frac{e^h-1}{h}\right)\left(\frac{\sin\pi h}{\pi h}\right)}$$

$$=-\frac{n^2-{}^nC_2}{\pi e}=-\left[\frac{2n^2-n(n-1)}{2\pi e}\right]=-\frac{n^2+n}{2(\pi e)}=-\frac{n(n+1)}{2(\pi e)}$$

If $n=100\ \Rightarrow\ l=-\left(\frac{5050}{\pi e}\right)$

● ***Ex. 10*** $\lim_{n\to\infty}\frac{1^2n+2^2(n-1)+3^2(n-2)+\ldots+n^2\cdot 1}{1^3+2^3+3^3+\ldots+n^3}$ *is equal to*

(a) $\frac{1}{3}$ (b) $\frac{2}{3}$ (c) $\frac{1}{2}$ (d) $\frac{1}{6}$

Sol. *(a)* We have,

$$\lim_{n\to\infty}\frac{1^2n+2^2(n-1)+3^2(n-2)+\ldots+n^2\{n-(n-1)\}}{\Sigma n^3}$$

Numerator $= n(1^2+2^2+\ldots+n^2)-\{1\cdot 2^2+2\cdot 3^2+3\cdot 4^2+\ldots+(n-1)n^2\}$

$$=n\Sigma n^2-\sum_{r=2}^{n}(r-1)\cdot r^2$$

$$=n\Sigma n^2-\sum_{r=1}^{n}(r^3-r^2)$$

$$=n\Sigma n^2-[\Sigma n^3-\Sigma n^2]=(n+1)\Sigma n^2-\Sigma n^3$$

$$\therefore\ l=\lim_{n\to\infty}\frac{(n+1)\Sigma n^2-\Sigma n^3}{\Sigma n^3}$$

$$=\lim_{n\to\infty}\frac{4(n+1)\,n(n+1)(2n+1)}{6n\,(n+1)\,n\,(n+1)}-1=\frac{4}{3}-1=\frac{1}{3}$$

Aliter $l=\dfrac{1^2n+2^2\,(n-1)+\ldots+n^2\cdot 1}{\underbrace{1^3+2^3+3^3+\ldots+n^3}}+1-1$

$$l=\frac{1^2(n+1)+2^2\,(n+1)+\ldots+n^2\,(n+1)}{\Sigma n^3}-1$$

$$l=\frac{(n+1)\,\Sigma n^2}{\Sigma n^3}-1$$

$$\Rightarrow\quad\lim_{n\to\infty}\frac{(n+1)\cdot n(n+1)(2n+1)}{6\cdot\dfrac{n^2\,(n+1)^2}{4}}-1=\frac{4}{3}-1=\frac{1}{3}$$

● ***Ex. 11*** *The value of* $\lim\limits_{x\to\infty}\dfrac{\cot^{-1}(x^{-a}\log_a x)}{\sec^{-1}(a^x\log_x a)}\,(a>1)$ *is equal to*

(a) 1 (b) 0 (c) $\dfrac{\pi}{2}$ (d) Doesn't exist

Sol. *(a)* We have, $\lim\limits_{x\to\infty}\dfrac{\cot^{-1}\left(\dfrac{\log_a x}{x^a}\right)}{\sec^{-1}\left(\dfrac{a^x}{\log_a x}\right)}$;

as $\lim\limits_{x\to\infty}\left(\dfrac{\log_a x}{x^a}\right)\to 0$ and $\left(\dfrac{a^x}{\log_a x}\right)\to\infty$

[using L' Hospital's rule]

$$\therefore\qquad l=\frac{\frac{\pi}{2}}{\frac{\pi}{2}}=1$$

● ***Ex. 12*** *Suppose that* a *and* $b\,(b\neq a)$ *are real positive numbers, thene the value of* $\lim\limits_{t\to 0}\left(\dfrac{b^{t+1}-a^{t+1}}{b-a}\right)^{1/t}$ *is equal to*

(a) $\dfrac{a\ln b-b\ln a}{b-a}$ (b) $\dfrac{b\ln b-a\ln a}{b-a}$

(c) $b\ln b-a\ln a$ (d) $\left(\dfrac{b^b}{a^a}\right)^{\frac{1}{b-a}}$

Sol. *(d)* Here, $\lim\limits_{t\to 0}\left(\dfrac{b^{t+1}-a^{t+1}}{b-a}\right)^{\frac{1}{t}}$.

Obviously, limit is of the form 1^∞.

Hence, $l=e^{\lim\limits_{t\to 0}\frac{1}{t}\left[\frac{b^{t+1}-a^{t+1}}{b-a}-1\right]}=e^{\lim\limits_{t\to 0}\left(\frac{b^{t+1}-a^{t+1}-b+a}{t(b-a)}\right)}$

$$=e^{\lim\limits_{t\to 0}\left(\frac{b(b^t-1)-a(a^t-1)}{t(b-a)}\right)}=e^{\frac{b\ln b-a\ln a}{b-a}}$$

$$=e^{\frac{\ln b^b-\ln a^a}{b-a}}=e^{\frac{\ln\frac{b^b}{a^a}}{b-a}}=e^{\ln\left(\frac{b^b}{a^a}\right)^{\frac{1}{b-a}}}=\left(\frac{b^b}{a^a}\right)^{\frac{1}{b-a}}$$

● ***Ex. 13*** $\lim\limits_{x\to\infty}\dfrac{\cot^{-1}(\sqrt{x+1}-\sqrt{x})}{\sec^{-1}\left\{\left(\dfrac{2x+1}{x-1}\right)^x\right\}}$ *is equal to*

(a) 1 (b) 0 (c) $\dfrac{\pi}{2}$ (d) None of these

Sol. *(a)* As, $\lim\limits_{x\to\infty}\sqrt{x+1}-\sqrt{x}=0\Rightarrow\cot^{-1}(0)=\dfrac{\pi}{2}$

$$\lim_{x\to\infty}\left(\frac{2x+1}{x-1}\right)^x\to\infty\quad\Rightarrow\ \sec^{-1}(\infty)=\frac{\pi}{2}$$

$$\therefore\qquad l=1$$

● ***Ex. 14*** $\lim\limits_{n\to\infty}\cos(\pi\sqrt{n^2+n})$ *(when* n *is an integer) is equal to*

(a) 1 (b) -1 (c) 0 (d) Doesn't exist

Sol. *(c)* Let $l=\lim\limits_{n\to\infty}\pm\cos(n\pi-\pi\sqrt{n^2+n})$

$$=\lim_{n\to\infty}\pm\cos(\pi(n-\sqrt{n^2+n}))$$

$$=\lim_{n\to\infty}\pm\cos\left(\frac{(\pi(+n))}{n+\sqrt{n^2+n}}\right)$$

$$=\lim_{n\to\infty}\pm\cos\left(\frac{n\pi}{n+n\sqrt{1+\frac{1}{n}}}\right)$$

$$=\lim_{n\to\infty}\pm\cos\left(\frac{\pi}{1+\sqrt{1+\frac{1}{n}}}\right)=\cos\frac{\pi}{2}\to 0$$

Aliter

We have, $\pi\sqrt{n^2+n}$

$$=\pi n\left(1+\frac{1}{n}\right)^{1/2}=n\pi\left[1+\frac{1}{2n}+\frac{1}{2}\left(\frac{1}{2}-1\right)\frac{1}{2!}\frac{1}{n^2}+\ldots\right]$$

$$=\pi\left[n+\frac{1}{2}+\frac{1}{2}\left(\frac{1}{2}-1\right)\frac{1}{2!}\frac{1}{n}+\ldots\right]$$

As $n\to\infty;\ \dfrac{\pi}{2}\cdot\left[2n+1+\left(\dfrac{1}{2}-1\right)\dfrac{1}{2!}\dfrac{1}{n}+\ldots\right]=(2n+1)\dfrac{\pi}{2}$

$$\therefore\qquad\lim_{n\to\infty}\cos\left((2n+1)\frac{\pi}{2}\right)=0$$

● **Ex. 15** *The value of* $\lim_{x\to 0}\dfrac{(\tan(\{x\}-1))\sin\{x\}}{\{x\}(\{x\}-1)}$, *where* $\{x\}$ *denotes the fractional part function is*

(a) 1 (b) tan 1 (c) sin 1 (d) Doesn't exist

Sol. *(d)* Let $f(x)=\lim_{x\to 0}\dfrac{(\tan(\{x\}-1))\sin\{x\}}{\{x\}(\{x\}-1)}$

$$\lim_{x\to 0^+} f(x)=\lim_{h\to 0^+}\frac{\tan(h-1)\cdot\sin h}{h(h-1)}=\frac{\tan(-1)}{-1}=\tan 1$$

$$\text{LHL}=\lim_{h\to 0}\frac{\tan((1-h)-1)\sin(1-h)}{(1-h)(1-h-1)}=\frac{\sin 1}{1}=\sin 1$$

Hence, $\lim_{x\to 0} f(x)$ doesn't exist.

● **Ex. 16** $\lim_{x\to 0^-}(-\ln(\{x\}+|[x]|))^{\{x\}}$ *is equal to*

(a) 0 (b) 1 (c) $\ln 2$ (d) $\ln\dfrac{1}{2}$

Sol. *(d)* We have, $\lim_{x\to 0^-}=(-\ln(\{x\}+|[x]|))^{\{x\}}$

$$=\lim_{x\to 0^-}(-\ln(\{0-h\}+|[-h]|))^{\{-h\}}$$

$$=\lim_{x\to 0^-}(-\ln(1-h+1))^{1-h}=-\ln 2=\ln\left(\frac{1}{2}\right)$$

● **Ex. 17** $\lim_{x\to\infty}\dfrac{2+2x+\sin 2x}{(2x+\sin 2x)\,e^{\sin x}}$ *is equal to*

(a) 0 (b) 1 (c) -1 (d) Non-existent

Sol. *(d)* We have, $\lim_{x\to\infty}\dfrac{2+2x+\sin 2x}{(2x+\sin 2x)e^{\sin x}}$

$$=\lim_{x\to\infty}\frac{\frac{2}{x}+2+\frac{\sin 2x}{x}}{\left(2+\frac{\sin 2x}{x}\right)e^{\sin x}},\ \text{as } x\to\infty$$

$\Rightarrow l=\lim_{x\to\infty}\dfrac{2}{2\cdot e^{\sin x}}=$ oscillatory between $\dfrac{1}{e}$ and $\dfrac{1}{e^{-1}}\Rightarrow$ Non-existent

● **Ex. 18** *The value of* $\lim_{x\to 0}(\cos ax)^{\operatorname{cosec}^2 bx}$ *is*

(a) $e^{\left(-\frac{8b^2}{a^2}\right)}$ (b) $e^{\left(-\frac{8a^2}{b^2}\right)}$

(c) $e^{\left(-\frac{a^2}{2b^2}\right)}$ (d) $e^{\left(-\frac{b^2}{2a^2}\right)}$

Sol. *(c)* Let $l=\lim_{x\to 0}(\cos ax)^{\operatorname{cosec}^2 bx}$

$$\Rightarrow\quad l=e^{\lim_{x\to\infty}\operatorname{cosec}^2 bx\,(\cos ax-1)}$$

Now, $-\lim_{x\to 0}\dfrac{1-\cos ax}{\sin^2 bx}=-\lim_{x\to 0}\dfrac{\sin^2 ax}{\sin^2 bx}\cdot\dfrac{1}{1+\cos ax}$

$$=-\frac{a^2}{2b^2},\quad l=e^{-\frac{a^2}{2b^2}}$$

● **Ex. 19** $\lim_{n\to\infty}\sum_{r=1}^{n}\dfrac{r}{n^2+n+r}$ *equals*

(a) 0 (b) 1/3 (c) 1/2 (d) 1

Sol. *(c)* Let $f(n)=\dfrac{1}{n^2+n+1}+\dfrac{2}{n^2+n+2}+\ldots+\dfrac{n}{n^2+n+n}$

Consider $g(n)=\dfrac{1}{n^2+n+n}+\dfrac{2}{n^2+n+n}+\ldots+\dfrac{n}{n^2+n+n}$

$$=\frac{1+2+3+\ldots+n}{n^2+2n}=\frac{n(n+1)}{2(n^2+2n)}$$

$$g(n)<f(n) \qquad \ldots(\text{i})$$

Similarly, $h(n)=\dfrac{1}{n^2+n+1}+\dfrac{2}{n^2+n+1}+\ldots+\dfrac{n}{n^2+n+1}$

$$=\frac{n(n+1)}{2(n^2+n+1)}$$

$$\therefore\quad f(n)<h(n) \qquad \ldots(\text{ii})$$

From Eqs. (i) and (ii), $g(n)<f(n)<h(n)$

But $\lim_{n\to\infty} g(n)=\lim_{n\to\infty} h(n)=\dfrac{1}{2}$.

Hence, using Sandwich theorem, $\lim_{n\to\infty} f(n)=\dfrac{1}{2}$.

● **Ex. 20** *The value of* $\lim_{n\to\infty}(\sqrt{n^2+n+1}-[\sqrt{n^2+n+1}])$, *where* $[\cdot]$ *denotes the greatest integer function is*

(a) 0 (b) 1/2 (c) 2/3 (d) 1/4

Sol. *(b)* We know that, $n<\sqrt{n^2+n+1}<n+1$.

Hence, $[\sqrt{n^2+n+1}]=n$

$$\therefore\ l=\lim_{n\to\infty}(\sqrt{n^2+n+1}-n)=\lim_{n\to\infty}\frac{n+1}{\sqrt{n^2+n+1}+n}=\frac{1}{2}$$

● **Ex. 21** $\lim_{x\to 1}\dfrac{\sin^2(x^3+x^2+x-3)}{1-\cos(x^2-4x+3)}$ *has the value equal to*

(a) 18 (b) 9/2 (c) 9 (d) None of these

Sol. *(a)* We have, $\lim_{x\to 1}\dfrac{\sin^2(x^3+x^2+x-3)}{1-\cos(x^2-4x+3)}$

$$=\lim_{x\to 1}\frac{\sin^2(x^3+x^2+x-3)}{(x^3+x^2+x-3)^2}\cdot\frac{(x^3+x^2+x-3)^2}{1-\cos(x^2-4x+3)}$$

$$=(1)\lim_{x\to 1}\frac{(x^2-4x+3)^2}{1-\cos(x^2-4x+3)}\cdot\frac{(x^3+x^2+x-3)^2}{(x^2-4x+3)^2}$$

$$= (1)(2)\lim_{x\to 1}\left(\frac{x^3+x^2+x-3}{x^2-4x+3}\right)^2 = 2l^2$$

where, $l = \lim_{x\to 1}\frac{3x^2+2x+1}{2x-4}$ [using L' Hospital's rule]

$$= \frac{6}{-2} = -3 \Rightarrow l = 2(-3)^2 = 18$$

● ***Ex. 22*** *The graph of function $y = f(x)$ has a unique tangent at $(e^a, 0)$ through which the graph passes, then* $\lim_{x\to e^a}\frac{\log(1+7f(x)) - \sin(f(x))}{3f(x)}$ *equals*

(a) 1 (b) 2
(c) 7 (d) None of these

Sol. *(b)* Here, $\lim_{x\to e^a}\frac{\log(1+7f(x)) - \sin(f(x))}{3f(x)}$ $\left[\frac{0}{0}\text{ form}\right]$

$$= \lim_{x\to e^a}\frac{7f'(x) - \{\cos(f(x))\cdot f'(x)\}\{1+7f(x)\}}{3f'(x)\cdot\{1+7f(x)\}}$$

[using L'Hospital's rule]

$$= \lim_{x\to e^a}\frac{7-\cos(f(x))\{1+7f(x)\}}{3\{1+7f(x)\}} = \frac{7-1}{3} = 2$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

● ***Ex. 23*** *If $f(x) = \frac{3x^2+ax+a+1}{x^2+x-2}$, which of the following can be correct?*

(a) $\lim_{x\to 1} f(x)$ exists $\Rightarrow a = -2$

(b) $\lim_{x\to -2} f(x)$ exists $\Rightarrow a = 13$

(c) $\lim_{x\to 1} f(x) = 4/3$

(d) $\lim_{x\to -2} f(x) = -1/3$

Sol. *(a, b, c, d)* Given, $f(x) = \frac{3x^2+ax+a+1}{(x+2)(x-1)}$

As $x\to 1$, Dr. $\to 0$, hence as $x\to 1$, Nr. $\to 0$

$\therefore \quad 3+2a+1=0 \Rightarrow a=-2$

As $x\to -2$, Dr. $\to 0$, hence as $x\to -2$, Nr. $\to 0$

$\therefore \quad 12-2a+a+1=0 \Rightarrow a=13$

Now, $\lim_{x\to 1} f(x) = \lim_{x\to 1}\frac{3x^2-2x-1}{(x+2)(x-1)}$

$$= \lim_{x\to 1}\frac{(3x+1)(x-1)}{(x+2)(x-1)} = \frac{4}{3}$$

and $\lim_{x\to -2}\frac{3x^2+13x+14}{(x+2)(x-1)} = \lim_{x\to -2}\frac{(3x+7)(x+2)}{(x+2)(x-1)} = -\frac{1}{3}$

● ***Ex. 24*** *Let* $f(x) = \begin{cases} \frac{\tan^2\{x\}}{x^2-[x]^2}, & \text{for } x>0 \\ 1, & \text{for } x=0 \\ \sqrt{\{x\}\cot\{x\}}, & \text{for } x<0 \end{cases}$ *where $[x]$ is the step up function and $\{x\}$ is the fractional part function of x, then*

(a) $\lim_{x\to 0^+} f(x) = 1$ (b) $\lim_{x\to 0^-} f(x) = 1$

(c) $\cot^{-1}\left(\lim_{x\to 0^-} f(x)\right)^2 = 1$ (d) None of these

Sol. *(a, c)* We have, $f(x) = \begin{cases} \frac{\tan^2\{x\}}{x^2-[x]^2}, & x>0 \\ 1, & x=0 \\ \sqrt{\{x\}\cot\{x\}}, & x<0 \end{cases}$

$$\text{RHL} = \lim_{x\to 0^+} f(x) = \lim_{h\to 0}\frac{\tan^2\{h\}}{h^2-[h]^2} = \lim_{h\to 0}\frac{\tan^2 h}{h^2} = 1$$

$$\text{LHL} = \lim_{x\to 0^-} f(x) = \lim_{h\to 0}\sqrt{\{-h\}\cot\{-h\}}$$

$$= \lim_{h\to 0}\sqrt{(1-h)\cot(1-h)} = \sqrt{\cot 1}$$

$$\therefore \quad \cot^{-1}\left(\lim_{x\to 0^-} f(x)\right)^2 = \cot^{-1}(\sqrt{\cot 1})^2 = 1$$

● ***Ex. 25*** *Given that the derivative $f'(a)$ exists. Indicate which of the following statement(s) is/are always true?*

(a) $f'(a) = \lim_{h\to a}\frac{f(h)-f(a)}{h-a}$

(b) $f'(a) = \lim_{h\to 0}\frac{f(a)-f(a-h)}{h}$

(c) $f'(a) = \lim_{t\to 0}\frac{f(a+2t)-f(a)}{t}$

(d) $f'(a) = \lim_{t\to 0}\frac{f(a+2t)-f(a+t)}{2t}$

Sol. *(a, b)* Here, options (a) and (b) are true by definition.
Option (c) is false, as

$$\lim_{t\to 0}\frac{f(a+2t)-f(a)}{t}=2f'(a)$$

and $\lim_{t\to 0}\frac{f(a+2t)-f(a+t)}{2t}=\frac{1}{2}[2f'(a)-f'(a)]=\frac{1}{2}f'(a)$

Hence, option (d) is false.

● **Ex. 26** *Let* $f(x)=\lim_{n\to\infty}\sum_{r=0}^{n}\frac{x}{(rx+1)\{(r+1)x+1\}}$. *Then,*

(a) $f(0)=0$ (b) $f(0)=x$
(c) $f(0^+)=1$ (d) $f(0^-)=1$

Sol. *(a, c, d)* Given, $f(x)=\lim_{n\to\infty}\sum_{r=0}^{n}\frac{x}{(rx+1)\{(r+1)x+1\}}$

$$=\lim_{n\to\infty}\sum_{r=0}^{n}\frac{[(r+1)x+1)]-(rx+1)}{(rx+1)[(r+1)x+1]}$$

$$=\lim_{n\to\infty}\sum_{r=0}^{n}\left(\frac{1}{rx+1}-\frac{1}{(r+1)x+1}\right)$$

$$=\lim_{n\to\infty}\left[\left(\frac{1}{1}-\frac{1}{x+1}\right)+\left(\frac{1}{x+1}-\frac{1}{2x+1}\right)+\ldots+\left(\frac{1}{nx+1}-\frac{1}{(n+1)x+1}\right)\right]$$

$$=\lim_{n\to\infty}\left[1-\frac{1}{(n+1)x+1}\right]=\lim_{n\to\infty}\frac{(n+1)x}{(n+1)x+1}$$

$\therefore\quad f(x)=\begin{cases}0, & x=0\\ 1, & x\neq 0\end{cases}\Rightarrow f(0)=0,\ f(0^+)=f(0^-)=1.$

(c) $3+2\sqrt{2}$ (d) $3-2\sqrt{2}$

● **Ex.29** *If centres of circles belonging to family having equal radii r are joined, the area of figure formed is*

(a) $2r^2$ (b) $4r^2$
(c) $8r^2$ (d) r^2

■ **Sol.** (Q. Nos. 27 to 29)

$$\text{LHD}=\lim_{h\to 0}\frac{\dfrac{-\sin h+\tan h+\cos h-1}{2h^2+\ln(2-h)-\tan h}-0}{-h}$$

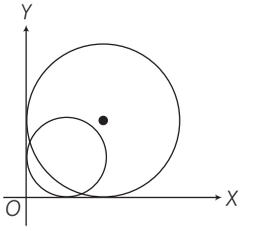
$$=\lim_{h\to 0}\frac{\dfrac{\sin h}{h}-\dfrac{\tan h}{h}+\dfrac{1-\cos h}{h^2}\times h}{2h^2+\ln(2-h)-\tan h}=0$$

$$f'(0^+)=\text{RHD}=\lim_{h\to 0}\frac{e^{h^2}-1-0}{h}=h\times\frac{e^{h^2}-1}{h^2}=0$$

$L_1\equiv y=0$ and $L_2\equiv x=0$

27. *(a)* $(x-r)^2+(y-r)^2=r^2$ [family of circle]

$x^2+y^2-2rx-2ry+r^2=0$



$\because\quad 2(r_1r_2+r_1r_2)=r_1^2+r_2^2$

or $\quad 4r_1r_2=r_1^2+r_2^2$

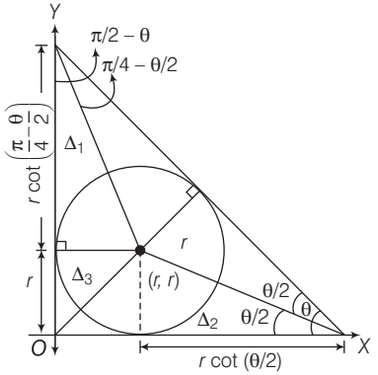
$$\left(\frac{r_2}{r_1}\right)^2-4\left(\frac{r_2}{r_1}\right)+1=0$$

$$\Rightarrow\quad \frac{r_2}{r_1}=\frac{4\pm\sqrt{12}}{2}=2\pm\sqrt{3}$$

28. *(c)* $2[\Delta_1 + \Delta_2 + \Delta_3]$

$$\Delta = 2 \times \frac{1}{2}\left(\cot\left(\frac{\pi}{4} - \frac{\theta}{2}\right) + \cot\frac{\theta}{2} + 1\right) \quad \left[\text{using, } \frac{1}{2}ab\right]$$

$$\Delta = \frac{\cos\left(\frac{\pi}{4} - \frac{\theta}{2}\right)}{\sin\left(\frac{\pi}{4} - \frac{\theta}{2}\right)} + \frac{\cos\frac{\theta}{2}}{\sin\frac{\theta}{2}} + 1$$



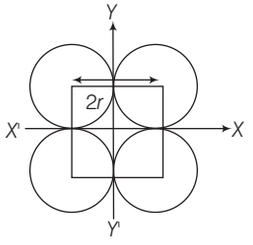
$$\Rightarrow \quad \Delta = 1 + \frac{2\sin\frac{\pi}{4}}{2\sin\frac{\theta}{2}\cdot\sin\left(\frac{\pi}{4} - \frac{\theta}{2}\right)}$$

$$\Delta = 1 + \frac{\sqrt{2}}{\cos\left(\theta - \frac{\pi}{4}\right) - \cos\left(\frac{\pi}{4}\right)}$$

Δ is minimum, if denominators is maximum when $\theta = \frac{\pi}{4}$,

$$\Delta_{\min} = 1 + \frac{\sqrt{2}}{1 - \frac{1}{\sqrt{2}}} = 1 + \frac{2}{\sqrt{2} - 1} = 1 + 2(\sqrt{2} + 1) = 3 + 2\sqrt{2}$$

29. *(b)* Area $= (2r)^2 = 4r^2$



Passage II

(Q. Nos. 30 to 32)

Let A be $n \times n$ matrix given by

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \ldots a_{1n} \\ a_{21} & a_{22} & a_{23} \ldots a_{2n} \\ \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & a_{n3} \ldots a_{nn} \end{bmatrix}$$

Such that each horizontal row is arithmetic progression and each vertical column is a geometrical progression. It is known that each column in geometric progression have the same common ratio. Given that $a_{24} = 1$, $a_{42} = \frac{1}{8}$ and $a_{43} = \frac{3}{16}$.

● ***Ex.30*** *Let $S_n = \sum_{j=1}^{n} a_{4j}$, $\lim_{n\to\infty} \frac{S_n}{n^2}$ is equal to*

(a) $\frac{1}{4}$ (b) $\frac{1}{8}$ (c) $\frac{1}{16}$ (d) $\frac{1}{32}$

Sol. (*d*) Here, $a_{43} = a_{42} + d$

$$\Rightarrow \quad \frac{3}{16} = \frac{1}{8} + d \;\Rightarrow\; d = \frac{1}{16}$$

[common difference of 4th row]

$$\therefore \quad a_{41} = a_{42} - d = \frac{1}{8} - \frac{1}{16} = \frac{1}{16}$$

$$\therefore \quad a_{41} = \frac{1}{16}, a_{42} = \frac{2}{16}, a_{43} = \frac{3}{16}, \ldots, a_{4n} = \frac{n}{16}$$

Now, all elements of 4th row are known

$$S_n = \sum_{j=1}^{n} a_{4j} = \frac{n(n+1)}{2(16)}; \lim_{n\to\infty} \frac{S_n}{n^2} = \frac{1}{32}$$

● ***Ex.31*** *Let d_i be the common difference of the elements in ith row, then $\sum_{i=1}^{n} d_i$ is*

(a) n (b) $\frac{1}{2} - \frac{1}{2^{n+1}}$ (c) $1 - \frac{1}{2^n}$ (d) $\frac{n+1}{2^n}$

Sol. (*c*) Also, $a_{24}r^2 = a_{44} = \frac{4}{16}$

$$\Rightarrow \quad r^2 = \frac{4}{16} \;\Rightarrow\; r = \frac{1}{2} \quad \left[\text{common ratio of all GP is } \frac{1}{2}\right]$$

$$\therefore \quad A = \begin{bmatrix} \frac{1}{2} & \frac{2}{2} & \frac{3}{2} & \ldots & \frac{n}{2} \\ \frac{1}{2^2} & \frac{2}{2^2} & \frac{3}{2^2} & \ldots & \frac{n}{2^2} \\ \frac{1}{2^3} & \frac{2}{2^3} & \frac{3}{2^3} & \ldots & \frac{n}{2^3} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{1}{2^n} & \frac{2}{2^n} & \frac{3}{2^n} & \ldots & \frac{n}{2^n} \end{bmatrix}_{n\times n}$$

Now, d_i = common difference in ith row $= \frac{1}{2^i}$

$$\therefore \quad \sum_{i=1}^{n} d_i = \sum_{i=1}^{n} \frac{1}{2^i} = \frac{\frac{1}{2}\left(1 - \frac{1}{2^n}\right)}{1 - \frac{1}{2}} = 1 - \frac{1}{2^n}$$

● **Ex.32** *The value of* $\lim_{n\to\infty}\sum_{i=1}^{n} a_{ii}$ *is equal to*

(a) $\frac{1}{4}$ (b) $\frac{1}{2}$ (c) 1 (d) 2

Sol. *(d)* Given, $\sum_{i=1}^{n} a_{ii} = S = \frac{1}{2}+\frac{2}{2^2}+\frac{3}{2^3}+\ldots+\frac{n}{2^n}$ ...(i)

$\Rightarrow \quad \frac{1}{2}S_n = \frac{1}{2^2}+\frac{2}{2^3}+\frac{3}{2^4}+\ldots+\frac{n-1}{2^n}+\frac{n}{2^{n+1}}$ ...(ii)

On subtracting Eq. (ii) from Eq. (i), we get

$$\frac{1}{2}S_n = \left(\frac{1}{2}+\frac{1}{2^2}+\frac{1}{2^3}+\ldots+\frac{1}{2^n}\right)-\frac{n}{2^{n+1}}$$

$$\Rightarrow \frac{1}{2}S_n = \frac{\frac{1}{2}\left(1-\frac{1}{2^n}\right)}{1-\frac{1}{2}}-\frac{n}{2^{n+1}} \Rightarrow S_n = 2\left(1-\frac{1}{2^n}\right)-\frac{n}{2^n}$$

$$\therefore \quad \lim_{n\to\infty}\sum_{i=1}^{n} a_{ii} = \lim_{n\to\infty} 2-\frac{2}{2^n}-\frac{2n}{2^n} = 2-0-0 = 2$$

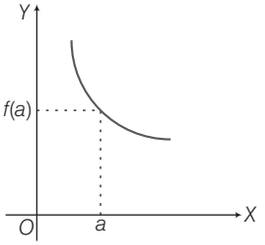
$$\Rightarrow \lim_{n\to\infty}\sum_{i=1}^{n} a_{ii} = 2$$

Passage III

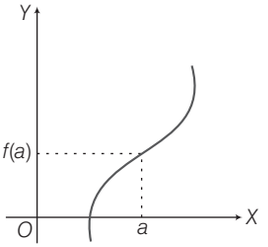
(Q. Nos. 33 to 35)

To evaluate $\lim_{x\to a}[f(x)]$, *we must analyse the* $f(x)$ *in right hand neighbourhood as well as in left hand neighbourhood of* $x = a$. e.g. *In case of continuous function, we may come across following cases.*

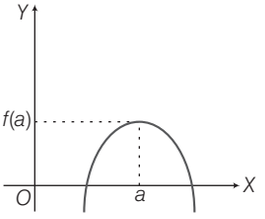
***Case* I**



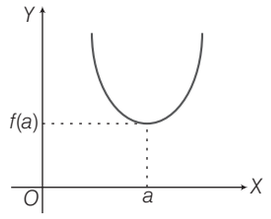
***Case* II**



***Case* III**



***Case* IV**



If $f(a)$ *is an integer, the limit will exist in Case* III *and Case* IV *but not in Case* I *and Case* II. *If* $f(a)$ *is not an integer, the limit exists in all the cases.*

● **Ex.33** *If* $f'(1) = -3$ *and* $\lim_{x\to 1}\left[f(x)-\frac{1}{2}\right]$ *does not exist, (where* $[\cdot]$ *denotes the greatest integer function), then*

(a) $f(1)$ may be integer

(b) $\{f(x)\} = \frac{1}{2}, \forall\ x \in R$ ($\{\cdot\}$ fractional part of x)

(c) $f(1)$ is not an integer

(d) None of the above

Sol. *(c)* $\lim_{x\to 1}\left[f(x)-\frac{1}{2}\right]$ does not exist, when $f(1)$ is not an integer, as $f'(1) = -3$, i.e. decreasing in the neighbourhood at $x = 1$.

● **Ex.34** $\lim_{x\to 0}\left[(1-e^x)\cdot\frac{\sin x}{|x|}\right]$ *(where* $[\cdot]$ *denotes the greatest integer function), equals*

(a) 0 (b) 1 (c) -1 (d) Doesn't exist

Sol. *(c)* Let $f(x) = \begin{cases}(1-e^x)\cdot\frac{\sin x}{x}, & x>0\\ (e^x-1)\cdot\frac{\sin x}{x}, & x<0\end{cases}$.

$$\therefore \quad f(x) = \begin{cases}<0, & \text{for } x>0\\ <0, & \text{for } x<0\end{cases} \Rightarrow \lim_{x\to 0}[f(x)] = -1$$

● **Ex.35** $\lim_{x\to 1}\left[\text{cosec}\frac{\pi x}{2}\right]^{-1/(1-x)}$ *is equal to (where* $[\cdot]$ *denotes the greatest integer function).*

(a) 0 (b) 1 (c) ∞ (d) Doesn't exist

Sol. *(b)* Let $f(x) = \text{cosec}\left(\frac{\pi x}{2}\right)$

$$\Rightarrow \quad f(1^+) = \lim_{h\to 0}\text{cosec}\left(\frac{\pi}{2}(1+h)\right) > 1$$

and $\quad f(1^-) = \lim_{h\to 0}\text{cosec}\left(\frac{\pi}{2}(1-h)\right) > 1$

$$\therefore \lim_{x\to 1}\left[\text{cosec}\frac{\pi x}{2}\right] = 1 \Rightarrow \lim_{x\to 1}\left[\text{cosec}\frac{\pi x}{2}\right]^{\frac{-1}{1-x}} = 1$$

JEE Type Solved Examples :
Statements I and II Type Questions

■ **Directions** (Ex. Nos. 36 to 38) This section is based on Statements I and II. Select the correct answer from the codes given below.

(a) Statement I is true, Statement II is true; Statement II is correct explanation for Statement I

(b) Statement I is true, Statement II is true; Statement II is not the correct explanation for Statement I

(c) Statement I is true, Statement II is false

(d) Statement I is false, Statement II is true

● ***Ex. 36***

Statement I $\lim\limits_{x \to \pi/2} \dfrac{\sin(\cot^2 x)}{(\pi - 2x)^2} = \dfrac{1}{2}$.

Statement II $\lim\limits_{\theta \to 0} \dfrac{\sin\theta}{\theta} = 1$ *and* $\lim\limits_{\theta \to 0} \dfrac{\tan\theta}{\theta} = 1$, *where* θ *is measured in radians.*

Sol. *(d)* $\lim\limits_{x \to \pi/2} \dfrac{\sin(\cot^2 x)}{\cot^2 x} \cdot \dfrac{\cot^2 x}{(\pi - 2x)^2}$; put $x = \dfrac{\pi}{2} - h$

$\Rightarrow \lim\limits_{h \to 0} \dfrac{\tan^2 h}{4h^2} = \dfrac{1}{4}$

$\therefore$ Statement I is false and Statement II is true.

● ***Ex. 37*** **Statement I** $\lim\limits_{m \to \infty} \lim\limits_{n \to \infty} \{\sin^{2m} n!\pi n\} = 0$ $m, n \in N$, when x is rational.

Statement II When $n \to \infty$ and x is rational $n!x$, is integer.

Sol. *(a)* When $n \to \infty$ and x is rational $x = \dfrac{b}{q}$.

Where p and q are integers and $q \neq 0$ $n!x = n! \times \dfrac{p}{q}$ is integer as $n!$ has factor q, when $n \to \infty$

Also, when $n\,!\,x$ is integer, $\sin(n!\pi x) = 0$.

Therefore, the given limit is zero.

● ***Ex. 38*** **Statement I** *If* $\lim\limits_{x \to 0} \left\{ f(x) + \dfrac{\sin x}{x} \right\}$ *does not exist, then* $\lim\limits_{x \to 0} f(x)$ *does not exist.*

Statement II $\lim\limits_{x \to 0} \left(\dfrac{e^{1/x} - 1}{e^{1/x} + 1} \right)$ does not exist.

Sol. *(b)* If $\lim\limits_{x \to 0} f(x)$ exist, then $\lim\limits_{x \to 0} \left(f(x) + \dfrac{\sin x}{x} \right)$ always exist as $\lim\limits_{x \to 0} \dfrac{\sin x}{x}$ exists finitely.

Hence, $\lim\limits_{x \to 0} f(x)$ must not exist.

JEE Type Solved Examples :
Matching Type Questions

● ***Ex. 39*** *Match the following.*

	Column I	Column II
(A)	$\lim\limits_{x \to \infty} \left(\dfrac{x}{1+x} \right)^x$ equals	(p) e^2
(B)	$\lim\limits_{x \to \infty} \left(\sin\dfrac{1}{x} + \cos\dfrac{1}{x} \right)^x$ equals	(q) $e^{-1/2}$
(C)	$\lim\limits_{x \to 0} (\cos x)^{\cot^2 x}$ equals	(r) e
(D)	$\lim\limits_{x \to 0} \left[\tan\left(\dfrac{\pi}{4} + x \right) \right]^{1/x}$ equals	(s) e^{-1}

Sol. (A) $\rightarrow$ (s); (B) $\rightarrow$ (r); (C) $\rightarrow$ (q); (D) $\rightarrow$ (p)

(A) Put $x = \dfrac{1}{y}$, $\lim\limits_{y \to 0} \left(\dfrac{1}{1+y} \right)^{1/y} = e^{\lim\limits_{y \to 0} \frac{1 - y - 1}{y(1+y)}} = e^{-1}$

(B) $\lim\limits_{y \to 0} (\sin y + \cos y)^{1/y} = e^{\lim\limits_{y \to 0} \frac{\sin y + \cos y - 1}{y}} = e$

(C) $e^{\lim\limits_{x \to 0} \frac{\cos x - 1}{\frac{\tan^2 x}{x^2} x^2}} = e^{-\frac{1}{2}}$

(D) $e^{\lim\limits_{x \to 0} \frac{\tan((\pi/4) + x) - \tan(\pi/4)}{x}}$

$= e^{\lim\limits_{x \to 0} \frac{\tan x [1 + \tan((\pi/4) + x) \cdot 1]}{x}} = e^2$

● ***Ex. 40*** *Match the following.*

	Column I	Column II
(A)	$\lim_{x\to\infty}(\sqrt{x+\sqrt{x}}-\sqrt{x-\sqrt{x}})$ equals	(p) -2
(B)	The value of the $\lim_{x\to 0}\frac{\sin 2x-2\tan x}{\ln(1+x^3)}$ is	(q) -1
(C)	$\lim_{x\to 0^+}(\ln\sin^3 x-\ln(x^4+ex^3))$ equals	(r) 0
(D)	Let $\tan(2\pi\mid\sin\theta\mid)=\cot(2\pi\mid\cos\theta\mid)$, where $\theta\in R$ and $f(x)=(\mid\sin\theta\mid+\mid\cos\theta\mid)^x$. The value of $\lim_{x\to\infty}\left[\frac{2}{f(x)}\right]$ equals (here, $[\cdot]$ represents greatest integer function)	(s) 1

Sol. (A) $\to$ (s); (B) $\to$ (p); (C) $\to$ (q); (D) $\to$ (r)

(A) $\lim_{x\to\infty}\dfrac{(x+\sqrt{x})-(x-\sqrt{x})}{\sqrt{x+\sqrt{x}}+\sqrt{x-\sqrt{x}}}$

$$=\lim_{x\to\infty}\frac{2\sqrt{x}}{\sqrt{x+\sqrt{x}}+\sqrt{x-\sqrt{x}}}=1$$

(B) $\lim_{x\to 0}\dfrac{\sin 2x-2\tan x}{x^3}\quad\lim_{x\to 0}\dfrac{x^3}{\log(1+x^3)}$

$$=\lim_{x\to 0}\frac{2\sin x(\cos^2 x-1)}{\cos x\cdot x^3}\cdot 1=\lim_{x\to 0}-\frac{2\tan^3 x}{x^3}=-2$$

(C) $\lim_{x\to 0^+}[\ln\sin^3 x-\ln(x^4+ex^3)]=\lim_{x\to 0}\ln\left(\dfrac{\sin^3 x}{x^3(x+e)}\right)$

$$=\ln\left(\frac{1}{e}\right)=-1$$

(D) $\tan(2\pi\mid\sin\theta\mid)=\tan\left(\dfrac{\pi}{2}-\mid\cos\theta\mid 2\pi\right)$

$$\Rightarrow\quad 2\pi\mid\sin\theta\mid=n\pi+\frac{\pi}{2}-\mid\cos\theta\mid 2\pi$$

$$\Rightarrow\quad 2\pi(\mid\sin\theta\mid+\mid\cos\theta\mid)=n\pi+\frac{\pi}{2}$$

$$\Rightarrow\quad \mid\sin\theta\mid+\mid\cos\theta\mid=\frac{n}{2}+\frac{1}{4}\qquad\ldots(i)$$

Since, $1\le\mid\sin\theta\mid+\mid\cos\theta\mid\le\sqrt{2}$; $1\le\dfrac{n}{2}+\dfrac{1}{4}\le\sqrt{2}$

$$4\le 2n+1\le 4\sqrt{2}$$

$$\Rightarrow\quad\frac{3}{2}\le n\le\frac{4\sqrt{2}-1}{2}$$

Thus, $n=2$ is only possible value. Putting in Eq. (i),

$$\mid\sin\theta\mid+\mid\cos\theta\mid=\frac{5}{4},$$

$$g(x)=\lim_{x\to\infty}\left[2\left(\frac{4}{5}\right)^x\right]=0$$

JEE Type Solved Examples :
Single Integer Answer Type Questions

● ***Ex. 41*** *If* $\lim_{x\to 0}(x^{-3}\sin 3x+ax^{-2}+b)$ *exists and is equal to zero, the value of* $a+2b$ *is ..... .*

Sol. (*6*) We have, $\lim_{x\to 0}\dfrac{\sin 3x}{x^3}+\dfrac{a}{x^2}+b=\lim_{x\to 0}\dfrac{\sin 3x+ax+bx^3}{x^3}$

$$=\lim_{x\to 0}\frac{3\dfrac{\sin 3x}{3x}+a+bx^2}{x^2}\ \text{for}$$

existence of limit $3+a=0\Rightarrow a=-3$

$$\therefore\qquad l=\lim_{x\to 0}\frac{\sin 3x-3x+bx^3}{x^3}$$

$$=27\cdot\frac{\sin t-t}{t^3}+b=0\qquad[\because 3x=t]$$

$$=-\frac{27}{6}+b=0\quad\Rightarrow\quad b=\frac{9}{2}$$

Hence, $a+2b=-3+2\times\dfrac{9}{2}=6$

[using L' Hospital's rule]

● ***Ex. 42*** *For a certain value of* c, $\lim_{x\to-\infty}[(x^5+7x^4+2)^c-x]=\lambda$, *is finite and non-zero. The value of* $3c+\lambda$ *is ..... .*

Sol. (*2*) We have, $\lim_{x\to-\infty}[(x^5+7x^4+2)^c-x]$

$$=\lim_{x\to-\infty}\left(x^{5c}\left(1+\frac{7}{x}+\frac{2}{x^5}\right)^c-x\right)$$

$$=\lim_{x\to-\infty}x\left(x^{5c-1}\left(1+\frac{7}{x}+\frac{2}{x^5}\right)^c-1\right)$$

This will be of the form $\infty\times 0$ only, if

$5c-1=0\quad\Rightarrow\quad c=\dfrac{1}{5}$ substituting $c=\dfrac{1}{5}$, λ becomes

$$\lambda=\lim_{x\to-\infty}x[(1+x)^{1/5}-1],\ \text{where}\ x=\frac{7}{x}+\frac{2}{x^5}$$

$$=\lim_{x\to-\infty}x\left[1+\frac{x}{5}+\ldots.-1\right]=\lim_{x\to-\infty}x\left(\frac{7}{x}+\frac{2}{x^5}\right)\cdot\frac{1}{5}=\frac{7}{5}$$

Hence, $c=\dfrac{1}{5}$ and $\lambda=\dfrac{7}{5}\Rightarrow 3c+\lambda=2$

● ***Ex. 43*** *Consider the curve* $y = \tan^{-1} x$ *and a point* $A\left(1, \frac{\pi}{4}\right)$ *on it. If the variable point* $P_i(x_i, y_i)$ *moves on the curve for* $i = 1, 2, 3, \ldots, n\ (n \in N)$ *such that* $y_r = \sum_{m=1}^{r} \tan^{-1}\left(\frac{1}{2m^2}\right)$ *and* $B(x, y)$ *be the limiting position of variable point* P_n *as* $n \to \infty$*, the value of reciprocal of the slope of AB will be ..... .*

Sol. (*2*) Here, $y = \lim_{n\to\infty} y_n = \lim_{n\to\infty} \sum_{m=1}^{n} \tan^{-1}\left(\frac{1}{2m^2}\right)$

$$= \lim_{n\to\infty} \sum_{m=1}^{n} \tan^{-1}\left(\frac{2}{1+(2m+1)(2m-1)}\right)$$

$$= \lim_{n\to\infty} \sum_{m=1}^{n} \tan^{-1}\left[\frac{(2m+1)-(2m-1)}{1+(2m+1)(2m-1)}\right]$$

$$= \lim_{n\to\infty} \sum_{m=1}^{n} (\tan^{-1}(2m+1) - \tan^{-1}(2m-1))$$

$$= \lim_{n\to\infty} (\tan^{-1}3 - \tan^{-1}1) + (\tan^{-1}5 - \tan^{-1}3) + \ldots + (\tan^{-1}(2n+1) - \tan^{-1}(2n-1))$$

$$= \lim_{n\to\infty} (\tan^{-1}(2n+1) - \tan^{-1}(1))$$

$$= \frac{\pi}{2} - \frac{\pi}{4} = \frac{\pi}{4}$$

$\because B \to \left[1, \frac{\pi}{4}\right)$, i.e. coordinates of B approaches towards those of A.

Chord AB approaches to the tangent to $y = f(x)$ at A.

$\therefore$ Slope of $AB = \left(\frac{d}{dx}\tan^{-1} x\right)_{\text{at } x=1}$

$$= \left(\frac{1}{1+x^2}\right)_{\text{at } x=1} = \frac{1}{2}$$

$\Rightarrow$ (Slope of $AB)^{-1} = 2$

● ***Ex. 44*** *If* $\lim_{x\to 0} \frac{\int_0^x \frac{2t\,dt}{\sqrt{\frac{2a}{3} - \frac{t}{2} + 104}}}{(e^x - 1 - x)} = \frac{1}{19}$, *then* $\frac{a}{2010}$ *equals ..... .*

Sol. (*1*) Here, $\lim_{x\to 0} \frac{\int_0^x \frac{2t}{\sqrt{\frac{2a}{3} - \frac{t}{2} + 104}}dt}{e^x - 1 - x} = \frac{1}{19}$

[using L'Hospital's rule]

$$\Rightarrow \lim_{x\to 0} \frac{2x}{\sqrt{\frac{2a}{3} - \frac{x}{2} + 104}(e^x - 1)} = \frac{1}{19}$$

$$\Rightarrow 2\lim_{x\to 0} \frac{1}{\sqrt{\frac{2a}{3} - \frac{x}{2} + 104}} \cdot \lim_{x\to 0} \frac{x}{e^x - 1} = \frac{1}{19}$$

$$\Rightarrow 2 \cdot \frac{1}{\sqrt{\frac{2a}{3} + 104}} \cdot 1 = \frac{1}{19}$$

$$\Rightarrow \frac{2a}{3} + 104 = 1444 \Rightarrow 2a = 4020 \Rightarrow \frac{a}{2010} = 1$$

● ***Ex. 45*** *Evaluate* $\lim_{x\to 0^+} \log_{\sin x} \sin 2x$.

Sol. (*1*) Here, $\lim_{x\to 0^+} \log_{\sin x} \sin 2x = \lim_{x\to 0^+} \frac{\log \sin 2x}{\log \sin x}$ $\left[\frac{-\infty}{-\infty}\text{form}\right]$

$$= \lim_{x\to 0^+} \frac{\frac{1}{\sin 2x} \cdot 2\cos 2x}{\frac{1}{\sin x} \cdot \cos x}$$ [using L'Hospital's rule]

$$= \lim_{x\to 0^+} \frac{\left[\frac{(2x)}{\sin(2x)}\right]\cos 2x}{\left(\frac{x}{\sin x}\right)\cos x} = \lim_{x\to 0^+} \frac{\cos 2x}{\cos x} = 1$$

$\left[\because \lim_{x\to 0} \frac{\sin x}{x} = 1\right]$

Subjective Type Questions

● **Ex. 46** *Evaluate a, b, c and d, if*

$$\lim_{x\to\infty}\left(\sqrt{x^4+ax^3+3x^2+bx+2}-\sqrt{x^4+2x^3-cx^2+3x-d}\right)=4.$$

Sol. Here, $\lim_{x\to\infty}\left(\sqrt{x^4+ax^3+3x^2+bx+2}-\sqrt{x^4+2x^3-cx^2+3x-d}\right)=4$ [$\infty-\infty$ form]

Rationalising

$$\lim_{x\to\infty}\frac{(a-2)x^3+(3+c)x^2+(b-3)x+(2+d)}{\left[\sqrt{x^4+ax^3+3x^2+bx+2}+\sqrt{x^4+2x^3-cx^2+3x-d}\right]}=4$$

Since, limit is finite, the degree of the numerator must be 2. So, $a-2=0$, i.e. $a=2$.

$$\Rightarrow \lim_{x\to\infty}\frac{(3+c)x^2+(b-3)x+(2+d)}{\left[\sqrt{x^4+ax^3+3x^2+bx+2}+\sqrt{x^4+2x^3-cx^2+3x-d}\right]}=4$$

On dividing numerator and denominator by x^2, we get

$$\lim_{x\to\infty}\frac{(3+c)+(b-3)/x+(2+d)/x^2}{\sqrt{1+\frac{a}{x}+\frac{3}{x^2}+\frac{b}{x^3}+\frac{2}{x^4}}+\sqrt{1+\frac{2}{x}-\frac{c}{x^2}+\frac{3}{x^3}-\frac{d}{x^4}}}$$

$$=4 \Rightarrow \frac{3+c}{2}=4$$

$\Rightarrow \quad c=5$

$\therefore \quad c=5,\ a=2$

Hence, $a=2,\ c=5$ and b, d are any real numbers.

● **Ex. 47** *If x is a real number in $[0, 1]$. Find the value of*

$$\lim_{m\to\infty}\lim_{n\to\infty}[1+\cos^{2m}(n!\pi x)].$$

Sol. If x is a real number in $[0, 1]$, then we have two cases either.

***Case* I** $x\in Q$ [rational number]

As $x\in Q$, we have $x=0, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \ldots, 1$

which shows $(n!\pi x)$ is integral multiple of π for large values of n.

$\therefore \quad \cos(n!\pi x)=\pm 1$

Thus, $\lim_{m\to\infty}\lim_{n\to\infty}[1+\cos^{2m}(n!\pi x)]=\lim_{m\to\infty}\lim_{n\to\infty}(1+1)=2$

***Case* II** $x\notin Q$ [irrational number]

As $x\notin Q$, we have $x=\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{5}}, \ldots$

which shows $(n!\pi x)$ is not an integral multiple of π and so, $\cos(n!\pi x)$ will lie between -1 and $+1$.

Thus, $\lim_{m\to\infty}\lim_{n\to\infty}[1+\cos^{2m}(n!\pi x)]$

$=\lim_{m\to\infty}\lim_{n\to\infty}[1+(\text{a value between } -1 \text{ and } +1)^{2m}]$

$=\lim_{n\to\infty}[1+0]=1$ [as $0<x<1 \Rightarrow x^{\infty}=0$]

Thus, $\lim_{m\to\infty}\lim_{n\to\infty}[1+\cos^{2m}(n!\pi x)]=\begin{cases}2, & x\in Q\\ 1, & x\notin Q\end{cases}$

● **Ex. 48** *If $a_1=1$ and $a_{n+1}=\frac{4+3a_n}{3+2a_n}$, $n\geq 1$, show that $a_{n+2}>a_{n+1}$ and if a_n has a limit l as $n\to\infty$, then evaluate $\lim_{n\to\infty}a_n$.*

Sol Here, $a_1=1$

$\therefore \quad a_2=\frac{4+3}{3+2}=\frac{7}{5}>1$

$\therefore \quad a_2>a_1$

Assuming $a_{n+1}>a_n$

$\therefore\ a_{n+2}-a_{n+1}=\frac{4+3a_{n+1}}{3+2a_{n+1}}-\frac{4+3a_n}{3+2a_n}$

$$=\frac{(4+3a_{n+1})(3+2a_n)-(4+3a_n)(3+2a_{n+1})}{(3+2a_{n+1})(3+2a_n)}$$

$$=\frac{a_{n+1}-a_n}{(3+2a_{n+1})(3+2a_n)}>0 \qquad [\because a_{n+1}>a_n]$$

$\therefore \quad a_{n+2}-a_{n+1}>0$

$\Rightarrow \quad a_{n+2}>a_{n+1}$

whenever $a_{n+1}>a_n$.

$\therefore$ The sequence of values a_n is increasing and since $a_1=1$, $a_n>0$, for all n.

Now, let $l=\lim_{n\to\infty}a_n=\lim_{n\to\infty}a_{n+1}$

$\therefore \quad l=\lim_{n\to\infty}\frac{4+3a_n}{3+2a_n}$

$\Rightarrow \quad l=\frac{4+3l}{3+2l}$ $\left[\because \lim_{n\to\infty}a_n=l\right]$

$\Rightarrow \quad 3l+2l^2=4+3l$

$\Rightarrow \quad l^2=2$

$\therefore \quad l=\sqrt{2}$ [neglecting $l=-\sqrt{2}$, as $l>0$]

● ***Ex. 49*** *Let $a_1, a_2, \ldots, a_n$ be sequence of real numbers with $a_{n+1} = a_n + \sqrt{1 + a_n^2}$ and $a_0 = 0$. Prove that* $\lim_{n \to \infty} \left(\frac{a_n}{2^{n-1}} \right) = \frac{4}{\pi}$.

Sol. Here, $a_{n+1} = a_n + \sqrt{1 + a_n^2}$, let $a_n = \cot(\alpha_n)$

$$\Rightarrow \quad a_{n+1} = \cot(\alpha_n) + \operatorname{cosec}(\alpha_n)$$

$$\Rightarrow \quad a_{n+1} = \frac{\cos(\alpha_n) + 1}{\sin(\alpha_n)}$$

$$= \frac{2\cos^2(\alpha_n/2)}{2\sin(\alpha_n/2)\cos(\alpha_n/2)} = \cot\left(\frac{\alpha_n}{2}\right)$$

Putting $n = 1, a_1 = \cot(\alpha_1)$

and $a_1 = a_0 + \sqrt{1 + a_0^2} = 1$

$$\Rightarrow \quad \cot(\alpha_1) = 1 \text{ or } \alpha_1 = \frac{\pi}{4}$$

Again, $a_2 = \cot\left(\frac{\alpha_1}{2}\right) = \cot\left(\frac{\pi}{8}\right)$

$$a_3 = \cot\left(\frac{\alpha_2}{2}\right) = \cot\left(\frac{\pi}{4 \cdot 2^2}\right)$$

$$a_4 = \cot\left(\frac{\alpha_3}{2}\right) = \cot\left(\frac{\pi}{4 \cdot 2^3}\right)$$

.....

.....

$$a_n = \cot\left(\frac{\pi}{4 \cdot 2^{n-1}}\right);$$

Hence,

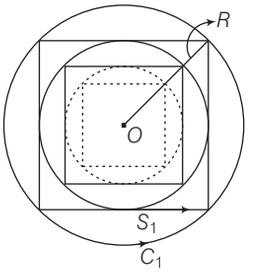
$$\lim_{n \to \infty} \left(\frac{a_n}{2^{n-1}} \right) = \lim_{n \to \infty} \frac{\cot\left(\frac{\pi}{4 \cdot 2^{n-1}}\right)}{2^{n-1}} = \lim_{x \to 0} \frac{1}{\frac{\tan\left(\frac{\pi}{4}x\right)}{x}}$$

$$\left[\text{put} \frac{1}{2^{n-1}} = x \right]$$

$$\therefore \quad \lim_{n \to \infty} \left(\frac{a_n}{2^{n-1}} \right) = \frac{4}{\pi}$$

● ***Ex. 50*** *A square is inscribed in a circle of radius R, a circle is inscribed in this square then a square in this circle and so on, n times. Find the limit of the sum of areas of all the squares as $n \to \infty$.*

Sol. Let the side of a square, S_1 be 'a' units.



Then, $a\sqrt{2} = 2R \Rightarrow R = \frac{a}{\sqrt{2}}$ is radius of circle C_1.

If a_1 be the side of another square, then

$$a_1\sqrt{2} = a \quad \Rightarrow \quad a_1 = \frac{a}{\sqrt{2}}$$

$$a_2\sqrt{2} = a_1 \Rightarrow \quad a_2 = \frac{a_1}{\sqrt{2}} = \frac{a}{2}.$$

.....

.....

So, sum of areas of all the squares,

$S_n = a^2 + a_1^2 + a_2^2 + \ldots$ upto n terms

$$= a^2 + \frac{a^2}{2} + \frac{a^2}{4} + \ldots \text{ upto } n \text{ terms}$$

$$= a^2 \left(1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \ldots \text{ upto } n \text{ terms}\right) = a^2 \left\{ \frac{1 - \frac{1}{2^n}}{1 - \frac{1}{2}} \right\}$$

$$= 2a^2 \left(1 - \frac{1}{2^n}\right)$$

$$\therefore \quad \lim_{n \to \infty} S_n = \lim_{n \to \infty} 2a^2 \left(1 - \frac{1}{2^n}\right) = 2a^2 = 4R^2$$

$$\left[\text{as } n \to \infty \Rightarrow \frac{1}{2^n} \to 0 \right]$$

Limits Exercise 1 : Single Option Correct Type Questions

1. $\lim_{x \to 0} \frac{\sin(\pi \cos^2(\tan(\sin x)))}{x^2}$ is equal to

(a) π (b) $\frac{\pi}{4}$

(c) $\frac{\pi}{2}$ (d) None of these

2. $\lim_{t \to 0} \frac{1-(1+t)^t}{\ln(1+t)-t}$ is equal to

(a) $\frac{1}{2}$ (b) $-\frac{1}{2}$

(c) 2 (d) -2

3. If $I_1 = \lim_{x \to \infty} (\tan^{-1} \pi x - \tan^{-1} x) \cos x$ and $I_2 = \lim_{x \to 0} (\tan^{-1} \pi x - \tan^{-1} x) \cos x$, then (I_1, I_2) is

(a) (0, 0)
(b) (0, 1)
(c) (1, 0)
(d) None of the above

4. If $f(x) = 0$ is a quadratic equation such that $f(-\pi) = f(\pi) = 0$ and $f\left(\frac{\pi}{2}\right) = -\frac{3\pi^2}{4}$, then $\lim_{x \to -\pi} \frac{f(x)}{\sin(\sin x)}$ is equal to

(a) 0 (b) π

(c) 2π (d) None of these

5. $\lim_{x \to 0} \frac{\sqrt[3]{1+\sin^2 x} - \sqrt[4]{1-2\tan x}}{\sin x + \tan^2 x}$ is equal to

(a) -1 (b) 1

(c) $\frac{1}{2}$ (d) $-\frac{1}{2}$

6. If $x_{n+1} = \sqrt{\frac{1+x_n}{2}}$ and $|x_0| < 1, n \geq 0$, then $\lim_{n \to \infty} \left(\frac{\sqrt{1-x_0^2}}{x_1 x_2 x_3 \ldots x_{n+1}} \right)$ is equal to

(a) -1
(b) 1
(c) $\cos^{-1}(x_0 + 1)$
(d) $\cos^{-1}(x_0)$

7. For $n \in N$, let $f_n(x) = \tan\frac{x}{2}(1+\sec x)(1+\sec 2x)$ $(1+\sec 4x)\ldots(1+\sec 2^n x)$. Then, $\lim_{x \to 0} \frac{f_n(x)}{2x}$ is

(a) 0 (b) 2^n

(c) 2^{n-1} (d) 2^{n+1}

8. Let $f(x)$ be a real valued function defined for all $x \geq 1$, satisfying $f(1) = 1$ and $f'(x) = \frac{1}{x^2 + (f(x))}$; then $\lim_{x \to \infty} f(x)$

(a) doesn't exist
(b) exists and less than $\frac{\pi}{4}$
(c) exists and less than $1 + \frac{\pi}{4}$
(d) exists and equal to 0

9. The quadratic equation whose roots are the minimum value of $\sin^2\theta - \sin\theta + \frac{1}{2}$ and $\lim_{x \to \infty} \sqrt{(x+1)(x+2)} - x$ is

(a) $3x^2 - 7x + 3 = 0$ (b) $8x^2 - 14x + 3 = 0$

(c) $x^2 - 7x + 3 = 0$ (d) $2x^2 - 7x + 3 = 0$

10. If $x_1 = \sqrt{3}$ and $x_{n+1} = \frac{x_n}{1+\sqrt{1+x_n^2}}, \forall\, n \in N$, then $\lim_{x \to \infty} 2^n x_n$ equal to

(a) $\frac{3}{2\pi}$ (b) $\frac{2}{3\pi}$ (c) $\frac{2\pi}{3}$ (d) $\frac{3\pi}{2}$

11. $\lim_{x \to a^-} \frac{\sqrt{x-b} - \sqrt{a-b}}{(x^2 - a^2)}, (a > b)$ is

(a) $\frac{1}{4a}$ (b) $\frac{1}{a\sqrt{a-b}}$

(c) $\frac{1}{2a\sqrt{a-b}}$ (d) $\frac{1}{4a\sqrt{a-b}}$

12. $\lim_{n \to \infty} (\sin^n 1 + \cos^n 1)^n$ is equal to

(a) cot 1 (b) tan 1 (c) cos 1 (d) sin 1

13. The value of $\lim_{x \to 0} \left(\frac{2}{x^3}(\sin^{-1} x - \tan^{-1} x) \right)^{2/x^2}$ equals

(a) e (b) $\sqrt{e}$ (c) $\frac{1}{e}$ (d) $\frac{1}{\sqrt{e}}$

14. The value of $\lim_{n \to \infty} \sum_{k=1}^{n} \frac{n-K}{n^2} \cos\left(\frac{4K}{n}\right)$ equals

(a) $\frac{1}{4}\sin 4 + \frac{1}{16}\cos 4 - \frac{1}{16}$
(b) $\frac{1}{4}\sin 4 - \frac{1}{16}\cos 4 + \frac{1}{16}$
(c) $\frac{1}{16}(1 - \sin 4)$
(d) $\frac{1}{16}(1 - \cos 4)$

15. If $\lim_{x\to 0}\dfrac{1-\sqrt{\cos 2x}\cdot\sqrt[3]{\cos 3x}\cdot\sqrt[4]{\cos 4x}\ldots\sqrt[n]{\cos nx}}{x^2}$ has the value equal to 10, the value of n is

(a) 6 (b) 7 (c) 8 (d) 9

16. $\lim_{z\to\infty}\dfrac{\int_{1/2}^{z}[\cot^{-1}x]\,dx}{\int_{1/2}^{z}\left[1+\dfrac{1}{x}\right]dx}$, where $[\cdot]$ denotes the greatest integer function, equals

(a) 0 (b) 1
(c) cot 1 (d) not defined

17. If α and β are roots of $x^2-(\sqrt{1-\cos 2\theta})x+\theta=0$, where $0<\theta<\dfrac{\pi}{2}$. Then, $\lim_{\theta\to 0^+}\left(\dfrac{1}{\alpha}+\dfrac{1}{\beta}\right)$ is

(a) $\dfrac{1}{\sqrt{2}}$ (b) $-\sqrt{2}$
(c) $\sqrt{2}$ (d) None of these

18. If $f(x)=\dfrac{1}{3}\left(f(x+1)+\dfrac{5}{f(x+2)}\right)$ and $f(x)>0,\ \forall\ x\in R$, then $\lim_{x\to\infty}f(x)$ is

(a) 0 (b) $\sqrt{\dfrac{2}{5}}$ (c) $\sqrt{\dfrac{5}{2}}$ (d) ∞

19. Let $f:(1,2)\to R$ satisfies the inequality $\dfrac{\cos(2x+4)-33}{2}<f(x)<\dfrac{x^2|4x-8|}{x-2},\ \forall\ x\in(1,2)$. Then, $\lim_{x\to 2^-}f(x)$ is

(a) 16 (b) −16
(c) 8 (d) doesn't exist

20. Let $f(x)$ be polynomial of degree 4 with roots 1, 2, 3, 4 and leading coefficient 1 and $g(x)$ be the polynomial of degree 4 with roots 1, $\dfrac{1}{2}$, $\dfrac{1}{3}$ and $\dfrac{1}{4}$ with leading coefficient 1. Then, $\lim_{x\to 1}\dfrac{f(x)}{g(x)}$ equals

(a) $\dfrac{1}{24}$ (b) −24 (c) $\dfrac{1}{12}$ (d) $-\dfrac{1}{12}$

21. The value of $\lim_{x\to\frac{\pi}{4}}\dfrac{4\sqrt{2}-(\cos x+\sin x)^5}{1-\sin 2x}$ is

(a) $\sqrt{2}$ (b) $3\sqrt{5}$
(c) $5\sqrt{2}$ (d) $-5\sqrt{2}$

22. If $\lim_{n\to\infty}\dfrac{n\cdot 3^n}{n(x-2)^n+n\cdot 3^{n+1}-3^n}=\dfrac{1}{3}$, where $n\in N$, the number of integer(s) in the range of 'x' is

(a) 3 (b) 4
(c) 5 (d) infinite

23. If $f(x)=\lim_{n\to\infty}\dfrac{1}{\left(\dfrac{3}{\pi}\tan^{-1}2x\right)^{2n}+5}$, then the set of values of x for which $f(x)=0$, is

(a) $|2x|>\sqrt{3}$ (b) $|2x|<\sqrt{3}$
(c) $|2x|\geq\sqrt{3}$ (d) $|2x|\leq\sqrt{3}$

24. The integer 'n' for which the $\lim_{x\to 0}\dfrac{\cos^2 x-\cos x-e^x\cos x+e^x-\dfrac{x^3}{2}}{x^n}$ is a finite non-zero number, is

(a) 2 (b) 3
(c) 4 (d) None of these

25. If $I_1=\lim_{x\to 0}\sqrt{\dfrac{\tan^{-1}x}{x}-\dfrac{\sin^{-1}x}{x}}$ and $I_2=\lim_{x\to 0}\sqrt{\dfrac{\sin^{-1}x}{x}-\dfrac{\tan^{-1}x}{x}}$, where $|x|<1$, which of the following statement is true?

(a) Neither I_1 nor I_2 exist
(b) I_1 exists and I_2 doesn't exist
(c) I_1 doesn't exist and I_2 exists
(d) None of the above

26. The value of $\lim_{x\to\pi/2}\dfrac{\left[\dfrac{x}{2}\right]}{\log(\sin x)}$ is equal to

(a) 0 (b) 1
(c) −1 (d) doesn't exist

27. The value of $\lim_{n\to\infty}\left(1+\dfrac{1}{a_1}\right)\left(1+\dfrac{1}{a_2}\right)\ldots\left(1+\dfrac{1}{a_n}\right)$, where $a_1=1$ and $a_n=n(1+a_{n-1}),\forall\ n\geq 2$, is

(a) e (b) $\dfrac{e}{2}$
(c) $2e$ (d) $3e$

28. If $f(x+y)=f(x)+f(y)$ for all $x,y\in R$ and $f(1)=1$, then $\lim_{x\to 0}\dfrac{2^{f(\tan x)}-2^{f(\sin x)}}{x^2\,f(\sin x)}$ equals

(a) log 2 (b) log 4 (c) log $\sqrt{2}$ (d) log 8

29. The value of $\lim_{n\to\infty}n^{-n^2}\left[(n+1)\left(n+\dfrac{1}{2}\right)\left(n+\dfrac{1}{2^2}\right)\ldots\left(n+\dfrac{1}{2^{n-1}}\right)\right]^n$ is

(a) e
(b) e^2
(c) e^3
(d) e^4

30. If $f(x)=\begin{cases}\dfrac{\sin[x]}{[x]}, & \text{for } [x]\neq 0\\ 0, & \text{for } [x]=0\end{cases}$, where $[x]$ denotes the greatest integer less than or equal to x, then $\lim\limits_{x\to 0} f(x)$ equals

(a) 1 (b) 0
(c) -1 (d) doesn't exist

31. Let $f(x)=\dfrac{|x^3-6x^2+11x-6|}{x^3-6x^2+11x-6}$, then the number of solutions of 'a', where $\lim\limits_{x\to a} f(x)$ doesn't exist is
(a) 3 (b) 2 (c) 1 (d) 4

32. Let the rth term, t_r of a series is given by $t_r=\dfrac{r}{1+r^2+r^4}$. The value of $\lim\limits_{n\to\infty}\sum\limits_{r=1}^{n} t_r$ is

(a) 2 (b) $\dfrac{1}{2}$ (c) 1 (d) $\dfrac{1}{4}$

33. The value of $\lim\limits_{n\to\infty}\sum\limits_{r=1}^{n}\cot^{-1}\left(\dfrac{r^3-r+\frac{1}{r}}{2}\right)$ is

(a) π (b) $\dfrac{\pi}{4}$
(c) $\dfrac{\pi}{2}$ (d) π

34. Let $(\tan\alpha)x+(\sin\alpha)y=\alpha$ and $(\alpha\operatorname{cosec}\alpha)x+(\cos\alpha)y=1$ be two variable straight lines, α being the parameter. Let P be the point of intersection of the lines. In the limiting position, when $\alpha\to 0$, the point of intersection of straight lines is
(a) $(2,-1)$ (b) $(2,1)$
(c) $(-2,1)$ (d) $(-2,-1)$

35. The polynomial of least degree, such that $\lim\limits_{x\to 0}\left(1+\dfrac{x^2+f(x)}{x^2}\right)^{1/x}=e^2$ is

(a) x^2 (b) x^3+2x^2
(c) $-x^2+2x^3$ (d) None of these

36. Let [ ] represents the greatest integer function less than or equal to x. The value of $\lim\limits_{x\to 0}\left(\left[\dfrac{n\sin x}{x}\right]+\left[\dfrac{n\tan x}{x}\right]\right)$ is
(a) $n+1$ (b) $2n$
(c) $n-1$ (d) $2n-1$

37. The value of $\lim\limits_{x\to a}[\sqrt{2-x}+\sqrt{1+x}]$, where $a\in\left[0,\dfrac{1}{2}\right]$ and $[\cdot]$ denotes the greatest integer function is
(a) 1 (b) 2
(c) 3 (d) 4

38. The value of

$$\lim_{x\to 0^+}\frac{-1+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)}+\ldots\infty}}}{-1+\sqrt{x^3+\sqrt{x^3+\sqrt{x^3+\ldots\infty}}}}$$ is

(a) $\dfrac{1}{2}$ (b) $\dfrac{1}{4}$
(c) $\dfrac{1}{8}$ (d) 1

39. The value of

$$\lim_{\theta\to 0}\frac{\cos^2(1-\cos^2(1-\cos^2(1\ldots\cos^2\theta))\ldots)}{\sin\left(\dfrac{\pi(\sqrt{\theta+4}-2)}{\theta}\right)}$$ is

(a) 2 (b) $\sqrt{2}$
(c) $\dfrac{1}{2}$ (d) $\dfrac{1}{\sqrt{2}}$

40. The value of $\lim\limits_{n\to\infty} a_n$ when $a_{n+1}=\sqrt{2+a_n}$, $n=1,2,3,\ldots$ is
(a) 1 (b) 2
(c) 3 (d) 4

Limits Exercise 2 : More than One Option Correct Type Questions

41. If $\lim\limits_{x\to\infty} 4x\left(\dfrac{\pi}{4}-\tan^{-1}\dfrac{x+1}{x+2}\right)=y^2+4y+5$, then y can be equal to
(a) 1 (b) -1
(c) -4 (d) -3

42. $\lim\limits_{x\to 0}\dfrac{1-\cos(x^2)}{x^3(4^x-1)}$ is equal to
(a) $\dfrac{1}{2}\ln 2$ (b) $\ln 2$
(c) $\ln 4$ (d) $1-\dfrac{1}{2}\ln\left(\dfrac{e^2}{4}\right)$

43. If $f(x)=e^{[\cot x]}$, where $[y]$ represents the greatest integer less than or equal to y, then

(a) $\lim\limits_{x\to\frac{\pi^+}{2}} f(x)=1$ (b) $\lim\limits_{x\to\frac{\pi^+}{2}} f(x)=\frac{1}{e}$

(c) $\lim\limits_{x\to\frac{\pi^-}{2}} f(x)=\frac{1}{e}$ (d) $\lim\limits_{x\to\frac{\pi^-}{2}} f(x)=1$

44. $\lim\limits_{x\to 0}\left[m\dfrac{\sin x}{x}\right]$ is equal to (where $m\in I$ and $[\cdot]$ denotes greatest integer function)

(a) m, if $m<0$

(b) $m-1$, if $m>0$

(c) $m-1$, if $m<0$

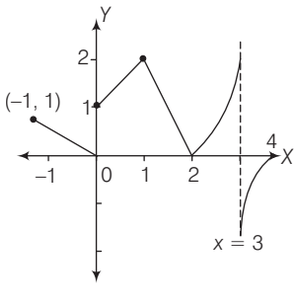
(d) m, if $m>0$

45. If $\lim\limits_{x\to 0}(1+ax+bx^2)^{2/x}=e^3$, then

(a) $a=3, b=0$ (b) $a=\frac{3}{2}, b=1$

(c) $a=\frac{3}{2}, b=4$ (d) $a=2, b=3$

46. The graph of the function $y=f(x)$ is shown in the adjacent figure, then correct statement is



(a) $\lim\limits_{x\to 0^+} f(x)=1$ (b) $\lim\limits_{x\to 1} f(x)=2$

(c) $\lim\limits_{x\to 3} f(x)=$ does not exist (d) $\lim\limits_{x\to 4} f(x)=4$

47. For $\lim\limits_{x\to 0}\dfrac{\cot^{-1}\left(\frac{1}{x}\right)}{x}$

(a) RHL exists (b) LHL does not exist

(c) limit does not exist as RHL is 1 and LHL is -1

(d) limit does not exist as RHL and LHL both are non-existent

48. If $l=\lim\limits_{x\to\infty}\left(\dfrac{x+1}{x-1}\right)^x$, the value of $\{l\}$ and $[l]$ are

(a) 7 (b) $7-e^2$ (c) -7 (d) e^2-7

49. If $f(x)=\begin{cases}\dfrac{\sin[x]}{[x]}, & [x]\neq 0\\ 0, & [x]=0\end{cases}$,

where $[\cdot]$ denotes the greatest integer less than or equal to x, then

(a) $\lim\limits_{x\to 0^-} f(x)=\sin 1$

(b) $\lim\limits_{x\to 0^+} f(x)=0$

(c) limit does not exist at $x=0$

(d) limit exists at $x=0$

50. $\lim\limits_{x\to c} f(x)$ does not exist when

(a) $f(x)=[[x]]-[2x-1]$, $c=3$ (b) $f(x)=[x]-x$, $c=1$

(c) $f(x)=\{x\}^2-\{-x\}^2$, $c=0$ (d) $f(x)=\dfrac{\tan(\operatorname{sgn} x)}{(\operatorname{sgn} x)}$, $c=0$

(where $[\cdot]$ and $\{\cdot\}$ denotes greatest integer and fractional part of x)

51. Identify the correct statement.

(a) $\lim\limits_{n\to\infty}\left[\sum\limits_{r=1}^{n}\dfrac{1}{2^r}\right]=1$

(b) If $f(x)=(x-1)\{x\}$, where $[\cdot]$ and $\{\cdot\}$ denotes greatest integer function and fractional part of x respectively, the limit of $f(x)$ does not exist at $x=1$

(c) $\lim\limits_{x\to 0^+}\left[\dfrac{\tan x}{x}\right]=1$

(d) $\left[\lim\limits_{x\to 0^+}\dfrac{\tan x}{x}\right]=1$

52. For $a>0$, let $l=\lim\limits_{x\to\frac{\pi}{2}}\dfrac{a^{\cot x}-a^{\cos x}}{\cot x-\cos x}$ and

$m=\lim\limits_{x\to-\infty}(\sqrt{x^2+ax}-\sqrt{x^2-ax})$, then

(a) $l>m$, for all $a>0$ (b) $l>m$, only when $a\geq 1$

(c) $l>m$, for all $a>e^{-a}$ (d) $e^l+m=0$

53. Consider the function $f(x)=\left(\dfrac{ax+1}{bx+2}\right)^x$, where $a, b>0$, the $\lim\limits_{x\to\infty} f(x)$ is

(a) exists for all values of a and b

(b) zero for $a<b$

(c) non-existent for $a>b$

(d) $e^{-(1/a)}$ or $e^{-(1/b)}$, if $a=b$

54. If $f(x)=\dfrac{x\cdot 2^x-x}{1-\cos x}$ and $g(x)=2^x\cdot\sin\left(\dfrac{\log 2}{2^x}\right)$, then

(a) $\lim\limits_{x\to 0} f(x)=\log 2$ (b) $\lim\limits_{x\to\infty} g(x)=\log 4$

(c) $\lim\limits_{x\to 0} f(x)=\log 4$ (d) $\lim\limits_{x\to\infty} g(x)=\log 2$

55. If $\lim\limits_{x\to 3}\dfrac{x^3+cx^2+5x+12}{x^2-7x+12}=l$ (finite real number), then

(a) $l=4$ (b) $c=-6$

(c) $c=4$ (d) $x\in R$

Limits Exercise 3 : Passage Based Questions

Passage I (Q. Nos. 56 to 58)

If $\lim_{x \to a} f(x) = 1$ and $\lim_{x \to a} g(x) = \infty$, *then*

$\lim_{x \to a} \{f(x)\}^{g(x)} = e^{\lim_{x \to a} (f(x) - 1) \times g(x)}$.

56. $\lim_{x \to 0} \left(\frac{\sin x}{x} \right)^{\frac{\sin x}{x - \sin x}}$ is equal to

(a) $1/e$ (b) $-1/e$
(c) e (d) $-e$

57. $\lim_{x \to 0} \left(\frac{x - 1 + \cos x}{x} \right)^{\frac{1}{x}}$ is equal to

(a) $e^{1/2}$ (b) $e^{-1/2}$ (c) e^{1} (d) $\frac{1}{e}$

58. $\lim_{x \to 0} \left(\frac{a^x + b^x + c^x}{3} \right)^{\frac{2}{x}}$ is equal to

(a) $a^{2/3} + b^{2/3} + c^{2/3}$ (b) abc
(c) $(abc)^{2/3}$ (d) 1

Passage II (Q. Nos. 59 to 61)

Let $f(x) = \lim_{n \to \infty} \left(\cos \sqrt{\frac{x}{n}} \right)^n$, $g(x) = \lim_{n \to \infty} (1 - x + x \sqrt[n]{e})^n$.

Now, consider the function $y = h(x)$, *where* $h(x) = \tan^{-1}(g^{-1} f^{-1}(x))$.

59. $\lim_{x \to 0} \frac{\ln(f(x))}{\ln(g(x))}$ is equal to

(a) $\frac{1}{2}$ (b) $-\frac{1}{2}$
(c) 0 (d) 1

60. Domain of the function $y = h(x)$ is

(a) $(0, \infty)$ (b) R
(c) $(0, 1)$ (d) $[0, 1]$

61. Range of the function $y = h(x)$ is

(a) $\left(0, \frac{\pi}{2}\right)$ (b) $\left(-\frac{\pi}{2}, 0\right)$
(c) R (d) $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$

Passage III (Q. Nos. 62 to 63)

Let K_1 = *Total number of ways of selecting of ball from a bag which contains* n *balls of first colour,* $(n + 1)$ *balls of second colour,* $(n + 2)$ *balls of third colour, ...,* $(2n - 1)$ *balls of* n *colour.*

K_2 = *number of* n*-digit numbers using the digits* 1, 2, 3, ..., n *and*
K_3 = *number of ways of arranging* $(n + 1)$ *objects on a circle.*

62. The value of $\lim_{n \to \infty} \left(\frac{K_1}{K_2} \right)^{1/n}$ is

(a) e^2 (b) $\log 4 - 1$ (c) $\frac{4}{e}$ (d) $\frac{1}{e}$

63. The value of $\lim_{n \to \infty} \left(\frac{K_1}{K_2 + K_3} \right)$ is

(a) e (b) 1
(c) 0 (d) does not exist

Passage IV (Q. Nos. 64 to 65)

Let $f : N \to R$ *and* $g : N \to R$ *be two functions and* $f(1) = 0.8$, $g(1) = 0.6$; $f(n + 1) = f(n)\cos(g(n)) - g(n)\sin(g(n))$ *and* $g(n + 1) = f(n)\sin(g(n)) + g(n)\cos(g(n))$ *for* $n \geq 1$.

64. $\lim_{n \to \infty} f(n)$ is equal to

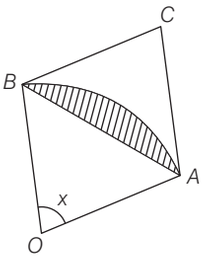
(a) -1 (b) 0
(c) 1 (d) does not exist

65. $\lim_{n \to \infty} g(n)$ is equal to

(a) -1 (b) 0
(c) 1 (d) does not exist

Passage V (Q. Nos. 66 to 68)

A circular arc of radius 1 subtends an angle of x *radian as shown in figure. The centre of the circle is O and the point C is the intersection of two tangent lines at A and B. Let* $T(x)$ *be the area of* ΔABC *and* $S(x)$ *be the area of shaded region.*



66. $\lim_{x \to 0} \frac{T(x)}{x^3}$ is

(a) $\frac{1}{2}$ (b) $\frac{1}{3}$ (c) $\frac{1}{4}$ (d) $\frac{1}{8}$

67. $\lim_{x \to 0} \frac{S(x)}{x}$ is

(a) 0 (b) $\frac{1}{2}$ (c) 1 (d) None of these

68. $\lim_{x \to 0} \frac{T(x)}{S(x)}$ is

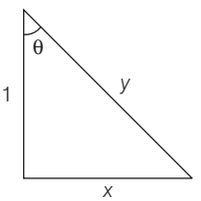
(a) $\frac{1}{4}$ (b) $\frac{3}{4}$ (c) $\frac{3}{2}$ (d) 0

Limits Exercise 4 : Matching Type Questions

69. Match the statements of Column I with values of Column II.

	Column I		Column II
(A)	$\lim\limits_{x \to \frac{\pi^+}{2}} \tan^{-1}(\tan x)$	(p)	0
(B)	$\lim\limits_{n \to \infty}\left[\sum\limits_{r=1}^{n} \frac{1}{2^r}\right]$ ([·] denotes the greatest integer function)	(q)	Doesn't exist
(C)	$\lim\limits_{x \to \infty} \sec^{-1}\left(\frac{x}{x+1}\right)$	(r)	$-\frac{\pi}{2}$
(D)	$\lim\limits_{x \to \frac{\pi}{2}} \frac{\cos x}{(1-\sin x)^{2/3}}$	(s)	$\frac{\pi}{2}$

70. A right angled triangle has legs 1 and x. The hypotenuse is y and the angle opposite to the side x is θ. Shown as



Match the column.

	Column I		Column II
(A)	$\lim\limits_{\theta \to \frac{\pi}{2}} (\sqrt{y} - \sqrt{x})$	(p)	0
(B)	$\lim\limits_{\theta \to \frac{\pi}{2}} (y - x)$	(q)	$\frac{1}{2}$
(C)	$\lim\limits_{\theta \to \frac{\pi}{2}} (y^2 - x^2)$	(r)	1
(D)	$\lim\limits_{\theta \to \frac{\pi}{2}} (y^3 - x^3)$	(s)	∞

71. Match the column.

	Column I		Column II
(A)	$\lim\limits_{x \to 0} \frac{1-\cos 2x}{e^{x^2} - e^x + x}$ equals	(p)	1
(B)	If the value of $\lim\limits_{x \to 0^+}\left(\frac{(3/x)+1}{(3/x)-1}\right)^{1/x}$ can be expressed in the form of $e^{p/q}$, where p and q are relative prime, then $(p+q)$ is equal to	(q)	2
(C)	$\lim\limits_{x \to 0} \frac{\tan^3 x - \tan x^3}{x^5}$ equals	(r)	4
(D)	$\lim\limits_{x \to 0} \frac{x + 2\sin x}{\sqrt{x^2 + 2\sin x + 1} - \sqrt{\sin^2 x - x + 1}}$ equals	(s)	5

72. Match the column.

	Column I		Column II
(A)	$\lim\limits_{n \to \infty} \cos^2(\pi(\sqrt[3]{n^3 + n^2 + 2n} - n))$, where n is an integer, equals	(p)	$\frac{1}{2}$
(B)	$\lim\limits_{n \to \infty} n \sin(2\pi\sqrt{1+n^2})\ (n \in N)$ equals	(q)	$\frac{1}{4}$
(C)	$\lim\limits_{n \to \infty} (-1)^n \sin(\pi\sqrt{n^2 + 0.5n + 1})$ $\left(\sin\frac{(n+1)\pi}{4n}\right)$ is (where $n \in N$)	(r)	π
(D)	If $\lim\limits_{x \to \infty}\left(\frac{x+a}{x-a}\right)^x = e$, where a is some real constant, the value of a is equal to	(s)	non -existent

Limits Exercise 5 : Single Integer Answer Type Questions

73. Let $L = \lim\limits_{x \to \infty}\left(x \log x + 2x \cdot \log \sin\left(\frac{1}{\sqrt{x}}\right)\right)$, then the value of $\left(-\frac{2}{L}\right)$ is ..... .

74. For $n \in N$, let x_n be defined as $\left(1 + \frac{1}{n}\right)^{(n+x_n)} = e$, then $2\lim\limits_{n \to \infty}(x_n)$ equals ..... .

75. Let $f(n) = \left[\sqrt{n} + \frac{1}{2}\right]$, where $[\cdot]$ denotes greatest integer function, $\forall\ n \in N$.

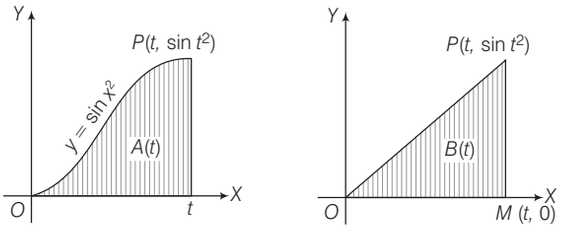
Then, $\sum\limits_{n=1}^{\infty} \frac{2^{f(n)} + 2^{-f(n)}}{2^n}$ is equal to ..... .

76. If the arithmetic mean of the product of all distinct pairs of positive integers whose sum is n, is S_n, then $\lim_{n\to\infty}\frac{n^2}{S_n}$ must equal to ..... .

77. If $k=\sum_{n=1}^{\infty}\frac{6^n}{(3^n-2^n)(3^{n+1}-2^{n+1})}$, the value of k is ..... .

78. The value of $\lim_{x\to\frac{\pi}{2}}\sqrt{\frac{\tan x-\sin\{\tan^{-1}(\tan x)\}}{\tan x+\cos^2(\tan x)}}$ is ..... .

79. The figure shows two regions in the first quadrant. $A(t)$ is the area under the curve $y=\sin x^2$ from 0 to t and $B(t)$ is the area of the triangle with vertices 0, P and $M(t,0)$. If $\lim_{t\to 0}\frac{A(t)}{B(t)}=\frac{m}{n}$, then $(m+n)$ is ..... .



80. If the two lines $AB:\left(\int_0^{2t}\left(\frac{\sin x}{x}+1\right)dx\right)x+y=3t$ and $AC:2tx+y=0$ intersect at a point A, the x-coordinate of a point A as $t\to 0$, is equal to $\frac{p}{q}$ (p and q are in their lowest form), the $(p+q)$ is ..... .

81. Consider a parabola $y=\frac{x^2}{4}$ and the point $F(0,1)$. Let $A_1(x_1,y_1), A_2(x_2,y_2), A_3(x_3,y_3),\ldots, A_n(x_n,y_n)$ are 'n' points on the parabola such that $x_k>0$ and $\angle OFA_k=\frac{k\pi}{2n}(k=1,2,\ldots,n)$. If the value of $\lim_{n\to\infty}\frac{1}{n}\cdot\sum_{k=1}^{n}FA_k=\frac{m}{\pi}$, then m is ..... .

82. If $L=\lim_{x\to\frac{\pi^+}{2}}\frac{\cos(\tan^{-1}(\tan x))}{x-\pi/2}$, then $\cos(2\pi L)$ is ..... .

83. Number of solutions of the equation $\operatorname{cosec}\theta=k$ in $[0,\pi]$, where $k=\lim_{n\to\infty}\prod_{r=2}^{n}\left(\frac{r^3-1}{r^3+1}\right)$, is ..... .

84. If C satisfies the equation $\lim_{x\to\infty}\left(\frac{x+c}{x-c}\right)^x=4$, then $\left|\frac{e^c}{2}\right|$ is ..... .

85. If $\lim_{x\to-\infty}\frac{(3x^4+2x^2)\cdot\sin\left(\frac{1}{x}\right)+|x|^3+5}{|x|^3+|x|^2+|x|+1}=k$, then $\left|\frac{k}{2}\right|$ is ..... .

86. If $f(x)=\lim_{t\to 0}\left[\frac{2x}{\pi}\cdot\tan^{-1}\left(\frac{x}{t^2}\right)\right]$, then $f(1)$ is ..... .

87. The value of $\lim_{n\to\infty}\left(\frac{1}{\sqrt{n^2}}+\frac{1}{\sqrt{n^2+1}}+\ldots+\frac{1}{\sqrt{n^2+2n}}\right)$ is

88. If $l=\lim_{x\to 1^+}2^{-2^{\frac{1}{1-x}}}$ and $m=\lim_{x\to 1^+}\frac{x\sin(x-[x])}{x-1}$ (where $[\cdot]$ denotes greatest integer function). Then, $(l+m)$ is ..... .

89. The value of $\lim_{x\to 0}\left[\frac{\sin x\cdot\tan x}{x^2}\right]$ is .....
(where $[\cdot]$ denotes greatest integer function).

90. If $\lim_{n\to\infty}\sum_{r=1}^{n}\frac{kr}{1\times3\times5\times\ldots\times(2r-1)\times(2r+1)}=1$, then k^2 is ..... .

91. If $f(x)=\lim_{n\to\infty}\sin^4 x+\frac{1}{4}\sin^4 2x+\ldots+\frac{1}{4^n}\cdot\sin^4(2^n x)$ and $g(x)$ is a differentiable function satisfying $g(x)+f(x)=1$, then the maximum value of $(\sqrt{f(x)}+\sqrt{g(x)})^4$ is ..... .

92. If $f(x+y+z)=f(x)+f(y)+f(z)$ with $f(1)=1$ and $f(2)=2$ and $x, y, z\in R$, the value of $\lim_{n\to\infty}\sum_{r=1}^{n}\frac{(4r)f(3r)}{n^3}$ is ....

93. If $\lim_{n\to\infty}\frac{n\cdot3^n}{n\cdot(x-1)^n+n\cdot3^{n+1}-3^n}=\frac{1}{3}$, the number of the integral values of x is ..... .

94. The value of $\lim_{x\to\infty}(((x-1)(x-2)(x+3)(x+10)(x+15))^{1/5}-x)$ is ..... .

95. If $\lim_{x\to\infty}([f(x)]+x^2)\{f(x)\}=k$, where $f(x)=\frac{\tan x}{x}$ and $[\cdot]$, $\{\cdot\}$ denotes greatest integer and fractional part of x respectively, the value of $[k/e]$ is ..... .

96. The value of $\lim_{n\to\infty}\{(\sqrt{3}+1)^{2n}\}$ is ..... (where $\{\cdot\}$ denotes fractional part of x).

97. If $f(x)$ is a polynomial of degree 4, having extremum at $x=1,2$ and $\lim_{x\to 0}\left(1+\frac{f(x)}{x^2}\right)=2$.
Then, $f(2)$ is ..... .

98. If α is the number of solutions of $|x| = \log(x - [x])$, (where $[\cdot]$ denotes greatest integer function) and $\lim\limits_{x \to \alpha} \dfrac{x\, e^{ax} - b \sin x}{x^3}$ is finite, the value of $(a + b)$ is

99. Suppose $x_1 = \tan^{-1} 2 > x_2 > x_3 > \ldots$ are the real numbers satisfying $\sin(x_{n+1} - x_n) + 2^{-(n+1)} \cdot \sin x_n \cdot \sin x_{n+1} = 0$ for all $n > 1$ and $l = \lim\limits_{n \to \infty} x_n$, the value of $[4l]$ is ..... (where $[\cdot]$ denotes greatest integer function).

Limits Exercise 6 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

100. Let $\alpha, \beta \in R$ be such that $\lim\limits_{x \to 0} \dfrac{x^2 \sin(\beta x)}{\alpha x - \sin x} = 1$. Then, $6(\alpha + \beta)$ equals **[Integer Answer Type, 2016 Adv]**

101. Let m and n be two positive integers greater than 1. If $\lim\limits_{\alpha \to 0} \left(\dfrac{e^{\cos(\alpha^n)} - e}{\alpha^m} \right) = -\left(\dfrac{e}{2} \right)$, then the value of $\dfrac{m}{n}$ is **[Integer Answer Type, 2015 Adv]**

102. Let $f : R \to R$ be a continuous odd function, which vanishes exactly at one point and $f(1) = \dfrac{1}{2}$. Suppose that

$$F(x) = \int_{-1}^{x} f(t)dt \text{ for all } x \in [-1, 2]$$

and $G(x) = \int_{-1}^{x} t\,|f\{f(t)\}|\, dt$ for all $x \in [-1, 2]$.

If $\lim\limits_{x \to 1} \dfrac{F(x)}{G(x)} = \dfrac{1}{14}$, then the value of $f\left(\dfrac{1}{2}\right)$ is **[Integer Answer Type, 2015 Adv]**

103. The largest value of the non-negative integer a for which $\lim\limits_{x \to 1} \left\{ \dfrac{-ax + \sin(x-1) + a}{x + \sin(x-1) - 1} \right\}^{\frac{1-x}{1-\sqrt{x}}} = \dfrac{1}{4}$, is **[Integer Answer Type , 2014 Adv]**

104. Let $L = \lim\limits_{x \to 0} \dfrac{a - \sqrt{a^2 - x^2} - \dfrac{x^2}{4}}{x^4}$, $a > 0$. If L is finite, then **[More than One Correct Option, 2009]**

(a) $a = 2$ (b) $a = 1$

(c) $L = \dfrac{1}{64}$ (d) $L = \dfrac{1}{32}$

(ii) JEE Main & AIEEE

105. The $\lim\limits_{x \to \frac{\pi}{2}} \dfrac{\cot x - \cos x}{(\pi - 2x)^3}$ equals **[2017 JEE Main]**

(a) $\dfrac{1}{4}$ (b) $\dfrac{1}{24}$ (c) $\dfrac{1}{16}$ (d) $\dfrac{1}{8}$

106. Let $p = \lim\limits_{x \to 0^+} (1 + \tan^2 \sqrt{x})^{1/2x}$, then $\log p$ is equal to **[2016 JEE Main]**

(a) 2 (b) 1 (c) $\dfrac{1}{2}$ (d) $\dfrac{1}{4}$

107. $\lim\limits_{n \to \infty} \left[\dfrac{(n+1)(n+2)\ldots 3n}{n^{2n}} \right]^{1/n}$ is equal to **[2016 JEE Main]**

(a) $\dfrac{18}{e^4}$ (b) $\dfrac{27}{e^2}$ (c) $\dfrac{9}{e^2}$ (d) $3\log 3 - 2$

108. $\lim\limits_{x \to 0} \dfrac{\sin(\pi \cos^2 x)}{x^2}$ is equal to **[2014 JEE Main]**

(a) $\dfrac{\pi}{2}$ (b) 1 (c) $-\pi$ (d) π

109. $\lim\limits_{x \to 0} \dfrac{(1 - \cos 2x)(3 + \cos x)}{x \tan 4x}$ is equal to **[2013 JEE Main]**

(a) 4 (b) 3 (c) 2 (d) $\dfrac{1}{2}$

110. If $\lim\limits_{x \to \infty} \left(\dfrac{x^2 + x + 1}{x + 1} - ax - b \right) = 4$, then **[2012 AIEEE]**

(a) $a = 1, b = 4$ (b) $a = 1, b = -4$

(c) $a = 2, b = -3$ (d) $a = 2, b = 3$

111. Let $\alpha(a)$ and $\beta(a)$ be the roots of the equation $(\sqrt[3]{1+a} - 1)x^2 - (\sqrt{1+a} - 1)x + (\sqrt[6]{1+a} - 1) = 0$, where $a > -1$. Then, $\lim\limits_{a \to 0^+} \alpha(a)$ and $\lim\limits_{a \to 0^+} \beta(a)$ are **[2012 AIEEE]**

(a) $-\dfrac{5}{2}$ and 1 (b) $-\dfrac{1}{2}$ and -1

(c) $-\dfrac{7}{2}$ and 2 (d) $-\dfrac{9}{2}$ and 3

112. If $\lim\limits_{x \to 0} [1 + x \log(1 + b^2)]^{\frac{1}{x}} = 2b \sin^2 \theta$, $b > 0$ and $\theta \in (-\pi, \pi]$, then the value of θ is **[2011 AIEEE]**

(a) $\pm \dfrac{\pi}{4}$ (b) $\pm \dfrac{\pi}{3}$

(c) $\pm \dfrac{\pi}{6}$ (d) $\pm \dfrac{\pi}{2}$

113. For $x > 0$, $\lim_{x \to 0} \left[(\sin x)^{1/x} + \left(\frac{1}{x}\right)^{\sin x} \right]$ is **[2006 AIEEE]**

(a) 0 (b) − 1 (c) 1 (d) 2

114. $\lim_{h \to 0} \frac{f(2h + 2 + h^2) - f(2)}{f(h - h^2 + 1) - f(1)}$, given that $f'(2) = 6$ and $f'(1) = 4$, **[2003 AIEEE]**

(a) does not exist (b) is equal to –3/2
(c) is equal to 3/2 (d) is equal to 3

115. If $\lim_{x \to 0} \frac{\{(a - n)nx - \tan x\} \sin nx}{x^2} = 0$, where n is non-zero real number, then a is equal to **[2003 AIEEE]**

(a) 0 (b) $\frac{n+1}{n}$ (c) n (d) $n + \frac{1}{n}$

116. The integer n for which $\lim_{x \to 0} \frac{(\cos x - 1)(\cos x - e^x)}{x^n}$ is a finite non-zero number, is **[2002 AIEEE]**

(a) 1 (b) 2 (c) 3 (d) 4

117. Let $f : R \to R$ be such that $f(1) = 3$ and $f'(1) = 6$. Then, $\lim_{x \to 0} \left[\frac{f(1+x)}{f(1)} \right]^{1/x}$ equals **[2002 AIEEE]**

(a) 1 (b) $e^{\frac{1}{2}}$ (c) e^2 (d) e^3

118. For $x \in R$, $\lim_{x \to \infty} \left(\frac{x-3}{x+2} \right)^x$ is equal to **[2000 AIEEE]**

(a) e (b) e^{-1}
(c) e^{-5} (d) e^5

Solutions

1. $\lim\limits_{x\to 0}\dfrac{\sin(\pi-\pi\sin^2\tan(\sin x))}{x^2}$

$$=\lim_{x\to 0}\frac{\sin(\pi\sin^2\tan(\sin x))}{\pi\sin^2\tan(\sin x)}\left(\frac{\pi\sin^2\tan(\sin x)}{\tan^2(\sin x)}\right)\left(\frac{\tan^2(\sin x)}{\sin^2 x}\right)\left(\frac{\sin^2 x}{x^2}\right)=\pi$$

2. $\lim\limits_{t\to 0}\dfrac{1-(1+t)^t}{\ln(1+t)-t}=\lim\limits_{t\to 0}\dfrac{\frac{1-(1+t)^t}{t^2}}{\frac{\ln(1+t)-t}{t^2}}$

$$=\lim_{t\to 0}\frac{1-e^{t(\ln(1+t))}}{\frac{t^2}{-1/2}}=2$$

3. $I_1=\lim\limits_{x\to\infty}(\tan^{-1}\pi x-\tan^{-1}x)$

$$=\lim_{x\to\infty}\tan^{-1}\left(\frac{(\pi-1)x}{1+\pi x^2}\right)=0\Rightarrow I_1=0 \text{ and } I_2=0$$

4. From given $f(x)=x^2-\pi^2$,

$$\lim_{x\to-\pi}\frac{x^2-\pi^2}{\sin(\sin x)}=\lim_{x\to-\pi}\frac{(-\pi+h)^2-\pi^2}{\sin\sin(-\pi+h)}$$

$$=\lim_{h\to 0}\frac{-2h\pi+h^2}{-\sin(\sin h)}=\lim_{h\to 0}\frac{h-2\pi}{\frac{-\sin(\sin h)}{\sin h}\times\frac{\sin h}{h}}=2\pi$$

5. Using approximations

$$L=\lim_{x\to 0}\frac{\frac{\sin^2 x}{3}+\frac{2\tan x}{4}}{\sin x+\tan^2 x}=\lim_{x\to 0}\frac{\frac{x^2}{3}+\frac{2x}{4}}{x+x^2}$$

$$=\lim_{x\to 0}\frac{x\left(\frac{x}{3}+\frac{1}{2}\right)}{x(1+x)}=\frac{1}{2}$$

6. Let $x_0=\cos\theta$, $x_1=\cos\frac{\theta}{2}$, $x_2=\cos\frac{\theta}{2^2}$

$$=\lim_{n\to\infty}\left(\frac{\sqrt{1-x_0^2}}{x_1x_2x_3\ldots x_{n+1}}\right)=\lim_{n\to\infty}\left(\frac{\sin\theta}{\cos\frac{\theta}{2}\cos\frac{\theta}{2^2}\ldots\cos\frac{\theta}{2^{n+1}}}\right)$$

$$=\lim_{n\to\infty}\left(\frac{2^n\cdot\sin\frac{\theta}{2^n}}{\cos\frac{\theta}{2^{n+1}}}\right)=\lim_{n\to\infty}\left(\frac{\sin\frac{\theta}{2^n}}{\frac{\theta}{2^n}}\right)\left(\frac{\theta}{\cos\frac{\theta}{2^{n+1}}}\right)$$

$$=\theta=\cos^{-1}(x_0)$$

7. $f_n(x)=\tan\dfrac{x}{2}\left(\dfrac{1+\cos x}{\cos x}\right)(1+\sec 2x)(1+\sec 4x)\ldots(1+\sec 2^n x)$

$$=\tan x\left(\frac{1+\cos 2x}{\cos 2x}\right)(1+\sec 4x)\ldots(1+\sec 2^n x)$$

$$=\tan 2x(1+\sec 2^2 x)\ldots(1+\sec 2^n x)$$

$$=\tan 2^{n-1}x(1+\sec 2^n x)=\tan 2^n x$$

Now, $\lim\limits_{x\to 0}\dfrac{f_n(x)}{2x}=\lim\limits_{x\to 0}\dfrac{\tan 2^n x}{2^n x}\cdot 2^{n-1}=2^{n-1}$

8. As, $f'(x)>0\Rightarrow f(x)$ is increasing.

So, for $t>1$; $f(t)>1$

Now, $f'(t)=\dfrac{1}{t^2+f(t)}<\dfrac{1}{1+t^2}$

$\therefore$ $f(x)=1+\int_1^x f'(t)\,dt<1+\int_1^x\dfrac{dt}{1+t^2}$

$\Rightarrow$ $\lim\limits_{x\to\infty}f(x)<1+\int_1^\infty\dfrac{dt}{1+t^2}\Rightarrow\lim\limits_{x\to\infty}f(x)<1+\dfrac{\pi}{4}$

9. $E=\sin^2\theta-\sin\theta+\dfrac{1}{2}=\left(\sin\theta-\dfrac{1}{2}\right)^2+\dfrac{1}{4}$

$\Rightarrow$ Minimum value is $\dfrac{1}{4}$.

Let $K=\sqrt{(x+1)(x+2)}$, then $K-x=\dfrac{K^2-x^2}{K+x}=\dfrac{3x+2}{K+x}$

$$\lim_{x\to\infty}(K-x)=\lim_{x\to\infty}\frac{3+\frac{2}{x}}{\frac{K}{x}+1}\Rightarrow\lim_{x\to\infty}\frac{K}{x}=1$$

$\therefore$ $\lim\limits_{x\to\infty}(K-x)=\dfrac{3+0}{1+1}=\dfrac{3}{2}$ $\left[\lim\limits_{x\to\infty}\dfrac{K}{x}=1\right]$

The required equation is $x^2-\dfrac{7}{4}x+\dfrac{3}{8}=0$,

i.e. $8x^2-14x+3=0$.

10. Let $x_n=\tan\theta_n$

Now, $\tan\theta_{n+1}=x_{n+1}=\dfrac{x_n}{1+\sqrt{1+x_n^2}}=\dfrac{\tan\theta}{1+\sqrt{1+\tan^2\theta_n}}$

$\Rightarrow$ $\tan\theta_{n+1}=\dfrac{\tan\theta_n}{1+\sec\theta_n}=\dfrac{\sin\theta_n}{1+\cos\theta_n}=\tan\dfrac{\theta_n}{2}$

$\Rightarrow$ $\theta_{n+1}=\dfrac{\theta_n}{2}\Rightarrow\theta_n=\dfrac{\theta_{n-1}}{2}$

Now, $\theta_1=\dfrac{\pi}{3}\Rightarrow\theta_n=\dfrac{\pi}{3\cdot 2^{n-1}}\Rightarrow x_n=\tan\left(\dfrac{2\pi}{3\cdot 2^n}\right)$

$\Rightarrow$ $\lim\limits_{n\to\infty}2^n x_n=\lim\limits_{n\to\infty}\dfrac{\tan\left(\frac{2\pi}{3\cdot 2^n}\right)}{\left(\frac{1}{2^n}\right)}=\dfrac{2\pi}{3}$

11. $L=\lim\limits_{x\to a^-}=\dfrac{(x-b)-(a-b)}{\sqrt{x-b}+\sqrt{a-b}}\times\dfrac{1}{(x^2-a^2)}$

$$=\lim_{x\to a^-}\frac{1}{(x+a)\{\sqrt{x-b}+\sqrt{a-b}\}}=\frac{1}{4a\sqrt{a-b}}$$

12. $\lim\limits_{n\to\infty}(\sin^n 1+\cos^n 1)^n=\sin 1\lim\limits_{n\to\infty}(1+\cot^n 1)^n$

$$=\sin 1\cdot e^{\lim\limits_{n\to\infty}\frac{n}{\tan^n 1}}=\sin 1\cdot e^{\lim\limits_{n\to\infty}\frac{1}{\tan^n 1\cdot\ln(\tan 1)}}=\sin 1$$

13. As, $\sin^{-1}x = x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5}{112}x^7 + \cdots$

and $\tan^{-1}x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \cdots$

$$\therefore \lim_{x\to 0}\frac{2}{x^3}(\sin^{-1}x - \tan^{-1}x)$$

$$= \lim_{x\to 0}\frac{2}{x^3}\left[\left(x + \frac{x^3}{6} + \frac{3x^5}{40} + \cdots\right) - \left(x - \frac{x^3}{3} + \frac{x^5}{5} + \cdots\right)\right]$$

$$= \lim_{x\to 0}\frac{2}{x^3}\left[x^3\left(\frac{1}{2}\right) + x^5\left(\frac{3}{40} - \frac{1}{5}\right) + \cdots\right] = 1$$

$$\therefore \lim_{x\to 0}\left[\frac{2}{x^3}(\sin^{-1}x - \tan^{-1}x)\right]^{2/x^2} \qquad [1^\infty \text{ form}]$$

$$= e^{\lim_{x\to 0}\left[\frac{2}{x^3}(\sin^{-1}x - \tan^{-1}x) - 1\right]\frac{2}{x^2}}$$

$$= e^{\lim_{x\to 0}\frac{2}{x^2}\cdot\frac{2\left[\left(x + \frac{x^3}{6} + \frac{3x^5}{5} + \cdots\right) - \left(x - \frac{x^3}{3} + \frac{x^5}{5} - \cdots\right)\right] - x^3}{x^3}}$$

$$= e^{\lim_{x\to 0}\frac{2}{x^5}\left[-\frac{1}{4}x^5 + \text{higher powers of } x\right]} = e^{-1/2} = \frac{1}{\sqrt{e}}$$

14. We have, $S = \frac{1}{n}\cdot\sum_{k=1}^{n}\left(1 - \frac{k}{n}\right)\cdot\cos 4\left(\frac{k}{n}\right)$

$$S = \int_0^1 (1-x)\cos 4x\cdot dx = \left((1-x)\cdot\frac{\sin 4x}{4}\right)_0^1 + \frac{1}{4}\int_0^1 \sin 4x\, dx$$

$$= 0 + \frac{1}{4}\cdot\frac{1}{(-4)}(\cos 4x)_0^1 = -\frac{1}{16}(\cos 4 - \cos 0) = \frac{1}{16}(1 - \cos 4)$$

15. Let $y = \sqrt{\cos 2x}\cdot\sqrt[3]{\cos 3x}\cdot\sqrt[4]{\cos 4x}\ \ldots\ \sqrt[n]{\cos nx}$

$$\log_e y = \frac{1}{2}\log\cos 2x + \frac{1}{3}\log\cos 3x + \frac{1}{4}\log\cos 4x + \ldots + \frac{1}{n}\log\cos nx$$

On differentiating both sides, we get

$$\frac{1}{y}\cdot dy/dx = \frac{1}{2}\cdot\frac{(-2\sin 2x)}{\cos 2x} + \frac{1}{3}\cdot\left(\frac{-3\sin 3x}{\cos 3x}\right) + \ldots + \frac{1}{n}\left[\frac{(-n\sin nx}{\cos nx}\right]$$

$$\therefore \frac{dy}{dx} = \prod_{r=2}^{n}(\cos rx)^{1/r}\cdot\sum_{r=2}^{n}[-\tan(rx)] \qquad \ldots(i)$$

$$\therefore L = \lim_{x\to 0}\frac{1 - \prod_{r=2}^{n}[\cos(rx)]^{1/r}}{x^2}$$

$$= \lim_{x\to 0}\frac{-\prod_{r=2}^{n}(\cos rx)^{1/2}\sum_{r=2}^{n}[-\tan(rx)]}{2x} \qquad \text{[using L' Hospital's rule]}$$

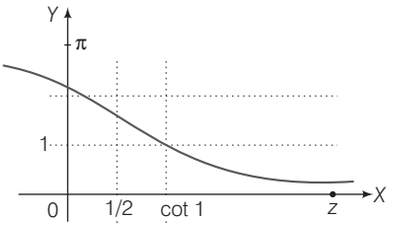
$$= \lim_{x\to 0}\frac{1}{2}\cdot\left[\frac{\tan 2x + \tan 3x + \cdots + \tan nx}{x}\right]$$

$$= \frac{1}{2}[2 + 3 + \cdots + n] = \frac{n^2 + n - 2}{4} = 10 \qquad \text{[given]}$$

$$\Rightarrow (n+7)(n-6) = 0 \quad \Rightarrow \quad n = 6$$

16. Here, $\lim_{z\to\infty}\frac{\int_{1/2}^{z}[\cot^{-1}x]\,dx}{\int_{1/2}^{z}\left[1 + \frac{1}{x}\right]dx} = \frac{\int_{1/2}^{\cot 1}1\cdot dx + \int_{\cot 1}^{z}0\cdot dx}{\int_{1/2}^{1}2\cdot dx + \int_{1}^{z}1\cdot dx}$

As,



$\because$ $[\cot^{-1}x] = 1$, when $1/2 < x < \cot 1$

and $[\cos^{-1}x] = 0$, when $\cot 1 < x < z$

$$\Rightarrow \lim_{z\to\infty}\frac{\int_{1/2}^{\cot 1}1\cdot dx}{\int_{1/2}^{1}2\cdot dx + \int_{1}^{z}1\cdot dx} = \lim_{z\to\infty}\frac{(\cot 1 - 1/2)}{2(1-1/2) + (z-1)} = 0$$

17. $\lim_{\theta\to 0^+}\left(\frac{1}{\alpha} + \frac{1}{\beta}\right) = \lim_{\theta\to 0^+}\frac{\alpha+\beta}{\alpha\beta} = \lim_{\theta\to 0^+}\frac{\sqrt{2}|\sin\theta|}{\theta} = \sqrt{2}$

18. Here, $\lim_{x\to\infty}f(x) = \lim_{x\to\infty}\frac{1}{3}\left[f(x+1) + \frac{5}{f(x+2)}\right]$

$$\Rightarrow \qquad l = \frac{1}{3}\cdot\left(l + \frac{5}{l}\right) \Rightarrow l^2 = \frac{1}{3}(l^2 + 5)$$

$$\Rightarrow \qquad 2l^2 = 5 \quad \Rightarrow l = \sqrt{\frac{5}{2}}$$

19. $\lim_{x\to 2^-}\frac{\cos(2x+4) - 33}{2} = -16$ and $\lim_{x\to 2^-}\frac{x^2|4x-8|}{2} = -4(4) = -16$

By Sandwich theorem, $\lim_{x\to 2^-}f(x) = -16$

20. As, $f(x)$ being polynomial having roots 1, 2, 3, 4 and leading coefficient 1.

$$\therefore \qquad f(x) = (x-1)(x-2)(x-3)(x-4)$$

Similarly, $\qquad g(x) = (x-1)\left(x - \frac{1}{2}\right)\left(x - \frac{1}{3}\right)\left(x - \frac{1}{4}\right)$

$$\therefore \qquad \lim_{x\to 1}\frac{f(x)}{g(x)} = \lim_{x\to 1}\frac{(x-1)(x-2)(x-3)(x-4)}{(x-1)\left(x - \frac{1}{2}\right)\left(x - \frac{1}{3}\right)\left(x - \frac{1}{4}\right)}$$

$$= \frac{(-1)(-2)(-3)}{\left(\frac{1}{2}\right)\left(\frac{2}{3}\right)\left(\frac{3}{4}\right)} = -24$$

21. We have, $\lim_{x\to\frac{\pi}{4}}\frac{4\sqrt{2} - (\cos x + \sin x)^5}{1 - \sin 2x}$

$$= \lim_{x\to\frac{\pi}{4}}\frac{[(\cos x + \sin x)^2]^{5/2} - (2)^{5/2}}{(1 + \sin 2x) - 2} = \lim_{x\to\frac{\pi}{4}}\frac{(1 + \sin 2x)^{5/2} - (2)^{5/2}}{(1 + \sin 2x) - 2}$$

Put $y = 1 + \sin 2x$

$$= \lim_{x\to\frac{\pi}{4}}\frac{y^{5/2} - 2^{5/2}}{y - 2} = \frac{5}{2}(2)^{\frac{5}{2}-1} = 5\sqrt{2}\left[\text{as } x\to\frac{\pi}{4} \Rightarrow y\to 2\right]$$

22. We have, $\lim_{n\to\infty}\frac{n\cdot 3^n}{n(x-2)^n + n\cdot 3^{n+1} - 3^n} = \frac{1}{3}$

$$\Rightarrow \lim_{n\to\infty}\frac{1}{\left(\frac{x-2}{3}\right)^n + 3 - \frac{1}{n}} = \frac{1}{3}$$

For, limit to exists and is equal to $\frac{1}{3}$.

We must have, $-1 < \frac{x-2}{3} < 1$.

$\Rightarrow\ -3 < x-2 < 3\ \Rightarrow\ -1 < x < 5$, as $x \in$ integer

$\therefore\quad x \in \{0,\ 1,\ 2,\ 3,\ 4\}$

$\Rightarrow$ Number of integer solutions = 5.

23. Given, $f(x) = \lim\limits_{n\to\infty} \dfrac{1}{\left(\frac{3}{\pi}\tan^{-1}2x\right)^{2n} + 5}$

Now, $f(x) = 0$, if and only if $\left(\frac{3}{\pi}\tan^{-1}2x\right)^2 > 1$

$\Rightarrow\ \tan^{-1}2x > \frac{\pi}{3}$ or $\tan^{-1}2x < -\frac{\pi}{3}$

$\Rightarrow\quad 2x > \sqrt{3}\quad$ or $\quad 2x < -\sqrt{3}\ \Rightarrow\ |2x| > \sqrt{3}$

24. We have, $\lim\limits_{x\to 0} \dfrac{\cos^2 x - \cos x - e^x\cos x + e^x - \frac{x^3}{2}}{x^n}$

$$= \lim_{x\to 0} \frac{(\cos x - 1)(\cos x - e^x) - \frac{x^3}{2}}{x^n}$$

$$= \lim_{x\to 0} \frac{\left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \ldots - 1\right)\left[\left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \ldots\right) - \left(1 + \frac{x}{1!} + \frac{x^2}{2!} + \ldots\right)\right] - \frac{x^3}{2}}{x^n}$$

$$= \lim_{x\to 0} \frac{\left(-\frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \ldots\right)\left(-x - x^2 - \frac{x^3}{3!} - \frac{2x^5}{5!} - \ldots\right) - \frac{x^3}{2}}{x^n}$$

$$= \lim_{x\to 0} \frac{\left(\frac{x^3}{2} + \frac{x^4}{2} + \frac{x^5}{12} - \ldots\right) - \frac{x^3}{2}}{x^n} = \lim_{x\to 0} \frac{\frac{x^4}{2} + \frac{x^5}{12} - \frac{x^5}{24}}{x^n}$$

= a non-zero finit number, if $n = 4$.

25. We know that,

$\frac{\tan^{-1}x}{x} < 1$ and $\frac{\sin^{-1}x}{x} > 1,\ \forall\ x \in R$

$\therefore\quad \frac{\tan^{-1}x}{x} - \frac{\sin^{-1}x}{x} < 0$ and $\frac{\sin^{-1}x}{x} - \frac{\tan^{-1}x}{x} > 0$

$\Rightarrow\ I_1$ doesn't exist and I_2 exists.

26. Here, $\lim\limits_{x\to\frac{\pi}{2}} \dfrac{[x/2]}{\log(\sin x)}$

As, $x \to \frac{\pi}{2}\ \Rightarrow\ \frac{x}{2} \to \frac{\pi}{4}$, where $\frac{x}{2} \to \frac{\pi}{4} < 1$

for $\quad x \to \frac{\pi^+}{2}$ or $x \to \frac{\pi^-}{2}$

$\therefore\quad \left[\frac{x}{2}\right] = 0$, since $0 < \left(\frac{x}{2} \to \frac{\pi}{4}\right) < 1$

$\Rightarrow\quad \lim\limits_{x\to\pi/2} \dfrac{\left[\frac{x}{2}\right]}{\log\sin x} = \lim\limits_{x\to\pi/2} 0 = 0$

27. We have, $\lim\limits_{n\to\infty} \left(\frac{a_1+1}{a_1}\right)\left(\frac{a_2+1}{a_2}\right)\ldots\left(\frac{a_n+1}{a_n}\right)$

and $\quad a_{n-1} + 1 = \frac{a_n}{n}$ ...(i)

$$\therefore \lim_{n\to\infty} \left(\frac{a_2}{2}\right)\left(\frac{a_3}{3}\right)\left(\frac{a_4}{4}\right)\ldots\left(\frac{a_{n+1}}{n+1}\right)\cdot\frac{1}{a_1\cdot a_2\ldots a_n}$$

$$= \lim_{n\to\infty} \frac{a_{n+1}}{(n+1)!} = \lim_{n\to\infty} \frac{1+a_n}{n!} \quad \text{[using Eq. (i)]}$$

$$= \lim_{n\to\infty} \left(\frac{1}{n!} + \frac{a_n}{n!}\right) = \lim_{n\to\infty} \left(\frac{1}{n!} + \frac{1}{(n-1)!} + \frac{a_{n-1}}{(n-1)!}\right) \text{[using Eq. (i)]}$$

$$= \lim_{n\to\infty} \left(\frac{1}{n!} + \frac{1}{(n-1)!} + \frac{1}{(n-2)!} + \ldots + \frac{1}{(2)!} + \frac{1}{1!} + \frac{a_1}{1!}\right)$$

$[a_1 = 1,\ \text{given}]$

$$= \lim_{n\to\infty} \left(\frac{1}{n!} + \frac{1}{(n-1)!} + \frac{1}{(n-2)!} + \ldots + \frac{1}{(2)!} + \frac{1}{1!} + \frac{1}{1}\right)$$

$$= e \qquad \left[\text{as } e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \ldots\infty\right]$$

28. Here, $\quad f(x+y) = f(x) + f(y)$

$$f(2) = f(1) + f(1) = 2$$

$$f(3) = f(1+2) = f(1) + f(2) = 3$$

$$f(4) = f(1+3) = f(1) + f(3) = 4$$

$$\vdots\quad\vdots\quad\vdots\quad\vdots\quad\vdots\quad\vdots\quad\vdots\quad\vdots$$

$$f(x) = x,\ \text{for all } x \in R$$

$\Rightarrow\quad f(\tan x) = \tan x,\ \ f(\sin x) = \sin x$

$$\therefore \lim_{x\to 0} \frac{2^{f(\tan x)} - 2^{f(\sin x)}}{x^2\, f(\sin x)} = \lim_{x\to 0} \frac{2^{\tan x} - 2^{\sin x}}{x^2 \sin x}$$

$$= \lim_{x\to 0} \frac{2^{\sin x}\cdot\{2^{\tan x - \sin x} - 1\}}{\sin x\cdot x^2} \times \frac{\tan x - \sin x}{\tan x - \sin x}$$

$$= \lim_{x\to 0} \frac{\{2^{\tan x - \sin x} - 1\}}{\tan x - \sin x} \times \left\{\frac{\tan x - \sin x}{x^2 \sin x}\right\} \times 2^{\sin x}$$

$$= \lim_{x\to 0} \frac{2^{\tan x - \sin x} - 1}{\tan x - \sin x} \times \frac{1 - \cos x}{x^2\cos x} \times 2^{\sin x}$$

$$= \lim_{x\to 0} \frac{2^{\tan x - \sin x} - 1}{\tan x - \sin x} \times \frac{2\sin^2 x/2}{4(x/2)^2} \times 2^{\sin x} \times \frac{1}{\cos x}$$

$$= \log 2 \times \frac{1}{2} \times 1 = \frac{1}{2}\log 2$$

29. We have, $\lim\limits_{n\to\infty} n^{-n^2}\left[(n+1)\left(n+\frac{1}{2}\right)\ldots\left(n+\frac{1}{2^{n-1}}\right)\right]^n$

$$= \lim_{n\to\infty} \left[\frac{(n+1)\left(n+\frac{1}{2}\right)\ldots\left(n+\frac{1}{2^{n-1}}\right)}{n^n}\right]^n$$

$$= \lim_{n\to\infty} \left(\frac{n+1}{n}\right)^n \cdot \left(\frac{n+\frac{1}{2}}{n}\right)^n \ldots \left(\frac{n+\frac{1}{2^{n-1}}}{n}\right)^n$$

$$= \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n \cdot \left(1+\frac{1}{2n}\right)^n \ldots \left(1+\frac{1}{2^{n-1}n}\right)^n \qquad [1^\infty \text{ form}]$$

$$= \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n \cdot \left(1+\frac{1}{2n}\right)^{\frac{2n}{2}} \ldots \left(1+\frac{1}{2^{n-1}n}\right)^{\frac{2^{n-1}\cdot n}{2^{n-1}}}$$

$$= e^1 \cdot e^{1/2} \cdot e^{1/4} \ldots e^{1/2^{n-1}} \ldots \infty \qquad \left[\text{using } \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^{an} = e^a\right]$$

$$= e^{(1+1/2+1/4+\ldots)} = e^{\frac{1}{1-\frac{1}{2}}} = e^2$$

30. Here, limit can be calculated only after removing greatest integral function (i.e. $[x]$).

$\therefore$ LHL at $x = 0$

$$= \lim_{x\to 0^-} f(x) = \lim_{x\to 0^-} \frac{\sin[x]}{[x]} = \lim_{h\to 0} \frac{\sin[0-h]}{[0-h]}$$

$$= \lim_{h\to 0} \frac{\sin(-1)}{(-1)} = \sin 1$$

$[\text{as } -1 \le [0-h] < 0 \ \therefore [0-h] = -1, \text{ i.e. } [x] \ne 0]$

Again, RHL at $x = 0$

$$= \lim_{x\to 0^+} f(x) = \lim_{x\to 0^+} 0 = 0 \qquad \left[\text{as } f(x) = \begin{cases} \dfrac{\sin[x]}{[x]}, & [x] \ne 0 \\ 0, & [x] = 0 \end{cases}\right]$$

$$\therefore \qquad \lim_{x\to 0^+} f(x) = 0$$

Here, $0 \le [0+h] < 1$

$$\therefore \qquad [x] = 0 \Rightarrow f(x) = 0$$

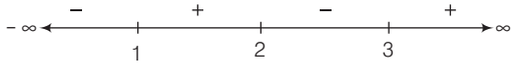
So, $\lim\limits_{x\to 0^-} f(x) \ne \lim\limits_{x\to 0^+} f(x)$. Thus, limit doesn't exist.

31. We write, $f(x) = \dfrac{|(x-1)(x-2)(x-3)|}{(x-1)(x-2)(x-3)}$

$$f(x) = \begin{cases} -1, & x < 1 \\ 1, & 1 < x < 2 \\ -1, & 2 < x < 3 \\ 1, & x > 3 \end{cases}$$

[leaving $x = 1, 2, 3$ as denominator $\ne 0$]

Using Wavy-curve method, as shown in figure



When $x > 3$, then

$|(x-1)(x-2)(x-3)| = +(x-1)(x-2)(x-3)$

When $2 < x < 3$, then

$|(x-1)(x-2)(x-3)| = -(x-1)(x-2)(x-3)$

When $1 < x < 2$, then

$|(x-1)(x-2)(x-3)| = +(x-1)(x-2)(x-3)$

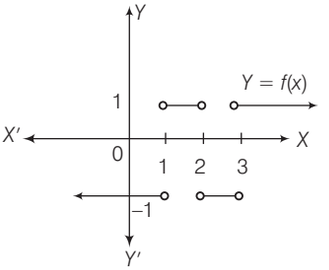
When $x < 1$, then

$|(x-1)(x-2)(x-3)| = -(x-1)(x-2)(x-3)$

Thus,
$$f(x) = \begin{cases} -1, & x < 1 \\ 1, & 1 < x < 2 \\ -1, & 2 < x < 3 \\ 1, & x > 3 \end{cases}$$

Shows limit exists at all points except at $x = 1, 2, 3$.

Graphically, this is shown in given figure.



which shows limit doesn't exist at $x = 1, 2, 3$.

32. Here, $t_r = \dfrac{r}{1+r^2+r^4}$

$$= \frac{1}{2}\left(\frac{2r}{1+2r^2+r^4-r^2}\right) = \frac{1}{2}\left[\frac{2r}{(1+r^2)^2-(r^2)}\right]$$

$$= \frac{1}{2}\left[\frac{2r}{(1+r^2+r)(1+r^2-r)}\right]$$

$$= \frac{1}{2}\left[\frac{(r^2+r+1)-(r^2-r+1)}{(1+r^2+r)(1+r^2-r)}\right] \qquad [\because 2r = (r^2+r+1)-(r^2-r+1)]$$

$$= \frac{1}{2}\left[\frac{1}{1+r^2-r} - \frac{1}{1+r^2+r}\right] = \frac{1}{2}\left[\frac{1}{1+r(r-1)} - \frac{1}{1+r(r+1)}\right] \ldots(\text{i})$$

Thus, $t_r = \dfrac{1}{2}\left(\dfrac{1}{1+r(r-1)} - \dfrac{1}{1+r(r+1)}\right)$

$$t_1 = \frac{1}{2}\left(\frac{1}{1+0} - \frac{1}{1+2}\right) = \frac{1}{2}\left(1-\frac{1}{3}\right)$$

$$t_2 = \frac{1}{2}\left(\frac{1}{1+2} - \frac{1}{1+2\cdot 3}\right) = \frac{1}{2}\left(\frac{1}{3}-\frac{1}{7}\right)$$

$$t_3 = \frac{1}{2}\left(\frac{1}{7}-\frac{1}{13}\right) = \frac{1}{2}\left(\frac{1}{7}-\frac{1}{13}\right)$$

.....

.....

$$t_n = \frac{1}{2}\left(\frac{1}{1+n(n-1)} - \frac{1}{1+n(n+1)}\right)$$

$$\therefore \qquad \lim_{n\to\infty} \sum_{r=1}^{n} t_r = \frac{1}{2}\left(1 - \frac{1}{1+n(n+1)}\right) \qquad \ldots(\text{ii})$$

Hence, $\lim\limits_{n\to\infty} \sum\limits_{r=1}^{n} t_r = \lim\limits_{n\to\infty} \dfrac{1}{2}\left(1 - \dfrac{1}{1+n(n+1)}\right) = \dfrac{1}{2}\left(1-\dfrac{1}{\infty}\right)$

$$\therefore \qquad \lim_{n\to\infty} \sum_{r=1}^{n} t_r = \frac{1}{2}$$

33. Here, $\lim\limits_{n\to\infty} \sum\limits_{r=1}^{n} \cot^{-1}\left(\dfrac{r^3 - r + \frac{1}{r}}{2}\right) = \lim\limits_{n\to\infty} \sum\limits_{r=1}^{n} \tan^{-1}\left(\dfrac{2r}{1-r^2+r^4}\right)$

$$= \lim_{n\to\infty} \sum_{r=1}^{n} \tan^{-1}\left(\frac{2r}{1+(r^2-r)(r^2+r)}\right)$$

$$= \lim_{n\to\infty}\sum_{r=1}^{n}\tan^{-1}\left(\frac{(r^2+r)-(r^2-r)}{1+(r^2+r)(r^2-r)}\right)$$

$$= \lim_{n\to\infty}\sum_{r=1}^{n}\{\tan^{-1}(r^2+r)-\tan^{-1}(r^2-r)\}$$

$$= \lim_{n\to\infty}[(\tan^{-1}2-\tan^{-1}0)+(\tan^{-1}6-\tan^{-1}2)+(\tan^{-1}12-\tan^{-1}6)$$
$$+\ldots+\{(\tan^{-1}(n^2+n)-\tan^{-1}(n^2-n)\}]$$

$$= \lim_{n\to\infty}\{\tan^{-1}(n^2+n)-\tan^{-1}(0)\}$$

$$= \tan^{-1}(\infty)-\tan^{-1}(0) = \frac{\pi}{2}$$

$$\therefore \lim_{n\to\infty}\sum_{r=1}^{n}\cot^{-1}\left(\frac{r^3-r+\frac{1}{r}}{2}\right)=\frac{\pi}{2}$$

34. Here, two straight lines $(\tan\alpha)\,x+(\sin\alpha)\,y=\alpha$ and $(\alpha\,\text{cosec}\,\alpha)\,x+(\cos\alpha)\,y=1$ have their point of intersection, as

$$x=\frac{\alpha\cos\alpha-\sin\alpha}{\sin\alpha-\alpha}\quad\text{and}\quad y=\frac{\alpha-x\tan\alpha}{\sin\alpha}$$

$\therefore$ When $\alpha\to 0$, we obtain the point P.

i.e. $\lim\limits_{\alpha\to 0}x=\lim\limits_{\alpha\to 0}\dfrac{\alpha\cos\alpha-\sin\alpha}{\sin\alpha-\alpha}$ $\left[\dfrac{0}{0}\text{ form}\right]$

$$= \lim_{\alpha\to 0}\frac{-\alpha\sin\alpha+\cos\alpha-\cos\alpha}{\cos\alpha-1}\quad[\text{applying L'Hospital's rule}]$$

$$= \lim_{\alpha\to 0}\frac{\alpha\left(2\sin\frac{\alpha}{2}\cos\frac{\alpha}{2}\right)}{2\sin^2\frac{\alpha}{2}} = \lim_{\alpha\to 0}\frac{\alpha}{\tan\frac{\alpha}{2}} = \lim_{\alpha\to 0}\frac{\frac{2\alpha}{2}}{\tan\frac{\alpha}{2}} = 2$$

Again, as $\lim\limits_{\alpha\to 0}y=\lim\limits_{\alpha\to 0}\dfrac{\alpha-x\tan\alpha}{\sin\alpha}$

$$= \lim_{\alpha\to 0}\left(\frac{\alpha}{\sin\alpha}-\frac{x}{\cos\alpha}\right) = \lim_{\alpha\to 0}\frac{\alpha}{\sin\alpha}-\lim_{\alpha\to 0}\frac{x}{\cos\alpha}$$

$= 1-2$ $\left[\text{as }\lim\limits_{\alpha\to 0}x=2\right]$

$\therefore \lim\limits_{\alpha\to 0}y=-1$

Hence, in limiting position $P(2,-1)$.

35. Here, $\lim\limits_{x\to 0}\left(1+\dfrac{x^2+f(x)}{x^2}\right)^{1/x}$

$\Rightarrow \lim\limits_{x\to 0}\left(1+\dfrac{x^2+f(x)}{x^2}\right)^{1/x}=L$ (say)

exists only when

$\lim\limits_{x\to 0}\dfrac{x^2+f(x)}{x^2}=0$ [it converts to 1^∞ form]

So, the least degree in $f(x)$ is of degree 2.

i.e. $f(x)=a_2x^2+a_3x^3+\ldots$

Now, $\lim\limits_{x\to 0}\left(1+\dfrac{x^2+f(x)}{x^2}\right)^{1/x}=e^2$

$$\Rightarrow e^{\lim\limits_{x\to 0}\left(\frac{x^2+f(x)}{x^2}\right)\frac{1}{x}}=e^2\Rightarrow e^{\lim\limits_{x\to 0}\frac{x^2+f(x)}{x^3}}=e^2$$

$$\therefore \lim_{x\to 0}\frac{x^2+f(x)}{x^3}=2\Rightarrow\lim_{x\to 0}\frac{x^2+a_2x^2+a_3x^3+\ldots}{x^3}=2$$

$\Rightarrow a_2=-1, a_3=2$ and a_4, a_5 are any arbitrary constants. Since, we want polynomial of least degree.

Hence, $f(x)=-x^2+2x^3$

36. We know, $n\le[x]<n+1\Rightarrow[x]=n$

Here, $\dfrac{n\sin x}{x}\to n$, as $x\to 0$ but less than n.

Also, $\dfrac{n\tan x}{x}\to n$, as $x\to 0$ but more than n.

Thus, $n-1<\left[\dfrac{n\sin x}{x}\right]<n$, as $x\to 0$

$\Rightarrow \left[\dfrac{n\sin x}{x}\right]=n-1$

Again, $n\le\left[\dfrac{n\tan x}{x}\right]<n+1$, as $x\to 0$

$\Rightarrow \left[\dfrac{n\tan x}{x}\right]=n$

Thus, $\lim\limits_{x\to 0}\left(\left[\dfrac{n\sin x}{x}\right]+\left[\dfrac{n\tan x}{x}\right]\right)=(n-1)+(n)=(2n-1)$

$\therefore \lim\limits_{x\to 0}\left(\left[\dfrac{n\sin x}{x}\right]+\left[\dfrac{n\tan x}{x}\right]\right)=(2n-1)$

37. Here, $\lim\limits_{x\to a}[\sqrt{2-x}+\sqrt{1+x}]$ and we know, we could only apply limit after defining greatest integral function.

Thus, finding range of $[\sqrt{2-x}+\sqrt{1+x}]$, when $x\in\left[0,\dfrac{1}{2}\right]$.

i.e. Let $f(x)=\sqrt{2-x}+\sqrt{1+x}$

For range $f'(x)=\dfrac{1}{2}\left(-\dfrac{1}{\sqrt{2-x}}+\dfrac{1}{\sqrt{1+x}}\right)$

$$= \frac{1}{2}\left(\frac{\sqrt{2-x}-\sqrt{1+x}}{\sqrt{2-x}\cdot\sqrt{1+x}}\right)$$

$\Rightarrow f'(x)$ will be the +ve for $\sqrt{2-x}>\sqrt{1+x}$.

$\Rightarrow f'(x)$ will be the +ve for $2-x>1+x$.

$\Rightarrow f'(x)$ will be the +ve for $2x<1$.

$\Rightarrow x<\dfrac{1}{2}$

$\therefore f(x)$ will be increasing for $x<\dfrac{1}{2}$.

$\therefore f(0)=\sqrt{2}+1$

$\Rightarrow f(1/2)=\sqrt{6}$

which shows range of $f(x)$ is $[1+\sqrt{2},\sqrt{6}]$, when $x\in\left[0,\dfrac{1}{2}\right]$.

$\therefore [\sqrt{2-x}+\sqrt{1+x}]=2$

$\Rightarrow \lim\limits_{x\to a}[\sqrt{2-x}+\sqrt{1+x}]=\lim\limits_{x\to a}2=2$

38. Let $y=\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)+\ldots\infty}}}$

$\Rightarrow \quad y=\sqrt{(\tan x-\sin x)+y}$

$\Rightarrow \quad y^2-y-(\tan x-\sin x)=0$

$\Rightarrow \quad y=\dfrac{1+\sqrt{1+(\tan x-\sin x)\,4}}{2}$ [as $y>0$] ...(i)

Again, let $Z=\sqrt{x^3+\sqrt{x^3+\sqrt{x^3+\ldots\infty}}}$

$\Rightarrow \quad Z=\sqrt{x^3+Z}$

$\Rightarrow \quad Z^2-Z-x^3=0$

$\Rightarrow \quad Z=\dfrac{1+\sqrt{(1+4x^3)}}{2}$ [as $Z>0$] ...(ii)

$$\therefore \lim_{x\to 0^+}\frac{-1+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)+\ldots\infty}}}{-1+\sqrt{x^3+\sqrt{x^3+\sqrt{x^3+\ldots\infty}}}}$$

$$=\lim_{x\to 0^+}\frac{-1+\left(\dfrac{1+\sqrt{1+4(\tan x-\sin x)}}{2}\right)}{-1+\left(\dfrac{1+\sqrt{1+4x^3}}{2}\right)}$$ [from Eqs. (i) and (ii)]

$$=\lim_{x\to 0^+}\frac{-1+\sqrt{1+4(\tan x-\sin x)}}{-1+\sqrt{1+4x^3}}$$

Rationalising numerator and denominator, we get

$$\lim_{x\to 0^+}\frac{4(\tan x-\sin x)(1+\sqrt{1+4x^3})}{4x^3(1+\sqrt{1+4(\tan x-\sin x)})}$$

$$=\lim_{x\to 0^+}\frac{\left(\dfrac{\sin x}{\cos x}-\dfrac{\sin x}{1}\right)(1+\sqrt{1+4x^3})}{x^3(1+\sqrt{1+4(\tan x-\sin x)})}$$

$$=\lim_{x\to 0^+}\frac{\sin x(1-\cos x)}{x^3\cos x}\cdot\frac{(1+\sqrt{1+4x^3})}{(1+\sqrt{1+4(\tan x-\sin x)})}$$

$$=\lim_{x\to 0^+}\frac{\sin x}{x}\cdot\frac{2\sin^2\dfrac{x}{2}}{\dfrac{4x^2}{4}}\cdot\frac{1}{\cos x}\cdot\frac{(1+\sqrt{1+4x^3})}{(1+\sqrt{1+4(\tan x-\sin x)})}$$

$$=1\cdot\frac{1}{2}\cdot 1\cdot\frac{(1+1)}{(1+1)}=\frac{1}{2}$$

$$\therefore \lim_{x\to 0^+}\frac{-1+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)+\sqrt{(\tan x-\sin x)}}+\ldots\infty}}{-1+\sqrt{x^3+\sqrt{x^3+\sqrt{x^3+\ldots\infty}}}}=\frac{1}{2}$$

39. Here, $\lim\limits_{\theta\to 0}\dfrac{\cos^2(1-\cos^2(1-\cos^2(1\ldots\cos^2\theta))\ldots)}{\sin\left(\dfrac{\pi(\sqrt{\theta+4}-2)}{\theta}\right)}$

$$=\lim_{\theta\to 0}\frac{\cos^2(\sin^2(\sin^2\ldots(\sin^2\theta))\ldots)}{\sin\left(\dfrac{\pi(\sqrt{\theta+4}-2)}{\theta}\right)}$$

$$=\lim_{\theta\to 0}\frac{\cos^2(\sin^2(\sin^2\ldots(\sin^2\theta))\ldots)}{\sin\left(\pi\lim\limits_{\theta\to 0}\dfrac{\theta}{\theta(\sqrt{\theta+4}+2)}\right)}=\frac{\cos^2(0)}{\sin\left(\dfrac{\pi}{4}\right)}=\sqrt{2}$$

40. Here, $\lim\limits_{n\to\infty}a_n=\lim\limits_{n\to\infty}a_{n+1}$.

So, let $l=\lim\limits_{n\to\infty}a_n=\lim\limits_{n\to\infty}a_{n+1}$

$\therefore \quad l=\lim\limits_{n\to\infty}a_{n+1}=\lim\limits_{n\to\infty}\sqrt{2+a_n}$

or $l=\sqrt{2+l}$ $\left[\because \lim\limits_{n\to\infty}a_n=l\right]$

$\Rightarrow \quad l^2=2+l \quad\Rightarrow\quad l^2-l-2=0$

$\Rightarrow \quad (l-2)(l+1)=0 \quad\Rightarrow\quad l=2,-1$

$\therefore \quad \lim\limits_{n\to\infty}a_n=2 \text{ or } -1$

$\Rightarrow \quad \lim\limits_{n\to\infty}a_n=2 \quad\left[\text{neglecting } \lim\limits_{n\to\infty}a_n=-1, \text{ as } a_n>0\right]$

41. $\lim\limits_{x\to\infty}4x\dfrac{\tan^{-1}\left(\dfrac{1}{2x+3}\right)}{\left(\dfrac{1}{2x+3}\right)}\times\dfrac{1}{2x+3}=2$

$\Rightarrow \quad y^2+4y+5=2$

$\Rightarrow \quad y=-1,-3.$

42. $\lim\limits_{x\to 0}\dfrac{2\sin^2\left(\dfrac{x^2}{2}\right)}{2}\cdot\dfrac{\left(\dfrac{x^2}{2}\right)^2}{(4^x-1)}\cdot\dfrac{x}{x^4}=\dfrac{1}{2}\ln 4=\ln 2=1-\dfrac{1}{2}\ln\left(\dfrac{e^2}{4}\right)$

43. $f(x)=e^{[\cot x]}$, as $\cot x$ is negative in the II quadrant and

$\cot\dfrac{\pi}{2}=0\,[\cot x]=-1 \quad\Rightarrow\quad \lim\limits_{x\to\frac{\pi^+}{2}}f(x)=e^{-1}=\dfrac{1}{e}$

As $x\to\dfrac{\pi^-}{2}$, $\cot x$ is positive (being in I quadrant) and hence

$[\cot x]=0 \quad\Rightarrow\quad \lim\limits_{x\to\frac{\pi^-}{2}}f(x)=e^0=1$

44. If $m<0$, then for values of x sufficiently close to 0.

$$1+\frac{1}{m}<\frac{\sin x}{x}<1 \quad\Rightarrow\quad m+1>m\frac{\sin x}{x}>m$$

$$\therefore \quad \left[m\frac{\sin x}{x}\right]=m \quad\Rightarrow\quad \lim_{x\to 0}\left[m\frac{\sin x}{x}\right]=m$$

If $m>0$, then for values of x sufficiently close to 0, we can have

$$1-\frac{1}{m}<\frac{\sin x}{x}<1$$

$$\therefore \quad m-1<m\frac{\sin x}{x}<m$$

$$\therefore \quad \lim_{x\to 0}\left[m\frac{\sin x}{x}\right]=m-1$$

45. $\lim_{x\to 0}(1+ax+bx^2)^{\frac{2}{x}}=e^3 \Rightarrow e^{\lim_{x\to\infty}\frac{2}{x}(ax+bx^2)}=e^3$

$\Rightarrow \quad e^{2a}=e^3$

Since, limit value does not involve b.

$\therefore$ b can have any value. Thus, $a=\frac{3}{2}$, $b\in R$

46. (a) $\lim_{x\to 0^+} f(x)=1$

(b) $\lim_{x\to 1} f(x)=2$, as RHL = LHL = 2 (at $x=1$)

(c) $\lim_{x\to 3^-} f(x)\to\infty$ and $\lim_{x\to 3^+} f(x)\to-\infty$

$\therefore$ $\lim_{x\to 3} f(x)$ does not exists.

(d) $\lim_{x\to 4} f(x)=0$

47. RHL $=\lim_{x\to 0^+}\frac{\cot^{-1}(1/x)}{x}=\lim_{x\to 0^+}\frac{\tan^{-1}}{x}=1$

LHL $=\lim_{x\to 0}\frac{\cot^{-1}(1/x)}{x}=\lim_{x\to 0}\frac{\pi+\tan^{-1}x}{x}=\infty$

$\therefore$ RHL exists and LHL does not exists.

48. As, $l=\lim_{x\to\infty}\left(\frac{x+1}{x-1}\right)^x=\lim_{x\to\infty}\left(1+\frac{2}{x-1}\right)^x=e^{\lim_{x\to\infty}\frac{2x}{x-1}}=e^2$

$\therefore$ $[l]=7$ and $\{l\}=e^2-7$.

49. (a) $\lim_{x\to 0^-} f(x)=\lim_{x\to 0^-}\frac{\sin[x]}{[x]}=\lim_{h\to 0}\frac{\sin(-1)}{(-1)}=\sin 1$

(b) $\lim_{x\to 0^+} f(x)=\lim_{h\to 0}[0+h]=0$

$\therefore$ Limit does not exist at $x=0$.

50. (a) $\lim_{x\to 3}[[x]]-[2x-1]$

RHL $=\lim_{h\to 0}[[3+h]]-[6+2h-1]=\lim_{h\to 0}3-5=-2$

LHL $=\lim_{h\to 0}[[3-h]]-[6-2h-1]=\lim_{h\to 0}2-4=-2$

$\therefore$ Limit exists.

(b) $\lim_{x\to 1}[x]-x$

RHL $=\lim_{h\to 0}[1+h]-(1+h)=\lim_{h\to 0}(1-1-h)=0$

LHL $=\lim_{h\to 0}[1-h]-(1+h)=\lim_{h\to 0}0-1+h=-1$

$\therefore$ Limit does not exist.

(c) $\lim_{x\to 0}\{x\}^2-\{-x\}^2$

RHL $=\lim_{h\to 0}\{h\}^2-\{-h\}^2=\lim_{h\to 0}h^2-(1-h)^2=-1$

LHL $=\lim_{h\to 0}\{-h\}^2-\{h\}^2=\lim_{h\to 0}(1-h)^2-h^2=1$

$\therefore$ Limit does not exist.

(d) $\lim_{x\to 0}\frac{\tan(\operatorname{sgn}x)}{\operatorname{sgn}x}$; RHL $=\lim_{h\to 0}\frac{\tan(1)}{1}=\tan 1$

LHL $=\lim_{h\to 0}\frac{\tan(-1)}{-1}=\tan 1$

$\therefore$ Limit exists.

51. (a) $\lim_{n\to\infty}\left[\frac{1}{2}+\frac{1}{2^2}+\ldots+\frac{1}{2^n}\right]$

$=\lim_{n\to\infty}\left[\frac{\frac{1}{2}\left(1-\frac{1}{2^n}\right)}{1-\frac{1}{2}}\right]=\lim_{n\to\infty}\left[1-\frac{1}{2^n}\right]=0$

(b) $\lim_{n\to\infty}(x-1)\{x\}$

RHL $=\lim_{h\to 0}(1+h-1)\{1+h\}=\lim_{h\to 0}h(h)=0$

LHL $=\lim_{h\to 0}(1-h-1)\{1-h\}=\lim_{h\to 0}-h(1-h)=0$

$\therefore$ $\lim_{x\to 1}(x-1)\{x\}=0$

(c) As, $\frac{\tan x}{x}>1$

$\therefore$ $\left[\frac{\tan x}{x}\right]\to 1$, as $x\to 0^+ \Rightarrow \lim_{x\to 0^+}\left[\frac{\tan x}{x}\right]=1$

(d) $\left[\lim_{x\to 0^+}\frac{\tan x}{x}\right]=[1+h]=1$

52. Put $x=\frac{\pi}{2}-h$

$l=\lim_{h\to 0}\frac{a^{\tan h}-a^{\sin h}}{\tan h-\sin h}=\lim_{h\to\infty}\frac{a^{\sin h}(a^{\tan h-\sin h}-1)}{\tan h-\sin h}=\log_e a$

and $m=\lim_{x\to-\infty}(\sqrt{x^2+ax}-\sqrt{x^2-ax})$

$=\lim_{x\to-\infty}\frac{(x^2+ax)-(x^2-ax)}{\sqrt{x^2+ax}+\sqrt{x^2-ax}}$

$=\lim_{x\to-\infty}\frac{2ax}{|x|\left(\sqrt{1+\frac{a}{x}}+\sqrt{1-\frac{a}{x}}\right)}=-a$

53. $f(x)=\lim_{x\to\infty}\left[1+\frac{ax+1}{bx+2}-1\right]^x$

$=\lim_{x\to\infty}\left[1+\frac{(a-b)x-1}{bx+2}\right]^x=e^{\lim_{x\to\infty}\left[\frac{(a-b)x-1}{bx+2}\right]^x}$

When $a=b$, $f(x)=e^{\lim_{x\to\infty}-\frac{x}{bx+2}}=e^{-\frac{1}{b}}$ or $e^{-\frac{1}{a}}$.

When $a>b$, $f(x)=e^{\infty}=\infty$, does not exist.

When $a<b$, $f(x)=e^{-\infty}=0$.

54. $\lim_{x\to 0}f(x)=\lim_{x\to 0}\frac{x\cdot(2^x-1)}{2\sin^2 x/2}=\lim_{x\to 0}\frac{2\cdot x^2\frac{1}{4}}{\sin^2\frac{x}{2}}\cdot\frac{2^x-1}{x}=2\cdot\log_e 2=\log_e 4$

and $\lim_{x\to\infty}2^x\cdot\sin(\log 2/2^x)=\lim_{x\to\infty}\frac{\sin(\log 2/2^x)}{(\log 2/2^x)}\cdot\log_e 2=\log_e 2$

55. As, $\lim_{x\to 3}\frac{x^3+cx^2+5x+12}{x^2-7x+12}=l$. [finite]

$\therefore$ $27+9c+15+12=0$

$\Rightarrow \quad 9c+54=0\Rightarrow c=-6$

$\therefore$ $\lim_{x\to 3}\frac{x^3+cx^2+5x+12}{x^2-7x+12}=\lim_{x\to 3}\frac{3x^2+2cx+5}{2x-7}$

$$= \frac{27+6c+5}{9-7} = \frac{27-36+5}{-1}$$

$\therefore \quad c = -6$ and $l = 4$

56. $\lim\limits_{x\to 0} \dfrac{\sin x}{x - \sin x} = \lim\limits_{x\to 0} \dfrac{\frac{\sin x}{x}}{1 - \frac{\sin x}{x}} = \infty$

Hence, $L = e^{\lim\limits_{x\to 0}\left(\frac{\sin x}{x} - 1\right)\frac{\sin x}{x - \sin x}} = e^{\lim\limits_{x\to 0}\frac{-\sin x}{x}} = e^{-1} = \dfrac{1}{e}$

57. $\lim\limits_{x\to 0} \dfrac{x - 1 + \cos x}{x} = \lim\limits_{x\to 0} 1 - \dfrac{2\sin^2\frac{x}{2}}{x} = 1$

Hence, $L = e^{\lim\limits_{x\to 0}\left(\frac{x-1+\cos x}{x} - 1\right)\times\frac{1}{x}}$

$$= e^{\lim\limits_{x\to 0}\left(\frac{-2\sin^2\frac{x}{2}}{x^2}\right)} = e^{-\frac{2}{4}} = e^{-1/2}$$

58. $L = e^{\lim\limits_{x\to 0}\left(\frac{a^x + b^x + c^x}{3} - 1\right)\frac{2}{x}} = e^{\lim\limits_{x\to 0}\left(\frac{a^x - 1}{x} + \frac{b^x - 1}{x} + \frac{c^x - 1}{x}\right)\frac{2}{3}}$

$= e^{\frac{2}{3}(\log a + \log b + \log c)} = e^{\frac{2}{3}\log abc} = (abc)^{2/3}$

Sol. (Q. Nos. 59 to 61)

$$f(x) = \lim_{n\to\infty}\left(\cos\sqrt{\frac{x}{n}}\right)^n = \lim_{n\to\infty}\left(1 + \left(\cos\sqrt{\frac{x}{n}} - 1\right)\right)^n$$

$$= e^{\lim\limits_{n\to\infty}\left(\cos\sqrt{\frac{x}{n}} - 1\right)n} = e^{-\lim\limits_{n\to\infty} 2\frac{\sin^2\left(\frac{1}{2}\sqrt{\frac{x}{n}}\right)n}{\left(\frac{1}{2}\sqrt{\frac{x}{n}}\right)^2}\times\left(\frac{1}{2}\sqrt{\frac{x}{n}}\right)^2}$$

$$= e^{-2\lim\limits_{n\to\infty}\frac{\left(\frac{1}{2}\sqrt{\frac{x}{n}}\right)^2}{\frac{1}{n}}} = e^{-2\lim\limits_{n\to\infty}\frac{1}{4}\frac{x/n}{1/n}} = e^{-\frac{x}{2}}$$

$y = f(x) = e^{-x/2}$, $x \ge 0$, range $= (0, 1]$

$\Rightarrow \quad g(x) = \lim\limits_{n\to\infty}(1 - x + x\sqrt[n]{e})^n$

$$= e^{\lim\limits_{n\to\infty} x\frac{(e^{1/n} - 1)}{1/n}} = e^x, \forall\ x \in R$$

$\Rightarrow \quad h(x) = \tan^{-1}(g^{-1}(f^{-1}(x)))$

Let $\quad y^2 = f(x) \Rightarrow y = e^{-x/2}$

$$-\frac{x}{2} = \ln y \Rightarrow x = 2\ln\frac{1}{y}$$

$\Rightarrow f^{-1}(x) = 2\ln\dfrac{1}{x}$, for $0 < x \le 1$

$y = g(x) = e^x \Rightarrow x = \ln y$, $g^{-1}(x) = \ln x$

$\therefore\ g^{-1}\left(2\ln\dfrac{1}{x}\right) = \ln\left(2\ln\left(\dfrac{1}{x}\right)\right)$, for $0 < x < 1$

$\therefore \quad h(x) = \tan^{-1}\left(\ln\left(\ln\dfrac{1}{x^2}\right)\right)$, for $0 < x < 1$

59. $\lim\limits_{x\to 0^+} \dfrac{\ln(f(x))}{\ln(g(x))} = \lim\limits_{x\to 0} \dfrac{-x/2}{x} = -\dfrac{1}{2}$

60. Domain of $h(x)$ is $(0, 1)$.

61. $h(x) = \tan^{-1}(\ln(\ln 1/x^2))$, for $0 < x < 1$

$$1 < \frac{1}{x^2} < \infty \quad \Rightarrow \quad 0 < \ln\frac{1}{x^2} < \infty$$

$\Rightarrow \quad -\infty < \ln(\ln(1/x^2)) < \infty$

$\therefore$ Range of $h(x)$ is $(-\pi/2, \pi/2)$.

Sol. (Q. Nos. 62 to 63)

Here, $K_1 = (n+1)(n+2)(n+3)\ldots(2n)$

$K_2 = n\times n\times n\times \ldots \times n$ times $= n^n$ and $K_3 = (n)!$

62. $L = \lim\limits_{n\to\infty}\left(\dfrac{K_1}{K_2}\right)^{1/n} = \lim\limits_{n\to\infty}\left(\dfrac{(n+1)(n+2)\ldots(2n)}{n\times n\times\ldots\times n \text{ times}}\right)^{1/n}$

Taking log on both sides, we get

$$\log L = \lim_{n\to\infty}\frac{1}{n}\cdot\sum_{r=1}^{n}\log\left(1 + \frac{r}{n}\right) = \int_0^1 \log(1+x)\,dx = \log(4/e)$$

$\therefore \quad L = 4/e$

63. Also, $M = \lim\limits_{n\to\infty}\dfrac{K_1}{K_2 + K_3} = \lim\limits_{n\to\infty}\dfrac{(n+1)(n+2)\ldots(n+n)}{n^n + n!}$

$$= \lim_{n\to\infty}\frac{n^n((1+1/n)(1+2/n)\ldots(1+n/n))}{n^n\left[1 + \frac{1\cdot 2\cdot 3\ldots n}{n\cdot n\ldots n}\right]} = 1$$

Sol. (Q. Nos. 64 to 65)

Here, $f(1) = 0\cdot 8$ and $g(1) = 0\cdot 6 \Rightarrow (f(1))^2 + (g(1))^2 = 1$

$\therefore$ Let $f(1) = \cos\alpha$ and $g(1) = \sin\alpha$, then

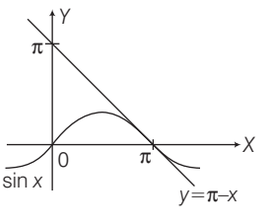
$$f(2) = f(1)\cos(g(1)) - g(1)\sin(g(1))$$

$$= \cos\alpha\cdot\cos(g(1)) - \sin\alpha\cdot\sin(g(1)) = \cos(\alpha + g(1))$$

Similarly, $f(n+1) = \cos(\alpha + g(1) + g(2) + \ldots + g(n))$ ...(i)

Here, for all $x \in (0, \pi)$

$$\sin x < \pi - x \Rightarrow x + \sin x < \pi$$



$\Rightarrow \quad \alpha + g(1) + g(2) + \ldots + g(n) < \pi$

$\therefore$ As $n \to \infty$, $\alpha + g(1) + g(2) + \ldots + g(n) \to \pi$ ...(ii)

64. $\lim\limits_{n\to\infty} f(n) = \lim\limits_{n\to\infty}\cos(\alpha + g(1) + g(2) + \ldots + g(n))$

$$= \cos\pi = -1$$

65. Similarly, $\quad g(n) = \sin(\alpha + g(1) + g(2) + \ldots + g(n-1))$

Again, $\quad g(2) = \sin(\alpha + g(1))$

As, $\quad \lim\limits_{n\to\infty} g(n) = \lim\limits_{n\to\infty}\sin(\alpha + g(1) + g(2) + \ldots + g(n-1))$

$$= \sin(\pi) = 0 \qquad \text{[using Eq. (ii)]}$$

Sol. (Q. Nos. 66 to 68)

Here, $\quad T(x) = \dfrac{1}{2}\left(\sin\left(\dfrac{x}{2}\right)\cdot\tan\left(\dfrac{x}{2}\right)\cdot\cos\left(\dfrac{\pi}{2} - \dfrac{x}{2}\right)\right)\times 2$

$$= \sin^2\left(\frac{x}{2}\right)\cdot\tan\left(\frac{x}{2}\right)$$

$$\therefore \quad S(x)=\frac{1}{2}(1)^2\cdot(x-\sin x)$$

66. $\lim\limits_{x\to 0}\dfrac{T(x)}{x^3}=\lim\limits_{x\to 0}\dfrac{\sin^2\frac{x}{2}\cdot\tan\frac{x}{2}}{x^3}=\dfrac{1}{8}$

67. $\lim\limits_{x\to 0}\dfrac{S(x)}{x}=\lim\limits_{x\to 0}\dfrac{1}{2}\dfrac{(x-\sin x)}{x}=0$

68. $\lim\limits_{x\to 0}\dfrac{T(x)}{S(x)}=\lim\limits_{x\to 0}\dfrac{\sin^2(x/2)\cdot\tan(x/2)}{\frac{1}{2}(x-\sin x)}=\lim\limits_{x\to 0}\dfrac{1}{4}\cdot\dfrac{x^3}{(x-\sin x)}=\dfrac{3}{2}$

69. (A) $\lim\limits_{x\to\frac{\pi^+}{2}}\tan^{-1}(\tan x)=-\dfrac{\pi}{2}$, as $\lim\limits_{x\to\frac{\pi^+}{2}}(\tan x)=-\infty$

(B) $\sum\limits_{r=1}^{n}\dfrac{1}{2^r}=\left(1-\dfrac{1}{2^n}\right)<1$, for all $n\in N$. Thus, $\lim\limits_{n\to 0}\left[\sum\limits_{r=1}^{n}\dfrac{1}{2^r}\right]=0$

(C) As $x\to\infty$, $\dfrac{x}{x+1}\to 1^-$

and hence $\lim\limits_{x\to\infty}\sec^{-1}\left(\dfrac{x}{x+1}\right)$ doesn't exist.

(D) Put $\dfrac{\pi}{2}-x=\theta$, then the given limit is

$$\lim_{\theta\to 0}\frac{\sin\theta}{(1-\cos\theta)^{2/3}}=\lim_{\theta\to 0}\frac{\sin\theta}{2^{2/3}\cdot\sin^{4/3}\frac{\theta}{2}}$$

$$=\lim_{\theta\to 0}\frac{2\sin\frac{\theta}{2}\cos\frac{\theta}{2}}{2^{2/3}\cdot\sin^{4/3}\frac{\theta}{2}}=2^{1/2}\lim_{\theta\to 0}\frac{\cos\frac{\theta}{2}}{\sin^{1/3}\frac{\theta}{2}},$$

which doesn't exist as for $\lim\limits_{\theta\to 0^+}$ limit is ∞ and for $\lim\limits_{\theta\to 0^+}$ limit is $-\infty$.

70. Here, $y=\sec\theta$ and $x=\tan\theta$

(A) $\lim\limits_{\theta\to\frac{\pi}{2}}(\sqrt{y}-\sqrt{x})=\lim\limits_{\theta\to\frac{\pi}{2}}(\sqrt{\sec\theta}-\sqrt{\tan\theta})$

$$=\lim_{\theta\to\frac{\pi}{2}}\frac{1-\sqrt{\sin\theta}}{\sqrt{\cos\theta}}$$

$$=\lim_{\theta\to\frac{\pi}{2}}\left(\frac{\cos\theta}{\sin\theta}\right)^{3/2}=0 \qquad \text{[using L'Hospital's rule]}$$

(B) $\lim\limits_{\theta\to\frac{\pi}{2}}(y-x)=\lim\limits_{\theta\to\frac{\pi}{2}}(\sec\theta-\tan\theta)=\lim\limits_{\theta\to\frac{\pi}{2}}\dfrac{1-\sin\theta}{\cos\theta}$

$$=\lim_{\theta\to\frac{\pi}{2}}\frac{\cos\theta}{\sin\theta}=0 \qquad \text{[using L'Hospital's rule]}$$

(C) $\lim\limits_{\theta\to\frac{\pi}{2}}(y^2-x^2)=\lim\limits_{\theta\to\frac{\pi}{2}}(\sec^2\theta-\tan^2\theta)=1$

(D) $\lim\limits_{\theta\to\frac{\pi}{2}}(y^3-x^3)=\lim\limits_{\theta\to\frac{\pi}{2}}(\sec^3\theta-\tan^3\theta)$

$$=\lim_{\theta\to\frac{\pi}{2}}\frac{1-\sin^3\theta}{\cos^3\theta}$$

$$=\lim_{\theta\to\frac{\pi}{2}}\frac{-3\sin^2\theta\cos\theta}{-3\cos^2\theta\sin\theta}=\frac{\sin\theta}{\cos\theta} \qquad \text{[using L' Hospital's rule]}$$

$$=\lim_{\theta\to\frac{\pi}{2}}\tan\theta=\infty$$

71. (A) $l=\lim\limits_{x\to 0}\dfrac{e^{x^2}-1+x-e^x+1}{2\frac{\sin^2 x}{x^2}\cdot x^2}$

$$=\frac{1}{2}\left[\lim_{x\to 0}\frac{e^{x^2}-1}{x^2}+\lim_{x\to 0}\frac{x-e^x+1}{x^2}\right]$$

$$=\frac{1}{2}\left[1-\lim_{x\to 0}\frac{e^x-x-1}{x^2}\right]$$

$$=\frac{1}{2}\left[1-\frac{1}{2}\right]=\frac{1}{4}\Rightarrow\frac{1}{l}=4$$

(B) $l=\lim\limits_{x\to 0}\left(\dfrac{3+x}{3-x}\right)^{1/x}=e^{\lim\limits_{x\to 0}\frac{1}{x}\left(\frac{3+x}{3-x}-1\right)}$

$$=e^{\lim\limits_{x\to 0}\frac{2x}{x(3-x)}}=e^{2/3}\Rightarrow 2+3=5$$

(C) $\lim\limits_{x\to 0}\dfrac{(\tan^3 x-x^3)-(\tan x^3-x^3)}{x^5}$

$$=\lim_{x\to 0}\frac{\tan^3 x-x^3}{x^5}-\underbrace{\lim_{x\to 0}\frac{\tan x^3-x^3}{x^5}}_{\text{zero (by expansion)}}$$

$$=\lim_{x\to 0}\frac{(\tan x-x)}{x^3}\cdot\frac{(\tan^2 x+x\tan x+x^2)}{x^2}=\frac{1}{3}\times 3=1$$

(D) Rationalising gives

$$\lim_{x\to 0}\frac{(x+2\sin x)\left[\sqrt{(x^2+2\sin x+1)}+\sqrt{\sin^2 x-x+1}\right]}{(x^2+2\sin x+1)-(\sin^2 x-x+1)}$$

$$=2\cdot\lim_{x\to 0}\frac{x+\sin 2x}{x^2-\sin^2 x+2\sin x+x}$$

$$=2\cdot\lim_{x\to 0}\frac{1+\frac{\sin 2x}{x}}{x-\frac{\sin^2 x}{x}+2+1}=2\left(\frac{1+2}{3}\right)=2$$

72. (A) $l=\lim\limits_{n\to\infty}\cos^2(\pi(\sqrt[3]{n^3+n^2+2n}-n))$

Consider $\lim\limits_{n\to\infty}[(n^3+n^2+2n)^{1/3}-n]$

$$=\lim_{n\to\infty}\left[n\left(1+\left(\frac{1}{n}+\frac{2}{n^2}\right)\right)^{1/3}-n\right]$$

$$=\lim_{n\to\infty}n\left[\left\{1+\left(\frac{1}{n}+\frac{2}{n^2}\right)\right\}^{1/3}-1\right]$$

$$= \lim_{n\to\infty} n\left[1+\frac{1}{3}\left(\frac{1}{n}+\frac{2}{n^2}\right)+\ldots-1\right]$$

$$= \frac{1}{3} + \text{terms containing } \frac{1}{n}, \frac{1}{n^2}, \frac{1}{n^3}, \ldots = \frac{1}{3}$$

$$\therefore \quad l = \cos^2\left(\frac{\pi}{3}\right) = \frac{1}{4}$$

(B) $l = \lim_{n\to\infty} n\sin\left(2\pi\sqrt{1+n^2} - 2n\pi\right)$

$$= \lim_{n\to\infty} n\sin\left[\frac{2\pi\left(\sqrt{1+n^2}-n\right)}{\left(\sqrt{1+n^2}+n\right)}\left(\sqrt{1+n^2}+n\right)\right]$$

$$= \lim_{n\to\infty}\left[\frac{n\sin\left(\frac{2\pi}{\sqrt{1+n^2}+n}\right)}{\left(\frac{2\pi}{\sqrt{1+n^2}+n}\right)}\left(\frac{2\pi}{\sqrt{1+n^2}+n}\right)\right]$$

$$= \lim_{n\to\infty} \frac{2n\pi}{n\left(\sqrt{1+\frac{1}{n^2}}+1\right)} = \frac{2\pi}{2} = \pi$$

(C) $l = \lim_{n\to\infty} (-1)^n (-1)^{n-1} \sin\left(n\pi - \pi\sqrt{n^2+\frac{n}{2}+1}\right)$

$$= \lim_{n\to\infty} (-1)^{2n-1}\sin\pi \left[\frac{\left(n-\sqrt{n^2+\frac{n}{2}+1}\right)\left(n+\sqrt{n^2+\frac{n}{2}+1}\right)}{n+\sqrt{n^2+\frac{n}{2}+1}}\right]$$

$$= \lim_{n\to\infty} (-1)^{2n-1}\sin\pi\left(\frac{n^2-n^2-\frac{n}{2}-1}{n\left(1+\sqrt{1+\frac{1}{2n}+\frac{1}{n^2}}\right)}\right)$$

$$= \lim_{n\to\infty} (-1)^{2n}\sin\pi\left(\frac{\frac{1}{2}+\frac{1}{n}}{1+\sqrt{1+\frac{1}{2n}+\frac{1}{n^2}}}\right)$$

$$= (1)\ \sin\frac{\pi}{4} = \frac{1}{\sqrt{2}}$$

Also, as $n\to\infty, \sin\dfrac{(n+1)\pi}{4n} \to \dfrac{1}{\sqrt{2}}$

$\therefore$ Final answer is $\dfrac{1}{2}$.

(D) $l = e^{\lim\limits_{x\to\infty} x\left(\frac{x+a}{x-a}-1\right)} = e^{\lim\limits_{x\to\infty} x\left(\frac{2a}{x-a}\right)}$

$$= e^{\lim\limits_{x\to\infty} x\left(\frac{2a}{1-(a/x)}\right)} = e^{2a}$$

$$\therefore \quad e^{2a} = e \Rightarrow a = 1/2$$

73. Here, $L = \lim_{x\to\infty} x\log x + 2x\cdot\log\sin\left(\frac{1}{\sqrt{x}}\right)$,

$$= \lim_{\theta\to 0} \frac{1}{\theta^2}\cdot\log\left(\frac{1}{\theta^2}\right) + \frac{2}{\theta^2}\cdot\log(\sin\theta) \qquad [\text{put } x = \frac{1}{\theta^2}]$$

$$= \lim_{\theta\to 0} \frac{2\log(\sin\theta) - 2\log\theta}{\theta^2}$$

$$= \lim_{\theta\to 0} \frac{2\left[\cot\theta - \frac{1}{\theta}\right]}{2\theta} \qquad [\text{using L' Hospital's rule}]$$

$$= \lim_{\theta\to 0} \frac{2\left[\theta\cot\theta - 1\right]}{2\theta^2} = \frac{\theta-\tan\theta}{\theta^2\tan\theta}$$

$$= \lim_{\theta\to 0} \frac{\theta-\tan\theta}{\theta^3}\cdot\frac{\theta}{\tan\theta} = \lim_{\theta\to 0}\frac{\theta-\tan\theta}{\theta^3}$$

$$L = \lim_{\theta\to 0}\frac{\theta-(\theta+\theta^3/3+\cdots)}{\theta^3} = -1/3$$

$$\therefore \quad \frac{-2}{L} = 6$$

74. We have, $\left(1+\frac{1}{n}\right)^{n+x_n} = e$ ...(i)

On taking log both sides of Eq. (i), we get

$$(n+x_n)\log_e\left(1+\frac{1}{n}\right) = 1$$

$$\Rightarrow n + x_n = \frac{1}{\log\left(1+\frac{1}{n}\right)} \Rightarrow x_n = \frac{1}{\log\left(1+\frac{1}{n}\right)} - n$$

Let $\dfrac{n+1}{n} = \mu \Rightarrow n\mu = n+1$

$$\Rightarrow \qquad n = \frac{1}{\mu-1}$$

$$\therefore \quad \lim_{n\to\infty} x_n = \lim_{\mu\to 1}\left(\frac{1}{\log\mu} - \frac{1}{\mu-1}\right)$$

$$= \lim_{\mu\to 1}\frac{(\mu-1)-\log\mu}{(\mu-1)\log\mu} \qquad \left[\frac{0}{0}\text{form}\right]$$

$$= \lim_{\mu\to 1}\frac{1-\frac{1}{\mu}}{(\mu-1)\cdot\frac{1}{\mu}+\log\mu} \qquad [\text{using L' Hospital's rule}]$$

$$= \lim_{\mu\to 1}\frac{1/\mu^2}{1/\mu^2+1/\mu} = \frac{1}{2}$$

$\therefore 2\lim\limits_{n\to\infty} x_n = 1$

75. Let $\left[\sqrt{n}+\frac{1}{2}\right] = K \Rightarrow K \le \sqrt{n}+\frac{1}{2} < (K+1)$

$$\Rightarrow (K-1/2)^2 \le n < (K+1/2)^2$$

$$\Rightarrow K^2 - K + 1/4 \le n < K^2 + K + 1/4,\ K\in N, n\in N$$

$$\Rightarrow K^2 - K + 1 \le n \le K^2 + K$$

So, $S = \sum_{n=1}^{\infty}\frac{2^{f(n)}+2^{-f(n)}}{2^n} = \sum_{n=1}^{\infty}\frac{2^K+2^{-K}}{2^n}$

$$= \left(\frac{2+2^{-1}}{2} + \frac{2^1+2^{-1}}{2^2}\right) + \left(\frac{2^2+2^{-2}}{2^3} + \frac{2^2+2^{-2}}{2^4} + \frac{2^2+2^{-2}}{2^5} + \frac{2^2+2^{-2}}{2^6}\right)$$

$$\text{As,}\begin{cases} K=1 & \Rightarrow \quad 1\le n\le 2 \\ K=2 & \Rightarrow \quad 3\le n\le 6 \\ K=3 & \Rightarrow \quad 7\le n\le 12 \\ \quad\vdots & \quad\vdots \end{cases}$$

$$\therefore\ S=\sum_{K=1}^{\infty}\sum_{n=K^2-K+1}^{K^2+K}\frac{2^K+2^{-K}}{2^n}=\sum_{K=1}^{\infty}(2^K+2^{-K})\cdot\sum_{n=K^2-K+1}^{K^2+K}\frac{1}{2^n}$$

$$=\sum_{K=1}^{\infty}(2^K+2^{-K})\cdot\left[\frac{1}{2^{K^2-K+1}}+\frac{1}{2^{K^2-K+2}}+\cdots+\frac{1}{2^{K^2+K}}\right]$$

$$=\sum_{K=1}^{\infty}(2^K+2^{-K})\frac{\frac{1}{2^{K^2-K+1}}\left\{1-\frac{1}{2^{2K}}\right\}}{1-1/2}$$

$$=\sum_{K=1}^{\infty}(2^K+2^{-K})\cdot(2^{-K^2+K}-2^{-K^2-K})$$

$$=\sum_{K=1}^{\infty}(2^{-K^2+2K}-2^{-K^2}+2^{-K^2}-2^{-K^2-2K})$$

$$=\sum_{K=1}^{\infty}(2^{-K^2+2K}-2^{-K^2-2K})=\sum_{K=1}^{\infty}(2^{-K(K-2)}-2^{-K(K+2)})$$

$$=(2^1-2^{-3})+(2^0-2^{-8})+(2^{-3}-2^{-15})+(2^{-8}-2^{-24})+\ldots\infty$$

$$=2+1=3$$

76. Arithmetic mean $=\dfrac{1\cdot(n-1)+2\cdot(n-2)+\ldots+(n-1)\cdot 1}{(n-1)}$

$$S_n=\frac{\sum_{r=1}^{n-1}r(n-r)}{(n-1)}=\frac{n\cdot\sum_{r=1}^{n-1}r-\sum_{r=1}^{n-1}r^2}{(n-1)}$$

$$=\frac{n\cdot\frac{n(n-1)}{2!}-\frac{n(n-1)(2n-1)}{6}}{(n-1)}\ \Rightarrow\ S_n=\frac{n^2}{2}-\frac{n(2n-1)}{6}$$

$$\therefore\quad\lim_{n\to\infty}\frac{n^2}{S_n}=\frac{n^2}{\frac{n^2}{2}-\frac{n(2n-1)}{6}}=\frac{1}{1/2-2/6}=6$$

77. Here, $k=\sum_{n=1}^{\infty}\dfrac{6^n}{(3^n-2^n)(3^{n+1}-2^{n+1})}$

$$=\sum_{n=1}^{\infty}\frac{1}{\left[1-\left(\frac{2}{3}\right)^n\right]\left[3\cdot\left(\frac{3}{2}\right)^n-2\right]}$$

$$=\sum_{n=1}^{\infty}\frac{1}{\left[1-\left(\frac{2}{3}\right)^n\right]\cdot\left(\frac{3}{2}\right)^n\cdot\left[3-2\cdot\left(\frac{2}{3}\right)^n\right]}$$

$$=\sum_{n=1}^{\infty}\frac{(2/3)^n\cdot(3-2)}{\left[1-\left(\frac{2}{3}\right)^n\right]\left[3-2\cdot\left(\frac{2}{3}\right)^n\right]}$$

$$=\sum_{n=1}^{\infty}\frac{\left[3-2\left(\frac{2}{3}\right)^n\right]-3\left[1-\left(\frac{2}{3}\right)^n\right]}{\left[1-\left(\frac{2}{3}\right)^n\right]\left[3-2\cdot\left(\frac{2}{3}\right)^n\right]}$$

$$=\lim_{n\to\infty}\sum_{n=1}^{n}\frac{1}{1-\left(\frac{2}{3}\right)^n}-\frac{3}{3-2\cdot\left(\frac{2}{3}\right)^n}$$

$$=\lim_{n\to\infty}\left[\frac{1}{1-(2/3)}-\frac{3}{3-2\cdot(2/3)}\right]+\left[\frac{1}{1-(2/3)^2}-\frac{3}{3-2\cdot(2/3)^2}\right]+\ldots$$

$$+\left[\frac{1}{1-(2/3)^n}-\frac{3}{3-2\cdot(2/3)^n}\right]$$

$$=\lim_{n\to\infty}\left[\frac{1}{1-2/3}-\frac{1}{1-(2/3)^{n+1}}\right]=3-1=2$$

78. We have, $\lim\limits_{x\to\frac{\pi}{2}}\sqrt{\dfrac{\tan x-\sin\{\tan^{-1}(\tan x)\}}{\tan x+\cos^2(\tan x)}}$

Now, RHL at $x=\dfrac{\pi}{2}$,

$$=\lim_{x\to\frac{\pi^+}{2}}\sqrt{\frac{\tan x-\sin\{\tan^{-1}(\tan x)\}}{\tan x+\cos^2(\tan x)}}$$

$$=\lim_{x\to\frac{\pi^+}{2}}\sqrt{\frac{\tan x-\sin(x-\pi)}{\tan x+\cos^2(\tan x)}}$$

$$\left[\because\ \tan^{-1}(\tan x)=x-\pi,\ \text{ when } x>\frac{\pi}{2}\right]$$

$$=\lim_{x\to\frac{\pi^+}{2}}\sqrt{\frac{1+\frac{\sin x}{\tan x}}{1+\frac{\cos^2(\tan x)}{\tan x}}}=\sqrt{\frac{1+0}{1+0}}=1$$

Again, LHL at $x=\dfrac{\pi}{2}$,

$$=\lim_{x\to\frac{\pi^-}{2}}\sqrt{\frac{\tan x-\sin\{\tan^{-1}(\tan x)\}}{\tan x+\cos^2(\tan x)}}$$

$$=\lim_{x\to\frac{\pi^-}{2}}\sqrt{\frac{\tan x-\sin(x)}{\tan x+\cos^2(\tan x)}}\quad\left[\because\tan^{-1}(\tan x)=x,\ \text{when}\ x<\frac{\pi}{2}\right]$$

$$=\lim_{x\to\frac{\pi^-}{2}}\sqrt{\frac{1-\frac{\sin x}{\tan x}}{1+\frac{\cos^2(\tan x)}{\tan x}}}=\sqrt{\frac{1+0}{1+0}}=1$$

$$\therefore\quad\lim_{x\to\frac{\pi}{2}}\sqrt{\frac{\tan x-\sin\{\tan^{-1}(\tan x)\}}{\tan x+\cos^2(\tan x)}}=1$$

79. We have, $A(t)=\int_0^t\sin x^2\cdot dx\ ;\ B(t)=\dfrac{t\sin t^2}{2}\cdot$

$$\therefore\quad\lim_{t\to 0}\frac{A(t)}{B(t)}=\lim_{t\to 0}\frac{2\int_0^t\sin x^2\cdot dx}{t\sin t^2}=\lim_{t\to 0}\frac{2\int_0^t\sin x^2dx}{t^3\cdot\frac{\sin^2 t}{t^2}}$$

$$=\lim_{t\to 0}\frac{2\int_0^t\sin x^2\cdot dx}{t^3}=\lim_{t\to 0}\frac{2\cdot\sin(t^2)}{3t^2}$$

[applying Newton-Leibnitz's rule followed by L' Hospital's rule]

$\therefore \quad \lim_{t\to 0}\frac{A(t)}{B(t)}=\frac{2}{3}$

Then, $m+n=2+3=5$

80. Here, $AB:\left[\int_0^{2t}\left(\frac{\sin x}{x}+1\right)dx\right]x+y=3t$

and $AC: 2tx+y=0$

On solving, we get

$AB:\left[\int_0^{2t}\left(\frac{\sin x}{x}+1\right)dx-2t\right]x=3t \qquad [\because y=-2tx]$

$\therefore \quad x_A=\frac{3t}{\int_0^{2t}\left(\frac{\sin x}{x}+1\right)dx-2t}$

$=\frac{3}{\left(\frac{\sin 2t}{2t}+1\right)2-2}=\frac{3}{2\cdot\frac{\sin 2t}{2t}}$

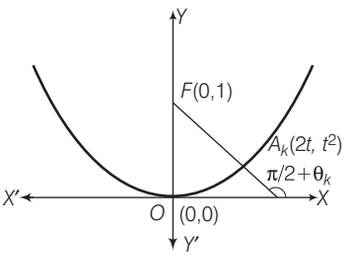
Now, $\lim_{t\to 0}\frac{3}{2\cdot\left(\frac{\sin 2t}{2t}\right)}=\frac{3}{2}$ [using L'Hospital's rule]

$\therefore \quad \frac{p}{q}=\frac{3}{2} \quad \Rightarrow \quad p+q=5$

81. Let $A_k=(2t, t^2)$

$\therefore$ Slope of $FA_k=\frac{t^2-1}{2t-0}$

$=\tan\left(\frac{\pi}{2}+\theta_k\right)$



$\tan(\theta_k)=\frac{2t}{1-t^2}=\tan(2\phi)$, where $t=\tan\phi$

$\therefore \quad \phi=\frac{\theta_k}{2}=\frac{k\pi}{4n}$, where $\tan\phi=t$.

Also, $FA_K=\sqrt{(t^2-1)^2+(2t)^2}$

$=t^2+1=1+\tan^2\phi$

$=\sec^2\left(\frac{k\pi}{4n}\right)$

$\therefore \lim_{n\to\infty}\frac{1}{n}\cdot\sum_{k=1}^{n}FA_k=\lim_{n\to\infty}\frac{1}{n}\cdot\sum_{k=1}^{n}\sec^2\left(\frac{k\pi}{4n}\right)$

$=\int_0^1\sec^2\left(\frac{\pi x}{4}\right)dx$

$=\frac{4}{\pi}\cdot\left[\tan\left(\frac{\pi x}{4}\right)\right]_0^1=\frac{4}{\pi}$

Hence, $m=4$.

82. Here, $L=\lim_{h\to 0}\frac{\cos(\tan^{-1}(\tan(\pi/2+h)))}{h}$

$=\lim_{h\to 0}\frac{\cos(\tan^{-1}(-\cot h))}{h}=\lim_{h\to 0}\frac{\cos\left(-\frac{\pi}{2}+h\right)}{h}=\frac{\sin h}{h}=1$

$\therefore \quad \cos(2\pi L)=\cos(2\pi)=1$

83. Here, $k=\lim_{n\to\infty}\prod_{r=2}^{n}\frac{(r-1)(r^2+r+1)}{(r+1)(r^2-r+1)}$

$=\lim_{n\to\infty}\frac{2}{n(n+1)}\times\frac{n^2+n+1}{3}=\frac{2}{3}.$

So, $\operatorname{cosec}\theta=\frac{2}{3} \Rightarrow$ Number of solution is zero.

84. Here, $\lim_{x\to\infty}\left(\frac{x+c}{x-c}\right)^x=4 \Rightarrow e^{\lim_{x\to\infty}\left(\frac{2c}{x-c}\right)}=4$

$\Rightarrow \quad e^{2c}=4 \Rightarrow e^c=2$ [only positive value]

$\therefore \quad \frac{e^c}{2}=1$

85. $\lim_{x\to-\infty}\frac{(3x^4+2x^2)\cdot\sin\left(\frac{1}{x}\right)-x^3+5}{-x^3+x^2-x+1}=k$

$\Rightarrow \quad \lim_{x\to-\infty}\frac{\left(3+\frac{2}{x^2}\right)\cdot\frac{\sin\left(\frac{1}{x}\right)}{\frac{1}{x}}-1+\frac{5}{x^3}}{-1+\frac{1}{x}-\frac{1}{x^2}+\frac{1}{x^3}}$

$\Rightarrow \quad \frac{(3-1)}{-1}=k \Rightarrow \left|\frac{k}{2}\right|=1$

86. $f(x)=\lim_{t\to 0}\frac{2x}{\pi}\tan^{-1}\left(\frac{x}{t^2}\right)$

***Case* I** When $x>0$,

$f(x)=\lim_{t\to 0}\frac{2x}{\pi}\cdot\tan^{-1}\left(\frac{x}{t^2}\right)=\frac{2x}{\pi}\times\frac{\pi}{2}=x$

***Case* II** When $x<0$,

$f(x)=\lim_{t\to 0}\frac{2x}{\pi}\cdot\tan^{-1}\left(\frac{x}{t^2}\right)=\frac{2x}{\pi}\cdot\left(\frac{-\pi}{2}\right)=-x$

***Case* III** When $x=0 \Rightarrow f(x)=0$

$\therefore \quad f(x)=(x) \Rightarrow f(1)=1$

87. Let $f(x)=\left(\frac{1}{\sqrt{n^2}}+\frac{1}{\sqrt{n^2+1}}+\frac{1}{\sqrt{n^2+2}}+\ldots+\frac{1}{\sqrt{n^2+2n}}\right)$

As, $\frac{1}{\sqrt{n^2+2n}}<\frac{1}{\sqrt{n^2}}=\frac{1}{\sqrt{n^2}}$

$\frac{1}{\sqrt{n^2+2n}}<\frac{1}{\sqrt{n^2+1}}<\frac{1}{\sqrt{n^2}}$

$\vdots$

On adding, we get

$\frac{2n+1}{\sqrt{n^2+2n}}<\frac{1}{\sqrt{n^2}}+\frac{1}{\sqrt{n^2+1}}+\ldots+\frac{1}{\sqrt{n^2+2n}}<\frac{2n+1}{\sqrt{n^2}}$

On applying, limit $n\to\infty$

$$2<\lim_{n\to\infty}\left(\frac{1}{\sqrt{n^2}}+\frac{1}{\sqrt{n^2+1}}+\frac{1}{\sqrt{n^2+2}}+\ldots+\frac{1}{\sqrt{n^2+2n}}\right)<2$$

$$\therefore\quad \lim_{n\to\infty}\left(\frac{1}{\sqrt{n^2}}+\frac{1}{\sqrt{n^2+1}}+\ldots+\frac{1}{\sqrt{n^2+2n}}\right)=2$$

88. $l=\lim\limits_{x\to1^+}2^{-2^{\frac{1}{1-x}}}=\lim\limits_{h\to0}2^{-2^{-\frac{1}{h}}}=2^0=1$

and $m=\lim\limits_{h\to0}\dfrac{(1+h)\cdot\sin h}{h}=1$

$\therefore\quad l+m=2$

89. As, $\dfrac{\sin x\tan x}{x^2}=\dfrac{4\cdot\tan^4\frac{x}{2}}{x^2\cdot(1-\tan^4 x/2)}$

Hence, when $x\to0$, $\dfrac{\sin x\cdot\tan x}{x^2}\to1$. But $\dfrac{\sin x\cdot\tan x}{x^2}>1$

$\therefore\quad \lim\limits_{x\to0}\left[\dfrac{\sin x\tan x}{x^2}\right]=1$

90. Let $S_n=\dfrac{k}{2}\sum\limits_{r=1}^{n}\dfrac{2r}{1\times3\times5\times\ldots\times(2r-1)\times(2r+1)}$

$$=\frac{k}{2}\sum_{r=1}^{n}\left[\frac{1}{1\times3\times5\times\ldots\times(2r-1)}-\frac{1}{1\times3\times5\times\ldots\times(2r+1)}\right]$$

$$=\frac{k}{2}\left[1-\frac{1}{1\times3\times5\times\ldots\times(2n+1)}\right],\text{ as } n\to\infty.$$

$\lim\limits_{n\to\infty}S_n=\dfrac{k}{2}=1\ \Rightarrow\ k^2=4$

91. Here, $\sin^4 x=\sin^2 x-\dfrac{1}{4}\cdot\sin^2 2x$

$$\therefore\ S_n=\left(\sin^2 x-\frac{1}{4}\cdot\sin^2 2x\right)+\left(\frac{1}{4}\cdot\sin^2 2x-\frac{1}{4^2}\cdot\sin^2 2^2x\right)$$

$$+\ldots+\left(\frac{1}{4^n}\cdot\sin^2 2^n x-\frac{1}{4^{n+1}}\cdot\sin^2 2^{n+1}x\right)$$

$$=\sin^2 x-\frac{1}{4^{n+1}}\cdot\sin^2 2^{n+1}x\ \Rightarrow\ f(x)=\sin^2 x,\ g(x)=\cos^2 x$$

$$\therefore\quad [\sqrt{f(x)}+\sqrt{g(x)}]^4=4$$

92. Here, $f(3)=3f(1)=1$

$f(4)=f(2+1+1)=f(2)+f(1)+f(1)=2+1+1=4$ and so on.

In general, $f(x)=x$, for $x\in N$

$$\therefore\quad \lim_{n\to\infty}\sum_{r=1}^{n}\frac{(4r)f(3r)}{n^3}=\frac{12n(n+1)(2n+1)}{6n^3}=4$$

93. As, $0\le\dfrac{x-1}{3}<1\ \Rightarrow 1\le x\le4$

Then, $\lim\limits_{n\to\infty}\dfrac{n}{n\cdot\left(\frac{x-1}{3}\right)^n+n\cdot3-1}=\dfrac{1}{3}$, when $0\le\dfrac{x-1}{3}<1$

$\Rightarrow\ x=1,2,3$

$\therefore$ Number of integral values = 3.

94. As, $x^5-y^5=(x-y)(x^4+x^3y+x^2y^2+xy^3+y^4)$

and the coefficient of x^n in

$$(x-1)(x-2)(x+3)(x+10)(x+15)-x^5$$

$$=-1-2+3+10+15=25$$

$$\therefore\lim_{x\to\infty}((x-1)(x-2)(x+3)(x+10)(x+15)^{1/3}-x)$$

$$=\frac{25}{5}=5$$

95. Here, $k=\lim\limits_{x\to\infty}(1+[f(x)]+x^2-1)\{f(x)\}$

$$=e^{\lim\limits_{x\to\infty}\frac{\left[\frac{\tan x}{x}\right]+x^2-1}{\left\{\frac{\tan x}{x}\right\}}}=e^{\lim\limits_{x\to\infty}\frac{1+x^2-1}{\frac{\tan x}{x}-\left[\frac{\tan x}{x}\right]}}$$

$$=e^{\lim\limits_{x\to\infty}\frac{x^2}{\left(1+\frac{x^2}{3}+\frac{x^4}{15}-1\right)}}=e^3$$

$\therefore\quad [k/e]=[e^2]=7$

96. Here, $(\sqrt{3}+1)^{2n}=I+f$ ...(i)

Let $f=(\sqrt{3}-1)^{2n}$ ...(ii)

$\therefore\quad I+f+F=$ even integer, $0<f,\ f<1$

$\Rightarrow\quad f+F=1\ \Rightarrow\ 0<f+F<2$

$\Rightarrow\quad f+F=1$

$\Rightarrow\quad \{(\sqrt{3}+1)\}^{2n}=f=1-f$

$\therefore\quad \lim\limits_{n\to\infty}f=\lim\limits_{n\to\infty}1-f=1-\lim\limits_{n\to\infty}(\sqrt{3}-1)^{2n}=1-0=1$

97. Here, $f(x)=a_0x^4+a_1x^3+a_2x^2+a_3x+a_4$.

As, $\lim\limits_{x\to0}1+\dfrac{f(x)}{x^2}=2\ \Rightarrow\ \lim\limits_{x\to0}\dfrac{f(x)}{x^2}=1$

So, $a_3=a_4=0$ and $a_2=1$

$f(x)=a_0x^4+a_1x^3+x^2$

$\Rightarrow f'(x)=4a_0x^3+3a_1x^2+2x$

As, $f(x)$ has extremum at $x=1$ and $x=2$.

$f'(1)=4a_0+3a_1+2$

and $f'(2)=32a_0+12a_1+4$

So, $a_0=\dfrac{1}{4}$ and $a_1=-1$

$\Rightarrow\quad f(2)=0$

98. Here, $|x|=\log(\{x\})$ has no solution.

Hence, $\alpha=0$

$$\therefore\lim_{x\to0}\frac{x\,e^{ax}-b\sin x}{x^3}=\lim_{x\to0}\frac{(1-b)x+ax^2+x^3\left(\frac{a^2}{2}-\frac{b}{6}\right)}{x^3}$$

$\Rightarrow\quad a=0,\ b=1$

$\Rightarrow\quad a+b=1$

99. Here, $\sin(x_{n+1}-x_n)+2^{-(n+1)}\sin x_n\cdot\sin x_{n+1}=0$

$\Rightarrow\quad \cot x_{n+1}-\cot x_n=2^{-(n+1)}$

$\Rightarrow\quad \cot x_n-\cot x_{n-1}=2^{-n}$

$\Rightarrow\quad \cot x_{n+1}-\cot x_1=\dfrac{1}{2^2}+\dfrac{1}{2^3}+\ldots+\dfrac{1}{2^{n+1}}$

$\Rightarrow\quad \cot x_{n+1}=\dfrac{1}{2}+\dfrac{1}{2^2}+\ldots\dfrac{1}{2^{n+1}}$

$$\Rightarrow \quad \lim_{n\to\infty} \cot x_{n+1} = 1$$

$$\therefore \quad \lim_{n\to\infty} x_{n+1} = \frac{\pi}{4}$$

$$l = \frac{\pi}{4} \quad \Rightarrow 4l = \pi$$

$$\therefore \quad [4l] = 3$$

100. Here, $\lim_{x\to 0} \frac{x^2 \sin(\beta x)}{\alpha x - \sin x} = 1$

$$\Rightarrow \lim_{x\to 0} \frac{x^2\left(\beta x - \frac{(\beta x)^3}{3!} + \frac{(\beta x)^5}{5!} - \ldots\right)}{\alpha x - \left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \ldots\right)} = 1$$

$$\Rightarrow \lim_{x\to 0} \frac{x^3\left(\beta - \frac{\beta^3 x^2}{3!} + \frac{\beta^5 x^4}{5!} - \ldots\right)}{(\alpha - 1)x + \frac{x^3}{3!} + \frac{x^5}{5!} - \ldots} = 1$$

Limit exists only, when $\alpha - 1 = 0$

$$\Rightarrow \quad \alpha = 1 \qquad \ldots(i)$$

$$\therefore \lim_{x\to 0} \frac{x^3\left(\beta - \frac{\beta^3 x^2}{3!} + \frac{\beta^5 x^4}{5!} - \ldots\right)}{x^3\left(\frac{1}{3!} - \frac{x^2}{5!} - \ldots\right)} = 1$$

$$\Rightarrow \quad 6\beta = 1 \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$6(\alpha + \beta) = 6\,\alpha + 6\beta = 6 + 1 = 7$$

101. Given, $\lim_{\alpha\to 0}\left[\frac{e^{\cos(\alpha^n)} - e}{\alpha^m}\right] = -\frac{e}{2}$

$$\Rightarrow \lim_{\alpha\to 0} \frac{e\{e^{\cos(\alpha^n)-1} - 1\}}{\cos(\alpha^n) - 1} \cdot \frac{\cos(\alpha^n) - 1}{\alpha^m} = \frac{-e}{2}$$

$$\Rightarrow \lim_{\alpha\to 0} e\left\{\frac{e^{\cos(\alpha^n)-1} - 1}{\cos(\alpha^n) - 1}\right\} \cdot \lim_{\alpha\to 0} \frac{-2\sin^2\frac{\alpha^n}{2}}{\alpha^m} = -\frac{e}{2}$$

$$\Rightarrow \quad e \times 1 \times (-2) \lim_{\alpha\to 0} \frac{\sin^2\left(\frac{\alpha^n}{2}\right)}{\frac{\alpha^{2n}}{4}} \cdot \frac{\alpha^{2n}}{4\alpha^m} = \frac{-e}{2}$$

$$\Rightarrow \quad e \times 1 \times -2 \times 1 \times \lim_{\alpha\to 0} \frac{\alpha^{2n-m}}{4} = \frac{-e}{2}$$

For this to be exists, $2n - m = 0 \;\Rightarrow\; \frac{m}{n} = 2$

102. Here, $\lim_{x\to 1} \frac{F(x)}{G(x)} = \frac{1}{14}$

$$\Rightarrow \quad \lim_{x\to 1} \frac{F'(x)}{G'(x)} = \frac{1}{14} \qquad \text{[using L'Hospital's rule]} \ldots(i)$$

As, $F(x) = \int_{-1}^{x} f(t)\,dt$

$$\Rightarrow \quad F'(x) = f(x) \qquad \ldots(ii)$$

and $G(x) = \int_{-1}^{x} t\left|f\{f(t)\}\right| dt$

$$\Rightarrow \quad G'(x) = x\left|f\{f(x)\}\right| \qquad \ldots(iii)$$

$$\therefore \quad \lim_{x\to 1} \frac{F(x)}{G(x)} = \lim_{x\to 1} \frac{F'(x)}{G'(x)} = \lim_{x\to 1} \frac{f(x)}{x\left|f\{f(x)\}\right|}$$

$$= \frac{f(1)}{1\left|f\{f(1)\}\right|} = \frac{\frac{1}{2}}{\left|f\left(\frac{1}{2}\right)\right|} \qquad \ldots(iv)$$

Given, $\lim_{x\to 1} \frac{F(x)}{G(x)} = \frac{1}{14}$

$$\therefore \quad \frac{\frac{1}{2}}{\left|f\left(\frac{1}{2}\right)\right|} = \frac{1}{14} \;\Rightarrow\; \left|f\left(\frac{1}{2}\right)\right| = 7$$

103. Given, $\lim_{x\to 1}\left\{\frac{\sin(x-1) + a(1-x)}{(x-1) + \sin(x-1)}\right\}^{\frac{(1+\sqrt{x})(1-\sqrt{x})}{1-\sqrt{x}}} = \frac{1}{4}$

$$\lim_{x\to 1}\left\{\frac{\frac{\sin(x-1)}{(x-1)} - a}{1 + \frac{\sin(x-1)}{(x-1)}}\right\}^{1+\sqrt{x}} = \frac{1}{4}$$

$$\Rightarrow \quad \left(\frac{1-a}{2}\right)^2 = \frac{1}{4}$$

$$\Rightarrow \quad (a-1)^2 = 1$$

$$\Rightarrow \quad a = 2 \text{ or } 0$$

Hence, the maximum value of a is 2.

104. $L = \lim_{x\to 0} \frac{a - \sqrt{a^2 - x^2} - \frac{x^2}{4}}{x^4}, a > 0$

$$= \lim_{x\to 0} \frac{a - a\cdot\left[1 - \frac{1}{2}\cdot\frac{x^2}{a^2} + \frac{\frac{1}{2}\left(\frac{1}{2}-1\right)}{2}\cdot\frac{x^4}{a^4} - \ldots\right] - \frac{x^2}{4}}{x^4}$$

$$= \lim_{x\to 0} \frac{\frac{x^2}{2a} + \frac{1}{8}\cdot\frac{x^4}{a^3} + \ldots - \frac{x^2}{4}}{x^4}$$

Since, L is finite $\Rightarrow 2a = 4 \;\Rightarrow\; a = 2$

$$\therefore \quad L = \lim_{x\to 0} \frac{1}{8\cdot a^3} = \frac{1}{64}$$

105. $\lim_{x\to\frac{\pi}{2}} \frac{\cot x(1 - \sin x)}{-8\left(x - \frac{\pi}{2}\right)^3}$

$$= \lim_{x\to\frac{\pi}{2}} \frac{\tan\left(\frac{\pi}{2} - x\right)}{8\left(\frac{\pi}{2} - x\right)} \frac{\left(1 - \cos\left(\frac{\pi}{2} - x\right)\right)}{\left(\frac{\pi}{2} - x\right)^2} = \frac{1}{8}\cdot 1\cdot\frac{1}{2} = \frac{1}{16}$$

106. Given, $p = \lim_{x \to 0^+} (1 + \tan^2 \sqrt{x})^{\frac{1}{2x}}$ [1^∞ form]

$$= e^{\lim_{x \to 0^+} \frac{\tan^2 \sqrt{x}}{2x}} = e^{\frac{1}{2} \lim_{x \to 0^+} \left(\frac{\tan \sqrt{x}}{\sqrt{x}}\right)^2} = e^{\frac{1}{2}}$$

$\therefore \log p = \log e^{\frac{1}{2}} = \frac{1}{2}$

107. Let $l = \lim_{n \to \infty} \left[\frac{(n+1) \cdot (n+2) \ldots (3n)}{n^{2n}}\right]^{\frac{1}{n}}$

$$= \lim_{n \to \infty} \left[\frac{(n+1) \cdot (n+2) \ldots (n+2n)}{n^{2n}}\right]^{\frac{1}{n}}$$

$$= \lim_{n \to \infty} \left[\left(\frac{n+1}{n}\right)\left(\frac{n+2}{n}\right) \ldots \left(\frac{n+2n}{n}\right)\right]^{\frac{1}{n}}$$

Taking log on both sides, we get

$$\log l = \lim_{n \to \infty} \frac{1}{n} \left[\log \left\{\left(1 + \frac{1}{n}\right)\left(1 + \frac{2}{n}\right) \ldots \left(1 + \frac{2n}{n}\right)\right\}\right]$$

$$\Rightarrow \log l = \lim_{n \to \infty} \frac{1}{n} \left[\log\left(1 + \frac{1}{n}\right) + \log\left(1 + \frac{2}{n}\right) + \ldots + \log\left(1 + \frac{2n}{n}\right)\right]$$

$$\Rightarrow \log l = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{2n} \log\left(1 + \frac{r}{n}\right)$$

$$\Rightarrow \log l = \int_0^2 \log (1 + x)\, dx$$

$$\Rightarrow \log l = \left[\log (1 + x) \cdot x - \int \frac{1}{1 + x} \cdot x\, dx\right]_0^2$$

$$\Rightarrow \log l = [\log (1 + x) \cdot x]_0^2 - \int_0^2 \frac{x + 1 - 1}{1 + x}\, dx$$

$$\Rightarrow \log l = 2 \cdot \log 3 - \int_0^2 \left(1 - \frac{1}{1 + x}\right) dx$$

$$\Rightarrow \log l = 2 \cdot \log 3 - [x - \log |1 + x|]_0^2$$

$$\Rightarrow \log l = 2 \cdot \log 3 - [2 - \log 3]$$

$$\Rightarrow \log l = 3 \cdot \log 3 - 2$$

$$\Rightarrow \log l = \log 27 - 2$$

$$\therefore \quad l = e^{\log 27 - 2}$$

$$= 27 \cdot e^{-2} = \frac{27}{e^2}$$

108. $\lim_{x \to 0} \frac{\sin(\pi \cos^2 x)}{x^2} = \lim_{x \to 0} \frac{\sin \pi (1 - \sin^2 x)}{x^2}$

$$= \lim_{x \to 0} \frac{\sin(\pi - \pi \sin^2 x)}{x^2}$$

$$= \lim_{x \to 0} \frac{\sin(\pi \sin^2 x)}{x^2} \qquad [\because \sin(\pi - \theta) = \sin \theta]$$

$$= \lim_{x \to 0} \frac{\sin \pi \sin^2 x}{\pi \sin^2 x} \times (\pi)\left(\frac{\sin^2 x}{x^2}\right) = \pi \qquad \left[\because \lim_{\theta \to 0} \frac{\sin \theta}{\theta} = 1\right]$$

109. We have, $\lim_{x \to 0} \frac{(1 - \cos 2x)(3 + \cos x)}{x \tan 4x} = \lim_{x \to 0} \frac{2 \sin^2 x\, (3 + \cos x)}{x \times \frac{\tan 4x}{4x} \times 4x}$

$$= \lim_{x \to 0} \frac{2 \sin^2 x}{x^2} \times \lim_{x \to 0} \frac{(3 + \cos x)}{4} \times \frac{1}{\lim_{x \to 0} \frac{\tan 4x}{4x}}$$

$$= 2 \times \frac{4}{4} \times 1 = 2 \qquad \left[\because \lim_{\theta \to 0} \frac{\sin \theta}{\theta} = 1 \text{ and } \lim_{\theta \to 0} \frac{\tan \theta}{\theta} = 1\right]$$

110. **Plan** $\left(\frac{\infty}{\infty}\right)$ form

$$\lim_{x \to \infty} \frac{a_0 x^n + a_1 x^{n-1} + \ldots + a_n}{b_0 x^m + b_1 x^{m-1} + \ldots + b_m} = \begin{cases} 0, & \text{if } n < m \\ \frac{a_0}{b_0}, & \text{if } n = m \\ +\infty, & \text{if } n > m \text{ and } a_0 b_0 > 0 \\ -\infty, & \text{if } n < m \text{ and } a_0 b_0 < 0 \end{cases}$$

Description of Situation As to make degree of numerator equal to degree of denominator.

$$\therefore \quad \lim_{x \to \infty} \left(\frac{x^2 + x + 1}{x + 1} - ax - b\right) = 4$$

$$\Rightarrow \quad \lim_{x \to \infty} \frac{x^2 + x + 1 - ax^2 - ax - bx - b}{x + 1} = 4$$

$$\Rightarrow \quad \lim_{x \to \infty} \frac{x^2(1 - a) + x(1 - a - b) + (1 - b)}{x + 1} = 4$$

Here, we make degree of numerator = degree of denominator

$$\therefore \quad 1 - a = 0$$

$$\Rightarrow \quad a = 1$$

and $\lim_{x \to \infty} \frac{x(1 - a - b) + (1 - b)}{x + 1} = 4$

$$\Rightarrow \quad 1 - a - b = 4$$

$$\Rightarrow \quad b = -4 \qquad [\because (1 - a) = 0]$$

111. **Plan** To make the quadratic into simple form, we should eliminate radical sign.

Description of Situation As for given equation, when $a \to 0$ the equation reduces to identity in x.

i.e. $ax^2 + bx + c = 0, \forall\, x \in R$ or $a = b = c \to 0$

Thus, first we should make above equation independent from coefficients as 0.

Let $a + 1 = t^6$. Thus, when $a \to 0, t \to 1$.

$$\therefore \quad (t^2 - 1)\, x^2 + (t^3 - 1)x + (t - 1) = 0$$

$$\Rightarrow \quad (t - 1)\{(t + 1)x^2 + (t^2 + t + 1)\, x + 1\} = 0, \text{ as } t \to 1$$

$$2x^2 + 3x + 1 = 0$$

$$\Rightarrow \quad 2x^2 + 2x + x + 1 = 0$$

$$\Rightarrow \quad (2x + 1)(x + 1) = 0$$

Thus, $x = -1, -1/2$

or $\lim_{a \to 0^+} \alpha(a) = -1/2$

and $\lim_{a \to 0^+} \beta(a) = -1$

112. Here, $\lim_{x \to 0} \{1 + x \log (1 + b^2)\}^{1/x}$ [1^∞ form]

$$= e^{\lim_{x \to 0} \{x \log (1 + b^2)\} \cdot \frac{1}{x}}$$

$$= e^{\log (1 + b^2)} = (1 + b^2) \quad \ldots(i)$$

Given, $\lim_{x \to 0} \{1 + x \log (1 + b^2)\}^{1/x} = 2b \sin^2 \theta$

$$\Rightarrow \quad (1 + b^2) = 2b \sin^2 \theta$$

$$\therefore \quad \sin^2 \theta = \frac{1 + b^2}{2b} \quad \ldots(ii)$$

By AM $\geq$ GM, $\quad \frac{b + \frac{1}{b}}{2} \geq \left(b \cdot \frac{1}{b}\right)^{1/2}$

$$\Rightarrow \quad \frac{b^2 + 1}{2b} \geq 1 \quad \ldots(iii)$$

From Eqs. (ii) and (iii), we get

$$\sin^2 \theta = 1$$

$$\Rightarrow \quad \theta = \pm \frac{\pi}{2}, \text{ as } \theta \in (-\pi, \pi]$$

113. Here, $\lim_{x \to 0} (\sin x)^{1/x} + \lim_{x \to 0} \left(\frac{1}{x}\right)^{\sin x}$

$$= 0 + \lim_{x \to 0} e^{\log\left(\frac{1}{x}\right)^{\sin x}} = e^{\lim_{x \to 0} \frac{\log (1/x)}{\operatorname{cosec} x}} \qquad \left[\begin{matrix} \lim_{x \to 0} (\sin x)^{1/x} \to 0 \\ \text{as, } (\text{decimal})^\infty \to 0 \end{matrix}\right]$$

Applying L' Hospital's rule, we get

$$e^{\lim_{x \to 0} \frac{x\left(-\frac{1}{x^2}\right)}{-\operatorname{cosec} x \cot x}} = e^{\lim_{x \to 0} \frac{\sin x}{x} \tan x} = e^0 = 1$$

114. Here, $\lim_{h \to 0} \frac{f(2h + 2 + h^2) - f(2)}{f(h - h^2 + 1) - f(1)}$

[$\because f'(2) = 6$ and $f'(1) = 4$, given]

Applying L' Hospital's rule,

$$= \lim_{h \to 0} \frac{\{f'(2h + 2 + h^2)\} \cdot (2 + 2h) - 0}{\{f'(h - h^2 + 1)\} \cdot (1 - 2h) - 0}$$

$$= \frac{f'(2) \cdot 2}{f'(1) \cdot 1}$$

$$= \frac{6 \cdot 2}{4 \cdot 1} = 3 \qquad [\text{using } f'(2)=6 \text{ and } f'(1) = 4]$$

115. Given, $\lim_{x \to 0} \frac{\{(a - n)\, nx - \tan x\} \sin nx}{x^2} = 0$

$$\Rightarrow \lim_{x \to 0} \left\{(a - n)\, n - \frac{\tan x}{x}\right\} \frac{\sin nx}{nx} \times n = 0$$

$$\Rightarrow \quad \{(a - n)\, n - 1\}\, n = 0$$

$$\Rightarrow \quad (a - n)\, n = 1$$

$$\Rightarrow \quad a = n + \frac{1}{n}$$

116. $\lim_{x \to 0} \frac{(\cos x - 1)(\cos x - e^x)}{x^n}$

$$= \lim_{x \to 0} \frac{\left(-2 \sin^2 \frac{x}{2}\right)\left\{\left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \ldots\right) - \left(1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \ldots\right)\right\}}{x^n}$$

$$= \lim_{x \to 0} \frac{\left(-2 \sin^2 \frac{x}{2}\right)\left(-x - \frac{2x^2}{2!} - \frac{x^3}{3!} - \ldots\right)}{4\left(\frac{x}{2}\right)^2 x^{n-2}}$$

$$= \lim_{x \to 0} \frac{\sin^2 \frac{x}{2}\left(1 + x + \frac{x^2}{3!} + \ldots\right)}{2\left(\frac{x}{2}\right)^2 x^{n-3}}$$

Above limit is finite, if $n - 3 = 0$, i.e. $n = 3$.

117. Let $y = \left[\frac{f(1 + x)}{f(1)}\right]^{1/x}$

$$\Rightarrow \log y = \frac{1}{x} [\log f(1 + x) - \log f(1)]$$

$$\Rightarrow \lim_{x \to 0} \log y = \lim_{x \to 0} \left[\frac{1}{f(1 + x)} \cdot f'(1 + x)\right]$$

[using L'Hospital's rule]

$$= \frac{f(1)}{f(1)} = \frac{6}{3}$$

$$\Rightarrow \log\left(\lim_{x \to 0} y\right) = 2 \Rightarrow \lim_{x \to 0} y = e^2$$

118. For $x \in R$, $\lim_{x \to \infty} \left(\frac{x - 3}{x + 2}\right)^x = \lim_{x \to \infty} \frac{(1 - 3/x)^x}{(1 + 2/x)^x} = \frac{e^{-3}}{e^2} = e^{-5}$

Session 1

Continuous Function, Continuity of a Function at a Point

Introduction to Continuity

A real function is continuous at a fixed point if we can draw the graph of the function around that point without lifting the pen from the plane of the paper. In case one has to lift the pen at a point, the graph of the function is said to have a break or discontinuous at that point, say $x = a$.

Different types of situations, which may come up at $x = a$ along the graph, can be shown as below

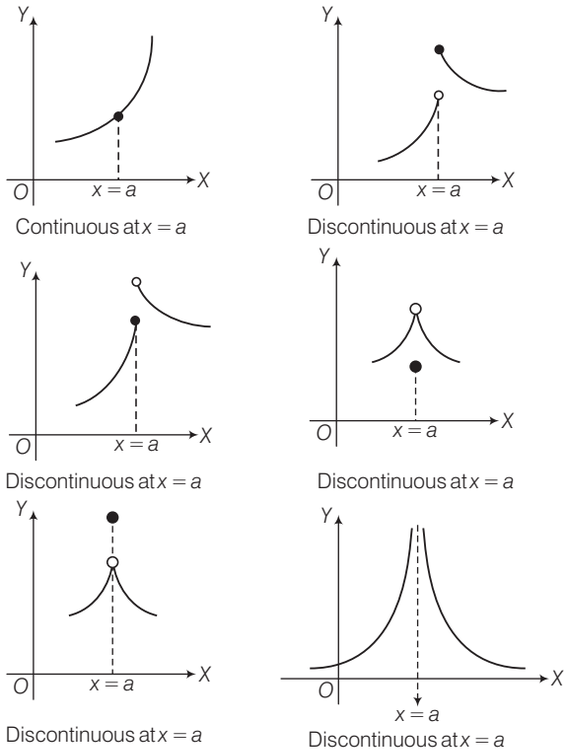

Figure 6.1

- There should be heading ''continuity of a function at point''
- A function $f(x)$ is said to be continuous at $x = a$; where $a \in$ domain of $f(x)$, if $\lim\limits_{x \to a^-} f(x) = \lim\limits_{x \to a^+} f(x) = f(a)$

  i.e. LHL = RHL = Value of a function at $x = a$

  or $\lim\limits_{x \to a} f(x) = f(a)$
- If $f(x)$ is not continuous at $x = a$, we say that $f(x)$ is discontinuous at $x = a$, $f(x)$ will be discontinuous at $x = a$ in any of the following cases

(i) $\lim\limits_{x \to a^-} f(x)$ and $\lim\limits_{x \to a^+} f(x)$ exist but are not equal.

(ii) $\lim\limits_{x \to a^-} f(x)$ and $\lim\limits_{x \to a^+} f(x)$ exist and are equal but not equal to $f(a)$.

(iii) $f(a)$ is not defined.

(iv) Atleast one of the limit doesn't exist.

Now, we will discuss different conditions for a function to be discontinuous in detail

(i) $\lim\limits_{x \to a^-} f(x)$ and $\lim\limits_{x \to a^+} f(x)$ exists but are not equal.

Here, $\lim\limits_{x \to a^-} f(x) = l_1$

and $\lim\limits_{x \to a^+} f(x) = l_2$

$\therefore$ $\lim\limits_{x \to a^-} f(x)$ and $\lim\limits_{x \to a^+} f(x)$ exist but are not equal.

Thus, $f(x)$ is discontinuous at $x = a$. It does not matter whether $f(a)$ exist or not.

Graphically This conditions can be illustrated as

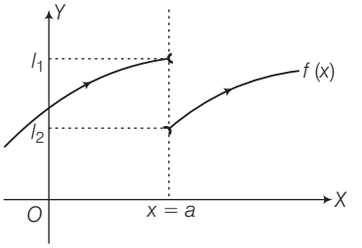

Figure 6.2

Example 1 ***If*** $f(x) = \dfrac{|x|}{x}$***. Discuss the continuity at*** $x = 0$.

Sol. Here, $f(x) = \dfrac{|x|}{x}$

$\therefore$ RHL at $x = 0$

Let $x = 0 + h$

i.e. $\lim\limits_{x \to 0^+} f(x) = \lim\limits_{h \to 0} f(0 + h) = \lim\limits_{h \to 0} \dfrac{|0 + h|}{0 + h} = \lim\limits_{h \to 0} \dfrac{h}{h} = 1$

$\Rightarrow$ $\lim\limits_{x \to 0^+} f(x) = 1$

Again, LHL at $x = 0$

Let $x = 0 - h$

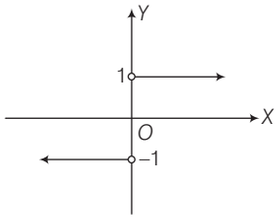
i.e. $\lim_{x \to 0^-} f(x) = \lim_{h \to 0} f(0-h)$

$= \lim_{h \to 0} \frac{|0-h|}{0-h} = \lim_{h \to 0} \frac{h}{-h} = -1$

$\Rightarrow \lim_{x \to 0^-} f(x) = -1 \Rightarrow \lim_{x \to 0^+} f(x) \neq \lim_{x \to 0^-} f(x).$

Thus, $f(x)$ is discontinuous at $x = 0$.

Graphically Here,



$$f(x) = \frac{|x|}{x} = \begin{cases} \frac{x}{x}, & x > 0 \\ -\frac{x}{x}, & x < 0 \end{cases} = \begin{cases} 1, & x > 0 \\ -1, & x < 0 \end{cases}$$

and $f(0) = \frac{0}{0}$ [indeterminate form]

$\Rightarrow$ It is not defined.

Which shows, the graph is broken at $x = 0$.

Where, $\lim_{x \to 0^-} f(x) = -1$ and $\lim_{x \to 0^+} f(x) = -1$

Thus, $\lim_{x \to 0} f(x)$ doesn't exist and hence function is discontinuous.

Remark

Here, $f(x)$ is not defined at $x = 0$, as $f(0) = \frac{0}{0}$. [indeterminate form]

So, we could say directly that the function is discontinuous at $x = 0$

(ii) $\lim_{x \to a^-} f(x)$ and $\lim_{x \to a^+} f(x)$ exist and are equal but not equal to $f(a)$.

Here, $\lim_{x \to a^-} f(x) = \lim_{x \to a^+} f(x) = L$

$f(a)$ is also defined but $f(a) \neq L$.

So, limit of $f(x)$ exists at $x = a$. But, it is not continuous at $x = a$.

Graphically This conditions can be illustrated as

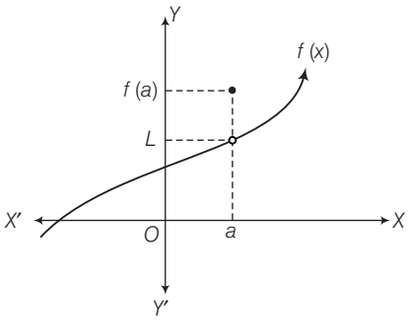


Figure 6.3

Example 2 If $f(x) = \begin{cases} 2x + 3, & \text{when } x < 0 \\ 0, & \text{when } x = 0. \\ x^2 + 3, & \text{when } x > 0 \end{cases}$

Discuss the continuity at $x = 0$.

Sol. Here, $f(x) = \begin{cases} 2x + 3, & \text{when } x < 0 \\ 0, & \text{when } x = 0 \\ x^2 + 3, & \text{when } x > 0 \end{cases}$

$\therefore$ RHL at $x = 0$, let $x = 0 + h$

i.e. $\lim_{x \to 0^+} f(x) = \lim_{h \to 0} f(0+h)$

$= \lim_{h \to 0} \{(0+h)^2 + 3\} = 3$

$\Rightarrow \lim_{x \to 0^+} f(x) = 3$

Again, LHL at $x = 0$, let $x = 0 - h$

i.e. $\lim_{x \to 0^-} f(x) = \lim_{h \to 0} f(0-h)$

$= \lim_{h \to 0} \{2(0-h) + 3\} = 3$

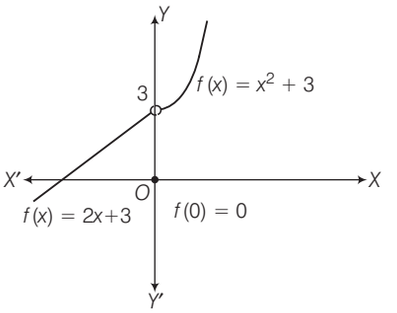
$\Rightarrow \lim_{x \to 0^-} f(x) = 3$

But $f(0) = 0$

Therefore, $\lim_{x \to 0^+} f(x) = \lim_{x \to 0^-} f(x) = 3 \neq f(0)$

Thus, $f(x)$ is discontinuous at $x = 0$.

Graphically



Here, $\lim_{x \to 0^-} f(x) = 3$

$\lim_{x \to 0^+} f(x) = 3$

$f(0) = 0$

Thus, $\lim_{x \to 0^-} f(x) = \lim_{x \to 0^+} f(x) = 3 \neq f(0)$

Hence, $f(x)$ is discontinuous at $x = 0$.

(iii) $f(a)$ is not defined.

Here, $\lim_{x \to a^+} f(x) = L$

and $\lim_{x \to a^-} f(x) = L$

But, $f(a)$ is not defined. So, $f(x)$ is discontinuous at $x = a$.

Graphically This conditions can be illustrated as

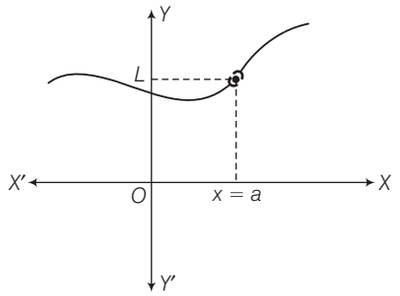


Figure 6.4

Example 3 *If* $f(x)=\dfrac{x^2-1}{x-1}$.

Discuss the continuity at $x=1$.

Sol. Here, $f(x)=\dfrac{x^2-1}{x-1}$

$$\lim_{x\to 1} f(x)=\lim_{x\to 1}\frac{x^2-1}{x-1}$$

$$=\lim_{x\to 1}\frac{(x-1)(x+1)}{(x-1)}$$

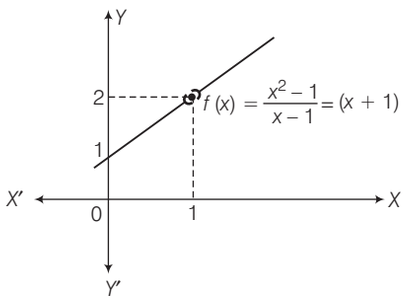
$$=\lim_{x\to 1}(x+1)=2$$

But $f(1)=\dfrac{0}{0}$ [indeterminate form]

$\therefore$ $f(1)$ is not defined at $x=1$.

Hence, $f(x)$ is discontinuous at $x=1$.

Graphically



Here, $\lim_{x\to 1} f(x)=2$ but $f(1)$ is not defined.

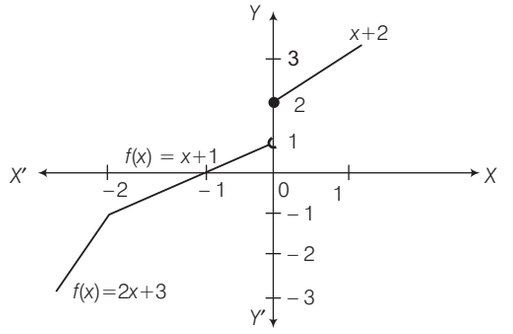
So, $f(x)$ is discontinuous at $x=1$.

Example 4 *Show that the function*

$$f(x)=\begin{cases}2x+3, & -3\le x<-2\\ x+1, & -2\le x<0\\ x+2, & 0\le x\le 1\end{cases}$$

is discontinuous at $x=0$ *and continuous at every other point in interval* $[-3,1]$.

Sol. **Graphically** $f(x)=\begin{cases}2x+3, & -3\le x<-2\\ x+1, & -2\le x<0\\ x+2, & 0\le x\le 1\end{cases}$ is plotted as shown



Here, if we observe the graph we could conclude that at $x=0$, $\lim_{x\to 0^-} f(x)=1$ and $\lim_{x\to 0^+} f(x)=2$, which shows that the function is discontinuous at $x=0$ and continuous at every other point in $[-3,1]$.

Example 5 Examine the function,

$$f(x)=\begin{cases}\dfrac{\cos x}{\pi/2-x}, & x\ne \pi/2\\ 1, & x=\pi/2\end{cases}$$ for continuity *at* $x=\pi/2$.

Sol. We have, $\lim_{x\to \pi/2} f(x)=\lim_{x\to \pi/2}\dfrac{\cos x}{\pi/2-x}$

[as $x\ne\pi/2$ but $x\to\pi/2$]

$$=\lim_{x\to \pi/2}\frac{\cos x}{\pi/2-x}\qquad\left[\frac{0}{0}\text{ form}\right]$$

$$=\lim_{x\to \pi/2}\frac{-\sin x}{0-1}\quad\text{[applying L'Hospital's rule]}$$

$\Rightarrow$ $\lim_{x\to \pi/2} f(x)=\sin\dfrac{\pi}{2}=1$

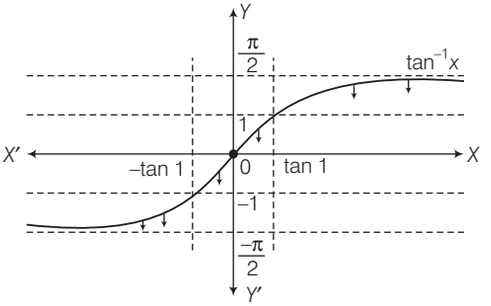
Also, $f(\pi/2)=1$

$\therefore$ $\lim_{x\to \pi/2} f(x)=f(\pi/2)$

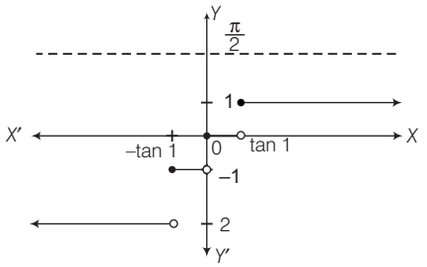
Thus, $f(x)$ is continuous at $x=\pi/2$.

Example 6 *Discuss the continuity of* $f(x)=[\tan^{-1}x]$.

Sol. We know, $y=\tan^{-1}x$ could be plotted as



Thus, $f(x) = [\tan^{-1} x]$ could be plotted as



Which clearly shows the graph is broken at $\{-\tan 1, 0, \tan 1\}$.

$\therefore$ $f(x)$ is not continuous when $x \in \{-\tan 1, 0, \tan 1\}$.

Example 7 Let $y = f(x)$ be defined parametrically as $y = t^2 + t|t|$, $x = 2t - |t|, t \in R$. Then, at $x = 0$, find $f(x)$ and discuss continuity.

Sol. As, $y = t^2 + t|t|$ and $x = 2t - |t|$

Thus, when $t \geq 0$

$\Rightarrow$ $x = 2t - t = t, y = t^2 + t^2 = 2t^2$

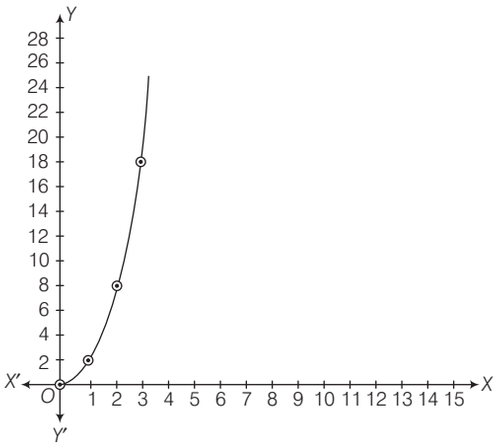
$\therefore$ $x = t$ and $y = 2t^2 \Rightarrow y = 2x^2, \forall\ x \geq 0$

Again, when $t < 0$

$\Rightarrow$ $x = 2t + t = 3t$ and $y = t^2 - t^2 = 0 \Rightarrow y = 0, \forall\ x < 0$

Hence, $f(x) = \begin{cases} 2x^2, & x \geq 0 \\ 0, & x < 0 \end{cases}$

which is clearly continuous for all x as shown graphically.



Example 8 Let $f(x) = \dfrac{e^{\tan x} - e^x + \log(\sec x + \tan x) - x}{\tan x - x}$ be a continuous function at $x = 0$. The value of $f(0)$ equals

(a) $\frac{1}{2}$ (b) $\frac{2}{3}$

(c) $\frac{3}{2}$ (d) 2

Sol. For continuity at $x = 0$, we have

$$f(0) = \lim_{x \to 0} f(x)$$

$$= \lim_{x \to 0} \frac{e^{\tan x} - e^x}{\tan x - x} + \lim_{x \to 0} \frac{\log(\sec x + \tan x) - x}{\tan x - x}$$

$$= \lim_{x \to 0} e^x \frac{(e^{\tan x - x} - 1)}{(\tan x - x)} + \lim_{x \to 0} \frac{\sec x - 1}{\sec^2 x - 1}$$

[using L'Hospital's rule]

$$= 1 + \lim_{x \to 0} \frac{1}{\sec x + 1} = 1 + \frac{1}{2} = \frac{3}{2}$$

Hence, (c) is the correct answer.

Example 9 ***If*** $f(x) = \sqrt{\dfrac{1}{\tan^{-1}(x^2 - 4x + 3)}}$, ***then*** $f(x)$ ***is continuous for***

(a) (1, 3) (b) $(-\infty, 0)$

(c) $(-\infty, 1) \cup (3, \infty)$ (d) None of these

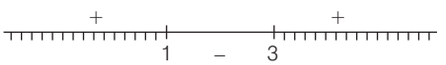
Sol. Here,

$$f(x) = \sqrt{\frac{1}{\tan^{-1}(x^2 - 4x + 3)}}$$

For domain, $\tan^{-1}(x^2 - 4x + 3) > 0$

$\Rightarrow$ $x^2 - 4x + 3 > 0$

$\Rightarrow$ $(x - 1)(x - 3) > 0$



$\therefore$ $x \in (-\infty, 1) \cup (3, \infty)$

Since, every general function is continuous in its domain.

$\therefore f(x)$ is continuous for $x \in (-\infty, 1) \cup (3, \infty)$.

Hence, (c) is correct answer.

Exercise for Session 1

1. If function $f(x)=\dfrac{\sqrt{1+x}-\sqrt[3]{1+x}}{x}$ is continuous function at $x=0$, then $f(0)$ is equal to

(a) 2 (b) $\frac{1}{4}$ (c) $\frac{1}{6}$ (d) $\frac{1}{3}$

2. If $f(x)=\begin{cases}\dfrac{1}{e^{1/x}+1}, & x\neq 0\\ 0, & x=0\end{cases}$, then

(a) $\lim\limits_{x\to 0^-} f(x)=0$ (b) $\lim\limits_{x\to 0^+} f(x)=1$

(c) $f(x)$ is discontinuous at $x=0$ (d) $f(x)$ is continuous at $x=0$

3. If $f(x)=\begin{cases}\dfrac{x^2-(a+2)x+2a}{x-2}, & x\neq 2\\ 2, & x=2\end{cases}$ is continuous at $x=2$, then a is equal to

(a) 0 (b) 1 (c) -1 (d) 2

4. If $f(x)=\begin{cases}\dfrac{\log(1+2ax)-\log(1-bx)}{x}, & x\neq 0\\ k, & x=0\end{cases}$ is continuous at $x=0$, then k is equal to

(a) $2a+b$ (b) $2a-b$ (c) $b-2a$ (d) $a+b$

5. If $f(x)=\begin{cases}[x]+[-x], & x\neq 2\\ \lambda, & x=2\end{cases}$ and f is continuous at $x=2$, where $[\cdot]$ denotes greatest integer function, then λ is

(a) -1 (b) 0 (c) 1 (d) 2

Session 2

Continuity in an Interval or Continuity at End Points

Let a function $y = f(x)$ be defined on $[a, b]$. Then,

the function $f(x)$ is said to be continuous at the left end $x = a$

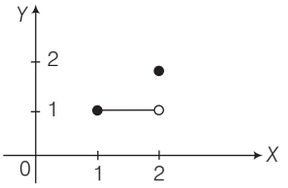
If $f(a) = \lim_{x \to a^+} f(x)$ [need not check LHL]

The function $f(x)$ is said to be continuous at the right end $x = b$

If $f(b) = \lim_{x \to b^-} f(x)$ [need not check RHL]

Example 10 ***If*** $f(x) = [x]$ ***, where*** $[\cdot]$ ***denotes greatest integral function. Then, check the continuity on*** $[1, 2]$**.**

Sol. **Graphically** $f(x) = [x]$ could be plotted as



Here, in the graph $f(x)$ is continuous at all points, where $1 < x < 2$.

To check continuity at $x = 1$ and $x = 2$

(i) **To check continuity at** $x = 1$

Here, $f(1) = 1$ and RHL at $x = 1$

$\Rightarrow \lim_{x \to 1^+} f(x) = 1$, i.e. $f(1) = \lim_{x \to 1^+} f(x)$

Thus, $f(x)$ is continuous at $x = 1$.

(ii) **To check continuity at** $x = 2$

Here, $f(2) = 2$

But LHL at $x = 2 \Rightarrow \lim_{x \to 2^-} f(x) = 1$

which shows $f(2) \neq \lim_{x \to 2^-} f(x)$

Thus, $f(x)$ is discontinuous at $x = 2$.

From the above information, it becomes clear that $f(x)$ is continuous at all points on $[1, 2]$ except at $x = 2$,

i.e. $f(x)$ is continuous for $x \in [1, 2)$.

Exercise for Session 2

1. Let $f(x) = \begin{cases} -2\sin x & \text{for } -\pi \le x \le -\frac{\pi}{2} \\ a\sin x + b & \text{for } -\frac{\pi}{2} < x < \frac{\pi}{2} \\ \cos x & \text{for } \frac{\pi}{2} \le x \le \pi \end{cases}$. If f is continuous on $[-\pi, \pi)$, then find the values of a and b.

2. Draw the graph of the function $f(x) = x - |x - x^2|, -1 \le x \le 1$ and discuss the continuity or discontinuity of f in the interval $-1 \le x \le 1$.

3. Discuss the continuity of 'f' in $[0, 2]$, where $f(x) = \begin{cases} |4x - 5|[x] & \text{for } x > 1 \\ [\cos \pi x] & \text{for } x \le 1 \end{cases}$; where $[x]$ is greatest integer not greater than x.

4. Let $f(x) = \begin{cases} Ax - B, & x \le -1 \\ 2x^2 + 3Ax + B, & x \in (-1, 1] \\ 4, & x > 1 \end{cases}$

Statement I $f(x)$ is continuous at all x, if $A = \frac{3}{4}$ and $B = -\frac{1}{4}$.

Statement II Polynomial function is always continuous.

A. Both Statement I and Statement II are correct and Statement II is the correct explanation of Statement I

B. Both Statement I and Statement II are correct but Statement II is not the correct explanation of Statement I

C. Statement I is correct but Statement II is incorrect

D. Statement II is correct but Statement I is incorrect

(a) A (b) B (c) C (d) D

Session 3

Discontinuity of a Function

A function f which is not continuous, said to be discontinuous functions, i.e. if there is a break in the function of any kind, then it is discontinuous functions.

There are two types of discontinuity

1. Removable discontinuity
2. Non-removable discontinuity

Removable Discontinuity

In this type of discontinuity, $\lim_{x \to a} f(x)$ necessarily exists, but is either not equal to $f(a)$ or $f(a)$ is not defined. Such function is said to have a removable discontinuity of the first kind.

In this case, it is possible to redefine the function in such a manner that $\lim_{x \to a} f(x) = f(a)$ and thus making function continuous.

These discontinuities can be further classified as

(i) Missing point discontinuity

(ii) Isolated point discontinuity

Examples of Missing Point Discontinuity

Here, $\lim_{x \to a} f(x)$ exists finitely but $f(a)$ is not defined. e.g.

(i) Let $f(x) = \dfrac{(x-1)(9-x^2)}{(x-1)}$,

clearly $f(1) \to \dfrac{0}{0}$ form

$\therefore$ $f(x)$ has missing point discontinuity. Shown as,

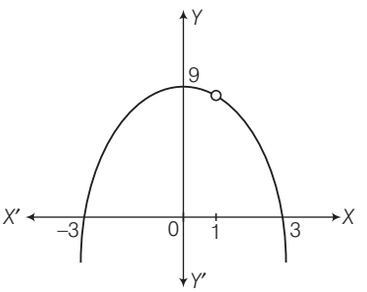


Figure 6.5

(ii) $f(x) = \dfrac{x^2-4}{x-2}$ has missing point discontinuity at $x = 2$.

Shown as,

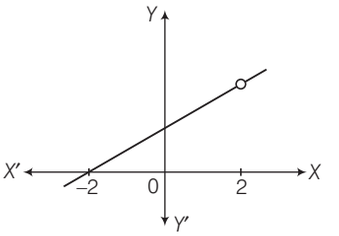

Figure 6.6

(iii) $f(x) = \dfrac{\sin x}{x}$ has missing point discontinuity at $x = 0$.

Shown as,

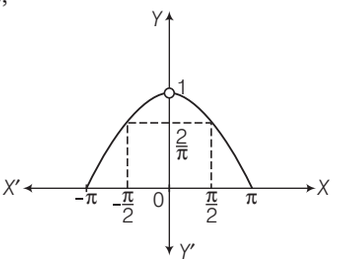

Figure 6.7

Examples of Isolated Point Discontinuity

Here, $\lim_{x \to a} f(x)$ exists and $f(a)$ also exists but $\lim_{x \to a} f(x) \neq f(a)$. e.g.

(i) Let $f(x) = [x] + [-x] \Rightarrow f(x) = \begin{cases} 0, \text{ if } x \in I \\ -1, \text{ if } x \notin I \end{cases}$

where x = Integer, has isolated point discontinuity, can be shown as

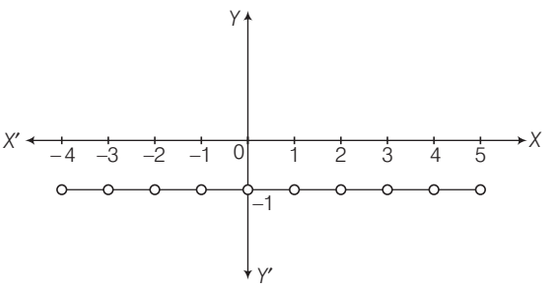

Figure 6.8

(ii) Let $f(x) = \text{sgn}(\cos 2x - 2\sin x + 3)$

$\Rightarrow$ $f(x) = \text{sgn}(1 - 2\sin^2 x - 2\sin x + 3)$

$= \text{sgn}(2(2 + \sin x)(1 - \sin x))$

$$= \begin{cases} 0, \text{ if } x = 2n\pi + \dfrac{\pi}{2} \\ 1, \text{ if } x \neq 2n\pi + \dfrac{\pi}{2} \end{cases}$$

$\therefore f(x)$ has an isolated point discontinuity at $x = 2n\pi + \dfrac{\pi}{2}$.

Shown as,

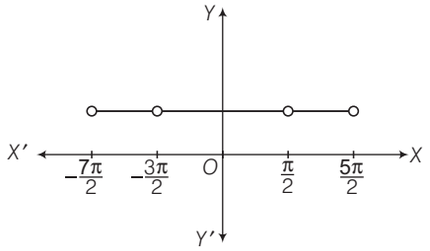

Figure 6.9

Non-removable Discontinuity

In this type of discontinuity $\lim\limits_{x \to a} f(x)$ doesn't exist and therefore, it is not possible to redefine the function in any manner and make it continuous. Such function is said to have non-removable discontinuity or discontinuity of second kind.

Such discontinuities can further be classified into three types.

(i) Finite Discontinuity

If for a function $f(x)$: $\lim\limits_{x \to a^-} f(x) = L_1$ and $\lim\limits_{x \to a^+} f(x) = L_2$ and $L_1 \neq L_2$, then such function is said to have a finite discontinuity or a jump discontinuity.

In this case, the non-negative difference between the two limits is called the **Jump of Discontinuity**. A function having a finite number of jumps in a given interval is called a **Piecewise Continuous** or **Sectionally Continuous Function.**

Examples of Finite Discontinuity

(i) $f(x) \tan^{-1}\left(\dfrac{1}{x}\right)$ at $x = 0$

$$\left.\begin{array}{ll} \text{RHL} & \text{i.e. } f(0^+) = \dfrac{\pi}{2} \\ \text{LHL} & \text{i.e. } f(0^-) = -\dfrac{\pi}{2} \end{array}\right\} \text{jump} = \pi$$

(ii) $f(x) = \dfrac{|\sin x|}{x}$ at $x = 0$

$$\left.\begin{array}{ll} \text{RHL} & \text{i.e. } f(0^+) = 1 \\ \text{LHL} & \text{i.e. } f(0^-) = -1 \end{array}\right\} \text{jump} = 2$$

(ii) Infinite Discontinuity

If for a function $f(x)$: $\lim\limits_{x \to a^-} f(x) = L_1$ and $\lim\limits_{x \to a^+} f(x) = L_2$ and either L_1 or L_2 is infinity, then such function is said to have infinite discontinuity.

In other words, If $x = a$ is a vertical asymptote for the graph of $y = f(x)$, then f is said to have infinite discontinuity at a.

Examples of Infinite Discontinuity

(i) $f(x) = \dfrac{x}{1 - x}$, at $x = 1$

RHL i.e. $f(1^+) = -\infty$

LHL i.e. $f(1^-) = \infty$

(ii) $f(x) = \dfrac{1}{x^2}$, at $x = 0$

RHL i.e. $f(0^+) = \infty$

LHL i.e. $f(0^-) = \infty$

(iii) Oscillatory Discontinuity

If for a function $f(x)$: $\lim\limits_{x \to a} f(x)$ doesn't exist but oscillate between two finite quantities, then such function is said to have oscillatory discontinuity.

Examples of Oscillatory Discontinuity

(i) $f(x) = \sin\left(\dfrac{1}{x}\right)$

$\Rightarrow \lim\limits_{x \to 0} f(x) =$ a value between -1 to 1.

$\therefore$ Limit doesn't exist, as it oscillates between -1 and 1 as $x \to 0$.

(ii) $f(x) = \cos\left(\dfrac{1}{x}\right)$

$\Rightarrow \lim\limits_{x \to 0} \cos\left(\dfrac{1}{x}\right) =$ a value between -1 to 1.

$\therefore$ Limit doesn't exist, as it oscillates between -1 to 1 at $x \to 0$.

List of Continuous Functions

	Function $f(x)$	Interval in which $f(x)$ is continuous
1.	constant c	$(-\infty, \infty)$
2.	x^n, n is an integer ≥ 0	$(-\infty, \infty)$
3.	x^{-n}, n is a positive integer	$(-\infty, \infty)-\{0\}$
4.	$\lvert x-a\rvert$	$(-\infty, \infty)$
5.	$P(x) = a_0x^n + a_1x^{n-1} + \ldots + a_n$	$(-\infty, \infty)$
6.	$\frac{p(x)}{q(x)}$, where $p(x)$ and $q(x)$ are polynomial in x	$(-\infty, \infty)-\{x : q(x) = 0\}$
7.	$\sin x$	$(-\infty, \infty)$
8.	$\cos x$	$(-\infty, \infty)$
9.	$\tan x$	$(-\infty, \infty)-\left\{(2n+1)\frac{\pi}{2} : n \in I\right\}$
10.	$\cot x$	$(-\infty, \infty)-\{n\pi : n \in I\}$
11.	$\sec x$	$(-\infty, \infty)-\{(2n+1)\pi/2 : n \in I\}$
12.	$\operatorname{cosec} x$	$(-\infty, \infty)-\{n\pi : n \in I\}$
13.	e^x	$(-\infty, \infty)$
14.	$\log_e x$	$(0, \infty)$

Example 11 ***Examine the function,*** $f(x)=\begin{cases} x-1, & x<0 \\ 1/4, & x=0 \\ x^2-1, & x>0 \end{cases}$

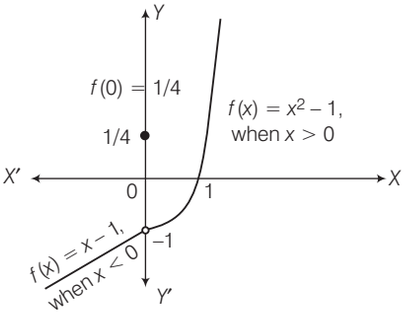
Discuss the continuity and if discontinuous remove the discontinuity.

Sol. $\lim\limits_{x \to 0^-} f(x) = \lim\limits_{x \to 0^+} f(x) = -1$

But $f(0) = 1/4$. Thus, $f(x)$ has removable discontinuity and $f(x)$ could be made continuous by taking

$$f(0) = -1 \Rightarrow f(x) = \begin{cases} x-1, & x<0 \\ -1, & x=0 \\ x^2-1, & x>0 \end{cases}$$

Graphically $f(x)$ could be plotted as showing



Example 12 ***Show the function,*** $f(x)=\begin{cases} \frac{e^{1/x}-1}{e^{1/x}+1}, & \text{when } x \neq 0 \\ 0, & \text{when } x=0 \end{cases}$

has non-removable discontinuity at $x = 0$.

Sol. We have, $f(x)=\begin{cases} \frac{e^{1/x}-1}{e^{1/x}+1}, & \text{when } x \neq 0 \\ 0, & \text{when } x=0 \end{cases}$

$\therefore$ RHL at $x = 0$, let $x = 0 + h$

$$\Rightarrow \lim_{x \to 0^+} f(x) = \lim_{h \to 0} f(0+h) = \lim_{h \to 0} \frac{e^{\frac{1}{0+h}}-1}{e^{\frac{1}{0+h}}+1} = \lim_{h \to 0} \frac{e^{\frac{1}{h}}-1}{e^{\frac{1}{h}}+1}$$

$$\Rightarrow \lim_{x \to 0^+} f(x) = \lim_{h \to 0} \frac{1-\frac{1}{e^{1/h}}}{1+\frac{1}{e^{1/h}}} \quad \Rightarrow \lim_{x \to 0^+} f(x) = \frac{1-0}{1+0} = 1$$

$$[\text{as } h \to 0; \frac{1}{h} \to \infty \Rightarrow e^{1/h} \to \infty; 1/e^{1/h} \to 0]$$

$\therefore \quad \lim\limits_{x \to 0^+} f(x) = 1$

Again, LHL at $x = 0$, let $x = 0 - h$

$$\Rightarrow \lim_{x \to 0^-} f(x) = \lim_{h \to 0} f(0-h)$$

$$= \lim_{h \to 0} \frac{e^{-1/h}-1}{e^{-1/h}+1} = \frac{0-1}{0+1} = -1$$

$$[\text{as } h \to 0; e^{-1/h} \to 0]$$

$$\lim_{x \to 0^-} f(x) = -1$$

$$\Rightarrow \lim_{x \to 0^+} f(x) \neq \lim_{x \to 0^-} f(x).$$

Thus, $f(x)$ has non-removable discontinuity.

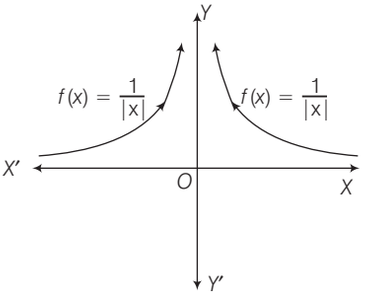
Example 13 ***Show*** $f(x)=\frac{1}{|x|}$ ***has discontinuity of second kind at*** $x = 0$.

Sol. Here, $f(0)=\frac{1}{|0|}$, which shows function has discontinuity of second kind.

Graphically Here, the graph is broken at $x = 0$ as

$$x \to 0$$

$$\Rightarrow \quad f(x) \to \infty$$



Therefore, $f(x)$ has discontinuity of second kind.

Exercise for Session 3

1. Which of the following function(s) has/have removable discontinuity at the origin?

(a) $f(x)=\dfrac{1}{1+2^{\cot x}}$

(b) $f(x)=\cos\left(\dfrac{|\sin x|}{x}\right)$

(c) $f(x)=x\sin\dfrac{\pi}{x}$

(d) $f(x)=\dfrac{1}{\ln|x|}$

2. Function whose jump (non-negative difference of LHL and RHL) of discontinuity is greater than or equal to one. is/are

(a) $f(x)=\begin{cases}\dfrac{(e^{1/x}+1)}{(e^{1/x}-1)}; & x<0\\ \dfrac{(1-\cos x)}{x}; & x>0\end{cases}$

(b) $g(x)=\begin{cases}\dfrac{(x^{1/3}-1)}{(x^{1/2}-1)}; & x>0\\ \dfrac{\ln x}{(x-1)}; & \dfrac{1}{2}<x<1\end{cases}$

(c) $u(x)=\begin{cases}\dfrac{\sin^{-1}2x}{\tan^{-1}3x}; & x\in\left(0,\dfrac{1}{2}\right]\\ \dfrac{|\sin x|}{x}; & x<0\end{cases}$

(d) $v(x)=\begin{cases}\log_3(x+2); & x>2\\ \log_{1/2}(x^2+5); & x<2\end{cases}$

3. Consider the piecewise defined function $f(x)=\begin{cases}\sqrt{-x}, & \text{if } x<0\\ 0, & \text{if } 0\le x\le 4\\ x-4, & \text{if } x>4\end{cases}$, choose the answer which best describes the continuity of this function.

(a) the function is unbounded and therefore cannot be continuous.

(b) the function is right continuous at $x=0$.

(c) the function has a removable discontinuity at 0 and 4, but is continuous on the rest of the real line.

(d) the function is continuous on the entire real line.

4. If $f(x)=\text{sgn}(\cos 2x-2\sin x+3)$, where sgn () is the signum function, then $f(x)$

(a) is continuous over its domain.

(b) has a missing point discontinuity.

(c) has isolated point discontinuity.

(d) has irremovable discontinuity

5. $f(x)=\dfrac{2\cos x-\sin 2x}{(\pi-2x)^2}$; $g(x)=\dfrac{e^{-\cos x}-1}{8x-4\pi}$

$h(x)=f(x)$ for $x<\pi/2=g(x)$ for $x>\pi/2$, then which of the followings does not hold?

(a) h is continuous at $x=\pi/2$

(b) h has an irremovable discontinuity at $x=\pi/2$

(c) h has a removable discontinuity at $x=\pi/2$

(d) $f\left(\dfrac{\pi^+}{2}\right)=g\left(\dfrac{\pi^-}{2}\right)$

Session 4

Theorems Based on Continuity; Continuity of Composite Function

Theorem 1 Sum, difference, product and quotient of two continuous functions is always a continuous function.

However, $h(x)=\dfrac{f(x)}{g(x)}$ is continuous at $x=a$ only if $g(a)\neq 0$.

Theorem 2 If $f(x)$ is continuous and $g(x)$ is discontinuous at $x=a$, then the product function $\phi(x)=f(x)\cdot g(x)$ is not necessarily be discontinuous at $x=a$.

e.g. (i) $f(x)=x$ and $g(x)=\begin{cases}\sin\dfrac{1}{x}, & x\neq 0\\ 0, & x=0\end{cases}$

where $f(x)$ is continuous and $g(x)$ is discontinuous at $x=0$.

But $\phi(x)=f(x)\cdot g(x)=\begin{cases}x\cdot\sin\dfrac{1}{x}, & x\neq 0\\ 0, & x=0\end{cases}$

is continuous at $x=0$.

(ii) $f(x)=\cos(2x-1)\dfrac{\pi}{2}$ is continuous at $x=1$ and $g(x)=[x]$ is discontinuous at $x=1$.

But $\phi(x)=f(x)\cdot g(x)=[x]\cos\left(\dfrac{2x-1}{2}\right)\pi$ is continuous at $x=1$.

Theorem 3 If $f(x)$ and $g(x)$ both are discontinuous at $x=a$, then the product function $\phi(x)=f(x)\cdot g(x)$ is not necessarily be discontinuous at $x=a$.

e.g. $f(x)=\begin{cases}1, & x\geq 0\\ -1, & x<0\end{cases}$ and $g(x)=\begin{cases}-1, & x\geq 0\\ 1, & x<0\end{cases}$

$\therefore\quad \phi(x)=f(x)\cdot g(x)=-1,\forall\, x\in R$

$\phi(x)$ is continuous, where $f(x)$ and $g(x)$ are discontinuous at $x=0$.

Example 14 $f(x)=\begin{cases}\left(\tan\left(\dfrac{\pi}{4}+x\right)\right)^{1/x}, & x\neq 0\\ k, & x=0\end{cases}$.

For what value of k, $f(x)$ ***is continuous at*** $x=0$***?***

Sol. Here, $\lim\limits_{x\to 0} f(x)=\lim\limits_{x\to 0}\left\{\tan\left(\dfrac{\pi}{4}+x\right)\right\}^{1/x}$

$\Rightarrow \lim\limits_{x\to 0} f(x)=\lim\limits_{x\to 0}\left[\dfrac{1+\tan x}{1-\tan x}\right]^{1/x}$ [1^{∞} form]

$\Rightarrow \lim\limits_{x\to 0} f(x)=\lim\limits_{x\to 0}\left[1+\left(\dfrac{1+\tan x}{1-\tan x}-1\right)\right]^{1/x}$

$\Rightarrow \lim\limits_{x\to 0} f(x)=e^{\lim\limits_{x\to 0}\left(\frac{2\tan x}{1-\tan x}\right)\cdot\frac{1}{x}}$

$\Rightarrow \lim\limits_{x\to 0} f(x)=e^{2\lim\limits_{x\to 0}\frac{\tan x}{x(1-\tan x)}}=e^2$

Here, $f(x)$ is continuous at $x=0$, when

$\lim\limits_{x\to 0} f(x)=f(0)$

$\Rightarrow \quad k=e^2$

Example 15 ***A function*** $f(x)$ ***is defined by,***

$$f(x)=\begin{cases}\dfrac{[x^2]-1}{x^2-1}, & \text{for } x^2\neq 1\\ 0, & \text{for } x^2=1\end{cases}$$

Discuss the continuity of $f(x)$ at $x=1$.

Sol. We have, $f(x)=\begin{cases}\dfrac{[x^2]-1}{x^2-1}, & \text{for } x^2\neq 1\\ 0, & \text{for } x^2=1\end{cases}$

$\Rightarrow f(x)=\begin{cases}\dfrac{-1}{x^2-1}, & \text{for } 0<x^2<1\\ 0, & \text{for } x^2=1\\ \dfrac{1-1}{x^2-1}, & \text{for } 1<x^2<2\end{cases}$

$\Rightarrow f(x)=\begin{cases}\dfrac{-1}{x^2-1}, & \text{for } 0<x^2<1\\ 0, & \text{for } x^2=1\\ 0, & \text{for } 1<x^2<2\end{cases}$

$\therefore$ RHL at $x=1$

$\Rightarrow \quad \lim_{x \to 1^+} f(x) = 0$

Also, LHL at $x^2 = 1$

$\Rightarrow \quad \lim_{x \to 1^-} f(x) = \lim_{h \to 0} f(1-h)$

$= \lim_{h \to 0} \frac{-1}{(1-h)^2 - 1} = -\infty$

$\therefore \lim_{x \to 1} f(x)$ doesn't exist. [as RHL $\neq$ LHL]

Hence, $f(x)$ is not continuous at $x = 1$.

Example 16 Discuss the continuity of the function

$$f(x) = \lim_{n \to \infty} \frac{\log(2+x) - x^{2n} \sin x}{1 + x^{2n}} \text{ at } x = 1.$$

Sol. We have, $f(1) = \lim_{n \to \infty} \frac{\log 3 - \sin 1}{2} = \frac{1}{2}(\log 3 - \sin 1)$ ...(i)

We know that, $\lim_{n \to \infty} x^{2n} = \begin{cases} 0, & \text{if } x^2 < 1 \\ \infty, & \text{if } x^2 > 1 \end{cases}$

$\therefore$ For $x^2 < 1$, we have

$$f(x) = \lim_{n \to \infty} \frac{\log(2+x) - x^{2n} \sin x}{1 + x^{2n}} = \log(2+x)$$

Again, for $x^2 > 1$, we have

$$f(x) = \lim_{n \to \infty} \frac{\frac{1}{x^{2n}} \log(2+x) - \sin x}{1 + \frac{1}{x^{2n}}} = -\sin(x)$$

Here, as $x \to 1$

$$\lim_{x \to 1^-} f(x) = \log(3)$$

and $$\lim_{x \to 1^+} f(x) = -\sin(1)$$

So, $$\lim_{x \to 1^-} f(x) \neq \lim_{x \to 1^+} f(x)$$

Therefore, $f(x)$ is not continuous at $x = 1$.

Example 17 Discuss the continuity of $f(x)$, where

$$f(x) = \lim_{n \to \infty} \left(\sin \frac{\pi x}{2} \right)^{2n}.$$

Sol. Since, $\lim_{n \to \infty} x^{2n} = \begin{cases} 0, & |x| < 1 \\ 1, & |x| = 1 \end{cases}$

$\therefore \quad f(x) = \lim_{n \to \infty} \left(\sin\left(\frac{\pi x}{2} \right) \right)^{2n} = \begin{cases} 0, & \left| \sin \frac{\pi x}{2} \right| < 1 \\ 1, & \left| \sin \frac{\pi x}{2} \right| = 1 \end{cases}$

Thus, $f(x)$ is continuous for all x, except for those values of x for which $\left| \sin \frac{\pi x}{2} \right| = 1$, i.e. x is an odd integer.

$\Rightarrow \quad x = (2n+1)$, where $n \in I$

Check continuity at $x = (2n+1)$

LHL $= \lim_{x \to (2n+1)^-} f(x) = 0$ and $f(2n+1) = 1$

Thus, LHL $\neq f(2n+1)$

$\Rightarrow f(x)$ is discontinuous at $x = (2n+1)$ [i.e. at odd integers]

Hence, $f(x)$ is discontinuous at $x = (2n+1)$; $n \in$ integer.

Example 18 ***Let***

$$f(x) = \begin{cases} \{1 + |\sin x|\}^{a/|\sin x|}, & -\pi/6 < x < 0 \\ b, & x = 0 \\ e^{\tan 2x / \tan 3x}, & 0 < x < \pi/6 \end{cases}$$

Determine a and b such that $f(x)$ is continuous at $x = 0$. ***[IIT JEE 1994]***

Sol. Since, f is continuous at $x = 0$.

Therefore, RHL = LHL = $f(0)$

RHL at $x = 0$

$$\lim_{x \to 0^+} f(x) = \lim_{h \to 0} f(0+h) = \lim_{h \to 0} e^{\tan 2h / \tan 3h}$$

$$= \lim_{h \to 0} e^{\frac{\tan 2h}{2h} \cdot \frac{3h}{\tan 3h} \cdot \frac{2}{3}} = e^{2/3} \quad \text{...(i)}$$

Again, LHL at $x = 0$

$$\lim_{x \to 0^-} f(x) = \lim_{h \to 0} f(0-h)$$

$$= \lim_{h \to 0} \{1 + |\sin(0-h)|\}^{a/|\sin(0-h)|}$$

$$= \lim_{h \to 0} \{1 + |\sin h|\}^{\frac{a}{|\sin h|}}$$

$$= e^{\lim_{h \to 0} |\sin h| \cdot \frac{a}{|\sin h|}} = e^a \quad \text{...(ii)}$$

and $f(0) = b$ ...(iii)

Thus, $e^{2/3} = e^a = b \Rightarrow a = 2/3$ and $b = e^{2/3}$

Example 19 Fill in the blanks so that the resulting statement is correct.

Let $f(x) = [x] \sin\left(\frac{\pi}{[x+1]} \right)$, where $[\cdot]$ denotes greatest integral function. The domain of f is ..... and the points of discontinuity of f in the domain are ..... . ***[IIT JEE 1996]***

Sol. Let $f(x) = [x] \sin\left(\frac{\pi}{[x+1]} \right)$

Domain of $f(x)$ is $x \in R$ excluding the points where $[x+1] = 0$ [$\because$ denominator can't be zero]

$\Rightarrow \quad 0 \leq x+1 < 1 \Rightarrow -1 \leq x < 0$

i.e. for all $x \in [-1, 0)$, denominator is zero.

So, domain is $x \in R - [-1, 0)$.

$\Rightarrow$ Domain is $x \in (-\infty, -1) \cup [0, \infty)$

and the internal point discontinuity $\in [-1, 0)$.

Example 20 Let $f(x+y)=f(x)+f(y)$ for all x and y. If the function $f(x)$ is continuous at $x=0$, show that $f(x)$ is continuous for all x.

Sol. As, the function is continuous at $x=0$, we have

$$\lim_{x\to 0^-} f(x)=\lim_{x\to 0^+} f(x)=f(0)$$

$$\Rightarrow \lim_{h\to 0} f(0-h)=\lim_{h\to 0} f(0+h)=f(0)$$

$$\Rightarrow \lim_{h\to 0}\{f(0)+f(-h)\}=\lim_{h\to 0}\{f(0)+f(h)\}=f(0)$$

[using $f(x+y)=f(x)+f(y)$]

$$\Rightarrow \lim_{h\to 0} f(-h)=\lim_{h\to 0} f(h)=0 \quad \ldots(i)$$

Now, consider some arbitrary point $x=a$

$$\text{LHL}=\lim_{h\to 0} f(a-h)=\lim_{h\to 0} f(a)+f(-h)$$

[using $f(x+y)=f(x)+f(y)$]

$$=f(a)+\lim_{h\to 0} f(-h)$$

$$\text{LHL}=f(a)+0=f(a)$$

[as $\lim_{h\to 0} f(-h)=0$, using Eq. (i)]

$$\text{RHL}=\lim_{h\to 0} f(a+h)=\lim_{h\to 0} f(a)+f(h)$$

$$=f(a)+\lim_{h\to 0} f(h)$$

$$\text{RHL}=f(a)+0=f(a)$$

[as $\lim_{h\to 0} f(h)=0$, using Eq. (i)]

At any arbitrary point $(x=a)$,

$$\text{LHL}=\text{RHL}=f(a)$$

Therefore, function is continuous for all values of x, if it is continuous at 0.

Example 21 ***Let $f(x)$ be a continuous function defined for $1\le x\le 3$. If $f(x)$ takes rational values for all x and $f(2)=10$, then find the value of $f(1.5)$.***

[IIT JEE 1997]

Sol. As, $f(x)$ is continuous in [1, 3], $f(x)$ will attain all values between $f(1)$ and $f(3)$. As, $f(x)$ takes rational values for all x and there are innumerable irrational values between $f(1)$ and $f(3)$ which implies that $f(x)$ can take rational values for all x, if $f(x)$ has a constant rational value at all points between $x=1$ and $x=3$.

So, $f(2)=f(1.5)=10$

Continuity of composite function

If the function $u=f(x)$ is continuous at the point $x=a$ and the function $y=g(u)$ is continuous at the point $u=f(a)$, then the composite function $y=(gof)(x)=g(f(x))$ is continuous at the point $x=a$.

Example 22 ***Discuss the continuity for*** $f(x)=\dfrac{1-u^2}{2+u^2}$, where $u=\tan x$.

Sol. Here, $u=\tan x$ is discontinuous at $n\pi\pm\dfrac{\pi}{2}$, $n\in I$

and $f(x)=\dfrac{1-u^2}{2+u^2}$ is continuous at every $u\in R$.

Hence, $f(x)$ is continuous on; $x\in R-\left\{n\pi\pm\dfrac{\pi}{2}, n\in I\right\}$.

Also, $\lim\limits_{x\to n\pi\pm\frac{\pi}{2}} f(x)=\lim\limits_{u^2\to\infty}\dfrac{1-u^2}{2+u^2}$

$$=\lim_{u\to\infty}\frac{\frac{1}{u^2}-1}{\frac{2}{u^2}+1}=-1$$

Hence, the points $n\pi\pm\dfrac{\pi}{2}$, $n\in I$ have removable discontinuity.

i.e. If $f(x)$ is defined as

$$f(x)=\begin{cases}\dfrac{1-u^2}{2+u^2}, & x\ne n\pi\pm\dfrac{\pi}{2} \text{ and } u=\tan x\\ -1, & x=n\pi\pm\dfrac{\pi}{2}\end{cases}$$, then

$f(x)$ is continuous for all $x\in R$.

Example 23 Find the points of discontinuity of $y=\dfrac{1}{u^2+u-2}$, where $u=\dfrac{1}{x-1}$.

Sol. The function $u=f(x)=\dfrac{1}{x-1}$ is discontinuous at the point $x=1$. ...(i)

The function $y=g(x)=\dfrac{1}{u^2+u-2}=\dfrac{1}{(u+2)(u-1)}$ is discontinuous at $u=-2$ and $u=1$.

when $u=-2$, $\dfrac{1}{x-1}=u=-2$

$$\Rightarrow x-1=-\frac{1}{2}$$

$$\Rightarrow x=1/2 \quad \ldots(ii)$$

when $u=1$, $\dfrac{1}{x-1}=u=1$

$$\Rightarrow x-1=1$$

$$\Rightarrow x=2 \quad \ldots(iii)$$

Hence, the composite function $y=g(f(x))$ is discontinuous at three points $x=\dfrac{1}{2}$, 1 and 2.

Exercise for Session 4

1. If $f(x)=\dfrac{1}{x^2-17x+66}$, then $f\left(\dfrac{2}{x-2}\right)$ is discontinuous at $x=$

(a) 2 (b) $\dfrac{7}{3}$ (c) $\dfrac{24}{11}$ (d) 6, 11

2. Let f be a continuous function on R.

If $f(1/4^n)=(\sin e^n)\,e^{-n^2}+\dfrac{n^2}{n^2+1}$, then $f(0)$ is

(a) not unique (b) 1

(c) data sufficient to find $f(0)$ (d) data insufficient to find $f(0)$

3. $f(x)$ is continuous at $x=0$, then which of the following are always true?

(a) $\lim\limits_{x\to 0} f(x)=0$

(b) $f(x)$ is non continuous at $x=1$

(c) $g(x)=x^2f(x)$ is continuous at $x=0$

(d) $\lim\limits_{x\to 0^+}(f(x)-f(0))=0$

4. If $f(x)=\cos\left[\dfrac{\pi}{x}\right]\cos\left(\dfrac{\pi}{2}(x-1)\right)$; where $[x]$ is the greatest integer function of x, then $f(x)$ is continuous at

(a) $x=0$ (b) $x=1$

(c) $x=2$ (d) None of these

5. Let $f(x)=[x]$ and $g(x)=\begin{cases}0, & x\in Z\\ x^2, & x\in R-Z\end{cases}$, then (where [.] denotes greatest integer function)

(a) $\lim\limits_{x\to 1} g(x)$ exists, but $g(x)$ is not continuous at $x=1$

(b) $\lim\limits_{x\to 1} f(x)$ does not exist and $f(x)$ is not continuous at $x=1$

(c) *gof* is continuous for all x

(d) *fog* is continuous for all x

6. Let $f(x)=\begin{cases}a\sin^{2n}x, & \text{for } x\geq 0 \text{ and } n\to\infty\\ b\cos^{2m}x-1, & \text{for } x<0 \text{ and } m\to\infty\end{cases}$, then

(a) $f(0^-)\neq f(0^+)$ (b) $f(0^+)\neq f(0)$

(c) $f(0^-)=f(0)$ (d) f is continuous at $x=0$

7. Consider $f(x)=\lim\limits_{n\to\infty}\dfrac{x^{n`}-\sin x^n}{x^n+\sin x^n}$ for $x>0, x\neq 1, f(1)=0$, then

(a) f is continuous at $x=1$

(b) f has a finite discontinuity at $x=1$

(c) f has an infinite or oscillatory discontinuity at $x=1$

(d) f has a removal type of discontinuity at $x=1$

Session 5

Intermediate Value Theorem

If $f(x)$ is continuous in $[a, b]$ and $f(a) \neq f(b)$, then for any value $c \in (f(a), f(b))$, there is atleast one number x_0 in (a, b) for which $f(x_0) = c$.

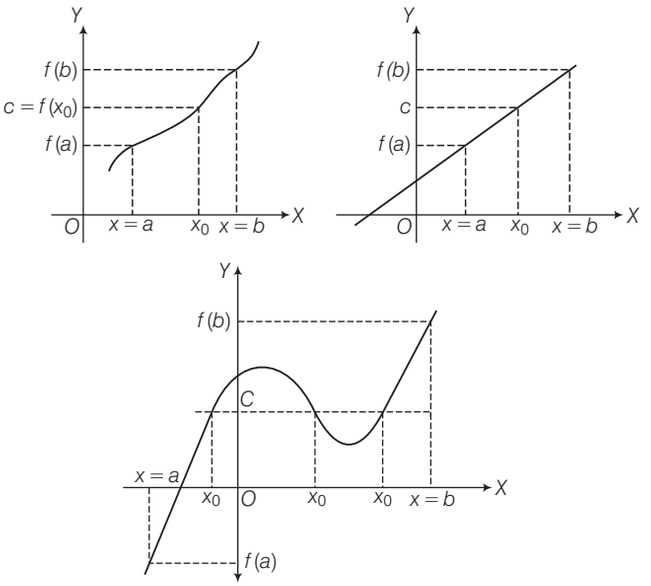


Figure 6.10

Example 24 Show that the function $f(x) = (x-a)^2 (x-b)^2 + x$ takes the value $\frac{a+b}{2}$ for some value of $x \in [a, b]$.

Sol. Here, $f(a) = a$ and $f(b) = b$

Also, $f(x)$ is continuous in $[a, b]$ and $\frac{a+b}{2} \in [a, b]$.

Therefore, using intermediate value theorem, there exists some $c \in [a, b]$, such that

$$f(c) = \frac{a+b}{2}$$

Example 25 ***Suppose that*** $f(x)$ ***is continuous in [0, 1] and*** $f(0) = 0, f(1) = 0$. ***Prove that*** $f(c) = 1 - 2c^2$ ***for some*** $c \in (0, 1)$.

Sol. Let $g(x) = f(x) + 2x^2 - 1$ in $[0, 1]$, $g(0) = -1, g(1) = 1$

$\therefore$ By intermediate value theorem, there exists some

$$c \in (0, 1); g(c) = 0 \Rightarrow f(c) = 1 - 2c^2$$

Continuity for Rational and Irrational Function

Functions should be continuous only at one point and to be defined everywhere. [Single Point Continuity]

e.g.

(i) $f(x) = \begin{cases} x, & \text{if } x \in Q \\ 0, & \text{if } x \notin Q \end{cases}$, is continuous only at $x = 0$.

(ii) $f(x) = \begin{cases} x, & \text{if } x \in Q \\ -x, & \text{if } x \notin Q \end{cases}$, is continuous only at $x = 0$ and defined everywhere.

(iii) $f(x) = \begin{cases} x, & \text{if } x \in Q \\ 1-x, & \text{if } x \notin Q \end{cases}$, is continuous only at $x = \frac{1}{2}$ and defined everywhere.

(iv) $f(x) = \begin{cases} x^2, & \text{if } x \in Q \\ 1, & \text{if } x \notin Q \end{cases}$, is continuous only at $x = 1$ or $x = -1$ and defined everywhere.

Exercise for Session 5

1. Examine the continuity at $x = 0$ of the sum function of the infinite series $\frac{x}{x+1} + \frac{x}{(x+1)(2x+1)} + \frac{x}{(2x+1)(3x+1)} + \ldots \infty$

2. If $g : [a, b]$ onto $[a, b]$ is continuous, then show that there is some $c \in [a, b]$ such that $g(c) = c$.

3. Show that (a) a polynomial of an odd degree has atleast one real root.

(b) a polynomial of an even degree has atleast two real roots, if it attains atleast one value opposite in sign to the coefficient of its highest-degree term.

4. Let $y_n(x) = x^2 + \frac{x^2}{1+x^2} + \frac{x^2}{(1+x^2)^2} + \ldots + \frac{x^2}{(1+x^2)^{n-1}}$ and $y(x) = \lim_{n \to \infty} y_n(x)$. Discuss the continuity of $y_n(x)\,(n = 1, 2, 3, \ldots n)$ and $y(x)$ at $x = 0$.

Session 6

Differentiability : Meaning of Derivative

The instantaneous rate of change of function with respect to the independent variable is called derivative. Let $f(x)$ be a given function of one variable and Δx denotes a number (positive or negative) to be added to the number x.

Let Δf denotes the corresponding change of f, then $\Delta f = f(x+\Delta x) - f(x)$.

$$\frac{\Delta f}{\Delta x} = \frac{f(x+\Delta x) - f(x)}{\Delta x}$$

If $\frac{\Delta f}{\Delta x}$ approaches a limit as Δx approaches to zero, this limit is the derivative of f at the point x. The derivative of a function f is denoted by symbols such as $f'(x)$, $\frac{df}{dx}$, $\frac{d}{dx} f(x)$ or $\frac{d\,f(x)}{dx}$.

$$\Rightarrow \quad \frac{df}{dx} = \lim_{\Delta x \to 0} \frac{\Delta f}{\Delta x} = \lim_{\Delta x \to 0} \frac{f(x+\Delta x) - f(x)}{\Delta x}$$

The derivative evaluated at a point a is written,

$$f'(a), \left(\frac{d\,f(x)}{dx}\right)_{x=a}, (f'(x))_{x=a} \text{ etc.}$$

Existence of Derivative at $x = a$

The derivative of a function $f(x)$ exists at $x = a$, if

$$\lim_{x \to a} \frac{f(x) - f(a)}{(x-a)} \text{ exists finitely.}$$

or $$\lim_{x \to a^-} \frac{f(x) - f(a)}{(x-a)} = \lim_{x \to a^+} \frac{f(x) - f(a)}{(x-a)}$$

or $$\lim_{h \to 0} \frac{f(a-h) - f(a)}{-h} = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$$

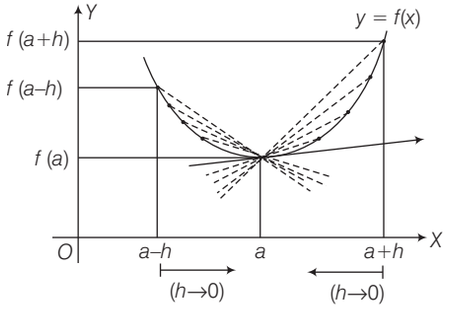

Figure 6.11

(a) **Right hand derivative** The right hand derivative of $f(x)$ at $x = a$ denoted by $f(a^+)$ is defined as

$f'(a^+) = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$, provided the limit exists and is finite $(h > 0)$.

(b) **Left hand derivative** The left hand derivative of $f(x)$ at $x = a$ denoted by $f(a^-)$ is defined as

$f'(a^-) = \lim_{h \to 0} \frac{f(a-h) - f(a)}{-h}$, provided the limit exists and is finite $(h > 0)$.

Hence, $f(x)$ is said to be derivable or differentiable at $x = a$.

If $f'(a^+) = f'(a^-) =$ finite quantity and it is denoted by $f'(a)$; where $f'(a) = f'(a^-) = f'(a^+)$ and it is called derivative or differential coefficient of $f(x)$ at $x = a$.

Relation between Continuity and Differentiability

If a function is differentiable at a point, then it should be continuous at that point as well and a discontinuous function cannot be differentiable. This fact is proved in the following theorem.

Theorem If a function is differentiable at a point, it is necessarily continuous at that point. But the converse is not necessarily true.

Or

$f(x)$ is differentiable at $x = c \Rightarrow f(x)$ is continuous at $x = c$.

Proof Let a function $f(x)$ be differentiable at $x = c$.

Then, $\lim_{x \to c} \frac{f(x) - f(c)}{x - c}$ exists finitely.

Let $$\lim_{x \to c} \frac{f(x) - f(c)}{x - c} = f'(c) \qquad \ldots(i)$$

In order to prove that $f(x)$ is continuous at $x = c$, it is sufficient to show that $\lim_{x \to c} f(x) = f(c)$.

Now, $$\lim_{x \to c} f(x) = \lim_{x \to c} \left[\left(\frac{f(x) - f(c)}{x - c}\right)(x - c) + f(c)\right]$$

$$= \lim_{x \to c} \left[\left\{ \frac{f(x) - f(c)}{x - c} \right\} \cdot (x - c) \right] + f(c)$$

$$= \lim_{x \to c} \frac{f(x) - f(c)}{x - c} \cdot \lim_{x \to c} (x - c) + f(c)$$

$$= f'(c) \times 0 + f(c)$$

$$= f(c)$$

Hence, $f(x)$ is continuous at $x = c$.

Converse The converse of above theorem is not necessarily true, i.e. a function may be continuous at a point but may not be differentiable at that point.
e.g. The function $f(x) = |x|$ is continuous at $x = 0$ but it is not differentiable at $x = 0$, as shown by figure.

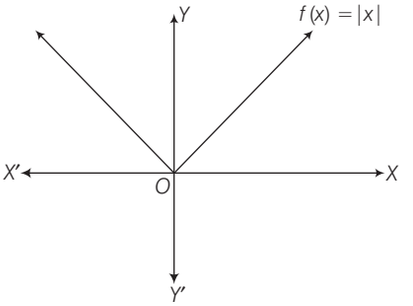

Figure 6.12

Which shows we have sharp edge at $x = 0$, hence not differentiable but continuous at $x = 0$.

Example 26 ***Show that*** $f(x) = \begin{cases} x \sin \dfrac{1}{x}, & \text{when } x \neq 0 \\ 0, & \text{when } x = 0 \end{cases}$

is continuous but not differentiable at $x = 0$.

Sol. (a) **To check continuity at $x = 0$**

Here, $f(0) = 0$

Also, $\lim_{x \to 0} f(x) = \lim_{x \to 0} x \sin \dfrac{1}{x}$

$= 0 \times$ (A finite quantity that lies between −1 to +1)

$=0$ [as $n \to 0$, $\sin \dfrac{1}{x} \to \sin \infty$, which is a finite quantity between −1 to +1]

$\therefore \lim_{x \to 0} f(x) = f(0)$ and hence, $f(x)$ is continuous.

Now,

(b) **To check differentiability at $x = 0$**

(LHD at $x = 0$)

$$= \lim_{x \to 0^-} \frac{f(x) - f(0)}{x - 0}$$

$$= \lim_{h \to 0} \frac{f(0 - h) - f(0)}{(0 - h) - (0)}$$

$$= \lim_{h \to 0} \frac{-h \sin(-1/h)}{(-h)}$$

$$= -\lim_{h \to 0} \sin\left(\frac{1}{h}\right)$$

[a number which oscillates between −1 and +1]

$\therefore$ (LHD at $x = 0$) doesn't exist.

Similarly, it could be shown that RHD at $x = 0$ doesn't exist.

Hence, $f(x)$ is continuous but not differentiable.

Example 27 ***Let*** $f(x) = \begin{cases} x \exp\left[-\left(\dfrac{1}{|x|} + \dfrac{1}{x} \right) \right], & x \neq 0 \\ 0, & x = 0 \end{cases}$

Test whether (a) $f(x)$ ***is continuous at*** $x = 0$

(b) $f(x)$ ***is differentiable at*** $x = 0$.

[IIT JEE 1997]

Sol. Here, $f(x) = \begin{cases} x \exp\left[-\left(\dfrac{1}{|x|} + \dfrac{1}{x} \right) \right], & x \neq 0 \\ 0, & x = 0 \end{cases}$

$$\Rightarrow \quad f(x) = \begin{cases} xe^{-\left\{\frac{1}{x} + \frac{1}{x}\right\}}, & x > 0 \\ xe^{-\left\{\frac{1}{-x} + \frac{1}{x}\right\}}, & x < 0 \\ 0, & x = 0 \end{cases} \qquad \left[\because |x| = \begin{cases} x, & x \geq 0 \\ -x, & x < 0 \end{cases} \right]$$

$$\Rightarrow \quad f(x) = \begin{cases} xe^{-2/x}, & x > 0 \\ x, & x < 0 \\ 0, & x = 0 \end{cases} \qquad \ldots(i)$$

(a) **To check continuity of $f(x)$ at $x = 0$**

$$\text{LHL} = \lim_{x \to 0^-} f(x) = \lim_{x \to 0^-} x$$

$$= \lim_{h \to 0} (0 - h) = 0$$

$$\text{RHL} = \lim_{x \to 0^+} f(x) = \lim_{x \to 0^+} xe^{-2/x}$$

$$= \lim_{h \to 0} \frac{h}{e^{2/h}} = 0, \; f(0) = 0$$

$\therefore f(x)$ is continuous at $x = 0$.

(b) **To check differentiability at $x = 0$**

$$\text{LHD} = Lf'(0) = \lim_{h \to 0} \frac{f(0 - h) - f(0)}{-h}, h > 0$$

$$= \lim_{h \to 0} \frac{(-h) - 0}{-h} = 1$$

$$\text{RHD} = Rf'(0) = \lim_{h \to 0} \frac{f(0+h) - f(0)}{h}$$

$$= \lim_{h \to 0} \frac{he^{\frac{-2}{h}} - 0}{h} = \lim_{h \to 0} e^{\frac{-2}{h}}$$

$$= e^{-\infty} = 0$$

$\therefore \quad Lf'(0) \neq Rf'(0)$

Therefore, $f(x)$ is not differentiable at $x = 0$.

Some Standard Results on Differentiability

Functions $f(x)$	Intervals in which $f(x)$ is differentiable
1. Polynomial	$(-\infty$ to $\infty)$
2. Exponential $(a^x, a > 0)$	$(-\infty$ to $\infty)$
3. Constant	$(-\infty$ to $\infty)$
4. Logarithmic	Each point in its domain
5. Trigonometric	Each point in its domain
6. Inverse trigonometric	Each point in its domain

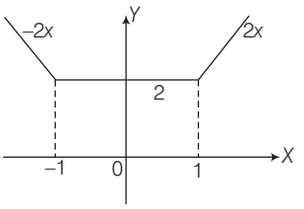
Example 28 Let $f(x) = |x-1| + |x+1|$. Discuss the continuity and differentiability of the function.

Sol. Here, $f(x) = |x-1| + |x+1|$

$$\Rightarrow \quad f(x) = \begin{cases} (x-1)+(x+1), & \text{when} \quad x > 1 \\ -(x-1)+(x+1), & \text{when} \quad -1 \le x \le 1 \\ -(x-1)-(x+1), & \text{when} \quad x < -1 \end{cases}$$

$$\Rightarrow \quad f(x) = \begin{cases} 2x, & \text{when} \quad x > 1 \\ 2, & \text{when} \quad -1 \le x \le 1 \\ -2x, & \text{when} \quad x < -1 \end{cases}$$

Graphically The graph of the function is shown below.



From the graph, it is clear that the function is continuous at all real x, also differentiable at all real x except at $x = \pm 1$. Since, it has sharp edges at $x = -1$ and $x = 1$.

At $x = 1$ we see that the slope from the right, i.e. RHD = 2, while slope from the left, i.e. LHD = 0.

Similarly, at $x = -1$ it is clear that RHD = 0, while LHD = -2

Aliter In this method, first of all we differentiate the function and from the derivative equality sign should be removed from doubtful points.

Here, $f'(x) = \begin{cases} -2, & x < -1 \\ 0, & -1 < x < 1 \\ 2, & x > 1 \end{cases}$ [no equality on -1 and $+1$]

Now, at $x = 1$, $f'(1^+) = 2$, while $f'(1^-) = 0$ and

at $x = -1$, $f'(-1^+) = 0$, while $f'(-1^-) = -2$

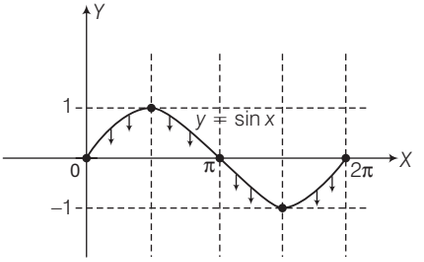
Thus, $f(x)$ is not differentiable at $x = \pm 1$.

Remark

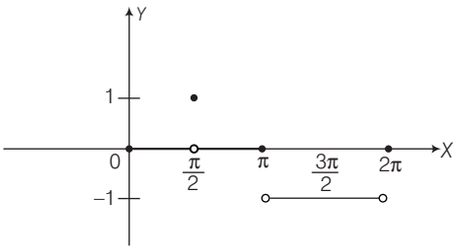
This method is not applicable when function is discontinuous.

Example 29 ***Discuss the continuity and differentiability for*** $f(x) = [\sin x]$ ***when*** $x \in [0, 2\pi]$***; where*** $[\cdot]$ ***denotes the greatest integer function*** x***.***

Sol. In last chapter, we have discussed the plotting of curves, so $y = [\sin x]$ could be plotted as



Or



which shows $f(x) = [\sin x]$ is discontinuous for $x = \frac{\pi}{2}, \pi, 2\pi$, when $x \in [0, 2\pi]$ and $f(x)$ is not differentiable at $x = \frac{\pi}{2}, \pi, 2\pi$.

As we know, function is neither differentiable nor continuous at those points for which graph is broken.

Example 30 *If* $f(x)=\{|x|-|x-1|\}^2$, *draw the graph of* $f(x)$ *and discuss its continuity and differentiability of* $f(x)$.

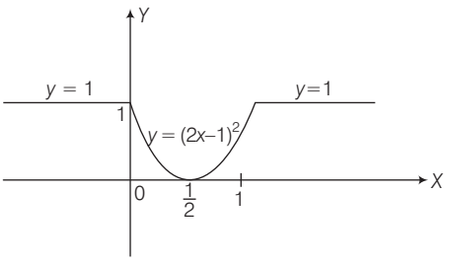
Sol. We know, $|x|-|x-1|=\begin{cases}-x+x-1, & x<0\\ x+x-1, & 0\le x<1\\ x-(x-1), & 1\le x\end{cases}$

$$\Rightarrow \quad |x|-|x-1|=\begin{cases}-1, & x<0\\ 2x-1, & 0\le x<1\\ 1, & 1\le x\end{cases}$$

$$\therefore \quad f(x)=\{|x|-|x-1|\}^2$$

$$=\begin{cases}1, \text{ when } x<0 \text{ or } x\ge 1\\ (2x-1)^2, \text{ when } 0\le x<1\end{cases}$$

Graphically $f(x)$ could be shown as



From above figure, it is clear that $f(x)$ is continuous for $x\in R$; but $f(x)$ is not differentiable at $x=0, 1$.

$\Rightarrow$ $f(x)$ is continuous for all $x\in R$.

$\Rightarrow$ $f(x)$ is differentiable for all $x\in R-\{0,1\}$.

Example 31 *If* $f(x)=\begin{cases}x-3, & x<0\\ x^2-3x+2, & x\ge 0\end{cases}$ *and let* $g(x)=f(|x|)+|f(x)|$. *Discuss the differentiability of* $g(x)$.

Sol. $f(|x|)=\begin{cases}|x|-3, & |x|<0\\ |x|^2-3|x|+2, & |x|\ge 0\end{cases}$

Where, $|x|<0$ is not possible, thus neglecting, we get

$$f(|x|)=\{|x|^2-3|x|+2, \quad |x|\ge 0$$

$$f(|x|)=\begin{cases}x^2+3x+2, & x<0\\ x^2-3x+2, & x\ge 0\end{cases} \qquad \ldots(i)$$

Again, $|f(x)|=\begin{cases}|x-3|, & x<0\\ |x^2-3x+2|, & x\ge 0\end{cases}$

$$|f(x)|=\begin{cases}(3-x), & x<0\\ (x^2-3x+2), & 0\le x<1\\ -(x^2-3x+2), & 1\le x<2\\ (x^2-3x+2), & 2\le x\end{cases} \qquad \ldots(ii)$$

Now, from Eqs. (i) and (ii), $g(x)=f(|x|)+|f(x)|$

$$g(x)=\begin{cases}x^2+2x+5, & x<0\\ 2x^2-6x+4, & 0\le x<1\\ 0, & 1\le x<2\\ 2x^2-6x+4, & x\ge 2\end{cases}$$

and $g'(x)=\begin{cases}2x+2, & x<0\\ 4x-6, & 0<x<1\\ 0, & 1<x<2\\ 4x-6, & x>2\end{cases}$

Therefore, $g(x)$ is continuous in $R-\{0\}$ and $g(x)$ is differentiable in $R-\{0,1,2\}$.

Example 32 *Let* $f(x)=[n+p\sin x], x\in(0,\pi), n\in Z$ *and* p *is a prime number, where* $[\cdot]$ *denotes the greatest integer function. Then, find the number of points, where* $f(x)$ *is not differentiable.*

Sol. Here, $f(x)=[n+p\sin x]$ is not differentiable at those points where $n+p\sin x$ is an integer.

As, p is a prime number.

$\Rightarrow$ $n+p\sin x$ is an integer if $\sin x=1, -1, r/p$

i.e. $x=\frac{\pi}{2}, -\frac{\pi}{2}, \sin^{-1}\frac{r}{p}, \pi-\sin^{-1}\frac{r}{p}$

where $0\le r\le p-1$

But $x\ne -\frac{\pi}{2}, 0$

$\therefore$ Function is not differentiable at

$$x=\frac{\pi}{2}, \sin^{-1}\frac{r}{p}, \pi-\sin^{-1}\frac{r}{p}$$

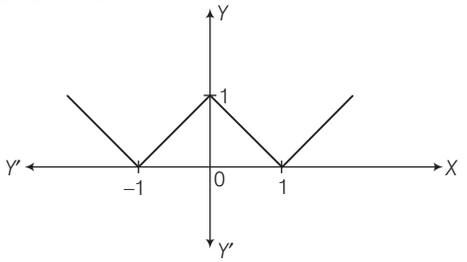
where $0<r\le p-1$

So, the required number of points are

$$=1+2(p-1)=2p-1.$$

Example 33 *If* $f(x)=||x|-1|$, *then draw the graph of* $f(x)$ *and* $fof(x)$ *and also discuss their continuity and differentiability. Also, find derivative of* $(fof)^2$ *at* $x=\frac{3}{2}$.

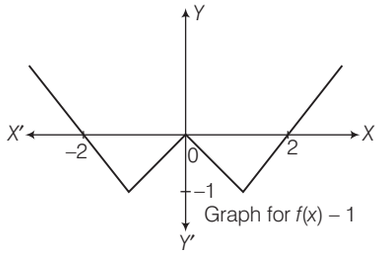
Sol. The graph of $f(x)$ is shown as



It is clear from the graph that, $f(x)$ is continuous for all x, but $f(x)$ is not differentiable at $x = \{-1, 0, 1\}$.

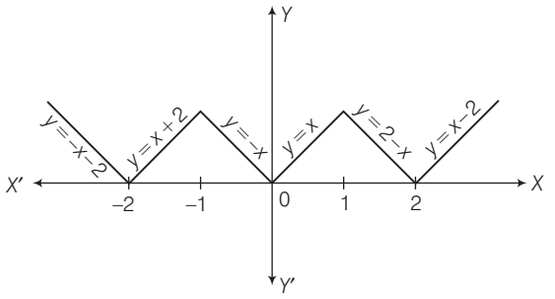
Now, $fof(x) = ||f(x)| - 1| = |f(x) - 1|$ [as $f(x) \geq 0$ for all x]

Now, if $f(x) \to f(x) - 1$, shift the graph one unit below the X-axis, i.e., as shown;



Thus, for graph of $fof(x) = |f(x) - 1|$ is taking image of the graph of $f(x) - 1$ below X-axis and leaving the portion above Y-axis as it is.

$\therefore$ Graph for $fof(x)$ is shown as



which is clearly continuous for all $x \in R$, but not differentiable at $x = \{-2, -1, 0, 1, 2\}$.

Also, $fof(x) = 2 - x, 1 \leq x \leq 2$

$\therefore$ $(fof)^2 = (2 - x)^2$, when $1 \leq x \leq 2$

$\Rightarrow$ $\dfrac{d}{dx}(fof)^2 = 2(2 - x)(-1)$, when $1 \leq x \leq 2$

$\therefore$ $\dfrac{d}{dx}(fof)^2$ (when $x = 3/2$) $= -2(2 - 3/2) = -1$

$\Rightarrow$ $\dfrac{d}{dx}\{(fof)^2\}_{\text{at } x = 3/2} = -1$

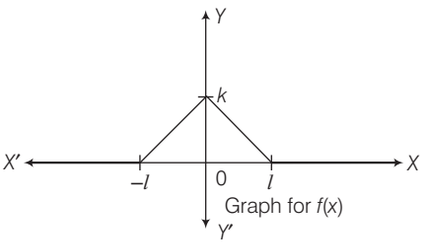
Example 34 Draw the graph of the function $g(x) = f(x + l) + f(x - l)$, where

$$f(x) = \begin{cases} k\left\{1 - \dfrac{|x|}{l}\right\}, & \text{for } |x| \leq l \\ 0, & \text{for } |x| > l \end{cases}$$

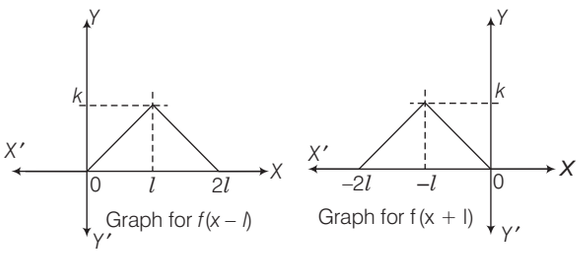
Also, discuss the continuity and differentiability of the function $g(x)$.

Sol. We have, $f(x) = \begin{cases} k\left(1 - \dfrac{|x|}{l}\right), & |x| \leq l \\ 0, & |x| > l \end{cases}$

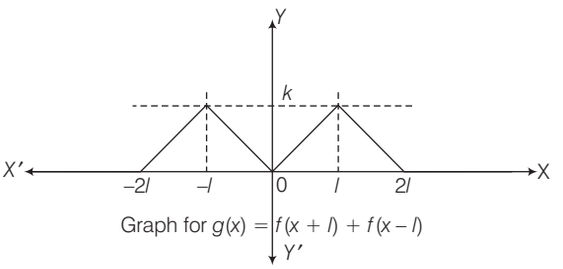
The graph of $f(x)$ is shown as



Now, to plot $g(x) = f(x + l) + f(x - l)$, we shall first plot the graphs of $f(x + l)$ and $f(x - l)$ which are given as



Thus, the graph of $g(x) = f(x + l) + f(x - l)$ is obtained by adding graph of $f(x + l)$ and $f(x - l)$ as



From the above figure, $g(x)$ is continuous for all $x \in R$ and $g(x)$ is differentiable for all $x \in R - \{\pm 2l, \pm l, 0\}$.

Example 35 Let $f(x)=\begin{cases}\int_0^x\{5+|1-t|\}dt, & \text{if } x>2\\ 5x+1, & \text{if } x\le 2\end{cases}$.

Test $f(x)$ for continuity and differentiability for all real x.

Sol. Here, $f(x)$ for $x>2$.

$$f(x)=\int_0^x\{5+|1-t|\}dt$$

$$=\int_0^1(5+1-t)dt+\int_1^x(5+t-1)dt \quad [\text{since } x>2]$$

$$=\left(6t-\frac{t^2}{2}\right)_0^1+\left(4t+\frac{t^2}{2}\right)_1^x.$$

$$=6-\frac{1}{2}+4x+\frac{x^2}{2}-4-\frac{1}{2}$$

$$=1+4x+\frac{x^2}{2}$$

$$\therefore \quad f(x)=\begin{cases}1+4x+x^2/2, & \text{if } x>2\\ 5x+1, & \text{if } x\le 2\end{cases}$$

$\therefore$ RHL (at $x=2$)

$$=\lim_{h\to 0}\left\{1+4(2+h)+\frac{(2+h)^2}{2}\right\}$$

$$=1+8+2=11$$

and LHL (at $x=2$) $=\lim_{h\to 0}\{5(2-h)+1\}$

$$=10+1=11$$

$\therefore$ $f(x)$ is continuous at $x=2$. [as $f(2)=11$]

Also, RHD (at $x=2$)

$$Rf'(2)=\lim_{h\to 0}\frac{f(2+h)-f(2)}{h}$$

$$=\lim_{h\to 0}\frac{1+4(2+h)+\frac{(2+h)^2}{2}-11}{h}$$

$$=\lim_{h\to 0}\frac{11+6h+\frac{h^2}{2}-11}{h}=6$$

LHD (at $x=2$)

$$Lf'(2)=\lim_{h\to 0}\frac{f(2-h)-f(2)}{-h}$$

$$=\lim_{h\to 0}\frac{5(2-h)+1-11}{-h}$$

$$=\lim_{h\to 0}\frac{11-5h-11}{-h}=5$$

$\therefore$ $f(x)$ is not differentiable at $x=2$.

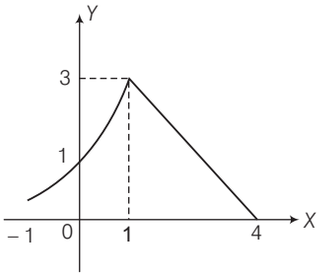
Thus, $f(x)$ is continuous for all $x\in R$ and differentiable for all $x\in R-\{2\}$.

Example 36 Draw the graph of the function and discuss the continuity and differentiability at $x=1$ for,

$$f(x)=\begin{cases}3^x, & \text{when } -1\le x\le 1\\ 4-x, & \text{when } 1<x<4\end{cases}$$

Sol. Here, $f(x)=\begin{cases}3^x, & \text{when } -1\le x\le 1\\ 4-x, & \text{when } 1<x<4\end{cases}$

is shown below graphically.



From the graph, it is clear that it is continuous for all x in $[-1, 4)$ and not differentiable at $x=1$.

Because at $x=1$, LHD >0, while RHD <0

Mathematically,

$$\text{RHD}=\lim_{h\to 0}\frac{f(1+h)-f(1)}{h}$$

$$=\lim_{h\to 0}\frac{4-(1+h)-3}{h}=-1$$

$$\text{LHD}=\lim_{h\to 0}\frac{f(1-h)-f(1)}{-h}$$

$$=\lim_{h\to 0}\frac{3^{(1-h)}-3}{-h}=\lim_{h\to 0}3\left(\frac{3^{-h}-1}{-h}\right)$$

$$=3\log_e 3$$

Since, LHD $\neq$ RHD, $f(x)$ is not differentiable at $x=1$.

But $f(x)$ is continuous at $x=1$, because the derivatives from both the sides are finite and definite.

Aliter

The given function is continuous.

Hence, $$f'(x)=\begin{cases}3^x\log 3, & -1\le x<1\\ -1, & 1<x<4\end{cases}$$

Here, $$f'(1^+)=-1$$

and $$f'(1^-)=\lim_{x\to 1^-}3^x\log 3=3\log 3$$

which shows, $$f'(1^+)\neq f'(1^-)$$

Therefore, $f(x)$ is not differentiable at $x=1$.

Example 37 Match the column I with column II.

	Column I		Column II
(i)	$\sin(\pi[x])$	(A)	differentiable everywhere
(ii)	$\sin\{(x-[x])\pi\}$	(B)	nowhere differentiable
		(C)	not differentiable at -1 and $+1$

where [ ] denotes greatest integral function. ***[IIT JEE 1992]***

Sol. (i) We know, $[x] \in I, \forall\ x \in R$

$\therefore\ \sin(\pi[x]) = \sin(I\pi) = 0, \forall\ x \in R$

By theory, we know that every constant function is differentiable in its domain.

Thus, $\sin(\pi[x])$ is differentiable everywhere.

Hence, (i) $\leftrightarrow$ (A)

(ii) Again, $f(x) = \sin\{(x-[x])\pi\}$

Here, we know $x - [x] = \{x\}$,

then $\pi(x-[x]) = \pi\{x\}$

which is not differentiable at integral points.

$\therefore\ f(x) = \sin\{\pi(x-[x])\}$ is not differentiable at $x \in I$. [integers]

Hence, (ii) $\leftrightarrow$ (C)

Example 38 Fill in the blank, in the statement given below.

Let $f(x) = x|x|$. The set of points, where $f(x)$ is twice differentiable is ..... . ***[IIT JEE 1992]***

Sol. The function $f(x) = x|x|$ can be written as,

$$f(x) = \begin{cases} x(x), & \text{if } x \geq 0 \\ x(-x), & \text{if } x < 0 \end{cases}$$

$$\Rightarrow \quad f(x) = \begin{cases} x^2, & \text{if } x \geq 0 \\ -(x)^2, & \text{if } x < 0 \end{cases}$$

$f(x)$ is differentiable, $\forall\ x \in R$.

Again, $$f'(x) = \begin{cases} 2x, & \text{if } x > 0 \\ -2x, & \text{if } x < 0 \end{cases}$$

$$f''(x) = \begin{cases} 2, & \text{if } x > 0 \\ -2, & \text{if } x < 0 \end{cases}$$

Here, $f''(x)$ is discontinuous at $x = 0$

$\therefore\ f''(x)$ is not differentiable at $x = 0$.

Hence, $f(x)$ is twice differentiable, $\forall\ x \in R - \{0\}$.

Example 39 The function $f(x) = (x^2-1)|x^2-3x+2| + \cos(|x|)$ is not differentiable at

(a) -1 (b) 0 (c) 1 (d) 2

[IIT JEE 1992]

Sol. The function $f(x) = (x^2-1)|x^2-3x+2| + \cos(|x|)$ ...(i)

Here, $|x|$ is not differentiable at $x = 0$, but

$$\cos(|x|) = \begin{cases} \cos(-x), & x < 0 \\ \cos(x), & x \geq 0 \end{cases}$$

$$\Rightarrow \quad \cos(|x|) = \begin{cases} \cos(x), & x \geq 0 \\ \cos(x), & x < 0 \end{cases}$$

$\therefore\ \cos(|x|)$ is differentiable at $x = 0$ ...(ii)

Again, $|x^2-3x+2| = |(x-1)(x-2)|$

$$= \begin{cases} (x-1)(x-2), & \text{if } x < 1 \\ -(x-1)(x-2), & \text{if } 1 \leq x < 2 \\ (x-1)(x-2), & \text{if } x \geq 2 \end{cases} \quad \text{...(iii)}$$

So, $$f(x) = \begin{cases} (x^2-1)(x-1)(x-2)+\cos x, & \text{if } -\infty < x < 1 \\ -(x^2-1)(x-1)(x-2)+\cos x, & \text{if } 1 \leq x < 2 \\ (x^2-1)(x-1)(x-2)+\cos x, & \text{if } 2 \leq x < \infty \end{cases}$$

Now, to check differentiability at $x = 1, 2$ [using shortcut method]

$$f'(x) = \begin{cases} (x^2-1)(2x-3)+(2x)(x^2-3x+2)-\sin x, & -\infty < x < 1 \\ -(x^2-1)(2x-3)-(2x)(x^2-3x+2)-\sin x, & 1 \leq x < 2 \\ (x^2-1)(2x-3)+(2x)(x^2-3x+2)-\sin x, & 2 \leq x < \infty \end{cases}$$

Thus, for $f'(1)$, we have

$$f'(1) = \begin{cases} -\sin 1, & x < 1 \\ -\sin 1, & x > 1 \end{cases}$$

Thus, $f(x)$ is differentiable at $x = 1$

Also, $$f'(2) = \begin{cases} -3-\sin 2, & x < 2 \\ 3-\sin 2, & x > 2 \end{cases}$$

Thus, $f(x)$ is not differentiable at $x = 2$.

Hence, (d) is the correct answer.

Example 40 ***If*** $f(x) = \sum_{r=1}^{n} a_r |x|^r$, ***where*** a_i's ***are real constants, then*** $f(x)$ ***is***

(a) continuous at $x = 0$, for all a_i

(b) differentiable at $x = 0$, for all $a_i \in R$

(c) differentiable at $x = 0$, for all $a_{2k+1} = 0$

(d) None of the above

Sol. We know that, $|x|^r, r = 0, 1, 2, \ldots$ are all continuous everywhere.

$\therefore\ f(x) = \sum_{r=1}^{n} a_r |x|^r$ is everywhere continuous.

Since, $|x|, |x|^3, |x|^5, \ldots$ are not differentiable at $x = 0$, whereas $|x|^2, |x|^4, \ldots$ are everywhere differentiable.

$\therefore\ f(x)=\sum_{r=1}^{n} a_r |x|^r$ is not differentiable at $x=0$, if anyone of $a_1, a_3, a_5, \ldots$ is non-zero.

Thus, for $f(x)$ to be differentiable at $x=0$, we must have $a_1 = a_3 = a_5 \ldots = 0$

i.e. $a_{2k+1} = 0$

Hence, (a) and (c) are the correct answers.

Example 41 ***Let f and g be differentiable functions satisfying*** $g'(a)=2$, $g(a)=b$ ***and*** $fog = I$ ***(Identity function***). ***Then,*** $f'(b)$ ***is equal to***

(a) 2 (b) $\frac{2}{3}$ (c) $\frac{1}{2}$ (d) None of these

Sol. We have, $fog = I$

$\Rightarrow \quad f\{g(x)\} = x$, for all $x \in R$

$\therefore \quad f'\{g(x)\}\cdot g'(x) = 1,$ for all $x \in R$

$\Rightarrow \quad f'(g(a)) = \frac{1}{g'(a)} \Rightarrow f'(b) = \frac{1}{2}$

Hence, (c) is the correct answer.

Example 42 If $f(x)=\frac{x}{1+(\log x)(\log x)\ldots\infty}, \forall\ x \in [1, 3]$ is non-differentiable at $x = k$. Then, the value of $[k^2]$, is (where $[\cdot]$ denotes greatest integer function).

(a) 5 (b) 6 (c) 7 (d) 8

Sol. Let $g(x) = (\log x)\cdot(\log x)\ldots\infty$

$$\therefore \quad g(x)=\begin{cases}1, & x=e\\ 0, & 1\le x<e\\ \infty, & x>e\end{cases}$$

$$\therefore \quad f(x)=\begin{cases}x, & 1\le x<e\\ x/2, & x=e\\ 0, & e<x\le 3\end{cases}$$

$\Rightarrow f(x)$ is neither continuous nor differentiable at $x = e = k$.

$\therefore \quad [k^2] = 7$

Hence, (c) is the correct answer.

Example 43 If $f(x)=|1-x|$, then the points where $\sin^{-1}(f(|x|))$ is non-differentiable, are

(a) $\{0, 1\}$ (b) $\{0, -1\}$

(c) $\{0, 1, -1\}$ (d) None of these

Sol. Here, $f(x) = |1-x|$

$$f(|x|) = |1-|x||=\begin{cases}x-1, & x>1\\ 1-x, & 0<x<1\\ 1+x, & -1\le x\le 0\\ -x-1, & x<-1\end{cases}$$

Here, for domain of $\sin^{-1}(f(|x|))$

$-1 \le f(|x|) \le 1$

$\Rightarrow \quad |1-|x||\le 1$

$\Rightarrow \quad -1 \le 1-|x|\le 1$

$\Rightarrow \quad -2 \le -|x|\le 0$

$\Rightarrow \quad 2 \ge |x| \ge 0$

$\therefore \quad x \in [-2, 2]$

Then, $\sin^{-1}(f(|x|))$, for $x \in [-2, 2]$ is not differentiable at $x = \{0, 1, -1\}$.

Hence, (c) is the correct answer.

Exercise for Session 6

1. If a function $f(x)$ is defined as $f(x)=\begin{cases}-x, & x<0\\ x^2, & 0\le x\le 1\\ x^2-x+1, & x>1\end{cases}$, then

(a) $f(x)$ is differentiable at $x=0$ and $x=1$

(b) $f(x)$ is differentiable at $x=0$ but not at $x=1$

(c) $f(x)$ is not differentiable at $x=1$ but not at $x=0$

(d) $f(x)$ is not differentiable at $x=0$ and $x=1$

2. If $f(x)=x^3\operatorname{sgn}(x)$, then

(a) f is differentiable at $x=0$

(b) f is continuous but not differentiable at $x=0$

(c) $f'(0^-)=1$

(d) None of these

3. Which of the following is continuous everywhere in its domain but has atleast one point where it is not differentiable?

(a) $f(x)=x^{1/3}$

(b) $f(x)=\dfrac{|x|}{x}$

(c) $f(x)=e^{-x}$

(d) $f(x)=\tan x$

4. If $f(x)=\begin{cases}x+\{x\}+x\sin\{x\}, & \text{for } x\neq 0\\ 0, & \text{for } x=0\end{cases}$, where $\{x\}$ denotes the fractional part function, then

(a) f is continuous and differentiable at $x=0$

(b) f is continuous but not differentiable at $x=0$

(c) f is continuous and differentiable at $x=2$

(d) None of these

5. If $f(x)=\begin{cases}x\left(\dfrac{e^{1/x}-e^{-1/x}}{e^{1/x}+e^{1/x}}\right), & x\neq 0\\ 0, & x=0\end{cases}$, then at $x=0$, $f(x)$ is

(a) differentiable

(b) not differentiable

(c) $f'(0^+)=-1$

(d) $f'(0^-)=1$

Session 7

Differentiability in an Interval

(i) A function $f(x)$ defined in an open interval (a, b) is said to be differentiable or derivable in open interval (a, b), if it is differentiable at each point of (a, b).

(ii) A function $f(x)$ defined in a close interval $[a, b]$ is said to be differentiable or derivable at the end points a and b, if it is differentiable from the right at a and from the left at b. In other words, $\lim_{x \to a^+} \frac{f(x) - f(a)}{x - a}$ and $\lim_{x \to b^-} \frac{f(x) - f(b)}{x - b}$ both exist.

Example 44 Discuss the differentiability of $f(x) = \sin^{-1}\left(\frac{2x}{1+x^2}\right)$.

Sol. We have, $f(x) = \sin^{-1}\left(\frac{2x}{1+x^2}\right)$

$$\Rightarrow f'(x) = \frac{1}{\sqrt{1-\left(\frac{2x}{1+x^2}\right)^2}} \times \frac{d}{dx}\left(\frac{2x}{1+x^2}\right)$$

$$= \frac{(1+x^2)}{\sqrt{(1+x^2)^2 - 4x^2}} \times \left[\frac{(1+x^2)(2) - 2x(2x)}{(1+x^2)^2}\right]$$

$$= \frac{(1+x^2)}{\sqrt{1+2x^2+x^4-4x^2}} \times \frac{(2+2x^2-4x^2)}{(1+x^2)^2}$$

$$= \frac{(1+x^2)}{\sqrt{1-2x^2+x^4}} \times \frac{(2-2x^2)}{(1+x^2)^2}$$

$$= \frac{(1+x^2)}{\sqrt{(1-x^2)^2}} \times \frac{(2-2x^2)}{(1+x^2)^2} = \frac{(1+x^2)}{|1-x^2|} \times \frac{2(1-x^2)}{(1+x^2)^2}$$

[since $1 + x^2 \neq 0$]

$$\Rightarrow f'(x) = \frac{1}{|(1-x^2)|} \times \frac{2(1-x^2)}{(1+x^2)} \quad \ldots(i)$$

Here, in Eq. (i), $f'(x)$ exists only if, $|1-x^2| \neq 0$

$$\Rightarrow \quad 1 - x^2 \neq 0$$

$$\Rightarrow \quad x^2 \neq 1 \Rightarrow x \neq \pm 1$$

Thus, $f'(x)$ exists only, if $x \in R - \{-1, 1\}$.

$\therefore$ $f(x)$ is differentiable for all $x \in R - \{1, -1\}$.

Remark

The above example, can also be solved as follows

$$y = f(x) = \sin^{-1}\left(\frac{2x}{1+x^2}\right), \text{ let } x = \tan\theta$$

$$\therefore \quad y = \sin^{-1}\left(\frac{2\tan\theta}{1+\tan^2\theta}\right) \Rightarrow \quad y = \sin^{-1}(\sin 2\theta)$$

$$\therefore \quad y = 2\theta \quad \text{or} \quad y = 2\tan^{-1}x$$

$\frac{dy}{dx} = \frac{2}{1+x^2}$, which states $f'(x)$ exists for all $x \in R$. "Which is wrong as we have not checked the domain of $f(x)$." So, students are advised to solve these problems carefully, while applying this method.

Example 45 ***Let [ ] denotes the greatest integer function and $f(x) = [\tan^2 x]$, then*** ***[IIT JEE 1993]***

(a) $\lim_{x \to 0} f(x)$ doesn't exist (b) $f(x)$ is continuous at $x = 0$

(c) $f(x)$ is not differentiable at $x = 0$

(d) $f'(0) = 1$

Sol. Here, [ ] denotes the greatest integral function.

Thus, $-45° < x < 45°$

$$\Rightarrow \quad \tan(-45°) < \tan x < \tan(45°)$$

$$\Rightarrow \quad -1 < \tan x < 1 \Rightarrow 0 < \tan^2 x < 1$$

Since, $f(x) = [\tan^2 x] = 0$

Therefore, $f(x)$ is zero for all values of x from $(-45°)$ to $(45°)$. Thus, $f(x)$ exists when $x \to 0$ and also it is continuous at $x = 0$, $f(x)$ is differentiable at $x = 0$ and has a value 0. (i.e. $f(0) = 0$).

Hence, (b) is the correct answer.

Theorems of Differentiability

Theorem 1 If $f(x)$ and $g(x)$ are both derivable at $x = a$, $f(x) \pm g(x)$, $f(x) \cdot g(x)$ and $\frac{f(x)}{g(x)}$ will also be derivable at $x = a$ $\left\{\text{only if } g(a) \neq 0 \text{ for } \frac{f(x)}{g(x)}\right\}$.

Theorem 2 If $f(x)$ is derivable at $x = a$ and $g(x)$ is not differentiable at $x = a$, then $f(x) \pm g(x)$ will not be derivable at $x = a$.

e.g. $f(x) = \cos|x|$ is derivable at $x = 0$ and $g(x) = |x|$ is not derivable at $x = 0$.

Then, $\cos|x|+|x|$ is not derivable at $x=0$.

However, nothing can be said about the product function, as in this case

$f(x)=x$ is derivable at $x=0$

$g(x)=|x|$ is not derivable at $x=0$

But, $f(x)\cdot g(x)=\begin{cases} x^2, & \text{if } x\geq 0 \\ -x^2, & \text{if } x<0 \end{cases}$

which is derivable at $x=0$.

Theorem 3 If both $f(x)$ and $g(x)$ are non-derivable, then nothing can be said about the sum/difference/product function.

e.g. $f(x)=\sin|x|$, not derivable at $x=0$

$g(x)=|x|$, not derivable at $x=0$

Then, the function

$F(x)=\sin|x|+|x|$, not derivable at $x=0$

$G(x)=\sin|x|-|x|$, derivable at $x=0$

Theorem 4 If $f(x)$ is derivable at $x=a$ and $f(a)=0$ and $g(x)$ is continuous at $x=a$.

Then, the product function $F(x)=f(x)\cdot g(x)$ will be derivable at $x=a$.

Proof $F'(a^+)=\lim\limits_{h\to 0}\dfrac{f(a+h)\cdot g(a+h)-0}{h}=f'(a)\cdot g(a)$

$$F'(a^-)=\lim_{h\to 0}\frac{f(a-h)\cdot g(a-h)-0}{-h}=f'(a)\cdot g(a)$$

$\therefore$ Derivable at $x=a$.

Theorem 5 Derivative of a continuous function need not be a continuous function.

e.g. $$f(x)=\begin{cases} x^2\cdot\sin\left(\dfrac{1}{x}\right), & \text{if } x\neq 0 \\ 0, & \text{if } x=0 \end{cases}$$

Here, $f(0^+)=0$ and $f(0^-)=0$

$\therefore$ Continuous at $x=0$.

and $$f'(x)=\begin{cases} 2x\cdot\sin\dfrac{1}{x}-x^2\cdot\cos\left(\dfrac{1}{x}\right)\cdot\dfrac{1}{x^2}, & x\neq 0 \\ 0, & x=0 \end{cases}$$

$\Rightarrow$ $f'(x)$ is not continuous at $x=0$.

$\left[\text{as } \lim\limits_{x\to 0} f'(x) \text{ doesn't exist}\right]$

Remark

One must remember the formula which we can write as

$$\max\{f(x),g(x)\}=\frac{f(x)+g(x)}{2}+\left|\frac{f(x)-g(x)}{2}\right|$$

$$\min\{f(x),g(x)\}=\frac{f(x)+g(x)}{2}-\left|\frac{f(x)-g(x)}{2}\right|$$

Example 46 ***Let*** $h(x)=\min\{x,x^2\}$ ***for every real number of*** x***. Then,*** ***[IIT JEE 1998]***

(a) h is not continuous for all x

(b) h is differentiable for all x

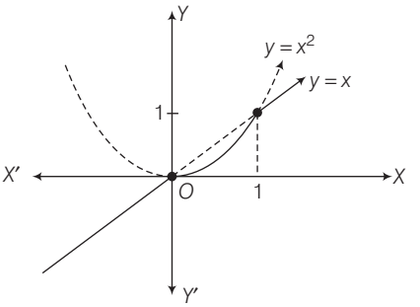
(c) $h'(x)=1$ for all x

(d) h is not differentiable at two values of x

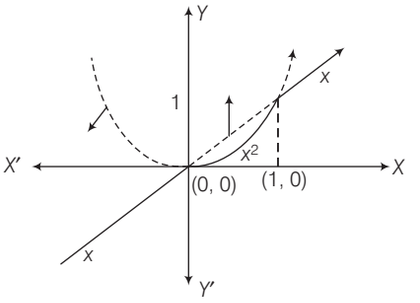
Sol. Here, $h(x)=\min\{x,x^2\}$ can be drawn on graph in two steps.

(a) Draw the graph of $y=x$ and $y=x^2$ also find their point of intersection.

Clearly, $x=x^2 \Rightarrow x=0,1$



(b) To find $h(x)=\min\{x,x^2\}$ neglecting the graph above the point of intersection, we get



Thus, from the above graph,

$$h(x)=\begin{cases} x, & x\leq 0 \text{ or } x\geq 1 \\ x^2, & 0\leq x\leq 1 \end{cases}$$

which shows $h(x)$ is continuous for all x. But not differentiable at $x=\{0,1\}$.

Thus, $h(x)$ is not differentiable at two values of x.

Hence, (d) is the correct answer.

Example 47 Let $f:R\to R$ be a function defined by $f(x)=\max\{x,x^3\}$. The set of all points where $f(x)$ is not differentiable, is ***[IIT JEE 2001]***

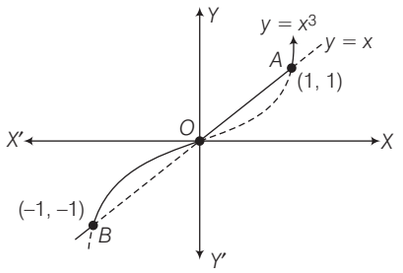
(a) $\{-1,1\}$ (b) $\{-1,0\}$

(c) $\{0,1\}$ (d) $\{-1,0,1\}$

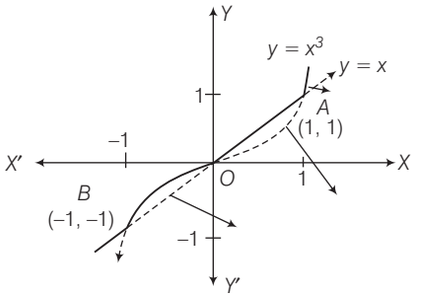
Sol. $f(x) = \max\{x, x^3\}$. Consider the graph separately of $y = x^3$ and $y = x$ and find their point of intersection;

Clearly, $x^3 = x$

$\Rightarrow$ $x = 0, 1, -1$



Now, to find $f(x) = \max\{x, x^3\}$ neglecting the graph below the point of intersection, we get the required graph of $f(x) = \max\{x, x^3\}$.



Thus, from above graph, $f(x) = \begin{cases} x, & \text{if } x \in (-\infty, -1] \cup [0,1] \\ x^3, & \text{if } x \in [-1, 0] \cup [1, \infty) \end{cases}$

which shows $f(x)$ is not differentiable at 3 points, i.e. $x = \{-1, 0, 1\}$. (Due to sharp edges)

Hence, (d) is the correct answer.

Example 48 *Let $f(x)$ be a continuous function, $\forall\ x \in R, f(0) = 1$ and $f(x) \neq x$ for any $x \in R$, then show $f(f(x)) > x, \forall\ x \in R^+$.*

Sol. Let $g(x) = f(x) - x$

So, $g(x)$ is continuous and $g(0) = f(0) - 0$.

$\Rightarrow$ $g(0) = 1$

Now, it is given that $g(x) \neq 0$ for any $x \in R$

[as $f(x) \neq x$ for any $x \in R$]

So, $g(x) > 0, \forall\ x \in R^+$

i.e. $f(x) > x, \forall\ x \in R^+$

$\Rightarrow$ $f(f(x)) > f(x) > x, \ \forall\ x \in R^+$

or $f(f(x)) > x, \forall\ x \in R^+$

Example 49 *The total number of points of non-differentiability of $f(x) = \max\left\{\sin^2 x, \cos^2 x, \frac{3}{4}\right\}$ in [0, 10π], is*

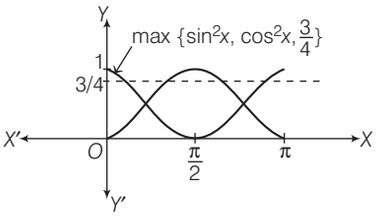
(a) 40

(b) 30

(c) 20

(d) 10

Sol. Here, $f(x) = \max\left\{\sin^2 x, \cos^2 x, \frac{3}{4}\right\}$



Since, $\sin^2 x$ and $\cos^2 x$ are periodic with period π and in $[0, \pi]$, there are four points of non-differentiability of $f(x)$.

$\therefore$ In $[0, 10\pi]$, there are 40 points of non-differentiability.

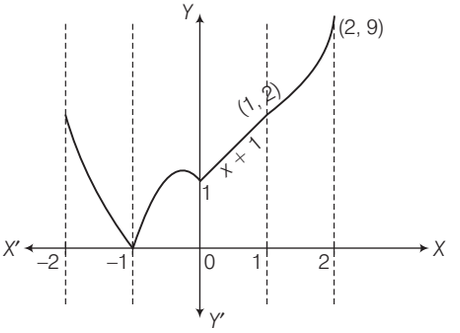
Hence, (a) is the correct answer.

Example 50 If $f(x) = |x + 1|\{|x| + |x - 1|\}$, then draw the graph of $f(x)$ in the interval $[-2, 2]$ and discuss the continuity and differentiability in $[-2, 2]$.

Sol. Here, $f(x) = |x + 1|\{|x| + |x - 1|\}$

$$f(x) = \begin{cases} (x+1)(2x-1), & -2 \le x < -1 \\ -(x+1)(2x-1), & -1 \le x < 0 \\ (x+1), & 0 \le x < 1 \\ (x+1)(2x-1), & 1 \le x \le 2 \end{cases}$$

Thus, the graph of $f(x)$ is



Clearly, continuous for $x \in R$ and has differentiability for $x \in R - \{-1, 0, 1\}$

Example 51 If the function

$$f(x)=\left[\frac{(x-2)^3}{a}\right]\sin(x-2)+a\cos(x-2),$$

(where [ ] denotes the greatest integer function) is continuous and differentiable in $(4,6)$*, then*

(a) $a\in[8,64]$ (b) $a\in(0,8]$

(c) $a\in[64,\infty)$ (d) None of these

Sol. We have, $x\in(4,6)\Rightarrow 2<x-2<4$

$$\Rightarrow \quad \frac{8}{a}<\frac{(x-2)^3}{a}<\frac{64}{a} \qquad [\because a>0]$$

For $f(x)$ to be continuous and differentiable in $(4,6)$, $\left[\frac{(x-2)^3}{a}\right]$ must attain a constant value for $x\in(4,6)$.

Clearly, this is possible only when $a\geq 64$.

In that case, we have

$f(x)=a\cos(x-2)$, which is continuous and differentiable

$\therefore \quad a\in[64,\infty)$

Hence, (c) is the correct answer.

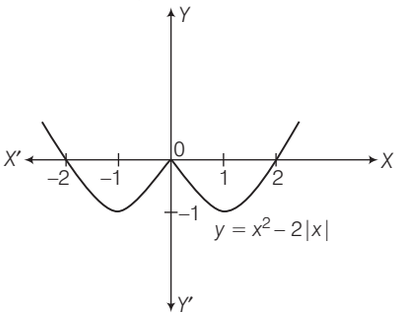
Example 52 If $f(x)=x^2-2|x|$ and

$$g(x)=\begin{cases}\min\{f(t):-2\leq t\leq x, & -2\leq x\leq 0\}\\ \max\{f(t):0\leq t\leq x, & 0\leq x\leq 3\}\end{cases}$$

(i) Draw the graph of $f(x)$ and discuss its continuity and differentiability.

(ii) Find and draw the graph of $g(x)$. Also, discuss the continuity.

Sol. (i) Graph of $f(x)=\begin{cases}x^2-2x, & x\geq 0\\ x^2+2x, & x<0\end{cases}$ is shown as



which shows $f(x)$ is continuous for all $x\in R$ and differentiable for all $x\in R-\{0\}$.

(ii) We know that,

If $f(x)$ is an increasing function on $[a,b]$, then

$\max\{f(t);a\leq t\leq x,\ a\leq x\leq b\}=f(x)$

$\min\{f(t);a\leq t\leq x,\ a\leq x\leq b\}=f(a)$

If $f(x)$ is decreasing function on $[a,b]$, then

$\max\{f(t);a\leq t\leq x,\ a\leq x\leq b\}=f(a)$

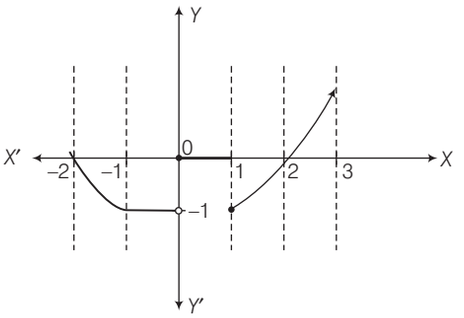
$\min\{f(t);a\leq t\leq x,\ a\leq x\leq b\}=f(x)$

From graph of $f(x)$,

$$g(x)=\begin{cases}f(x), & \text{for } -2\leq x<-1\\ -1, & \text{for } -1\leq x<0\\ 0, & \text{for } 0\leq x<1\\ f(x), & \text{for } x\geq 1\end{cases}$$

$$\Rightarrow\ g(x)=\begin{cases}x^2+2x, & \text{for } -2\leq x<-1\\ -1, & \text{for } -1\leq x<0\\ 0, & \text{for } 0\leq x<1\\ x^2-2x, & \text{for } x\geq 1\end{cases}$$

Thus, graph of $g(x)$ is



From above figure, it is clear that $g(x)$ is not continuous at $x=0,1$.

Example 53 ***Let*** $f(x)=\phi(x)+\psi(x)$ ***and*** $\phi'(a),\psi'(a)$ ***are finite and definite. Then,***

(a) $f(x)$ is continuous at $x=a$

(b) $f(x)$ is differentiable at $x=a$

(c) $f'(x)$ is continuous at $x=a$

(d) $f'(x)$ is differentiable at $x=a$

Sol. We know that the sum of two continuous (differentiable) functions is continuous (differentiable).

$\therefore$ $f(x)$ is continuous and differentiable at $x=a$.

Hence, (a) and (b) are the correct answers.

Example 54 If $f(x)=x+\tan x$ and $g(x)$ is the inverse of $f(x)$, then $g'(x)$ is equal to

(a) $\dfrac{1}{1+(g(x)-x)^2}$ (b) $\dfrac{1}{2+(g(x)+x)^2}$

(c) $\dfrac{1}{2+(g(x)-x)^2}$ (d) None of these

Sol. We have, $f(x)=x+\tan x$

$$\Rightarrow \quad f(f^{-1}(x))=f^{-1}(x)+\tan(f^{-1}(x))$$

$$\Rightarrow \quad x=g(x)+\tan(g(x)) \qquad \text{...(i)}$$

$$[\because g(x)=f^{-1}(x)]$$

$$1=g'(x)+\sec^2(g(x))\cdot g'(x)$$

$$\Rightarrow \quad g'(x)=\frac{1}{1+\sec^2(g(x))}$$

$$\Rightarrow \quad g'(x) = \frac{1}{2 + \tan^2(g(x))}$$

$$\Rightarrow \quad g'(x) = \frac{1}{2 + (x - g(x))^2} \qquad \text{[from Eq. (i)]}$$

Hence, (c) is the correct answer.

Example 55 If $f(x)$ is differentiable function and $(f(x)\cdot g(x))$ is differentiable at $x = a$, then

(a) $g(x)$ must be differentiable at $x = a$

(b) $g(x)$ is discontinuous, then $f(a) = 0$

(c) $f(a) \neq 0$, then $g(x)$ must be differentiable

(d) None of the above

Sol. $$\left[\frac{d}{dx}(f(x)\cdot g(x))\right]_{x=a} = f'(a)g(a) + \lim_{h\to 0}\frac{g(a+h)-g(a)}{h}\cdot f(a)$$

If $f(a) \neq 0 \Rightarrow g'(a)$ must exist.

Also, if $g(x)$ is discontinuous, $f(a)$ must be 0 for $f(x)\cdot g(x)$ to be differentiable.

Hence, (b) and (c) are the correct answers.

Example 56 If $f(x) = [x^{-2}[x^2]]$, (where $[\cdot]$ denotes the greatest integer function) $x \neq 0$, then incorrect statement

(a) $f(x)$ is continuous everywhere

(b) $f(x)$ is discontinuous at $x = \sqrt{2}$

(c) $f(x)$ is non-differentiable at $x = 1$

(d) $f(x)$ is discontinuous at infinitely many points

Sol. Here, $0 \le [x^2] \le x^2$

$$\Rightarrow \quad 0 \le x^{-2}[x^2] \le 1 \Rightarrow [x^{-2}[x^2]] = 0 \text{ or } 1$$

$f(x)$ is discontinuous at $x^2 = n, n \in N \Rightarrow x = \sqrt{n}$

$\therefore f(x)$ is neither continuous nor differentiable at $x = \sqrt{n}, n \in N$.

Hence, (b), (c) and (d) are the correct answers.

Example 57 ***If*** $f(x) = \begin{cases} x^2(\text{sgn}[x]) + \{x\}, & 0 \le x \le 2 \\ \sin x + |x-3|, & 2 \le x \le 4 \end{cases}$, ***where*** $[\ ]$ ***and*** $\{\ \}$ ***represents greatest integer and fractional part function respectively, then***

(a) $f(x)$ is differentiable at $x = 1$

(b) $f(x)$ is continuous but non-differentiable at $x = 2$

(c) $f(x)$ is non-differentiable at $x = 2$

(d) $f(x)$ is discontinuous at $x = 2$

Sol. For continuity at $x = 1$

$$\lim_{x\to 1^+} f(x) = \lim_{x\to 1^+} x^2 \text{sgn}[x] + \{x\} = 1 + 0 = 1$$

$$\lim_{x\to 1^-} f(x) = \lim_{x\to 1^-} x^2 \text{sgn}[x] + \{x\} = 0 + 1 = 1$$

Also, $f(1) = 1$

$\therefore f(x)$ is Continuous at $x = 1$

$$f(x) = \begin{cases} x, & 0 \le x < 1 \\ x^2 + x - 1, & 1 \le x < 2 \end{cases}, \text{ non-differentiable at } x = 1$$

$$\lim_{x\to 2^-} f(x) = \lim_{x\to 2^-} x^2 \text{sgn}[x] + \{x\}$$

$$= 4 \times 1 + 1 = 5$$

$$\lim_{x\to 2^+} f(x) = \lim_{x\to 2^+} \sin x + |x-3| = 1 + \sin 2$$

Thus, $f(x)$ is neither continuous nor differentiable at $x = 2$.

Hence, (c) and (d) are the correct answers.

Example 58 ***A real valued function*** $f(x)$ ***is given as***

$$f(x) = \begin{cases} \int_0^x 2\{x\}dx, & x + \{x\} \in I \\ x^2 - x + \frac{1}{2}, & \frac{1}{2} < x < \frac{3}{2} \text{ and } x \neq 1, \\ x^2 - x + \frac{1}{6}, & \text{otherwise} \end{cases}$$

where $[\ ]$ ***denotes greatest integer less than or equals to*** x ***and*** $\{\ \}$ ***denotes fractional part function of*** x***. Then,***

(a) $f(x)$ is continuous and differentiable in $x \in \left(-\frac{1}{2}, \frac{1}{2}\right)$

(b) $f(x)$ is continuous and differentiable in $x \in \left[-\frac{1}{2}, \frac{1}{2}\right]$

(c) $f(x)$ is continuous and differentiable in $x \in \left[\frac{1}{2}, \frac{3}{2}\right]$

(d) $f(x)$ is continuous but not differentiable in $x \in (0, 1)$

Sol. Here, $x + \{x\} \in I \Rightarrow x + x - [x] \in I$

$$\Rightarrow \quad 2x - [x] \in I, \text{ possible for } x = \frac{n}{2}, n \in I$$

$$\therefore \quad f\left(\frac{1}{2}\right) = \int_0^{1/2} 2\{x\}dx = \frac{1}{4}, f\left(\frac{3}{2}\right) = \int_0^{3/2} 2\{x\}dx = \frac{5}{4}$$

and $$f\left(\frac{-1}{2}\right) = \int_0^{-1/2} 2\{x\}dx = \frac{-3}{4}, \ f(1) = 1$$

Then, $$f(x) = \begin{cases} \frac{1}{4}, & x = \frac{1}{2} \\ \frac{5}{4}, & x = \frac{3}{2} \\ \frac{-3}{4}, & x = \frac{-1}{2} \\ 1, & x = 1 \\ x^2 - x + \frac{1}{2}, & \frac{1}{2} < x < \frac{3}{2} \text{ and } x \neq 1 \\ x^2 - x + \frac{1}{6}, & \text{otherwise} \end{cases}$$

Clearly, continuous for $x \in (0, 1)$ but not differentiable.

Hence, (d) is the correct answer.

Exercise for Session 7

1. If $f(x)=\sin(\pi\,(x-[x]))$, $\forall\ x\in\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$, where $[\cdot]$ denotes the greatest integer function, then

(a) $f(x)$ is discontinuous at $x=\{-1, 0, 1\}$ (b) $f(x)$ is differentiable for $x\in\left(-\frac{\pi}{2},\frac{\pi}{2}\right)-\{0\}$

(c) $f(x)$ is differentiable for $x\in\left(-\frac{\pi}{2},\frac{\pi}{2}\right)-\{-1, 0, 1\}$ (d) None of these

2. Let $f(x)=\begin{cases}x-1, & -1\le x<0\\ x^2, & 0\le x\le 1\end{cases}$, $g(x)=\sin x$ and $h(x)=f(|g(x)|)+|f(g(x))|$. Then,

(a) $h(x)$ is continuous for $x\in[-1, 1]$ (b) $h(x)$ is differentiable for $x\in[-1, 1]$

(c) $h(x)$ is differentiable for $x\in[-1, 1]-\{0\}$ (d) $h(x)$ is differentiable for $x\in(-1, 1)-\{0\}$

3. If $f(x)=\begin{cases}|1-4x^2|, & 0\le x<1\\ [x^2-2x], & 1\le x<2\end{cases}$, where [ ] denotes the greatest integer function, then

(a) $f(x)$ is continuous for all $x\in[0, 2)$ (b) $f(x)$ is differentiable for all $x\in[0, 2)-\{1\}$

(c) $f(x)$ is differentiable for all $x\in[0, 2)-\left\{\frac{1}{2}, 1\right\}$ (d) None of these

4. Let $f(x)=\int_0^1 |x-t|\,t\,dt$, then

(a) $f(x)$ is continuous but not differentiable for all $x\in R$ (b) $f(x)$ is continuous and differentiable for all $x\in R$

(c) $f(x)$ is continuous for $x\in R-\left\{\frac{1}{2}\right\}$ and $f(x)$ is differentiable for $x\in R-\left\{\frac{1}{4}, \frac{1}{2}\right\}$

(d) None of these

5. Let $f(x)$ be a function such that $f(x+y)=f(x)+f(y)$ for all x and y and $f(x)=(2x^2+3x)\cdot g(x)$ for all x, where $g(x)$ is continuous and $g(0)=3$. Then, $f'(x)$ is equal to

(a) 6 (b) 9 (c) 8 (d) None of these

6. If a function $g(x)$ which has derivatives $g'(x)$ for every real x and which satisfies the following equation $g(x+y)=e^y g(x)+e^x g(y)$ for all x and y and $g'(0)=2$, then the value of $\{g'(x)-g(x)\}$ is equal to

(a) e^x (b) $\frac{2}{3}e^x$ (c) $\frac{1}{2}e^x$ (d) $2e^x$

7. Let $f:R\to R$ be a function satisfying $f\left(\frac{xy}{2}\right)=\frac{f(x)\cdot f(y)}{2}$, $\forall\ x, y\in R$

and $f(1)=f'(1)\ne 0$. Then, $f(x)+f(1-x)$ is (for all non-zero real values of x)

(a) constant (b) can't be discussed (c) x (d) $\frac{1}{x}$

8. Let $f(x)$ be a derivable function at $x=0$ and $f\left(\frac{x+y}{K}\right)=\frac{f(x)+f(y)}{K}$ $(K\in R, K\ne 0, 2)$. Then, $f(x)$ is

(a) even function (b) neither even nor odd function

(c) either zero or odd function (d) either zero or even function

9. Let $f:R-(-\pi,\pi)$ be a differentiable function such that $f(x)+f(y)=f\left(\frac{x+y}{1-xy}\right)$.

If $f(1)=\frac{\pi}{2}$ and $\lim_{x\to 0}\frac{f(x)}{x}=2$. Then, $f(x)$ is equal to

(a) $2\tan^{-1}x$ (b) $\frac{1}{2}\tan^{-1}x$ (c) $\frac{\pi}{2}\tan^{-1}x$ (d) $2\pi\ \tan^{-1}x$

10. Let $f(x)=\sin x$ and $g(x)=\begin{cases}\max\{f(t), 0\le t\le x\}, & \text{for } 0\le x\le\pi\\ \frac{1-\cos x}{2}, & \text{for } x>\pi\end{cases}$. Then, $g(x)$ is

(a) differentiable for all $x\in R$ (b) differentiable for all $x\in R-\{\pi\}$

(c) differentiable for all $x\in(0, \infty)$ (d) differentiable for all $x\in(0, \infty)-\{\pi\}$

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *The values of a and b so that the function*

$$f(x)=\begin{cases} x+a\sqrt{2}\sin x, & 0\le x<\pi/4 \\ 2x\cot x+b, & \pi/4\le x\le\pi/2 \\ a\cos 2x-b\sin x, & \pi/2<x\le\pi \end{cases}$$ *is continuous for*

$x\in[0,\pi]$, *are*

(a) $a=\dfrac{\pi}{6}, b=-\dfrac{\pi}{6}$ (b) $a=-\dfrac{\pi}{6}, b=\dfrac{\pi}{12}$

(c) $a=\dfrac{\pi}{6}, b=-\dfrac{\pi}{12}$ (d) None of these

Sol. (c) Since, $f(x)$ is continuous for $x\in[0,\pi]$.

$\therefore$ $f(x)$ is continuous at $x=\pi/4$ and $x=\pi/2$ and hence to discuss continuity at $x=\pi/4$ and $x=\pi/2$.

Now, at $x=\pi/4$

Left hand limit (at $x=\pi/4$)

$$=\lim_{x\to\frac{\pi}{4}^-} f(x)=\lim_{x\to\frac{\pi}{4}^-}(x+a\sqrt{2}\sin x)$$

$$=\lim_{h\to 0}\{(\pi/4-h)+a\sqrt{2}\sin(\pi/4-h)\}$$

$\therefore$ $\text{LHL}=\lim\limits_{x\to\frac{\pi}{4}^-} f(x)=\dfrac{\pi}{4}+a$

Right hand limit at $x=\pi/4$

$$=\lim_{x\to\frac{\pi}{4}^+} f(x)=\lim_{x\to\frac{\pi}{4}^+}(2x\cot x+b)$$

$$=\lim_{h\to 0} 2\left(\frac{\pi}{4}+h\right)\cot\left(\frac{\pi}{4}+h\right)+b$$

$\Rightarrow$ $\text{RHL}=\lim\limits_{x\to\frac{\pi}{4}^+} f(x)=\dfrac{\pi}{2}+b$

Also, $f\left(\dfrac{\pi}{4}\right)=\dfrac{\pi}{2}+b$

For continuity, LHL (at $x=\pi/4$) = RHL (at $x=\pi/4$) $=f\left(\dfrac{\pi}{4}\right)$

$\Rightarrow$ $\dfrac{\pi}{4}+a=\dfrac{\pi}{2}+b$

$\Rightarrow$ $a-b=\dfrac{\pi}{4}$ ...(i)

At $x=\pi/2$

Left hand limit (at $x=\pi/2$)

$$=\lim_{x\to\frac{\pi}{2}^-}(2x\cot x+b)=\lim_{h\to 0} 2\left(\frac{\pi}{2}-h\right)\cot\left(\frac{\pi}{2}-h\right)+b$$

$$\text{LHL}=b$$

Right hand limit (at $x=\pi/2$)

$$=\lim_{x\to\frac{\pi}{2}^+}(a\cos 2x-b\sin x)$$

$$=\lim_{h\to 0}\left[a\cos 2\left(\frac{\pi}{2}+h\right)-b\sin\left(\frac{\pi}{2}+h\right)\right]$$

$$\text{RHL}=-a-b$$

and $f(\pi/2)=2\dfrac{\pi}{2}\cot\dfrac{\pi}{2}+b=b$

For continuity, LHL (at $x=\pi/2$) = RHL (at $x=\pi/2$) $=f(\pi/2)$

$\Rightarrow$ $b=-a-b \Rightarrow a+2b=0$ ...(ii)

On solving Eqs. (i) and (ii), we get

$$a=\pi/6,\ b=-\pi/12$$

● **Ex. 2** *Let f be an even function and $f'(0)$ exists, then $f'(0)$ is*

(a) 1 (b) 0

(c) −1 (d) −2

Sol. (b) Since, f is an even function.

So, $f(-x)=f(x)$, for all x ...(i)

Also, $f'(0)$ exists.

So, $Rf'(0)=Lf'(0)$

$\Rightarrow$ $\lim\limits_{h\to 0}\dfrac{f(0+h)-f(0)}{h}=\lim\limits_{h\to 0}\dfrac{f(0-h)-f(0)}{-h}$

$\Rightarrow$ $\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{h}=\lim\limits_{h\to 0}\dfrac{f(-h)-f(0)}{-h}$

$\Rightarrow$ $\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{h}=\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{-h}$

[using Eq. (i), $f(-h)=f(h)$]

$\Rightarrow$ $\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{h}=-\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{h}$

$\Rightarrow$ $2\lim\limits_{h\to 0}\dfrac{f(h)-f(0)}{h}=0$

$\Rightarrow$ $2f'(0)=0 \Rightarrow f'(0)=0$

● **Ex. 3** *The set of points where $x^2|x|$ is thrice differentiable, is*

(a) R (b) $R-\{0,1\}$

(c) $[0,\infty)$ (d) $R-\{0\}$

Sol. (d) Let $f(x)=x^2|x|$ which could be expressed as

$$f(x)=\begin{cases} -x^3, & x<0 \\ 0, & x=0 \\ x^3, & x>0 \end{cases}$$

This gives, $f'(x)=\begin{cases}-3x^2, & x<0\\ 0, & x=0\\ 3x^2, & x>0\end{cases}$

So, $f'(x)$ exists for all real x.

$$f''(x)=\begin{cases}-6x, & x<0\\ 0, & x=0\\ 6x, & x>0\end{cases}$$

So, $f''(x)$ exists for all real x.

$$f'''(x)=\begin{cases}-6, & x<0\\ 0, & x=0\\ 6, & x>0\end{cases}$$

However, $f'''(0)$ doesn't exist, since $f'''(0^-)=-6$ and $f'''(0^+)=6$ which are not equal.

Thus, the set of points where $f(x)$ is thrice differentiable is $R-\{0\}$.

● ***Ex. 4*** *The function* $f(x)=\dfrac{|x+2|}{\tan^{-1}(x+2)}$, *is continuous for*

(a) $x\in R$ (b) $x\in R-\{0\}$
(c) $x\in R-\{-2\}$ (d) None of these

Sol. (*c*) Clearly, f is continuous except possibility at $x=-2$

$$\text{RHL (at } x=-2)=\lim_{x\to -2^+} f(x)$$
$$=\lim_{x\to -2^+}\frac{(x+2)}{\tan^{-1}(x+2)}=1$$
$$\text{LHL (at } x=-2)=\lim_{x\to -2^-} f(x)$$
$$=\lim_{x\to -2^-}\frac{-(x+2)}{\tan^{-1}(x+2)}=-1$$

So, f is not continuous at $x=-2$.

● ***Ex. 5*** *If* $f(x)=\begin{cases}\dfrac{\sin[x^2]\pi}{x^2-3x-18}+ax^3+b, & \text{for } 0\le x\le 1\\ 2\cos\pi x+\tan^{-1}x, & \text{for } 1<x\le 2\end{cases}$

differentiable function in $[0, 2]$, *where* $[\cdot]$ *denotes the greatest integer function, then*

(a) $a=\dfrac{1}{6}, b=\dfrac{\pi}{4}-\dfrac{13}{6}$ (b) $a=-\dfrac{1}{6}, b=\dfrac{\pi}{4}$
(c) $a=-\dfrac{1}{6}, b=\dfrac{\pi}{4}-\dfrac{13}{6}$ (d) None of these

Sol. (*a*) Here, $[x^2]=0$, for all $0\le x<1$

and $[x^2]=1$, for $x=1$

$\therefore\ \sin[x^2]\pi=0$, for $0\le x\le 1$

Hence, $f(x)=\begin{cases}ax^3+b, & 0\le x\le 1\\ 2\cos\pi x+\tan^{-1}x, & 1<x\le 2\end{cases}$

As, $f(x)$ is differentiable in $[0, 2]$.

$\Rightarrow$ $f(x)$ is continuous and differentiable at $x=1$

$\Rightarrow$ $\lim\limits_{x\to 1^-} f(x)=\lim\limits_{x\to 1^+} f(x)=f(1)$

$$a+b=-2+\frac{\pi}{4}=a+b$$

$\Rightarrow$ $a+b=-2+\dfrac{\pi}{4}$ ...(i)

Again, since $f(x)$ is differentiable at $x=1$

(LHD at $x=1$) = (RHD at $x=1$)

$\Rightarrow$ $\lim\limits_{x\to 1^-}\dfrac{f(x)-f(1)}{x-1}=\lim\limits_{x\to 1^+}\dfrac{f(x)-f(1)}{x-1}$

$\Rightarrow$ $\lim\limits_{x\to 1^-}\dfrac{(ax^3+b)-(a+b)}{x-1}$

$$=\lim_{x\to 1^+}\frac{(2\cos\pi x+\tan^{-1}x)-(a+b)}{x-1}$$

$\Rightarrow$ $3a=\lim\limits_{x\to 1^+}\dfrac{-2\pi\sin\pi x+\dfrac{1}{1+x^2}}{1}$

$\Rightarrow$ $3a=\dfrac{1}{2}$ or $a=\dfrac{1}{6}$ ...(ii)

From Eqs. (i) and (ii), we get

$$a=\frac{1}{6}\quad\text{and}\quad b=\frac{\pi}{4}-\frac{13}{6}$$

● ***Ex. 6*** *If* $g(x)=\lim\limits_{m\to\infty}\dfrac{x^m f(1)+h(x)+1}{2x^m+3x+3}$ *is continuous at* $x=1$ *and* $g(1)=\lim\limits_{x\to 1}\{\log_e(ex)\}^{2/\log_e x}$, *then the value of* $2g(1)+2f(1)-h(1)$ *when* $f(x)$ *and* $h(x)$ *are continuous at* $x=1$, *is*

(a) 0 (b) 1 (c) 2 (d) 3

Sol. (*b*) Here, $g(1)=\lim\limits_{x\to 1}\{\log e+\log_e x\}^{2/\log_e x}$

$$=\lim_{x\to 1}\{1+\log_e x\}^{2/\log_e x}$$
$$=e^{\lim\limits_{x\to 1}\log_e x\frac{2}{\log_e x}}$$
$$g(1)=e^2 \quad ...(i)$$

Also, $\lim\limits_{x\to 1^-} g(x)=\lim\limits_{x\to 1^-}\lim\limits_{m\to\infty}\left\{\dfrac{x^m f(1)+h(x)+1}{2x^m+3x+3}\right\}$

$$=\lim_{m\to\infty}\left\{\lim_{x\to 1^-}\frac{x^m f(1)+h(x)+1}{2x^m+3x+3}\right\}$$
$$=\frac{h(1)+1}{3+3}\qquad[\text{as } x<1\Rightarrow\lim_{m\to\infty}x^m=0]$$

$$\lim_{x\to 1^-} g(x)=\frac{h(1)+1}{6} \quad ...(ii)$$

$$\text{Again, } \lim_{x\to 1^+} g(x) = \lim_{x\to 1^+}\lim_{m\to\infty}\left\{\frac{x^m f(1)+h(x)+1}{2x^m+3x+3}\right\}$$

$$= \lim_{m\to\infty}\left\{\lim_{x\to 1^+}\frac{x^m f(1)+h(x)+1}{2x^m+3x+3}\right\}$$

$$= \lim_{m\to\infty}\lim_{x\to 1^+}\frac{f(1)+h(x)/x^m+1/x^m}{2+3/x^{m-1}+3/x^m} = \frac{f(1)}{2}$$

$$\therefore \quad \lim_{x\to 1^+} g(x) = \frac{f(1)}{2} \qquad \text{...(iii)}$$

From Eqs. (i), (ii) and (iii), we get

$$e^2 = \frac{h(1)+1}{6} = \frac{f(1)}{2} \quad [\text{as } g(x) \text{ is continuous at } x=1]$$

$$\Rightarrow \quad h(1) = 6e^2 - 1 \quad \text{and} \quad f(1) = 2e^2$$

$$\therefore \quad 2g(1) + 2f(1) - h(1) = 2e^2 + 4e^2 - 6e^2 + 1 = 1$$

$$\Rightarrow 2g(1) + 2f(1) - h(1) = 1$$

● ***Ex. 7*** *Let $g(x) = \log f(x)$, where $f(x)$ is a twice differentiable positive function on $(0, \infty)$ such that $f(x+1) = xf(x)$. Then, for $N = 1, 2, 3, \ldots, g''\left(N+\frac{1}{2}\right) - g''\left(\frac{1}{2}\right)$ is equal to*

[IIT JEE 2008]

(a) $-4\left\{1+\frac{1}{9}+\frac{1}{25}+\ldots+\frac{1}{(2N-1)^2}\right\}$

(b) $4\left\{1+\frac{1}{9}+\frac{1}{25}+\ldots+\frac{1}{(2N-1)^2}\right\}$

(c) $-4\left\{1+\frac{1}{9}+\frac{1}{25}+\ldots+\frac{1}{(2N+1)^2}\right\}$

(d) $4\left\{1+\frac{1}{9}+\frac{1}{25}+\ldots+\frac{1}{(2N+1)^2}\right\}$

Sol. (*a*) We have, $g(x) = \log f(x)$ ...(i)

$$\Rightarrow \quad f(x) = e^{g(x)}$$

$$\Rightarrow \quad f(x+1) = e^{g(x+1)}$$

$$\Rightarrow \quad x\,f(x) = e^{g(x+1)} \quad [\text{given } f(x+1) = x\,f(x)]$$

$$\Rightarrow \log x + \log f(x) = \log e^{g(x+1)} \quad [\text{taking log both sides}]$$

$$\Rightarrow \quad \log x + g(x) = g(x+1) \quad [\text{from Eq. (i)}]$$

$$\text{i.e.} \quad g(x+1) - g(x) = \log x \qquad \text{...(ii)}$$

On replacing x by $x - \frac{1}{2}$ in Eq. (ii), we get

$$g\left(x+\frac{1}{2}\right) - g\left(x-\frac{1}{2}\right) = \log\left(x-\frac{1}{2}\right)$$

$$= \log(2x-1) - \log 2$$

$$\therefore \quad g''\left(x+\frac{1}{2}\right) - g''\left(x-\frac{1}{2}\right) = \frac{-4}{(2x-1)^2} \qquad \text{...(iii)}$$

On substituting $x = 1, 2, 3, \ldots, N$ in Eq. (iii) and adding

$$g''\left(N+\frac{1}{2}\right) - g''\left(\frac{1}{2}\right) = -4\left\{1+\frac{1}{9}+\frac{1}{25}+\ldots+\frac{1}{(2N-1)^2}\right\}$$

● ***Ex. 8*** *Let $y = f(x)$ be a differentiable function, $\forall\ x \in R$ and satisfies;*

$$f(x) = x + \int_0^1 x^2 z\, f(z)\,dz + \int_0^1 x\,z^2\, f(z)\,dz, \text{ then}$$

(a) $f(x) = \frac{20x}{119}(2+9x)$ (b) $f(x) = \frac{20x}{119}(4+9x)$

(c) $f(x) = \frac{10x}{119}(4+9x)$ (d) $f(x) = \frac{5x}{119}(4+9x)$

Sol. (*b*) We have, $f(x) = x + \int_0^1 x^2 z\, f(z)\,dz + \int_0^1 x z^2 f(z)dz$

$$\text{or} \quad f(x) = x + x^2\int_0^1 z\, f(z)dz + x\int_0^1 z^2 f(z)dz$$

$$\text{Let} \quad \lambda_1 = \int_0^1 z\, f(z)dz \text{ and } \lambda_2 = \int_0^1 z^2\, f(z)dz$$

$$\therefore \quad f(x) = x + x^2\lambda_1 + x\lambda_2 \qquad \text{...(i)}$$

$$\text{Now,} \quad \lambda_1 = \int_0^1 z\, f(z)dz$$

$$\lambda_1 = \int_0^1 z\,(z + z^2\lambda_1 + z\lambda_2)dz$$

[using Eq. (i), as $f(z) = z + z^2\lambda_1 + z\lambda_2$]

$$\Rightarrow \quad \lambda_1 = (1+\lambda_2)\int_0^1 z^2\,dz + \lambda_1\int_0^1 z^3 dz$$

$$\Rightarrow \quad \lambda_1 = (1+\lambda_2)\left(\frac{z^3}{3}\right)_0^1 + \lambda_1\left(\frac{z^4}{4}\right)_0^1$$

$$\Rightarrow \quad \lambda_1 = \frac{1+\lambda_2}{3} + \frac{\lambda_1}{4}$$

$$\Rightarrow \quad 9\lambda_1 - 4\lambda_2 = 4 \qquad \text{...(ii)}$$

$$\text{Also,} \quad \lambda_2 = \int_0^1 z^2\, f(z)\,dz \text{ or } \lambda_2 = \int_0^1 z^2\,\{z + z^2\lambda_1 + z\lambda_2\}dz$$

[using Eq. (i), as $f(z) = z + z^2\lambda_1 + z\lambda_2$]

$$\Rightarrow \quad \lambda_2 = \int_0^1 z^3(1+\lambda_2)dz + \lambda_1\int_0^1 z^4\,dz$$

$$\Rightarrow \quad \lambda_2 = \frac{(1+\lambda_2)}{4} + \frac{\lambda_1}{5}$$

$$\text{or} \quad 15\lambda_2 - 4\lambda_1 = 5 \qquad \text{...(iii)}$$

From Eqs. (ii) and (iii), we get

$$9\lambda_1 - 4\lambda_2 = 4 \quad \text{and} \quad 15\lambda_2 - 4\lambda_1 = 5$$

$$\lambda_1 = \frac{80}{119}, \lambda_2 = \frac{61}{119} \qquad \text{...(iv)}$$

Thus, Eq. (i) becomes

$$f(x) = x + \frac{80}{119}x^2 + \frac{61}{119}x \qquad [\text{from Eq. (iv)}]$$

$$\text{Hence,} \quad f(x) = \frac{20x}{119}(4+9x)$$

● ***Ex. 9*** *A function $f: R \to R$ satisfies the equation $f(x+y) = f(x) \cdot f(y)$ for all , $f(x) \neq 0$. Suppose that the function is differentiable at $x = 0$ and $f'(0) = 2$. Then,*

(a) $f'(x) = 2f(x)$ (b) $f'(x) = f(x)$
(c) $f'(x) = f(x) + 2$ (d) $f'(x) = 2f(x) + x$

Sol. (*a*) We are given that

$$f(x+y) = f(x) \cdot f(y) \quad \text{...(i)}$$

and $$f'(0) = \lim_{h \to 0} \frac{f(h) - f(0)}{h} = 2 \quad \text{...(ii)}$$

Now, $$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$$

$\Rightarrow$ $$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x+0)}{h}$$

$\Rightarrow$ $$f'(x) = \lim_{h \to 0} \frac{f(x) \cdot f(h) - f(x) \cdot f(0)}{h}$$

[using Eq. (i)]

$\Rightarrow$ $$f'(x) = f(x) \lim_{h \to 0} \frac{f(h) - f(0)}{h}$$

$\Rightarrow$ $f'(x) = 2f(x)$ [using Eq. (ii)]

● ***Ex. 10*** *Let f be a function such that $f(x + f(y)) = f(x) + y, \forall\ x, y \in R$, then find $f(0)$. If it is given that there exists a positive real δ, such that $f(h) = h$ for $0 < h < \delta$, then find $f'(x)$,*

(a) 0, 1 (b) −1, 0 (c) 2, 1 (d) −2, 0

Sol. (*a*) Let $x = 0, y = 0$ in $f(x + f(y)) = f(x) + y$

$$f(0 + f(0)) = f(0) + 0$$

$\Rightarrow$ $f(f(0)) = f(0)$

$\Rightarrow$ $f(a) = a$ or $f(0) = 0$

Given, $f(h) = h$

Then, $$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \text{ for } 0 < h < \delta$$

$\Rightarrow$ $$f'(x) = \lim_{h \to 0} \frac{f(x + f(h)) - f(x)}{h}$$

[given $f(h) = h$]

$\Rightarrow$ $$f'(x) = \lim_{h \to 0} \frac{f(x) + h - f(x)}{h}$$

$\Rightarrow$ $$f'(x) = \lim_{h \to 0} \frac{h}{h}$$

$\Rightarrow$ $f'(x) = 1$

● ***Ex. 11*** *If the function of $f(x) = \left[\frac{(x-5)^2}{A}\right] \sin(x-5) + a\cos(x-2)$, where $[\cdot]$ denotes the greatest integer function, is continuous and differentiable in $(7, 9)$, then*

(a) $A \in [8, 64]$ (b) $A \in [0, 8)$
(c) $A \in [16, \infty)$ (d) $A \in [8, 16]$

Sol. (*c*) As we know, $[x]$ is neither continuous nor differentiable at integer values.

So, $f(x)$ is continuous and differentiable in (7, 9).

If $\left[\frac{(x-5)^2}{A}\right] = 0$

$\Rightarrow$ $A > (x-5)^2$ ...(i)

As, $x \in (7, 9) \Rightarrow x - 5 \in (2, 4)$

$\Rightarrow$ $(x-5)^2 \in (4, 16)$ ...(ii)

From Eqs. (i) and (ii), we get

$A \geq 16$

● ***Ex. 12*** *If $f(x) = [2 + 5|n| \sin x]$, where $n \in I$ has exactly 9 points of non-derivability in $(0, \pi)$, then possible values of n are (where $[x]$ denotes greatest integer function)*

(a) ± 3 (b) ± 2
(c) ± 1 (d) None of these

Sol. (*c*) We have, $[2 + 5|n|\sin x] = 2 + [5|n|\sin x]$, let $y = 5|n|\sin x$

∴ Number of points of non-derivability

$$= 2(5|n| - 1) + 1 = 10|n| - 1$$

According to the question, $10|n| - 1 = 9$

$\Rightarrow$ $10|n| = 10$

$\Rightarrow$ $|n| = 1$

Here, $n = \pm 1$

● ***Ex. 13*** *The number of points of discontinuity of $f(x) = [2x]^2 - \{2x\}^2$ (where $[\cdot]$ denotes the greatest integer function and $\{\cdot\}$ denotes the fractional part of x) in the interval $(-2, 2)$ are*

(a) 6 (b) 8
(c) 4 (d) 3

Sol. (*a*) Here, $f(x) = ([2x] + \{2x\})([2x] - \{2x\}) = 2x(2x - 2\{2x\})$

$$= 4x^2 - 4x\{2x\} \quad \text{...(i)}$$

We know, $\{2x\}$ is discontinuous at integers.

Here, $-2 < x < 2$

$\Rightarrow$ $-4 < 2x < 4$

∴ Integer values of $2x = \{-3, -2, -1, 0, 1, 2, 3\}$, but $f(x) = 4x(x - \{2x\})$ is continuous at $x = 0$

∴ Total number of points of discontinuity are 6.

● ***Ex. 14*** *If $x \in R^+$ and $n \in N$, we can uniquely write $x = mn + r$, where $m \in W$ and $0 \leq r < n$. We define x mod n = r. e.g. 10.3 mod 3 = 1.3. The number of points of discontinuity of the function, $f(x) = (x \bmod 2)^2 + (x \bmod 4)$ in the interval $0 < x < 9$ is*

(a) 0 (b) 2
(c) 4 (d) None of these

Sol. (*c*) Here, $f(x)=(x \bmod 2)^2+(x \bmod 4)$

$$=\begin{cases} x^2+x, 0<x<2 \\ (x-2)^2+x, 2\le x<4 \\ (x-4)^2+(x-4), 4\le x<6 \\ (x-6)^2+(x-4), 6\le x<8 \\ (x-8)^2+(x-8), 8\le x<9 \end{cases}$$

Clearly, $f(2^-)=6, f(2^+)=2 \Rightarrow$ discontinuous at $x=2$.

$f(4^-)=8, f(4^+)=0 \Rightarrow$ discontinuous at $x=4$.

$f(6^-)=6, f(6^+)=2 \Rightarrow$ discontinuous at $x=6$.

$f(8^-)=8, f(8^+)=0 \Rightarrow$ discontinuous $x=8$.

$\therefore$ Number of points of discontinuity = 4.

● ***Ex. 15*** *Let $f: R \to R$ be a differentiable function at $x=0$ satisfying $f(0)=0$ and $f'(0)=1$, then the value of* $\lim_{x\to 0}\frac{1}{x}\cdot\sum_{n=1}^{\infty}(-1)^n\cdot f\left(\frac{x}{n}\right)$, *is*

(a) 0 (b) $-\log 2$

(c) 1 (d) e

Sol. (*b*) Let $L=\lim_{x\to 0}\frac{f(x/n)}{x}=\lim_{x\to 0}\frac{f(x/n)-f(0)}{n\cdot x/n}$,

[using $f(0)=0$]

$\therefore \quad L=\frac{1}{n}\lim_{x\to 0}\frac{f(x/n)-f(0)}{x/n}$

$\Rightarrow \quad L=\frac{1}{n}\cdot f'(0)=\frac{1}{n}$ [as $f'(0)=1$]

$\therefore \quad \lim_{x\to 0}\frac{1}{x}\cdot\sum_{n=1}^{\infty}(-1)^n f\left(\frac{x}{n}\right)=\sum_{n=1}^{\infty}(-1)^n\cdot\frac{1}{n}$

$$=-1+\frac{1}{2}-\frac{1}{3}+\frac{1}{4}-\frac{1}{5}+\frac{1}{6}-\ldots$$

$$=-\left(1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\frac{1}{5}-\frac{1}{6}+\ldots\right)=-\log 2$$

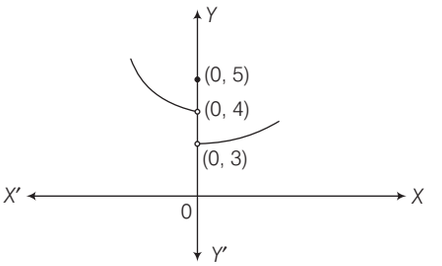
● ***Ex. 16*** *Let $f(x)$ is a function continuous for all $x\in R$ except at $x=0$ such that $f'(x)<0, \forall x\in(-\infty,0)$ and $f'(x)>0, \forall x\in(0,\infty)$. If $\lim_{x\to 0^+} f(x)=3$, $\lim_{x\to 0^-} f(x)=4$ and $f(0)=5$, then the image of the point $(0,1)$ about the line, $y\cdot\lim_{x\to 0} f(\cos^3 x-\cos^2 x)=x\cdot\lim_{x\to 0} f(\sin^2 x-\sin^3 x)$, is*

(a) $\left(\frac{12}{25},\frac{-9}{25}\right)$ (b) $\left(\frac{12}{25},\frac{9}{25}\right)$

(c) $\left(\frac{16}{25},\frac{-8}{25}\right)$ (d) $\left(\frac{24}{25},\frac{-7}{25}\right)$

Sol. (*d*) We have,

$$y\cdot\lim_{x\to 0} f(\cos^3 x-\cos^2 x)=x\cdot\lim_{x\to 0} f(\sin^2 x-\sin^3 x)$$



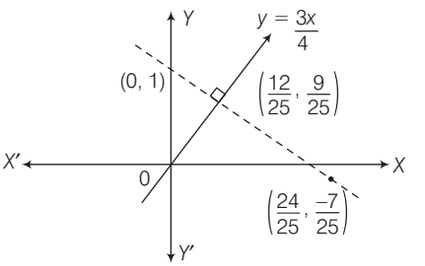
Here, $\cos^3 x-\cos x\to 0$ from LHS

$\therefore \quad \lim_{x\to 0} f(\cos^3 x-\cos x)=4$

$\sin^2 x-\sin^3 x\to 0$ from RHS

$\therefore \quad \lim_{x\to 0} f(\sin^2 x-\sin^3 x)\to 3$

$\therefore$ Equation of straight line is $4y=3x$ ...(i)



Equation of line perpendicular to $y=\frac{3}{4}x$ and passing through (0, 1), is $(y-1)=\frac{-4}{3}(x-0)$

$\Rightarrow \quad y-1=\frac{-4}{3}x$ ...(ii)

On solving Eqs. (i) and (ii), we get

$$x=\frac{12}{25}, y=\frac{9}{25}$$

Hence, image point is $\left(\frac{24}{25},\frac{-7}{25}\right)$.

JEE Type Solved Examples :
More than One Correct Option Type Questions

● ***Ex. 17*** *If $f(x)$ be such that $f(x) = max\,(|3-x|, 3-x^3)$, then*

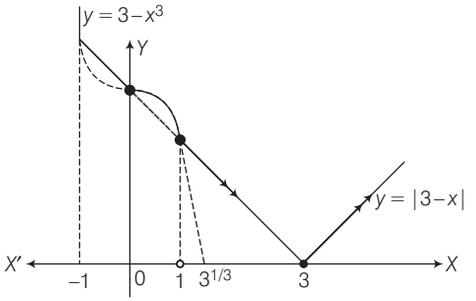
(a) $f(x)$ is continuous $\forall\ x \in R$

(b) $f(x)$ is differentiable $\forall\ x \in R$

(c) $f(x)$ is non-differentiable at three points only

(d) $f(x)$ is non-differentiable at four points only

Sol. (*a,d*) From the graph of $f(x)$, $f(x)$ is continuous, $\forall\ x \in R$ and $f(x)$ is not differentiable at $x = -1, 0, 1, 3$.



● ***Ex. 18*** *Let $f(x) = |x-1|([x]-[-x])$, then which of the following statement(s) is/are correct. (where $[\cdot]$ denotes greatest integer function.)*

(a) $f(x)$ is continuous at $x = 1$

(b) $f(x)$ is derivable at $x = 1$

(c) $f(x)$ is non-derivable at $x = 1$

(d) $f(x)$ is discontinuous at $x = 1$

Sol. (*a, c*) We have, $f(x) = |x-1|([x]-[-x])$

Here, $[x] = 0$, when $0 < x < 1$

$[-x] = -1$, when $0 < x < 1$

$[x] = 1$, when $1 < x < 2$

$[-x] = -2$, when $1 < x < 2$

$[x] = 1, [-x] = -1$, when $x = 1$

$$\therefore\quad f(x) = \begin{cases} (x-1)(1+2), \text{ when } 1 < x < 2 \\ 0, \text{ when } x = 1 \\ (1-x), \text{ when } 0 < x < 1 \end{cases}$$

$$\Rightarrow\quad f'(1^+) = \lim_{h\to 0}\frac{3(h)-0}{h} = 3$$

and $$f'(1^-) = \lim_{h\to 0}\frac{(1-(1-h))-0}{-h} = -1$$

$\Rightarrow$ $f(x)$ is continuous at $x = 1$ and non-derivable at $x = 1$.

● ***Ex. 19*** *If $y = f(x)$ defined parametrically by $x = 2t - |t-1|$ and $y = 2t^2 + t|t|$, then*

(a) $f(x)$ is continuous for all $x \in R$

(b) $f(x)$ is continuous for all $x \in R - \{2\}$

(c) $f(x)$ is differentiable for all $x \in R$

(d) $f(x)$ is differentiable for all $x \in R - \{2\}$

Sol. (*a,d*) Here, $x = 2t - |t-1|$ and $y = 2t^2 + t|t|$

Now, when $t < 0$,

$$x = 2t - \{-(t-1)\} = 3t - 1$$

and $$y = 2t^2 - t^2 = t^2 \Rightarrow y = \frac{1}{9}(x+1)^2$$

When $0 \le t < 1$,

$$x = 2t - (-(t-1)) = 3t - 1$$

and $$y = 2t^2 + t^2 = 3t^2 \Rightarrow y = \frac{1}{3}(x+1)^2$$

When $t \ge 1$,

$$x = 2t - (t-1) = t + 1$$

and $$y = 2t^2 + t^2 = 3t^2 \Rightarrow y = 3(x-1)^2$$

Thus, $$y = f(x) = \begin{cases} \frac{1}{9}(x+1)^2, & x < -1 \\ \frac{1}{3}(x+1)^2, & -1 \le x < 2 \\ 3(x-1)^2, & x \ge 2 \end{cases}$$

Now, to check continuity at $x = -1$ and 2.

Continuity at $x = -1$,

$$\text{LHL} = \lim_{h\to 0} f(-1-h) = \lim_{h\to 0}\frac{1}{9}(-1-h+1)^2 = 0$$

$$\text{RHL} = \lim_{h\to 0} f(-1+h) = \lim_{h\to 0}\frac{1}{3}(-1+h+1)^2 = 0$$

$$f(-1) = 0$$

$\therefore$ $f(x)$ is continuous at $x = -1$.

Now, to check continuity at $x = 2$,

$$\text{LHL} = \lim_{h\to 0} f(2-h) = \lim_{h\to 0}\frac{1}{3}(2-h+1)^2 = 3$$

$$\text{RHL} = \lim_{h\to 0} f(2+h) = \lim_{h\to 0} 3(2+h-1)^2 = 3$$

$$f(2) = 3$$

Thus, $f(x)$ is continuous at $x = 2$.

Now, to check differentiability at $x = -1$ and 2.

Differentiability at $x = -1$,

$$\text{LHD} = Lf'(-1) = \lim_{h\to 0}\frac{f(-1-h)-f(-1)}{-h}$$

$$= \lim_{h\to 0}\frac{\frac{1}{9}(-1-h+1)^2 - 0}{-h} = 0$$

$$\text{RHD} = Rf'(-1) = \lim_{h\to 0}\frac{f(-1+h)-f(-1)}{h}$$

$$= \lim_{h \to 0} \frac{\frac{1}{3}(-1+h+1)^2 - 0}{h} = 0$$

Hence, $f(x)$ is differentiable at $x = -1$.

Differentiability at $x = 2$,

$$\text{LHD} = Lf'(2) = \lim_{h \to 0} \frac{f(2-h) - f(2)}{-h}$$

$$= \lim_{h \to 0} \frac{\frac{1}{3}(2-h+1)^2 - 3}{-h} = 2$$

$$\text{RHD} = Rf'(2) = \lim_{h \to 0} \frac{f(2+h) - f(2)}{h}$$

$$= \lim_{h \to 0} \frac{3(2+h-1)^2 - 3}{h} = 6$$

Hence, $f(x)$ is not differentiable at $x = 2$.

$\therefore f(x)$ is continuous for all x and differentiable for all x, except $x = 2$.

● **Ex. 20** *$f(x) = \sin^{-1}[e^x] + \sin^{-1}[e^{-x}]$, where $[\cdot]$ greatest integer function, then*

(a) domain of $f(x) = (-\ln 2, \ln 2)$

(b) range of $f(x) = \{\pi\}$

(c) $f(x)$ has removable discontinuity at $x = 0$

(d) $f(x) = \cos^{-1} x$ has only solution

Sol. (a, c) $0 < e^x < 2$ and $0 < e^{-x} < 2$

$\Rightarrow \quad -\infty < x < \log_e 2$ and $-\infty < -x < \log_e 2$

$\Rightarrow \quad (-\infty < x < \log_e 2)$

and $\quad (-\log_e 2 < x < \infty)$

$\Rightarrow \quad -\log_e 2 < x < \log_e 2$

$$\therefore \quad f(x) = \begin{cases} \pi, & x = 0 \\ \frac{\pi}{2}, & x \in (-\log_e 2, 0) \cup (0, \log_e 2) \end{cases}$$

● **Ex. 21** *$f : R \to R$ is one-one, onto and differentiable function and graph of $y = f(x)$ is symmetrical about the point (4, 0), then*

(a) $f^{-1}(2010) + f^{-1}(-2010) = 8$

(b) $\int_{-2010}^{2018} f(x)\,dx = 0$

(c) if $f'(-100) > 0$, then roots of $x^2 - f'(10)\,x - f'(10) = 0$ may be non-real

(d) if $f'(10) = 20$, then $f'(-2) = 20$

Sol. (a, b, d) Graph is symmetrical about (4, 0).

$\Rightarrow \quad f(4+x) = -f(4-x)$

$\Rightarrow \quad f(x) = -f(8-x)$ ...(i)

Now, let $f(x) = 2010$, then $f(8-x) = -2010$

$\Rightarrow \quad f^{-1}(2010) + f^{-1}(-2010) = 8$

$\Rightarrow$ Option (a) is true.

and $\quad \int_{-2010}^{4} f(x)dx = -\int_{4}^{2018} f(x)\,dx$

$\Rightarrow$ Option (b) is true.

Also, $\quad D = (f'(10))^2 + 4f'(10) > 0$

As, $\quad f'(-100) > 0 \Rightarrow f'(10) \geq 0$

$\Rightarrow \quad x^2 - f'(10)x - f'(10) = 0$ has real roots.

$\Rightarrow$ Option (c) is false.

As, $\quad f'(4+x) = f'(4-x)$

$f'(x)$ is symmetric about $x = 4$

$\Rightarrow \quad f'(10) = f'(-2) = 20$

$\Rightarrow$ Option (d) is true.

● **Ex. 22** *Let f be a real valued function defined on the interval $(0, \infty)$, by $f(x) = \ln x + \int_0^x \sqrt{1+\sin t}\,dt$. Then, which of the following statement(s) is/are true?* **[IIT JEE 2010]**

(a) $f''(x)$ exists for all $x \in (0, \infty)$

(b) $f'(x)$ exists for all $x \in (0, \infty)$ and f' is continuous on $(0, \infty)$ but not differentiable on $(0, \infty)$

(c) There exists $\alpha > 1$ such that $|f'(x)| < |f(x)|$ for all $x \in (\infty, \infty)$

(d) There exists $\beta > 0$ such that $|f(x)| + |f'(x)| \leq \beta$ for all $x \in (0, \infty)$

Sol. (b, c) Here, $f'(x) = \frac{1}{x} + \sqrt{1+\sin x}$, $x > 0$ but $f(x)$ is not differentiable in $(0, \infty)$ as $\sin x$ may be -1 and then $f''(x) = -\frac{1}{x^2} + \frac{1}{2}\frac{\cos x}{\sqrt{1+\sin x}}$ will not exist.

$\Rightarrow f'(x)$ is continuous for all $x \in (0, \infty)$ but $f'(x)$ is not differentiable on $(0, \infty)$.

$\therefore$ Option (b) is true.

Also, $\quad f'(x) \leq 3$, if $x > 1$

and $\quad f(x) > 3$, if $x > e^3$

$\therefore$ Let $\quad \alpha = e^3$

$\Rightarrow$ Option (c) is true.

(d) is not possible, as $f(x) \to \infty$ when $x \to \infty$.

● **Ex. 23** *If $f(x) + f(y) = f\left(\frac{x+y}{1-xy}\right)$ for all $x, y \in R$ $(xy \neq 1)$ and $\lim_{x \to 0} \frac{f(x)}{x} = 2$, then*

(a) $f\left(\frac{1}{\sqrt{3}}\right) = \frac{\pi}{3}$ (b) $f\left(\frac{1}{\sqrt{3}}\right) = -\frac{\pi}{3}$

(c) $f'(1) = 1$ (d) $f'(1) = -1$

Sol. (a, c) $f(x) + f(y) = f\left(\frac{x+y}{1-xy}\right)$ ...(i)

On putting $x = y = 0$, we get $f(0) = 0$

On putting $y = -x$, we get $f(x) + f(-x) = f(0)$

$\Rightarrow \quad f(-x) = -f(x)$ ...(ii)

Also, $\lim_{x\to 0}\frac{f(x)}{x}=2$

Now, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$ ...(iii)

$=\lim_{h\to 0}\frac{f(x+h)+f(-x)}{h}$

[using Eq. (ii), $-f(x)=f(-x)$]

$f'(x)=\lim_{h\to 0}\frac{f\left(\frac{x+h-x}{1-(x+h)(-x)}\right)}{h}$ [using Eq. (i)]

$\Rightarrow \quad f'(x)=\lim_{h\to 0}\left[\frac{f\left(\frac{h}{1+x(x+h)}\right)}{h}\right]$

$\Rightarrow \quad f'(x)=\lim_{h\to 0}\frac{f\left(\frac{h}{1+xh+x^2}\right)}{\left(\frac{h}{1+xh+x^2}\right)}\times\left(\frac{1}{1+xh+x^2}\right)$

$\Rightarrow \quad f'(x)=\lim_{h\to 0}\frac{f\left(\frac{h}{1+xh+x^2}\right)}{\left(\frac{h}{1+xh+x^2}\right)}\times\lim_{h\to 0}\frac{1}{1+xh+x^2}$

$\left[\text{using } \lim_{x\to 0}\frac{f(x)}{x}=2\right]$

$\Rightarrow \quad f'(x)=2\times\frac{1}{1+x^2} \quad \Rightarrow \quad f'(x)=\frac{2}{1+x^2}$

On integrating both sides, we get

$f(x)=2\tan^{-1}(x)+C$

Where $f(0)=0 \Rightarrow C=0$

Thus, $f(x)=2\tan^{-1}x$

Hence, $f\left(\frac{1}{\sqrt{3}}\right)=2\tan^{-1}\left(\frac{1}{\sqrt{3}}\right)=2\cdot\frac{\pi}{6}=\frac{\pi}{3}$

and $f'(1)=\frac{2}{1+1^2}=\frac{2}{2}=1$

● ***Ex. 24*** *Let $f:R\to R$ is a function which satisfies condition $f(x+y^3)=f(x)+[f(y)]^3$ for all $x,y\in R$. If $f'(0)\geq 0$, then*

(a) $f(x)=0$ only (b) $f(x)=x$ only

(c) $f(x)=0$ or x only (d) $f(10)=10$

Sol. (*c, d*) Given, $f(x+y^3)=f(x)+[f(y)]^3$ ...(i)

and $f'(0)\geq 0$ ...(ii)

On replacing x, y by 0,

$f(0)=f(0)+f(0)^3 \Rightarrow f(0)=0$ ...(iii)

Also, $f'(0)=\lim_{h\to 0}\frac{f(0+h)-f(0)}{h}=\lim_{h\to 0}\frac{f(h)}{h}$ ...(iv)

Let $I=f'(0)=\lim_{h\to 0}\frac{f(0+(h^{1/3})^3)-f(0)}{(h^{1/3})^3}$

$=\lim_{h\to 0}\frac{(f(h^{1/3}))^3}{(h^{1/3})^3}=\lim_{h\to 0}\left(\frac{f(h^{1/3})}{(h^{1/3})}\right)^3=I^3$

$\Rightarrow \quad I=I^3$ or $I=0,1,-1$ as $f'(0)\geq 0$

$\therefore \quad f'(0)=0,1$ ...(v)

Thus, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$=\lim_{h\to 0}\frac{f(x+(h^{1/3})^3)-f(x)}{(h^{1/3})^3}$

$f'(x)=\lim_{h\to 0}\frac{f(x)+(f(h^{1/3}))^3-f(x)}{(h^{1/3})^3}$ [using Eq. (i)]

$\Rightarrow \quad f'(x)=\lim_{h\to 0}\left(\frac{f(h^{1/3})}{(h^{1/3})}\right)^3=(f'(0))^3$

$\Rightarrow \quad f'(x)=0$ or 1 [as $f'(0)=0$ or 1, using Eq. (v)]

On integrating both sides, we get

$f(x)=C$ or $x+C$ as $f(0)=0$

$\Rightarrow \quad f(x)=0$ or x

Thus, $f(10)=0$ or 10

● ***Ex. 25*** *Let $f(x)=x^3-x^2+x+1$*

and $g(x)=\begin{cases}\max f(t), & 0\leq t\leq x \text{ for } 0\leq x\leq 1\\ 3-x, & 1<x\leq 2\end{cases}$

Then, $g(x)$ in $[0,2]$ is

(a) continuous for $x\in[0,2]-\{1\}$

(b) continuous for $x\in[0,2]$

(c) differentiable for all $x\in[0,2]$

(d) differentiable for all $x\in[0,2]-\{1\}$

Sol. (*b, d*) Here, $f(x)=x^3-x^2+x+1$

$\Rightarrow f'(x)=3x^2-2x+1$, which is strictly increasing in (0, 2).

$\therefore \quad g(x)=\begin{cases}f(x), & 0\leq x\leq 1\\ 3-x, & 1<x\leq 2\end{cases}$

[as $f(x)$ is increasing, so $f(x)$ is maximum when $0\leq t\leq x$]

So, $g(x)=\begin{cases}x^3-x^2+x+1, & 0\leq x\leq 1\\ 3-x, & 1<x\leq 2\end{cases}$

Also, $g'(x)=\begin{cases}3x^2-2x+1, & 0\leq x\leq 1\\ -1, & 1<x\leq 2\end{cases}$

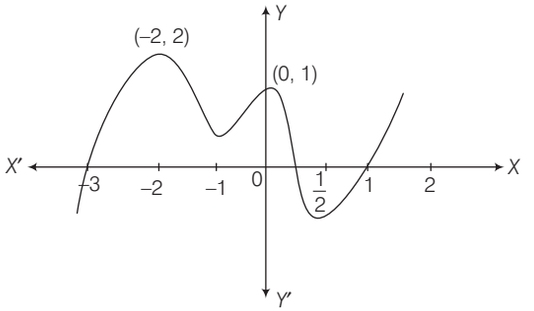
Which clearly shows $g(x)$ is continuous for all $x\in[0,2]$ but $g(x)$ is not differentiable at $x=1$.

JEE Type Solved Examples : Passage Based Questions

Passage I

(Ex. Nos. 26 to 27)

In the given figure graph of $y = P(x) = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$, *is given.*



26. If $P''(x)$ has real roots α, β, γ, then $[\alpha]+[\beta]+[\gamma]$, is

(a) -2 (b) -3 (c) -1 (d) 0

27. The minimum number of real roots of equation $(P''(x))^2 + P'(x)\cdot P'''(x) = 0$, is

(a) 5 (b) 7 (c) 6 (d) 4

Sol. (Ex. Nos. 26 to 27) Here, $P'(x) = 0$ at $x = \left\{-2, -1, 0, \frac{1}{2}\right\}$

$\Rightarrow$ $P''(x)$ will have real roots $\in (-2, -1), (-1, 0), \left(0, \frac{1}{2}\right)$.

$\Rightarrow$ $[\alpha]+[\beta]+[\gamma] = -2-1+0 = -3$

Also, let $f(x) = (P''(x))^2 + P'(x)\cdot P'''(x)$

$\therefore$ $f(x) = \frac{d}{dx}(P'(x)\cdot P''(x))$

Since, $P'(x)$ has 4 real roots.

$\Rightarrow$ $P''(x)$ has 3 real roots.

$\Rightarrow$ $f(x)$ has 6 real roots.

26. (b) **27.** (c)

Passage II

(Ex. Nos. 28 to 30)

If α, β (*where* $\alpha < \beta$) *are the points of discontinuity of the function* $g(x) = f(f(f(x)))$, *where* $f(x) = \frac{1}{1-x}$ *and* $P(a, a^2)$ *is any point on XY-plane. Then,*

28. The points of discontinuity of $g(x)$ is

(a) $x = 0, -1$ (b) $x = 1$ only (c) $x = 0$ only (d) $x = 0, 1$

Sol. (*d*) Here, $f(x) = \frac{1}{1-x}$

$\Rightarrow$ $x \neq 1$

$$f(f(x)) = \frac{1}{1-f(x)} = \frac{1}{1-\frac{1}{1-x}} = \frac{x-1}{x}$$

$\Rightarrow$ $x \neq 0, 1$

and $f(f(f(x))) = \frac{f(x)-1}{f(x)} = \frac{\frac{1}{1-x}-1}{\frac{1}{x-1}} = x$, where $x \neq 0, 1$.

Here, point of discontinuity are $x = 0, 1$.

29. The domain of $f(g(x))$, is

(a) $x \in R$
(b) $x \in R - \{1\}$
(c) $x \in R - \{0, 1\}$
(d) $x \in R - \{0, 1, -1\}$

Sol. (*c*) Here, $g(x) = f(f(f(x))) = x$, $x \in R - \{0, 1\}$

$$f(g(x)) = f(x) = \frac{1}{1-x}$$

$\Rightarrow$ $x \neq 0, 1$

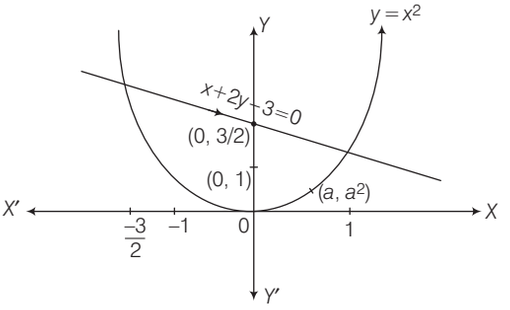
$\therefore$ Domain of $f(g(x)) \in R - \{0, 1\}$

30. If point $P(a, a^2)$ lies on the same side as that of (α, β) with respect to line $x + 2y - 3 = 0$, then

(a) $a \in \left(-\frac{3}{2}, 1\right)$ (b) $a \in R$

(c) $a \in \left(-\frac{3}{2}, 0\right)$ (d) $a \in (0, 1)$

Sol. (*a*) From graph, $a \in \left(-\frac{3}{2}, 1\right)$, as $(\alpha, \beta) = (0, 1)$.



JEE Type Solved Examples :
Matching Type Questions

● ***Ex. 31*** *Let* $f(x)=\begin{cases}[x], & -2\le x<0\\ |x|, & 0\le x\le 2\end{cases}$
(*where* $[\cdot]$ *denotes the greatest integer function*)
$g(x)=\sec x, x\in R-(2n+1)\pi/2$.
Match the following statements in Column I *with their values in Column* II *in the interval* $\left(-\frac{3\pi}{2},\frac{3\pi}{2}\right)$.

	Column I		Column II
(A)	Limit of *fog* exists at	(p)	-1
(B)	Limit of *gof* doesn't exist at	(q)	π
(C)	Points of discontinuity of *fog* is/are	(r)	$\frac{5\pi}{6}$
(D)	Points of differentiability of *fog* is/are	(s)	$-\pi$

Sol. (A) → (p, q, s), (B) → (p), (C) → (q, s), (D) → (p, r)

$$f(x)=\begin{cases}[x], & -2\le x<0\\ |x|, & 0\le x\le 2\end{cases}\Rightarrow f(x)=\begin{cases}-2, & -2\le x<-1\\ -1, & -1\le x<0\\ x, & 0\le x\le 2\end{cases}$$

$$gof=\begin{cases}\sec(-2), & x\in[-2,-1)-\left\{-\frac{\pi}{2}\right\}\\ \sec(-1), & x\in[-1,0)\\ \sec x, & x\in[0,2]-\left\{\frac{\pi}{2}\right\}\end{cases}$$

Limit of *gof* doesn't exist at $x=-1$.

● ***Ex. 32*** *Match the functions in Column* I *with the properties Column* II.

	Column I		Column II
(A)	$g:R\to Q$ (Rational number), $f:R\to Q$ (Rational number); f and g are continuous functions such that $\sqrt{3}\,f(x)+g(x)=3$, then $(1-f(x))^3+(g(x)-3)^3$ is	(p)	1
(B)	If $f(x)$, $g(x)$ and $h(x)$ are continuous and positive functions such that $f(x)+g(x)+h(x)=\sqrt{f(x)g(x)}+\sqrt{g(x)h(x)}+\sqrt{h(x)f(x)}$, then $f(x)+g(x)-2h(x)$ is	(q)	0
(C)	$y=f(x)$ satisfies the equation $y^3-2y^2(x+1)+4xy+(x^2-1)(y-2)=0$, then $y'(1)+y(1)$ would be equal to	(r)	2
(D)	If $y=f(x)$ satisfies $(xf(x))^{99}+(xf(x))^{98}+\ldots+(xf(x))+1=0$, then $(1+f(1))$ is	(s)	3
		(t)	-1

Sol. (A) → (p), (B) → (q), (C) → (p, r,s), (D) → (q)

(A) On comparing, $f(x)=0, g(x)=3$

$\therefore\quad (1-f(x))^3+(g(x)-3)^3=1$

(B) Here, $f(x)+g(x)+h(x)$

$=\sqrt{f(x)\cdot g(x)}+\sqrt{g(x)\cdot h(x)}+\sqrt{h(x)\cdot f(x)}$

$$\Rightarrow\ \frac{1}{2}\{(\sqrt{f(x)}-\sqrt{g(x)})^2+(\sqrt{g(x)}-\sqrt{h(x)})^2+(\sqrt{h(x)}-\sqrt{f(x)})^2\}=0$$

$\Rightarrow\quad f(x)=g(x)=h(x)$

$\therefore\quad f(x)+g(x)-2h(x)=0$

(C) $y^3 - 2y^2(x+1) + 4xy + (x^2-1)(y-2) = 0$

Put $y = 2 \Rightarrow 8 - 8(x+1) + 8x = 0$

$\therefore$ $y = 2$ is solution.

Put $y = (x+1)$

$\Rightarrow (x+1)^3 - 2(x+1)^3 + 4x(x+1) + (x^2-1)(x-1)$

$= -(x+1)^3 + 4x(x+1) + (x+1)(x-1)^2$

$= -(x+1)^3 + (x+1)\{4x + (x-1)^2\}$

$= -(x+1)^3 + (x+1)^3 = 0$

$\therefore$ $y = (x+1)$ is the solution.

Similarly, $y = (x-1)$ is the solution

$\Rightarrow \quad y = 2, x+1, x-1$

$\therefore \quad \frac{dy}{dx} = 0, 1$

$\Rightarrow$ $\begin{cases} y'(1) + y(1) = 0 + 2 = 2, \text{ when } y = 2 \\ y'(1) + y(1) = 1 + 2 = 3, \text{ when } y = x+1 \\ y'(1) + y(1) = 1 + 0 = 1, \text{ when } y = x-1 \end{cases}$

(D) $\frac{(xf(x))^{100} - 1}{xf(x) - 1} = 0 \Rightarrow xf(x) = -1$

As, $xf(x) \neq 1$

$\therefore$ $xf(x) = -1$

$\Rightarrow$ $f(1) = -1$ or $1 + f(1) = 0$

● ***Ex. 33*** *Suppose a function $f(x)$ satisfies the following conditions*

$f(x+y) = \frac{f(x) + f(y)}{1 + f(x)\,f(y)}, \forall\, x, y$ *and* $f'(0) = 1$. *Also,*

$-1 < f(x) < 1, \forall\, x \in R$.

Match the entries of the following two columns.

	Column I		Column II
(A)	$f(x)$ is differentiable over the set	(p)	$R - (-1, 0, 1)$
(B)	$f(x)$ increases in the interval	(q)	R
(C)	Number of the solutions of $f(x) = 0$ is	(r)	0
(D)	The value of the limit $\lim_{x \to \infty} [f(x)]^x$ is	(s)	1

Sol. (A) $\to$ (q), (B) $\to$ (q), (C) $\to$ (s), D $\to$ (s)

Put $x = y = 0 \Rightarrow f(0) = 0$

Now, $f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$

$= \lim_{h \to 0} \frac{\frac{f(x) + f(h)}{1 + f(x)\,f(h)} - f(x)}{h}$

$= \lim_{h \to 0} \frac{f(h)[1 - \{f(x)\}^2]}{h[1 + f(x)\,f(h)]}$

$= \lim_{h \to 0} \left\{\frac{f(h) - f(0)}{h - 0}\right\} \left[\frac{1 - \{f(x)\}^2}{1 + f(x)\,f(h)}\right]$

$= f'(0)[1 - \{f(x)\}^2] = 1 - \{f^2(x)\}$

$\therefore \quad f'(x) = 1 - \{f^2(x)\}$ ...(i)

On integrating both sides, we get

$\frac{1}{2} \ln\left[\frac{1 + f(x)}{1 - f(x)}\right] = x + c$

or $\frac{1 + f(x)}{1 - f(x)} = ke^{2x}$

Now, $f(0) = 0 \Rightarrow k = 1$

$\therefore \quad f(x) = \frac{e^{2x} - 1}{e^{2x} + 1} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$

Clearly, $f(x)$ is differentiable for all $x \in R$ and from Eq. (i), $f'(x) > 0$ for all $x \in R$. Again, $f(x)$ is an odd function, $f(x) = 0 \Rightarrow x = 0$.

Now, $\lim_{x \to \infty} [f(x)]^x = \lim_{x \to \infty} \left(\frac{e^x - e^{-x}}{e^x + e^{-x}}\right)^x$

$= e^{\lim_{x \to \infty} \left(\frac{e^x - e^{-x}}{e^x + e^{-x}} - 1\right) x} = e^{-2 \lim_{x \to \infty} \left(\frac{xe^{-x}}{e^x + e^{-x}}\right)}$

$= e^{-2 \lim_{x \to \infty} \left(\frac{x}{e^{2x} + 1}\right)}$

$= e^{-2 \lim_{x \to \infty} \left(\frac{1}{2e^{2x}}\right)} = e^0 = 1$

JEE Type Solved Examples :

● **Ex. 34** *Let* $f(x)=\begin{cases}\dfrac{1-\cos 4x}{x^2}, & x<0\\ a, & x=0\\ \dfrac{\sqrt{x}}{\sqrt{16+\sqrt{x}}-4}, & x>0\end{cases}$

Then, the value of a if possible, so that the function is continuous at $x=0$ *, is ..... .*

Sol. (8) As, $f(x)$ is continuous at $x=0$.

$\therefore$ We must have,

$$\text{RHL (at } x=0)=\text{LHL (at } x=0)=f(0)$$

$$\text{RHL (at } x=0)=\lim_{x\to 0^+} f(x)=\lim_{x\to 0^+}\frac{\sqrt{x}}{\sqrt{16+\sqrt{x}}-4}$$

$$=\lim_{h\to 0}\frac{\sqrt{0+h}}{\sqrt{16+\sqrt{0+h}}-4}\times\frac{\sqrt{16+\sqrt{h}}+4}{\sqrt{16+\sqrt{h}}+4} \qquad [\text{putting } x=0+h]$$

$$=\lim_{h\to 0}\frac{\sqrt{h}\{\sqrt{16+\sqrt{h}}+4\}}{16+\sqrt{h}-16}$$

$$=\lim_{h\to 0}\{\sqrt{16+\sqrt{h}}+4\}=8$$

$$\text{Also, LHL (at } x=0)=\lim_{x\to 0^-} f(x)=\lim_{x\to 0^-}\frac{1-\cos 4x}{x^2}$$

$$=\lim_{h\to 0}\frac{1-\cos 4(0-h)}{(0-h)^2} \qquad [\text{putting } x=0-h]$$

$$=\lim_{h\to 0}\frac{1-\cos 4h}{h^2}$$

$$=\lim_{h\to 0}\frac{2\sin^2 2h}{h^2}$$

$$=\lim_{h\to 0} 8\left(\frac{\sin 2h}{2h}\right)^2=8$$

And $f(0)=a$

Since, $f(x)$ is continuous at $x=0$

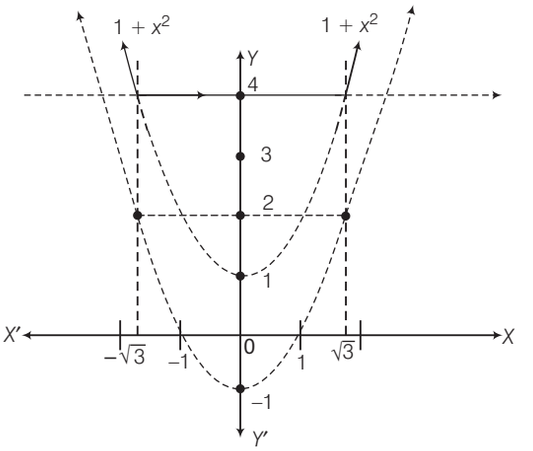
$\Rightarrow$ $f(0)=\text{RHL}=\text{LHL}$

or $f(0)=8$ or $a=8$

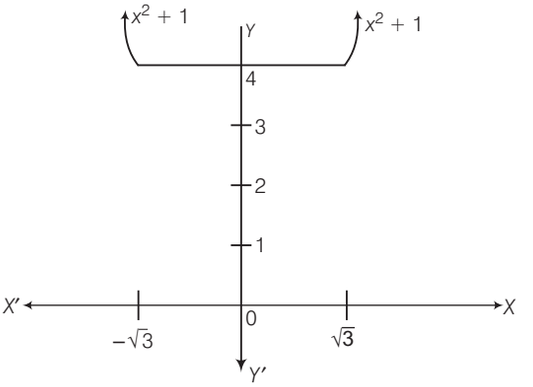
● **Ex. 35** *Let* $f(x)=\text{maximum}\{4,1+x^2,x^2-1\},\forall\, x\in R$.

Then, the total number of points, where $f(x)$ *is not differentiable, ...*

Sol. (2) We have, discussed in the last chapter for sketching maximum $\{4, 1+x^2, x^2-1\}$ as



Or



Thus, from above graph, we can simply say

$f(x)$ is not differentiable at $x=\pm\sqrt{3}$.

$\therefore$ Not differentiable at 2 points.

● **Ex. 36** *Let* $f(x)=x^n$*, n being non-negative integer. Then, the number of value of n for which the equality* $f'(a+b)=f'(a)+f'(b)$ *is valid for all* $a,b>0$*, is*

Sol. (2) Since, $f(x)=x^n$, n being non-negative integer.

Then, $f'(x)=nx^{n-1}$

$$f'(a)=na^{n-1},\ f'(b)=nb^{n-1},$$

$$f'(a+b)=n(a+b)^{n-1}$$

Now, the equality $f'(a+b)=f'(a)+f'(b)$ holds, if

$$n(a+b)^{n-1}=na^{n-1}+nb^{n-1}$$

or $(a+b)^{n-1}=a^{n-1}+b^{n-1}$ ...(i)

Above statement is true, only if $(n-1)=1 \Rightarrow n=2$

i.e. $(a+b)^{n-1}=a^{n-1}+b^{n-1}$ [if $n=2$]

or $(a+b)^1 = a^1 + b^1$

Also, when $n = 1$, then LHS < RHS

and when $n = 3, 4, 5, \ldots$, then LHS > RHS

Again, when $n = 0$, $f'(x) = 0$ for all x.

So, the equality is true for $n = 0$ and 2.

∴ Number of values is 2.

● ***Ex. 37*** *Find the number of points where* $f(x) = [\sin x + \cos x]$ *(where* $[\cdot]$ *denotes greatest integral function),* $x \in [0, 2\pi]$ *is not continuous, is/are..... .*

Sol. (5) We know $[\cdot]$ is not continuous at integral points.

Thus, $f(x) = [\sin x + \cos x]$ will be discontinuous at those points, where $\sin x + \cos x$ is an integer, i.e.

$$x \in \left\{\frac{\pi}{2}, \frac{3\pi}{4}, \pi, \frac{3\pi}{2}, \frac{7\pi}{4}\right\}$$

Thus, the number of points at which $f(x)$ is discontinuous is 5.

● ***Ex. 38*** *The number of points where* $|xf(x)| + ||x-2|-1||$ *is non-differentiable in* $x \in (0, 3\pi)$*, where*

$$f(x) = \prod_{k=1}^{\infty}\left(\frac{1+2\cos\left(\frac{2x}{3^k}\right)}{3}\right), \text{ is ..... .}$$

Sol. (5) We know,

$$\sin 3\theta = 3\sin\theta - 4\sin^3\theta = \sin\theta(1+2\cos 2\theta)$$

$$\therefore \quad \sin 3\theta = \sin\theta\,(1+2\cos 2\theta) \qquad \ldots(i)$$

Now, on putting $3\theta = x, \frac{x}{3}, \frac{x}{3^2}, \ldots$ one by one in Eq. (i), we get

$$\Rightarrow \quad \sin x = \sin\left(\frac{x}{3}\right)\cdot\left(1+2\cos\frac{2x}{3}\right)$$

and $$\sin\frac{x}{3} = \sin\left(\frac{x}{3^2}\right)\cdot\left(1+2\cos\frac{2x}{3^2}\right)$$

$$\therefore \quad \sin\frac{x}{3^2} = \sin\left(\frac{x}{3^3}\right)\cdot\left(1+2\cos\frac{2x}{3^3}\right) \ldots \text{and so on}$$

$$\Rightarrow \quad \sin x = \sin\left(\frac{x}{3^n}\right)\cdot\prod_{k=1}^{n}\left(1+2\cos\frac{2x}{3^k}\right)$$

$$\Rightarrow \quad \frac{\sin x}{x} = \lim_{n\to\infty}\frac{\sin x/3^n}{x/3^n}\prod_{k=1}^{n}\frac{\left(1+2\cos\left(\frac{2x}{3^k}\right)\right)}{3^n}$$

$$\Rightarrow \quad \frac{\sin x}{x} = \prod_{k=1}^{\infty}\left(\frac{1+2\cos\left(\frac{2x}{3^k}\right)}{3}\right) = f(x) \qquad \ldots(ii)$$

Thus, $|xf(x)| + ||x-2|-1| = \frac{|x||\sin x|}{|x|} + ||x-2|-1|$ is not differentiable at $\{\pi, 2\pi, 0, 1, 3\}$.

∴ Number of points are 5.

● ***Ex. 39*** *If* $f\left(\frac{xy}{2}\right) = \frac{f(x)\cdot f(y)}{2}$; $x, y \in R$, $f(1) = f'(1)$.

Then, $\frac{f(3)}{f'(3)}$ *is ..... .*

Sol. (3) Here, $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$$= \lim_{h\to 0}\frac{f\left(\frac{2x+2h}{2}\right)-f(x)}{h}$$

$$= \lim_{h\to 0}\frac{f\left(\frac{2x(1+h/x)}{2}\right)-f\left(\frac{2x\cdot 1}{2}\right)}{h}$$

$$= \lim_{h\to 0}\frac{\frac{f(2x)\cdot f(1+h/x)}{2}-\frac{f(2x)\cdot f(1)}{2}}{h}$$

$$= \frac{f(2x)}{2x}\cdot\lim_{h\to 0}\frac{f(1+h/x)-f(1)}{h/x}$$

$$= \frac{f(2x)}{2x}\cdot f'(1)$$

$$= \frac{f(2x)}{2x}\cdot f(1), \text{ given } f(1) = f'(1)$$

$$= \frac{f\left(\frac{2x\cdot 1}{2}\right)}{x}, \text{ using } f\left(\frac{xy}{2}\right) = \frac{f(x)\cdot f(y)}{2}$$

$$\therefore \quad f'(x) = \frac{f(x)}{x}$$

$$\Rightarrow \quad \frac{f(x)}{f'(x)} = x \Rightarrow \frac{f(3)}{f'(3)} = 3$$

● ***Ex. 40*** *Let* $f: R \to R$ *be a differentiable function satisfying* $f(x) = f(y)\,f(x-y), \forall x, y \in R$ *and* $f'(0) = \int_0^4 \{2x\}\,dx$*, where* $\{\cdot\}$ *denotes the fractional part function and* $f'(-3) = \alpha e^{\beta}$*. Then,* $|\alpha+\beta|$ *is equal to ..... .*

Sol. (4) Given, $f(x) = f(y)\,f(x-y)$

On replacing x by $(x+y)$,

$$f(x+y) = f(y)\cdot f(x)$$

$$\Rightarrow \quad f(x) = e^{kx} \Rightarrow f'(x) = ke^{kx}$$

But, $$f'(0) = \int_0^4 \{2x\}dx = 2$$

$$\Rightarrow \quad f'(0) = k = 2 \Rightarrow f'(x) = 2e^{2x}$$

$$\Rightarrow \quad f'(-3) = 2e^{-6} \Rightarrow |\alpha+\beta| = 4$$

● **Ex. 41** *Let $f(x)$ is a polynomial function and $(f(\alpha))^2 + (f'(\alpha))^2 = 0$, then find $\lim_{x\to\alpha} \frac{f(x)}{f'(x)}\left[\frac{f'(x)}{f(x)}\right]$, where $[\cdot]$ denotes greatest integer function, is .....*

Sol. (1) Here, $(f(\alpha))^2 + (f'(\alpha))^2 = 0 \Rightarrow f(\alpha) = f'(\alpha) = 0$

$\therefore$ α is repeated root of $f(x)$.

Now, $\lim_{x\to\alpha} \frac{f(x)}{f'(x)}\left[\frac{f'(x)}{f(x)}\right] = \lim_{x\to\alpha} \frac{f(x)}{f'(x)}\left(\frac{f'(x)}{f(x)} - \left\{\frac{f'(x)}{f(x)}\right\}\right)$

$= \lim_{x\to\alpha}\left(1 - \frac{f(x)}{f'(x)} \cdot \left\{\frac{f'(x)}{f(x)}\right\}\right)$

$\left[\text{as, } x = \alpha \text{ is the repeated root and } \left\{\frac{f(x)}{f'(x)}\right\} \text{ is bounded; } \therefore \lim_{x\to\alpha} \frac{f(x)}{f'(x)} = 0\right]$

$= 1 - 0 = 1$

● **Ex. 42** *Let $f : R \to R$ is a function satisfying $f(10 - x) = f(x)$ and $f(2 - x) = f(2 + x), \forall\, x \in R$. If $f(0) = 101$. Then, the minimum possible number of values of x satisfying $f(x) = 101$, $x \in [0, 25]$ is ..... .*

Sol. (9) Since, $f(10 - x) = f(x) = f(4 - x)$

$\Rightarrow$ $f(10 - x) = f(4 - x)$

Say, $4 - x = t \Rightarrow f(6 + t) = f(t)$

$\Rightarrow f(x)$ is periodic function with period 6.

So, for $x \in [0, 25]$

$f(x) = 101$ at $x = 0, 6, 12, 18, 24$

Total numbers = 5

Since, $f(2 - x) = f(2 + x)$

$\Rightarrow f(x)$ is symmetric about $x = 2$ line.

Due to symmetry in one period length.

$f(x) = 101$ has one solution at $x = 4$ other than 0 and 6.

Now, $f(x) = 101$ at $x = 4, 10, 16, 22$

Total numbers = 4

Hence, atleast minimum possible number of values of $x = 9$.

● **Ex. 43** *If $f(x)$ is a differentiable function for all $x \in R$ such that $f(x)$ has fundamental period 2. $f(x) = 0$ has exactly two solutions in $[0, 2]$, also $f(0) \neq 0$. If minimum number of zeros of $h(x) = f'(x)\cos x - f(x)\sin x$ in $(0, 99)$ is $120 + k$, then k is ..... .*

Sol. (7) $h(x) = \frac{d}{dx}(f(x) \cdot \cos x)$

First find the minimum number of zeros of $(f(x) \cdot \cos x) = 0$.

$f(x) = 0$ has minimum 98 roots in $[0, 99)$ and $\cos x = 0$ has 31 roots is $[0, 99)$.

Maximum common possible root is only 1.

Hence, minimum number of roots of $f(x)\cos x = 0$ is 128.

Thus, $\frac{d}{dx}(f(x)\cos x) = 0$ has minimum 127 roots.

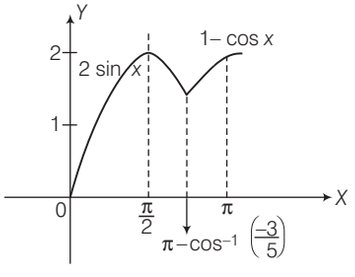
$127 = 120 + 7$

Hence, value of k is 7.

Subjective Type Questions

● **Ex. 44** *Let $f(x) = \max\{2\sin x, 1 - \cos x\}, \forall\, x \in (0, \pi)$, then discuss differentiability of $f(x)$ in $(0, \pi)$.*

Sol. We know that, $f(x) =$ maximum $\{2\sin x, 1 - \cos x\}$ can be plotted as



Thus, $f(x) =$ maximum $\{2\sin x, 1 - \cos x\}$ is not differentiable.

When, $2\sin x = 1 - \cos x$

or $4\sin^2 x = (1 - \cos x)^2$

or $4(1 + \cos x) = (1 - \cos x)$

or $4 + 4\cos x = 1 - \cos x$

or $\cos x = -3/5$

$\Rightarrow$ $x = \cos^{-1}(-3/5)$

$\therefore$ $f(x)$ is not differentiable at

$x = \pi - \cos^{-1}(3/5)$.

● **Ex. 45** *Discuss the continuity of the function $g(x) = [x] + [-x]$ at integral values of x.*

Sol. Here, x can assume two values

(a) integers (b) non-integers

(a) **If x is an integer**

$[x] = x$ and $[-x] = -x$

$\Rightarrow$ $g(x) = x - x = 0$

(b) **If x is not an integer**

Let $x = n + f$, where n is an integer and $f \in (0, 1)$

$\Rightarrow \quad [x] = [n + f] = n$

$\Rightarrow [-x] = [-n - f] = [(-n-1) + (1-f)] = (-n-1)$

$[\because 0 < f < 1 \Rightarrow (1-f) < 1]$

Hence, $g(x) = [x] + [-x] = n + (-n-1) = -1$

$\therefore \quad g(x) = \begin{cases} 0, & \text{if } x \text{ is an integer} \\ -1, & \text{if } x \text{ is not an integer} \end{cases}$

Let us discuss the continuity of $g(x)$ at a point $x = a$ [where $a \in$ integer]

$\text{LHL} = \lim_{x \to a^-} g(x) = -1$

$[\because \text{as } x \to a^-, x \text{ is not an integer}]$

$\text{RHL} = \lim_{x \to a^+} g(x) = -1$

$[\because \text{as } x \to a^+, x \text{ is not an integer}]$

But $g(a) = 0$ because a is an integer.

Hence, $g(x)$ has a removable discontinuity at integral values of x.

● ***Ex. 46*** *If* $f(x) = \dfrac{\sin 2x + A \sin x + B \cos x}{x^3}$ *is continuous at* $x = 0$. *Find the values of A and B. Also, find* $f(0)$.

Sol. As, $f(x)$ is continuous at $x = 0$.

$f(0) = \lim_{x \to 0} f(x)$ and both $f(0)$ and $\lim_{x \to 0} f(x)$ are finite.

$\Rightarrow \quad f(0) = \lim_{x \to 0} \dfrac{\sin 2x + A \sin x + B \cos x}{x^3}$

As, denominator $\to 0$ as $x \to 0$,

Numerator should also $\to 0$ as $x \to 0$

Which is possible only if (for $f(0)$ to be finite).

$\Rightarrow \quad \sin 2(0) + A \sin (0) + B \cos (0) = 0$

$\Rightarrow \quad B = 0$

$\therefore \quad f(0) = \lim_{x \to 0} \dfrac{\sin 2x + A \sin x}{x^3}$

$\Rightarrow \quad f(0) = \lim_{x \to 0} \left(\dfrac{\sin x}{x}\right)\left(\dfrac{2\cos x + A}{x^2}\right)$

$= \lim_{x \to 0} \left(\dfrac{2\cos x + A}{x^2}\right)$

Again, we can see that denominator $\to 0$ as $x \to 0$.

$\therefore$ Numerator should also approach to 0 as $x \to 0$ [$\because$ for $f(0)$ to be finite]

$\Rightarrow \quad 2 + A = 0$

$\Rightarrow \quad A = -2$

$\Rightarrow \quad f(0) = \lim_{x \to 0} \left(\dfrac{2\cos x - 2}{x^2}\right) = \lim_{x \to 0} \left(\dfrac{-4\sin^2 x/2}{x^2}\right)$

$= \lim_{x \to 0} -\left(\dfrac{-\sin^2 x/2}{x^2/4}\right) = -1$

So, we get $A = -2, B = 0$

and $f(0) = -1$

● ***Ex. 47*** *Let* $f : R \to R$ *satisfying* $|f(x)| \le x^2, \forall x \in R$, *then show that* $f(x)$ *is differentiable at* $x = 0$.

Sol. Since, $|f(x)| \le x^2, \forall x \in R$

$\therefore$ At $x = 0, |f(0)| \le 0$

$\Rightarrow \quad f(0) = 0 \quad \ldots(i)$

$\therefore \quad f'(0) = \lim_{h \to 0} \dfrac{f(h) - f(0)}{h} = \lim_{h \to 0} \dfrac{f(h)}{h} \quad \ldots(ii)$

$[f(0) = 0, \text{ from Eq. (i)}]$

Now, $\left|\dfrac{f(h)}{h}\right| \le |h|$

$\Rightarrow \quad -|h| \le \dfrac{f(h)}{h} \le |h|$

$\Rightarrow \quad \lim_{h \to 0} \dfrac{f(h)}{h} \to 0$

[using Cauchy-Squeeze theorem] ...(iii)

$\therefore$ From Eqs. (ii) and (iii), we get $f'(0) = 0$

i.e. $f(x)$ is differentiable at $x = 0$

● ***Ex. 48*** *Show that the function defined by*

$$f(x) = \begin{cases} x^2 \sin 1/x, & x \neq 0 \\ 0, & x = 0 \end{cases}$$

is differentiable for every value of x, but the derivative is not continuous for $x = 0$.

Sol. For $x \neq 0$,

$$f'(x) = 2x \sin (1/x) + x^2 \left(-\frac{1}{x^2}\right) \cos \left(\frac{1}{x}\right)$$

$$f'(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x}$$

For $x = 0$,

$$f'(x) = \lim_{h \to 0} \frac{f(0+h) - f(0)}{h}$$

$$= \lim_{h \to 0} \frac{h^2 \sin \frac{1}{h} - 0}{h}$$

$\Rightarrow \quad f'(x) = \lim_{h \to 0} h \sin \dfrac{1}{h} = 0$

Thus, $f'(x) = \begin{cases} 2x \sin \dfrac{1}{x} - \cos \dfrac{1}{x}, & x \neq 0 \\ 0, & x = 0 \end{cases}$

Now, $f'(x)$ is continuous at $x = 0$, if

(i) $\lim_{x \to 0} f'(x)$ exists (ii) $\lim_{x \to 0} f'(x) = f'(0)$

Again, $\lim_{x \to 0} f'(x) = \lim_{x \to 0} \left(2x \sin \dfrac{1}{x} - \cos \dfrac{1}{x}\right)$, doesn't exist

Since, $\lim_{x \to 0} \cos \dfrac{1}{x}$ doesn't exist.

Hence, $f'(x)$ is not continuous at $x = 0$.

● ***Ex. 49*** *If* $f(x)=\begin{cases} x-[x], & x\notin I \\ 1, & x\in I \end{cases}$

where I is an integer and $[\cdot]$ *represents the greatest integer function and*

$$g(x)=\lim_{n\to\infty}\frac{\{f(x)\}^{2n}-1}{\{f(x)\}^{2n}+1},\ \textit{then}$$

(a) Draw graphs of $f(2x)$, $g(x)$ and $g\{g(x)\}$.

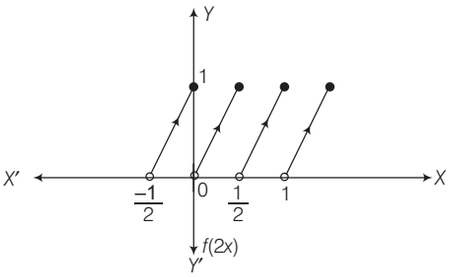
(b) Find the domain and range of these functions.

(c) Are these functions periodic? If yes, find their periods.

Sol. Here, $f(x)=\begin{cases} x-[x], & x\notin I \\ 1, & x\in I \end{cases}$

(a) **Graph of $f(2x)$**

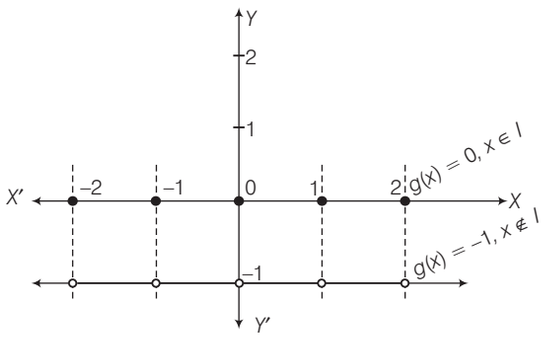
As, $f(2x)=\begin{cases} 2x-[2x], & 2x\notin I \\ 1, & 2x\in I \end{cases}$



Graph of $g(x)$

Here, $g(x)=\lim_{n\to\infty}\frac{\{f(x)\}^{2n}-1}{\{f(x)\}^{2n}+1}$

$$g(x)=\begin{cases} 0, & x\in I \\ -1, & x\notin I, \text{ as } \lim_{n\to\infty}\{f(x)\}^{2n}=0 \end{cases}$$



Graph of $g\{g(x)\}$

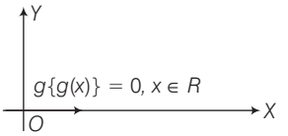
We have, $g(x)=\begin{cases} 0, & x\in I \\ -1, & x\notin I \end{cases}$

$\Rightarrow$ $g\{g(x)\}=\begin{cases} 0, & g(x)\in I \\ -1, & g(x)\notin I \end{cases}$

where $g(x)\in\{0,-1\}$

and thus $g(x)\notin I$, should be neglected.

$\Rightarrow$ $g\{g(x)\}=0,\ x\in R$ and could be plotted as,



(b) From the above three graphs, we have

Domain of $f(2x)\in R$

and Range of $f(2x)\in(0,1]$

Domain of $g(x)\in R$

and Range of $g(x)\in\{0,-1\}$

Domain of $g(g(x))\in R$

and Range of $g(g(x))\in\{0\}$

(c) Here, $f(2x)$ and $g(x)$ are periodic with period 1/2 and 1. Also, $g\{g(x)\}$ is constant function. Therefore, periodic and its period is undetermined.

● ***Ex. 50*** *Prove that* $f(x)=[\tan x]+\sqrt{\tan x-[\tan x]}$. *(where* $[\cdot]$ *denotes greatest integer function) is continuous in* $\left[0,\frac{\pi}{2}\right)$.

Sol. Here, $f(x)=[\tan x]+\sqrt{\tan x-[\tan x]}$

or $g(x)=[x]+\sqrt{x-[x]}$, where $x=\tan x\geq 0$

Then, for $a\in N$. We discuss continuity of $f(x)$ as

LHL (at $x=a$)

$$=\lim_{x\to a^-}g(x)=\lim_{h\to 0}([a-h]+\sqrt{a-h-[a-h]})$$

$$=\lim_{h\to 0}((a-1)+\sqrt{a-h-a+1})=a-1+1=a$$

$$\begin{cases} \text{where}, & a-1<a-h<a \\ \therefore [a-h]=a-1 \end{cases}$$

Now, RHL (at $x=a$)

$$=\lim_{x\to a^+}g(x)=\lim_{h\to 0}([a+h]+\sqrt{a+h-[a+h]})$$

$$=\lim_{h\to 0}(a+\sqrt{a+h-a})=a$$

$$[\because a<a+h<a+1\ \Rightarrow\ [a+h]=a]$$

and $g(a)=[a]+\sqrt{a-[a]}=a$

as $a\in N$

So, $g(x)$ is continuous, $\forall\ a\in N$, now $g(x)$ is clearly continuous in $(a-1,\ a)$, $\forall\ a\in N$.

Hence, $g(x)$ is continuous in $[0,\infty)$.

Now, let $\phi(x)=\tan x$ which is continuous in $[0,\pi/2]$.

So, $g\{\phi(x)\}$ is continuous in $[0,\pi/2)$.

Hence, $f(x)=[\tan x]+\sqrt{\tan x-[\tan x]}$ is continuous in $[0,\pi/2)$.

● **Ex. 51** *Determine the values of x for which the following functions fails to be continuous or differentiable*

$$f(x)=\begin{cases}(1-x), & x<1\\ (1-x)(2-x), & 1\le x\le 2\\ (3-x), & x>2\end{cases}$$

Justify your answer. ***[IIT JEE 1995]***

Sol. By the given definition, it is clear that the function f is continuous and differentiable at all points except possibility at $x=1$ and $x=2$.

Continuity at $x=1$

$$\text{LHL}=\lim_{x\to 1^-} f(x)=\lim_{x\to 1^-}(1-x)=\lim_{h\to 0}(1-(1-h))=0$$

$$\text{RHL}=\lim_{x\to 1^+} f(x)=\lim_{x\to 1^+}(1-x)(2-x)$$

$$=\lim_{h\to 0}\{1-(1+h)\}\{2-(1+h)\}=0$$

Also, $f(1)=0$.

Hence, LHL = RHL = $f(1)$

Therefore, $f(x)$ is continuous at $x=1$.

Differentiability at $x=1$

$$Lf'(1)=\lim_{h\to 0}\frac{f(1-h)-f(1)}{-h}=\lim_{h\to 0}\frac{1-(1-h)-0}{-h}=-1$$

$$Rf'(1)=\lim_{h\to 0}\frac{f(1+h)-f(1)}{h}$$

$$=\lim_{h\to 0}\frac{\{1-(1+h)\}\{2-(1+h)\}-0}{h}=-1$$

Since, $L\{f'(1)\}=R\{f'(1)\}$ so, we get $f(x)$ is differentiable at $x=1$.

Continuity at $x=2$

$$\text{LHL}=\lim_{x\to 2^-} f(x)=\lim_{x\to 2^-}(1-x)(2-x)$$

$$=\lim_{h\to 0}(1-(2-h))(2-(2-h))=0$$

$$\text{RHL}=\lim_{x\to 2^+} f(x)=\lim_{x\to 2^+}(3-x)=\lim_{h\to 0}3-(2+h)=1$$

Since, RHL ≠ LHL

Therefore, $f(x)$ is not continuous at $x=2$.

As such $f(x)$ cannot be differentiable at $x=2$.

Hence, $f(x)$ is continuous and differentiable at all points except at $x=2$.

● **Ex. 52** *If $g(x)$ is continuous function in $[0,\infty)$ satisfying $g(1)=1$. If $\int_0^x 2x\cdot g^2(t)\,dt=\left(\int_0^x 2g(x-t)\,dt\right)^2$, find $g(x)$.*

Sol. Here, $\int_0^x g(t)\,dt=\int_0^x g(x-t)\,dt$, the given equation could be written as

$$x\int_0^x g^2(t)\,dt=2\left(\int_0^x g(t)\,dt\right)^2 \qquad ...(i)$$

On differentiating both sides w.r.t. 'x', we get

$$\int_0^x g^2(t)\,dt+xg^2(x)=4g(x)\left\{\int_0^x g(t)\,dt\right\}$$

or $$x\int_0^x g^2(t)\,dt+x^2g^2(x)=4xg(x)\int_0^x g(t)\,dt \qquad ...(ii)$$

Using Eq. (i),

$$2\left(\int_0^x g(t)\,dt\right)^2+x^2g^2(x)=4xg(x)\int_0^x g(t)\,dt$$

$$\Rightarrow\quad 2\left(\int_0^x g(t)\,dt\right)^2-4xg(x)\int_0^x g(t)\,dt+x^2g^2(x)=0$$

which is quadratic in $\int_0^x g(t)\,dt$,

$$\therefore\qquad \int_0^x g(t)\,dt=\frac{2\pm\sqrt{2}}{2}xg(x)$$

On differentiating both sides w.r.t. x, we get

$$\frac{g'(x)}{g(x)}=\frac{1\pm\sqrt{2}}{x}$$

$$\Rightarrow\qquad g(x)=kx^{1\pm\sqrt{2}},\ \text{since } g(1)=1$$

$$\Rightarrow\qquad k=1$$

$$\therefore\qquad g(x)=x^{1\pm\sqrt{2}}$$

which is continuous in $[0,\infty)$.

● **Ex. 53** *Let $f(x)=\begin{cases}x+a, & \text{if } x<0\\ |x-1|, & \text{if } x\ge 0\end{cases}$ and $g(x)=\begin{cases}x+1, & \text{if } x<0\\ (x-1)^2+b, & \text{if } x\ge 0\end{cases}$ where a and b are non-negative real numbers. Determine the composite function gof. If $(gof)(x)$ is continuous for all real x. Determine the values of a and b. Further for these values of a and b, is gof differentiable at $x=0$. Justify your answer.* ***[IIT JEE 2002]***

Sol. Here, $$f(x)=\begin{cases}x+a, & \text{if } x<0\\ |x-1|, & \text{if } x\ge 0\end{cases}$$

and $$g(x)=\begin{cases}x+1, & \text{if } x<0\\ (x-1)^2+b, & \text{if } x\ge 0\end{cases}$$

$$\therefore\qquad gof(x)=g\{f(x)\}=\begin{cases}g(x+a), & x<0\\ g(|x-1|), & x\ge 0\end{cases}$$

$$=\begin{cases}x+a+1, & x+a<0\\ (x+a-1)^2+b, & x+a\ge 0\\ \{|x-1|-1\}^2+b, & x\ge 0\end{cases}$$

$$=\begin{cases}x+a+1, & x<-a\\ (x+a-1)^2+b, & 0>x\ge -a\\ x^2+b, & 0\le x<1\\ (x-2)^2+b, & x\ge 1\end{cases}$$

$\Rightarrow gof(x)$ is continuous for all real x.

$\therefore$ $gof(x)$ is continuous at $x=-a, 0, 1$.

Since, $gof(x)$ is continuous at $x=-a$.

$$\Rightarrow \lim_{x \to -a^-} gof(x) = \lim_{x \to -a^+} gof(x) = gof(-a)$$

$$\Rightarrow \lim_{x \to -a^-} (x + a + 1) = \lim_{x \to -a^+} (x + a - 1)^2 + b$$

$$= (-a + a - 1)^2 + b$$

$$\Rightarrow -a + a + 1 = (-a + a - 1)^2 + b = (-a + a - 1)^2 + b$$

$$\Rightarrow b = 0$$

and $gof(x)$ is continuous at $x = 0$.

$$\Rightarrow \lim_{x \to 0^-} gof(x) = \lim_{x \to 0^+} gof(x) = gof(0)$$

$$\Rightarrow (a-1)^2 + b = b \Rightarrow a = 1$$

Now, $\text{(LHD at } x = 0) = \dfrac{d}{dx}\{(x + a - 1)^2 + b\}_{\text{at } x = 0}$

$$= 2(a - 1) = 0 \qquad [\text{as } a = 1]$$

Again, $\text{(RHD at } x = 0) = \dfrac{d}{dx}\{(x^2 + b)\}_{\text{at } x = 0} = 0$

$\therefore$ $gof(x)$ is differentiable at $x = 0$.

● ***Ex. 54*** *If a function $f : [-2a, 2a] \to R$ is an odd function such that $f(x) = f(2a - x)$ for $x \in [a, 2a]$ and the left hand derivative at $x = a$ is 0, then find the left hand derivative at $x = -a$* ***[IIT JEE 2003]***

Sol. It is given that, LHD (at $x = a$) $= 0$

$$\therefore \lim_{h \to 0} \frac{f(a-h) - f(a)}{-h} = 0$$

$$\Rightarrow \lim_{h \to 0} \frac{f(a-h) - f(a)}{h} = 0 \qquad \text{...(i)}$$

Now, LHD (at $x = -a$)

$$= \lim_{h \to 0} \frac{f(-a-h) - f(-a)}{-h}$$

$$= \lim_{h \to 0} \frac{-f(a+h) + f(a)}{-h} \quad [\text{as } f(-x) = -f(x), \text{ given}]$$

$$= \lim_{h \to 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \to 0} \frac{f[2a - (a-h)] - f(a)}{h}$$

$$= \lim_{h \to 0} \frac{f(a-h) - f(a)}{h} = 0 \qquad [\text{as } f(x) = f(2a - x)]$$

[using Eq. (i)]

$\therefore$ LHD (at $x = -a$) $= 0$

● ***Ex. 55*** *Discuss the continuity of $f(x)$ in $[0, 2]$, where*

$$f(x) = \begin{cases} [\cos \pi x], & x \le 1 \\ |2x - 3|[x - 2], & x > 1 \end{cases}$$

where $[\cdot]$ denotes the greatest integral function.

Sol. First we shall find the points where $f(x)$ may be discontinuous.

Consider $x \in [0, 1]$

$f(x) = [\cos \pi x]$ is discontinuous where $\cos \pi x \in I$.

In $[0, 1]$, $\cos \pi x$ is an integer at $x = 0, 1/2, 1$.

$\Rightarrow x = 0, x = \dfrac{1}{2}$ and $x = 1$ may be the points at which $f(x)$ may be discontinuous ...(i)

Now, consider $x \in (1, 2]$

$$f(x) = [x - 2]|2x - 3|$$

If $x \in (1, 2)$, then $[x - 2] = -1$ and if $x = 2$, then $[x - 2] = 0$

Also, $|2x - 3| = 0 \Rightarrow x = 3/2$

$\Rightarrow x = 3/2$ and 2 may be the points at which $f(x)$ may be discontinuous ...(ii)

On combining Eqs. (i) and (ii), we have

$$x = 0, 1/2, 1, 3/2, 2$$

On dividing $f(x)$ by about the 5 critical points, we get

$$f(x) = \begin{cases} 1, & x = 0 \quad \because \cos(\pi\, 0) = 1 \\ 0, & 0 < x \le \dfrac{1}{2} \quad \because 0 \le \cos \pi x < 1 \Rightarrow [\cos \pi x] = 0 \\ -1, & \dfrac{1}{2} < x \le 1 \quad \because -1 \le \cos \pi x < 0 \Rightarrow [\cos \pi x] = -1 \\ -(3 - 2x), & 1 < x \le 3/2 \because |2x - 3| = 3 - 2x \\ & \text{and } [x - 2] = -1 \\ -(2x - 3), & 3/2 < x < 2 \because |2x - 3| = 2x - 3 \\ & \text{and } [x - 2] = -1 \\ 0, & x = 2 \quad \because [x - 2] = 0 \end{cases}$$

Checking continuity at $x = 0$

$$\text{RHL} = \lim_{x \to 0^+} f(x) = \lim_{x \to 0^+} 0 = 0$$

And $f(0) = 1$

As $\text{RHL} \ne f(0)$

Thus, $f(x)$ is discontinuous at $x = 0$

Checking continuity at $x = 1/2$

$$\text{LHL} = \lim_{x \to \frac{1}{2}^-} f(x) = \lim_{x \to \frac{1}{2}^-} 0 = 0$$

$$\text{RHL} = \lim_{x \to \frac{1}{2}^+} f(x) = \lim_{x \to \frac{1}{2}^+} (-1) = -1$$

As $\text{RHL} \ne \text{LHL}$

Therefore, $f(x)$ is discontinuous at $x = 1/2$

Checking continuity at $x = 1$

$$\text{LHL} = \lim_{x \to 1^-} f(x) = \lim_{x \to 1^-} (-1) = -1$$

$$\text{RHL} = \lim_{x \to 1^+} f(x) = \lim_{x \to 1^+} -(3 - 2x) = -1$$

And $f(1) = -1$

As $\text{RHL} = \text{LHL} = f(1)$

Therefore, $f(x)$ is continuous at $x = 1$

Checking continuity at $x = 3/2$

$$\text{LHL} = \lim_{x \to 3/2^-} (2x - 3) = 0$$

$$\text{RHL} = \lim_{x \to 3/2^+} (3 - 2x) = 0$$

And $f(3/2) = 0$

As $\text{RHL} = \text{LHL} = f(3/2)$

Hence, $f(x)$ is continuous at $x = 3/2$

Checking continuity at $x = 2$

$$\text{LHL} = \lim_{x \to 2^-} (3 - 2x) = -1$$

And $f(2) = 0$

As $\text{LHL} \neq f(2)$

Hence, $f(x)$ is discontinuous at $x = 2$

Thus, $f(x)$ is continuous when $x \in [0, 2] - \{0, 1/2, 2\}$.

● ***Ex. 56*** *Let f is a differentiable function such that $f(x) = x^2 + \int_0^x e^{-t} f(x - t)\, dt$. Find $f(x)$.*

Sol. We have, $f(x) = x^2 + \int_0^x e^{-t}\, f(x - t)\, dt$

$$\Rightarrow \quad f(x) = x^2 + \int_0^x e^{-(x-t)}\, f(x-(x-t))\, dt$$

$$\left[\text{using} \int_0^a f(x)dx = \int_0^a f(a-x)dx\right]$$

$$\Rightarrow \quad f(x) = x^2 + e^{-x} \int_0^x e^t\, f(t)\, dt \qquad ...(i)$$

On differentiating both the sides, we get

$$f'(x) = 2x + e^{-x}[e^x\, f(x)] - e^{-x} \int_0^x e^t\, f(t)\, dt \qquad ...(ii)$$

[using Leibnitz rule]

$$\Rightarrow \quad f(x) + f'(x) = x^2 + 2x + f(x)$$

$$\Rightarrow \quad f'(x) = x^2 + 2x \qquad ...(iii)$$

On integrating both the sides of Eq. (iii), we get

$$f(x) = \frac{x^3}{3} + x^2 + C$$

But $f(0) = 0 \Rightarrow C = 0$

Hence, $f(x) = \frac{x^3}{3} + x^2$

● ***Ex. 57*** *Let $f : R^+ \to R$ satisfies the functional equation $f(xy) = e^{xy - x - y}\, \{e^y f(x) + e^x f(y)\}, \forall\, x, y \in R^+$. If $f'(1) = e$, determine $f(x)$.*

Sol. Given that,

$$f(xy) = e^{xy - x - y}\, \{e^y f(x) + e^x f(y)\}, \forall\, x, y \in R^+ \qquad ...(i)$$

On putting $x = y = 1$, we get

$$f(1) = e^{-1}\, \{e^1 f(1) + e^1 f(1)\} \Rightarrow f(1) = 0 \qquad ...(ii)$$

Now, $f'(x) = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h}$

$$= \lim_{h \to 0} \frac{f\left\{x\left(1 + \frac{h}{x}\right)\right\} - f(x)}{h}$$

$$= \lim_{h \to 0} \frac{e^{x\left(1+\frac{h}{x}\right) - x - \left(1+\frac{h}{x}\right)} \left\{e^{1+\frac{h}{x}} f(x) + e^x f\left(1 + \frac{h}{x}\right)\right\} - f(x)}{h}$$

$$= \lim_{h \to 0} \frac{e^h\, f(x) + e^{h - 1 - \frac{h}{x} + x} f\left(1 + \frac{h}{x}\right) - f(x)}{h}$$

$$= \lim_{h \to 0} \frac{f(x)(e^h - 1) + e^{h - 1 - \frac{h}{x} + x} \left\{f\left(1 + \frac{h}{x}\right) - f(1)\right\}}{h}$$

$$[\because f(1) = 0]$$

$$= \lim_{h \to 0} \frac{f(x)(e^h - 1)}{h} + \lim_{h \to 0} \frac{e^{h - 1 - \frac{h}{x} + x} \left\{f\left(1 + \frac{h}{x}\right) - f(1)\right\}}{\frac{h}{x} \cdot x}$$

$$= f(x) + \frac{e^{x-1} \cdot f'(1)}{x}$$

$$\left[\because \lim_{h \to 0} \frac{f\left(1 + \frac{h}{x}\right) - f(1)}{\frac{h}{x}} = f'(1) \text{ and } \lim_{h \to 0} \frac{e^h - 1}{h} = 1\right]$$

$$= f(x) + \frac{e^x}{ex} \cdot f'(1)$$

$$\therefore f'(x) = f(x) + \frac{e^x}{x} \Rightarrow \frac{e^x}{x} = f'(x) - f(x) \quad [\because f'(1) = e]$$

$$\Rightarrow \quad \frac{1}{x} = \frac{e^x f'(x) - f(x) \cdot e^x}{e^{2x}}$$

$$\left[\text{as by quotient rule, we can write } \frac{e^x f'(x) - f(x) \cdot e^x}{(e^x)^2} = \frac{d}{dx}\left\{\frac{f(x)}{e^x}\right\}\right]$$

$$\therefore \quad \frac{1}{x} = \frac{d}{dx}\left\{\frac{f(x)}{e^x}\right\}$$

On integrating both the sides w.r.t. 'x', we get

$$\log|x| + C = \frac{f(x)}{e^x}$$

$$f(x) = e^x \{\log|x| + C\}$$

Since, $f(1) = 0 \Rightarrow C = 0$

Thus, $f(x) = e^x \log|x|$

● ***Ex. 58*** *Let f is a differentiable function such that $f'(x) = f(x) + \int_0^2 f(x)\, dx$, $f(0) = \frac{4 - e^2}{3}$, find $f(x)$.*

Sol. It is given that

$$f'(x) = f(x) + \int_0^2 f(x)\, dx$$

$$\Rightarrow \quad f'(x) = f(x) + c \qquad \left[\therefore c = \int_0^2 f(x)\, dx\right]$$

$$\Rightarrow \quad \frac{f'(x)}{f(x) + c} = 1$$

On integrating both the sides of above expression,

$$\log_e\{f(x) + c\} = x + c \Rightarrow f(x) + c = ke^x \qquad ...(i)$$

[k being constant of integration]

Since, $f(0)=\dfrac{4-e^2}{3}$ and $f(0)+c=k$

$$\therefore \quad k=\frac{4-e^2}{3}+c \Rightarrow c=k-\left(\frac{4-e^2}{3}\right) \qquad ...(ii)$$

From Eqs. (i) and (ii), we get

$$f(x)+k-\left(\frac{4-e^2}{3}\right)=k(e^x)$$

$$\Rightarrow \quad f(x)=k(e^x-1)+\left(\frac{4-e^2}{3}\right) \qquad ...(iii)$$

Now, to find constant of integration k.

On integrating both the sides from 0 to 2, we get

$$\int_0^2 f(x)\,dx=k\int_0^2(e^x-1)\,dx+\frac{4-e^2}{3}\int_0^2 dx$$

$$\Rightarrow \quad c=k\,(e^2-2-1)+\frac{4-e^2}{3}(2)$$

$$\Rightarrow \quad c=\frac{2}{3}(4-e^2)+k\,(e^2-3) \qquad ...(iv)$$

From Eqs. (ii) and (iv), we get

$$k-\left(\frac{4-e^2}{3}\right)=\frac{2}{3}(4-e^2)+k(e^2-3) \Rightarrow k=1$$

On putting $k=1$ in Eq. (iii), we get

$$f(x)=(e^x-1)+\frac{4-e^2}{3}$$

Hence, $$f(x)=e^x-\frac{(e^2-1)}{3}$$

● ***Ex. 59*** *A function $f(x)$ satisfies the following property $f(x+y)=f(x)\cdot f(y)$.*
Show that the function is continuous for all values of x, if it is continuous at $x=1$.

Sol. As the function is continuous at $x=1$, we have

$$\lim_{x\to 1^-} f(x)=\lim_{x\to 1^+} f(x)=f(1)$$

$$\Rightarrow \quad \lim_{h\to 0} f(1-h)=\lim_{h\to 0} f(1+h)=f(1)$$

[using $f(x+y)=f(x)\cdot f(y)$]

$$\Rightarrow \quad \lim_{h\to 0} f(1)\,f(-h)=\lim_{h\to 0} f(1)\cdot f(h)=f(1)$$

$$\Rightarrow \quad \lim_{h\to 0} f(-h)=\lim_{h\to 0} f(h)=1 \qquad ...(i)$$

Now, consider some arbitrary points $x=a$.

Left hand limit

$$\Rightarrow \quad \lim_{h\to 0} f(a-h)=\lim_{h\to 0} f(a)\cdot f(-h)=f(a)\lim_{h\to 0} f(-h)$$

$$\text{LHL} = f(a) \text{ [as } \lim_{h\to 0} f(-h)=1, \text{ using Eq. (i)]}$$

Right hand limit

$$\Rightarrow \quad \lim_{h\to 0} f(a+h)=\lim_{h\to 0} f(a)\cdot f(h)=f(a)\lim_{h\to 0} f(h)$$

$$\text{RHL} = f(a) \quad \text{[as } \lim_{h\to 0} f(h)=1, \text{ using Eq. (i)]}$$

Hence, at any arbitrary point $(x=a)$

$$\text{LHL} = \text{RHL} = f(a)$$

Therefore, function is continuous for all values of x, if it is continuous at 1.

● ***Ex. 60*** *Let $f\left(\dfrac{x+y}{2}\right)=\dfrac{f(x)+f(y)}{2}$ for all real x and y. If $f'(0)$ exists and equals to -1 and $f(0)=1$, then find $f'(x)$.* ***[IIT JEE 1995]***

Sol. Given equation is $f\left(\dfrac{x+y}{2}\right)=\dfrac{f(x)+f(y)}{2}$ ...(i)

On putting $y=0$ and $f(0)=1$ in Eq. (i), we have

$$f\left(\frac{x}{2}\right)=\frac{1}{2}[f(x)+1] \qquad [\because f(0)=1]$$

$$\Rightarrow \quad f(x)=2f\left(\frac{x}{2}\right)-1 \qquad ...(ii)$$

Now, $$f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$$

$$=\lim_{h\to 0}\frac{f\left(\dfrac{2x+2h}{2}\right)-f(x)}{h}$$

$$=\lim_{h\to 0}\frac{\dfrac{f(2x)+f(2h)}{2}-f(x)}{h} \qquad \text{[using Eq. (i)]}$$

$$=\lim_{h\to 0}\frac{f(2x)+f(2h)-2f(x)}{2h}$$

$$=\lim_{h\to 0}\frac{2f(x)-1+f(2h)-2f(x)}{2h} \qquad \text{[using Eq. (ii)]}$$

$$\lim_{h\to 0}\frac{f(2h)-1}{2h}=f'(0)$$

Therefore, $$f'(x)=-1$$

● ***Ex. 61*** *Let $f(x)=1+4x-x^2, \forall\ x\in R$*

$$g(x)=\max\{f(t);\ x\le t\le(x+1);\ 0\le x<3\}$$
$$=\min\{(x+3);\ 3\le x\le 5\}$$

Verify continuity of $g(x)$, for all $x\in[0,5]$.

Sol. Here, $$f(t)=1+4t-t^2$$

$$f'(t)=4-2t$$

When $f'(t)=0$, then $t=2$

At $t=2$, $f(t)$ has a maxima.

Since, $g(x)=\max\{f(t) \text{ for } t\in[x,x+1], 0\le x<3\}$

$$\therefore \quad g(x)=\begin{cases} f(x+1), & \text{if } [x,x+1]<2 \\ f(2), & \text{if } x\le 2\le x+1 \\ f(x), & \text{if } 2<[x,x+1] \end{cases}$$

$$g(x)=\begin{cases}4+2x-x^2, & \text{if} \quad 0\le x<1\\ 5, & \text{if} \quad 1\le x\le 2\\ 1+4x-x^2, & \text{if} \quad 2<x<3\\ 6, & \text{if} \quad 3\le x\le 5\end{cases}$$

Which is clearly continuous for all $x\in[0,5]$ except $x=3$.

$\therefore$ $g(x)$ is continuous for $x=[0,3)\cup(3,5]$

● ***Ex. 62*** *Let* $f(x)=x^4-8x^3+22x^2-24x$ *and*

$$g(x)=\begin{cases}\min f(x);\ x\le t\le x+1,-1\le x\le 1\\ x-10;\quad x>1\end{cases}$$

Discuss the continuity and differentiability of $g(x)$ *in* $[-1,\infty)$.

Sol. Here, $f(x)=x^4-8x^3+22x^2-24x$

$\Rightarrow$ $f'(x)=4x^3-24x^2+44x-24$

or $f'(x)=4(x-1)(x-2)(x-3)$

Which shows $f(x)$ is increasing in $[1,2]\cup[3,\infty)$ and decreasing in $(-\infty,1]\cup[2,3]$.

Thus, minimum $f(x);\ x\le t\le x+1,-1\le x\le 1$

$\Rightarrow$ Minimum $f(x)=\begin{cases}f(x+1),-1\le x\le 0\\ f(1), \quad 0<x\le 1\end{cases}$

Thus, $g(x)=\begin{cases}f(x+1),-1\le x\le 0\\ f(1), \quad 0<x\le 1\\ x-10, \quad x>1\end{cases}$

$$=\begin{cases}(x+1)^4-8(x+1)^3+22(x+1)^2-24(x+1), & -1\le x\le 0\\ 1-8+22-24, & 0<x\le 1\\ x-10, & x>1\end{cases}$$

$$g(x)=\begin{cases}x^4-4x^3+4x^2-9, & -1\le x\le 0\\ -9, & 0<x\le 1\\ x-10, & x>1\end{cases}$$

Also, $g'(x)=\begin{cases}4x^3-12x^2+8x, & -1\le x\le 0\\ 0, & 0<x\le 1\\ 1, & x>1\end{cases}$

Which clearly shows $g(x)$ is continuous in $[-1,\infty)$ but not differentiable at $x=1$.

● ***Ex. 63*** *Let* $g(x)=\int_0^x f(t)\,dt$, *where* f *is such that*

$1/2\le f(t)\le 1$ *for* $t\in[0,1]$ *and* $0\le f(t)\le 1/2$ *for* $t\in[1,2]$. *Then, find the interval in which* $g(2)$ *lies.* ***[IIT JEE 2000]***

Sol. Here, $g(x)=\int_0^x f(t)dt \Rightarrow g(2)=\int_0^2 f(t)dt$

$\Rightarrow$ $g(2)=\int_0^1 f(t)dt+\int_1^2 f(t)dt$ ...(i)

Now, $1/2\le f(t)\le 1$ for $t\in[0,1]$

We get, $\int_0^1\frac{1}{2}dt\le\int_0^1 f(t)dt\le\int_0^1 1\,dt$

$\Rightarrow$ $\frac{1}{2}\le\int_0^1 f(t)dt\le 1$ ...(ii)

Again, $0\le f(t)\le\frac{1}{2}$, for $t\in[1,2]$

$\Rightarrow$ $\int_1^2 0\,dt\le\int_1^2 f(t)dt\le\int_1^2\frac{1}{2}dt$

$\Rightarrow$ $0\le\int_1^2 f(t)dt\le\frac{1}{2}$ ...(iii)

On adding Eq. (ii) and (iii), we get

$$0+\frac{1}{2}\le\int_0^1 f(t)dt+\int_1^2 f(t)dt\le 1+\frac{1}{2}$$

or $\frac{1}{2}\le g(2)\le\frac{3}{2}$ $\Rightarrow$ $g(2)\in\left[\frac{1}{2},\frac{3}{2}\right]$

● ***Ex. 64*** *Let* f *be a one-one function such that* $f(x)\cdot f(y)+2=f(x)+f(y)+f(xy),\ \forall\ x,y\in R-\{0\}$ *and* $f(0)=1$, $f'(1)=2$. *Prove that* $3\left(\int f(x)\,dx\right)-x(f(x)+2)$ *is constant.*

Sol. We have, $f(x)\cdot f(y)+2=f(x)+f(y)+f(xy)$ ...(i)

On replacing $x, y\to 1$, we get

$$(f(1))^2+2=3f(1)$$

$\Rightarrow$ $f^2(1)-3f(1)+2=0$

$\Rightarrow$ $f(1)=2$ or 1

But $f(1)$ cannot be equal to one as $f(0)=1$

$\Rightarrow$ $f(1)=2$ ...(ii)

On replacing y by $1/x$ in Eq. (i), we get

$f(x)\cdot f(1/x)+2=f(x)+f(1/x)+f(1)$

$\Rightarrow$ $f(x)\cdot f(1/x)+2=f(x)+f(1/x)+2$ [using Eq. (ii)]

$\Rightarrow$ $f(x)\cdot f(1/x)=f(x)+f(1/x)$

$\Rightarrow$ $f(x)=\frac{f(1/x)}{f(1/x)-1}$

and $f(1/x)=\frac{f(x)}{f(x)-1}$ ...(iii)

Now, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$$=\lim_{h\to 0}\frac{f(x+h)+\frac{f(1/x)}{1-f(1/x)}}{h}$$

$$=\lim_{h\to 0}\frac{f(x+h)-f(x+h)\cdot f(1/x)+f(1/x)}{h\{1-f(1/x)\}}$$

$$=\lim_{h\to 0}\frac{f(x+h)-f(x+h)-f(1/x)-f\left(\frac{x+h}{x}\right)+2+f(1/x)}{h\{1-f(1/x)\}}$$

[using Eq. (i)]

$$= \lim_{h\to 0}\frac{f\left(1+\frac{h}{x}\right)-2}{h\{f(1/x)-1\}} = \lim_{h\to 0}\frac{f(1+h/x)-f(1)}{\frac{h}{x}\cdot x\,\{f(1/x)-1\}}$$

[using Eq. (ii)]

$$= \frac{f'(1)}{x\,\{f(1/x)-1\}}$$

$$\left[\because \text{from Eq. (iii)}, f(x)\cdot f\left(\frac{1}{x}\right) = \frac{f(x)f\left(\frac{1}{x}\right)}{\left\{f\left(\frac{1}{x}\right)-1\right\}\{f(x)-1\}}\right]$$

$$f'(x) = \frac{2\{f(x)-1\}}{x} \Rightarrow xf'(x) = 2\{f(x)-1\}$$

On integrating both the sides of the above expression, we get

$$x\,f(x) - \int f(x)\,dx = 2\int f(x)\,dx - 2x + \lambda,$$

where λ is the constant of integral

$$\Rightarrow \quad 3\int f(x)\,dx = x\{2+f(x)\} - \lambda$$

Hence, $3\int f(x)\,dx - x\{2+f(x)\} = \lambda$ (constant)

● ***Ex. 65*** *Let $f: R \to R$, such that $f'(0)=1$ and $f(x+2y) = f(x)+f(2y)+e^{x+2y}(x+2y) - x\cdot e^x - 2y\cdot e^{2y} + 4xy,\ \forall\ x, y \in R$. Find $f(x)$.*

Sol. We have,

$$f(x+2y) = f(x)+f(2y)+e^{x+2y}(x+2y) - x\cdot e^x - 2y\cdot e^{2y} + 4xy$$

On replacing $x, y \to 0$, we get

$$f(0) = f(0)+f(0)+0-0-0+0 \Rightarrow f(0)=0$$

On replacing $2y \to -x$, we get

$$f(0) = f(x)+f(-x)-x\cdot e^x + xe^{-x} - 2x^2$$

$$\Rightarrow \quad -f(x) = f(-x) - x\cdot e^x + xe^{-x} - 2x^2 \qquad ...(i)$$

Now, $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$$= \lim_{h\to 0}\frac{f(x+h)+f(-x)-xe^x+x\cdot e^{-x}-2x^2}{h}$$

$$\Rightarrow f'(x) = \lim_{h\to 0}\frac{\left[\begin{array}{l} f(h)-e^h\cdot h+(x+h)e^{(x+h)}-xe^{-x}+ \\ \qquad 2(x+h)x - xe^x + xe^{-x} - 2x^2\end{array}\right]}{h}$$

$$= \lim_{h\to 0}\frac{f(h)-e^h\cdot h + x\cdot e^x\cdot e^h + h\cdot e^x\cdot e^h + 2hx - xe^x}{h}$$

$$= \lim_{h\to 0}\frac{f(h)-f(0)}{h} + \frac{h(e^x-1)}{h}e^h + \frac{xe^x(e^h-1)}{h} + \frac{2hx}{h}$$

$$= f'(0) + (e^x-1) + x\cdot e^x + 2x$$

$$\therefore \quad f'(x) = 1 + e^x - 1 + xe^x + 2x$$

$$\text{or} \quad f'(x) = e^x(x+1) + 2x \qquad ...(ii)$$

On integrating Eq. (ii) both sides, we get

$$f(x) = \int e^x(x+1)\,dx + 2\int x\,dx$$

$$= (x+1)e^x - \int 1\cdot e^x dx + 2\frac{x^2}{2} + C$$

$$= (x+1)e^x - e^x + x^2 + C$$

$$\Rightarrow \quad f(x) = x^2 + xe^x + C$$

But $f(0)=0 \Rightarrow C=0$

So, $f(x) = x^2 + x\cdot e^x$

● ***Ex. 66*** *Let f be a function such that $f(xy) = f(x)\cdot f(y), \forall\ y \in R$ and $f(1+x) = 1 + x(1+g(x))$, where $\lim_{x\to 0} g(x) = 0$. Find the value of $\int_1^2 \frac{f(x)}{f'(x)}\cdot\frac{1}{1+x^2}dx$.*

Sol. We know, $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$$= \lim_{h\to 0}\frac{f\left(x\left(1+\frac{h}{x}\right)\right)-f(x)}{h}$$

$$\Rightarrow \quad f'(x) = \lim_{h\to 0}\frac{f(x)\cdot f\left(1+\frac{h}{x}\right)-f(x)}{h}$$

[given $f(xy) = f(x)\cdot f(y)$]

$$\Rightarrow \quad f'(x) = \lim_{h\to 0}\frac{f(x)\cdot\left\{1+\frac{h}{x}(1+g(h/x))\right\}-f(x)}{h}$$

[given $f(1+x) = 1 + x(1+g(x))$]

$$\Rightarrow \quad f'(x) = \lim_{h\to 0}\frac{f(x)\cdot\left\{1+\frac{h}{x}(1+g(h/x))-1\right\}}{h}$$

$$\therefore \quad f'(x) = \frac{f(x)}{x} \qquad [\text{as } \lim_{x\to 0} g(x) = 0] \quad ...(i)$$

To find, $\int_1^2 \frac{f(x)}{f'(x)}\cdot\frac{1}{1+x^2}dx = \int_1^2 \frac{x}{1+x^2}dx$ [using Eq. (i)]

$$= \frac{1}{2}[\log|1+x^2|]_1^2 = \frac{1}{2}[\log(5/2)]$$

● ***Ex. 67*** *If $f(x) = ax^2 + bx + c$ is such that $|f(0)| \le 1$, $|f(1)| \le 1$ and $|f(-1)| \le 1$, prove that $|f(x)| \le 5/4, \forall\ x \in [-1,1]$.*

Sol. We have, $f(x) = ax^2 + bx + c$ ...(i)

$$\Rightarrow \quad f(-1) = a - b + c \qquad ...(ii)$$

$$\Rightarrow \quad f(0) = c \qquad ...(iii)$$

$$\Rightarrow \quad f(1) = a + b + c \qquad ...(iv)$$

From Eqs. (ii), (iii) and (iv), we get

$$a=\frac{1}{2}[f(-1)+f(1)-2f(0)],$$

$$b=\frac{1}{2}[f(1)-f(-1)] \text{ and } c=f(0)$$

On substituting the values of a, b and c in Eq. (i), we get

$$\Rightarrow \quad f(x)=\frac{1}{2}[f(-1)+f(1)-2f(0)]x^2 + \frac{1}{2}[f(1)-f(-1)]x+f(0)$$

$$f(x)=\frac{x(x-1)}{2}f(-1)-(x+1)(x-1)f(0) + \frac{(x+1)x}{2}f(1) \quad ...(v)$$

Since, $|f(-1)|, |f(0)|$ and $|f(1)|$ are ≤ 1, we have

$$2|f(x)| \le |x(x-1)| + 2|x^2-1| + |x(x+1)| \quad ...(vi)$$

In the interval, $x \in [-1, 1]$

$$0 \le 1+x \le 2, \quad 0 \le 1-x \le 2 \text{ and } 0 \le 2(1-x^2) \le 2$$

$$\Rightarrow \quad 2|f(x)| \le |x|(1-x+1+x)+2(1-x^2)$$

$$2|f(x)| \le 2(|x|+1-x^2)$$

Therefore, $$|f(x)| \le \left(|x|-\frac{1}{2}\right)^2 + 5/4 \le 5/4$$

$$\Rightarrow \quad |f(x)| \le \frac{5}{4}, \forall\ x \in [-1, 1]$$

● ***Ex. 68*** *Let $\alpha+\beta=1$, $2\alpha^2+2\beta^2=1$ and $f(x)$ be a continuous function such that $f(2+x)+f(x)=2$ for all $x \in [0, 2]$ and $p=\int_0^4 f(x)\,dx-4$, $q=\frac{\alpha}{\beta}$. Then, find the least positive integral value of 'a' for which the equation $ax^2-bx+c=0$ has both roots lying between p and q, where $a, b, c \in N$.*

Sol. Given, $$\alpha+\beta=1 \quad ...(i)$$

$$2\alpha^2+2\beta^2=1 \quad ...(ii)$$

On solving Eqs. (i) and (ii), we get

$$\alpha=\beta=\frac{1}{2} \Rightarrow q=\frac{\alpha}{\beta}=1 \quad ...(iii)$$

and given $f(2+x)+f(x)=2, \forall\ x \in [0, 2]$ ...(iv)

Now, $$p=\int_0^4 f(x)\,dx-4=\int_0^2 f(x)\,dx+\int_2^4 f(x)\,dx-4$$

$$=\int_0^2 f(x)\,dx+\int_0^2 f(t+2)\,dt-4$$

[let $x=t+2$ for second integration]

$$=\int_0^2 f(x)\,dx+\int_0^2 \{2-f(x)\}\,dx-4$$

[given, $f(2+x)+f(x)=2$]

$$\Rightarrow \quad p=\int_0^2 f(x)\,dx+2\int_0^2 dx-\int_0^2 f(x)\,dx-4=0 \quad ...(v)$$

Then, from Eqs. (v) and (iii), $p=0, q=1$

Let the roots of equation $ax^2-bx+c=0$ be α and β.

$$\therefore \quad f(x)=ax^2-bx+c=a(x-\alpha)(x-\beta) \quad ...(vi)$$

Since, equation $f(x)=0$ has both roots lying between 0 and 1.

$$\therefore \quad f(0)\cdot f(1)>0 \quad ...(vii)$$

But $$f(0)\cdot f(1)=c(a-b+c)=\text{an integer} \quad ...(viii)$$

$\therefore$ Least value of $f(0)\cdot f(1)=1$ ...(ix)

Now, from Eq. (vi),

$$f(0)\cdot f(1)=a\alpha\beta\, a(1-\alpha)(1-\beta)$$

$$=a^2\alpha\beta(1-\alpha)(1-\beta) \quad ...(x)$$

As we know,

$\alpha(1-\alpha)$ has greatest value $\frac{1}{4}$ at $\alpha=\frac{1}{2}$ and $\beta(1-\beta)$ has greatest value $\frac{1}{4}$ at $\beta=\frac{1}{2}$. But $\alpha \ne \beta$

Thus, from Eq. (x) greatest value of $f(0)\cdot f(1)<\frac{a^2}{16}$ ...(xi)

$\therefore$ From Eqs. (ix) and (xi), we get $1<\frac{a^2}{16}$

$$\Rightarrow \quad a^2-16>0$$

$$\Rightarrow \quad a<-4 \text{ or } a>4 \quad [\because a \in N]$$

$\Rightarrow$ Least value of $a=5$ [as $a \in$ natural number]

● ***Ex. 69*** *Prove that the function $f(x)=a\sqrt{x-1}+b\sqrt{2x-1}-\sqrt{2x^2-3x+1}$, where $a+2b=2$ and $a, b \in R$ always has a root in $(1, 5)$, $\forall\ b \in R$.*

Sol. Let $b>0$, then $f(1)=b>0$

and $$f(5)=2a+3b-6=2(a+2b)-b-6$$

$$=4-b-6=-(2+b)<0$$

Hence, by IVT, $\exists$ some $c \in (1, 5)$ such that

$$\Rightarrow \quad f(c)=0$$

If $b=0$, then $a=2$

$$f(x)=2\sqrt{x-1}-\sqrt{2x^2-3x+1}=0$$

$$\Rightarrow \quad 4(x-1)=2x^2-3x+1=(2x-1)(x-1)$$

$$\Rightarrow \quad (x-1)(2x-5)=0$$

$$\Rightarrow \quad x=\frac{5}{2}$$

Hence, $f(x)=0$, if $x=\frac{5}{2}$, which lies in (1, 5).

If $b < 0$, $f(1) = b < 0$ and $f(2) = a + b\sqrt{3} - \sqrt{3}$

$= (a + 2b) + (\sqrt{3} - 2)b - \sqrt{3}$

$= (2 - \sqrt{3}) - (2 - \sqrt{3})b$

$= (2 - \sqrt{3})(1 - b) > 0$ [as $b < 0$]

Hence, $f(1)$ and $f(2)$ have opposite signs

$\exists$ some $c \in (1, 2) \subset (1, 5)$ for which $f(c) = 0$.

● ***Ex. 70*** *Let $\alpha \in R$. Prove that a function $f : R \to R$ is differentiable at α, if and only if there is a function $g : R \to R$ which is continuous at $x = \alpha$ and satisfies*
$f(x) - f(\alpha) = g(x)(x - \alpha)$ for all $x \in R$. ***[IIT JEE 2001]***

Sol. If $g(x)$ is continuous at $x = \alpha$.

$\Rightarrow$ $\lim\limits_{x \to \alpha} g(x) = g(\alpha)$ ...(i)

and $f(x) - f(\alpha) = g(x)(x - \alpha), \forall\, x \in R$

$\Rightarrow$ $\dfrac{f(x) - f(\alpha)}{(x - \alpha)} = g(x)$

$\Rightarrow$ $\lim\limits_{x \to \alpha} \dfrac{f(x) - f(\alpha)}{(x - \alpha)} = \lim\limits_{x \to \alpha} g(x) \Rightarrow f'(\alpha) = g(\alpha)$

Therefore, $f(x)$ is differentiable at $x = \alpha$ ...(ii)

Conversely, f is differentiable at $x = \alpha$, then $\lim\limits_{x \to \alpha} \dfrac{f(x) - f(\alpha)}{(x - \alpha)}$ exists finitely.

Let $g(x) = \begin{cases} \dfrac{f(x) - f(\alpha)}{x - \alpha}, & x \neq \alpha \\ f'(\alpha), & x = \alpha \end{cases}$

Clearly, $\lim\limits_{x \to \alpha} g(x) = f'(\alpha)$

Thus, $g(x)$ is continuous at $x = \alpha$.

Hence, $f(x)$ is differentiable at $x = \alpha$, iff $g(x)$ is continuous at $x = \alpha$.

Continuity and Differentiability Exercise 1 :
Single Option Correct Type Questions

1. If $f(x)=\begin{cases}\sin\frac{\pi x}{2}, & x<1\\ [x], & x\geq 1\end{cases}$, where $[x]$ denotes the greatest integer function, then

(a) $f(x)$ is continuous at $x=1$

(b) $f(x)$ is discontinuous at $x=1$

(c) $f(1^+)=0$

(d) $f(1^-)=-1$

2. Consider $f(x)=\begin{cases}\frac{8^x-4^x-2^x+1}{x^2}, & x>0\\ e^x\sin x+\pi x+k\log 4, & x<0\end{cases}$

Then, $f(0)$ so that $f(x)$ is continuous at $x=0$, is

(a) $\log 4$ (b) $\log 2$

(c) $(\log 4)(\log 2)$ (d) None of these

3. Let $f(x)=\begin{cases}\frac{a(1-x\sin x)+b\cos x+5}{x^2}, & x<0\\ 3, & x=0\\ \left[1+\left(\frac{cx+dx^3}{x^2}\right)\right]^{1/x}, & x>0\end{cases}$

If f is continuous at $x=0$, then $(a+b+c+d)$ is

(a) 5 (b) -5 (c) $\log_e 3-5$ (d) $5-\log_e 3$

4. If $f(x)=\begin{cases}\cos^{-1}\{\cot x\}, & x<\pi/2\\ \pi[x]-1, & x\geq\pi/2\end{cases}$, then the jump of discontinuity, (where $[\cdot]$ denotes greatest integer and $\{\}$ denotes fractional part function) is

(a) 1 (b) $\pi/2$ (c) $\frac{\pi}{2}-1$ (d) 2

5. Let $f:[0,1]\xrightarrow{\text{onto}}[0,1]$ be a continuous function, then $f(x)=x$ holds for

(a) at least one $x\in[0,1]$ (b) at least one $x\in[1,2]$

(c) at least one $x\in[-1,0]$ (d) can't be discussed

6. If $f(x)=\frac{x+1}{x-1}$ and $g(x)=\frac{1}{x-2}$, then $(fog)(x)$ is discontinuous at

(a) $x=3$ only (b) $x=2$ only

(c) $x=2$ and 3 (d) $x=1$ only

7. Let $y_n(x)=x^2+\frac{x^2}{(1+x^2)}+\frac{x^2}{(1+x^2)^2}+\ldots+\frac{x^2}{(1+x^2)^{n-1}}$ and $y(x)=\lim_{n\to\infty}y_n(x)$, then $y_n(x)$, $n=1, 2, 3, \ldots, n$ and $y(x)$ is

(a) continuous for $x\in R$ (b) continuous for $x\in R-\{0\}$

(c) continuous for $x\in R-\{1\}$ (d) data unsufficient

8. If $g(x)=\begin{cases}\frac{1+a^x\cdot x\cdot\log a-a^x}{a^x\cdot x^2}, & \text{for } x\leq 0\\ \frac{2^x\cdot a^x-x\log 2-x\log a-1}{x^2}, & \text{for } x>0\end{cases}$

where $a>0$, then a for which $g(x)$ is continuous, is

(a) $-\frac{1}{\sqrt{2}}$ (b) $\frac{1}{\sqrt{2}}$ (c) 2 (d) -2

9. Let $f(x)=\begin{cases}\frac{\left(\frac{\pi}{2}-\sin^{-1}(1-\{x\}^2)\right)\cdot\sin^{-1}(1-\{x\})}{\sqrt{2}(\{x\}-\{x\}^3)}, & x\neq 0,\\ \frac{\pi}{2}, & x=0,\end{cases}$ where $\{\cdot\}$ is fractional part of x, then

(a) $f(0^+)=-\frac{\pi}{2}$

(b) $f(0^-)=\frac{\pi}{4\sqrt{2}}$

(c) $f(x)$ is continuous at $x=0$

(d) None of the above

10. Let $f(x)=\begin{cases}\text{sgn}\,(x)+x, & -\infty<x<0\\ -1+\sin x, & 0\leq x\leq\pi/2\\ \cos x, & \pi/2\leq x<\infty\end{cases}$, then the number of points, where $f(x)$ is not differentiable, is/are

(a) 0 (b) 1

(c) 2 (d) 3

11. Let $f(x)=\begin{cases}\frac{1}{|x|}, & |x|\geq 1\\ ax^2+b, & |x|<1\end{cases}$ be continuous and differentiable for all x. Then, a and b are

(a) $-\frac{1}{2},\frac{3}{2}$ (b) $\frac{1}{2},-\frac{3}{2}$

(c) $\frac{1}{2},\frac{3}{2}$ (d) None of these

12. If $f(x)=\begin{cases}A+Bx^2, & x<1\\ 3Ax-B+2, & x\geq 1\end{cases}$, then A and B, so that $f(x)$ is differentiable at $x=1$, are

(a) $-2, 3$ (b) $2, -3$

(c) $2, 3$ (d) $-2, -3$

13. If $f(x)=\begin{cases}|x-1|([x]-x), & x\neq 1\\ 0, & x=1\end{cases}$, then

(a) $f'(1^+)=0$ (b) $f'(1^-)=0$

(c) $f'(1^-)=-1$ (d) $f(x)$ is differentiable at $x=1$

14. If $f(x)=\begin{cases}[\cos \pi x], & x \le 1 \\ 2\{x\}-1, & x>1\end{cases}$, where $[\cdot]$ and $\{\cdot\}$ denote greatest integer and fractional part of x, then

(a) $f'(1^-)=2$ (b) $f'(1^+)=2$

(c) $f'(1^-)=-2$ (d) $f'(1^+)=0$

15. If $f(x)=\begin{cases}x-3, & x<0 \\ x^2-3x+2, & x \ge 0\end{cases}$, then $g(x)=f(|x|)$ is

(a) $g'(0^+)=-3$

(b) $g'(0^-)=-3$

(c) $g'(0^+)=g'(0^-)$

(d) $g(x)$ is not continuous at $x=0$

16. If $f(x)=\begin{cases}\left\{x+\frac{1}{3}\right\}[\sin \pi x], & 0 \le x<1 \\ [2x]\operatorname{sgn}\left(x-\frac{4}{3}\right), & 1 \le x \le 2\end{cases}$, where $[\cdot]$ and $\{\cdot\}$ denote greatest integer and fractional part of x respectively, then the number of points of non-differentiability, is

(a) 3 (b) 4 (c) 5 (d) 6

17. Let f be differentiable function satisfying $f\left(\frac{x}{y}\right)=f(x)-f(y)$ for all $x, y>0$. If $f'(1)=1$, then $f(x)$ is

(a) $2\log_e x$ (b) $3\log_e x$ (c) $\log_e x$ (d) $\frac{1}{2}\log_e x$

18. Let $f(x+y)=f(x)+f(y)-2xy-1$ for all x and y. If $f'(0)$ exists and $f'(0)=-\sin\alpha$, then $f\{f'(0)\}$ is

(a) -1 (b) 0

(c) 1 (d) 2

19. A derivable function $f: R^+ \to R$ satisfies the condition

$$f(x)-f(y) \ge \log\left(\frac{x}{y}\right)+x-y, \forall\ x, y \in R^+.$$

If g denotes the derivative of f, then the value of the sum $\sum_{n=1}^{100} g\left(\frac{1}{n}\right)$ is

(a) 5050 (b) 5510 (c) 5150 (d) 1550

20. If $\frac{d(f(x))}{dx}=e^{-x}f(x)+e^{x}f(-x)$, then $f(x)$ is, (given $f(0)=0$)

(a) an even function

(b) an odd function

(c) neither even nor odd function

(d) can't say

21. Let $f:(0,\infty) \to R$ be a continuous function such that

$$f(x)=\int_0^x t\ f(t)\,dt.$$

If $f(x^2)=x^4+x^5$, then $\sum_{r=1}^{12} f(r^2)$ is equal to

(a) 216 (b) 219

(c) 222 (d) 225

22. For $x>0$, let $h(x)=\begin{cases}\frac{1}{q}, & \text{if } x=\frac{p}{q} \\ 0, & \text{if } x \text{ is irrational}\end{cases}$, where p and $q>0$ are relatively prime integers, then which one of the following does not hold good?

(a) $h(x)$ is discontinuous for all x in $(0, \infty)$

(b) $h(x)$ is continuous for each irrational in $(0, \infty)$

(c) $h(x)$ is discontinuous for each rational in $(0, \infty)$

(d) $h(x)$ is not derivable for all x in $(0, \infty)$

23. Let $f(x)=\frac{g(x)}{h(x)}$, where g and h are continuous functions on the open interval (a, b). Which of the following statements is true for $a<x<b$?

(a) f is continuous at all x for which $x \ne 0$

(b) f is continuous at all x for which $g(x)=0$

(c) f is continuous at all x for which $g(x) \ne 0$

(d) f is continuous at all x for which $h(x) \ne 0$

24. If $f(x)=\frac{2\cos x-\sin 2x}{(\pi-2x)^2}$, $g(x)=\frac{e^{-\cos x}-1}{8x-4\pi}$ and $h(x)=\begin{cases}f(x), & \text{for } x<\pi/2 \\ g(x), & \text{for } x>\pi/2\end{cases}$,

then which of the following holds?

(a) h is continuous at $x=\pi/2$

(b) h has an irremovable discontinuity at $x=\pi/2$

(c) h has a removable discontinuity at $x=\pi/2$

(d) $f\left(\frac{\pi^+}{2}\right)=g\left(\frac{\pi^-}{2}\right)$

25. If $f(x)=\frac{x-e^x+\cos 2x}{x^2}$, $x \ne 0$ is continuous at $x=0$, then

(a) $f(0)=\frac{5}{2}$ (b) $[f(0)]=-2$

(c) $\{f(0)\}=-0.5$ (d) $[f(0)]\cdot\{f(0)\}=-1.5$

where, $[x]$ and $\{x\}$ denote the greatest integer and fractional part function.

26. Consider the function $f(x)=\begin{cases}x\{x\}+1, & \text{if } 0 \le x<1 \\ 2-\{x\}, & \text{if } 1 \le x \le 2\end{cases}$, where $\{x\}$ denotes the fractional part function. Which one of the following statements is not correct?

(a) $\lim_{x \to 1} f(x)$ exists

(b) $f(0) \ne f(2)$

(c) $f(x)$ is continuous in $[0, 2]$

(d) Rolle's theorem is not applicable to $f(x)$ in $[0, 2]$

27. Let $f(x)=\begin{cases}\dfrac{2^x+2^{3-x}-6}{\sqrt{2^{-x}}-2^{1-x}}, & \text{if } x>2\\ \dfrac{x^2-4}{x-\sqrt{3x-2}}, & \text{if } x<2\end{cases}$, then

(a) $f(2)=8\Rightarrow f$ is continuous at $x=2$
(b) $f(2)=16\Rightarrow f$ is continuous at $x=2$
(c) $f(2^-)\neq f(2^+)\Rightarrow f$ is discontinuous
(d) f has a removable discontinuity at $x=2$

28. Let $[x]$ denotes the integral part of $g(x)=x-[x], x\in R$. Let $f(x)$ be any continuous function with $f(0)=f(1)$, then the function $h(x)=f(g(x))$
(a) has finitely many discontinuities
(b) is discontinuous at some $x=c$
(c) is continuous on R
(d) is a constant function

29. Let f be a differentiable function on the open interval (a, b).

I. f is continuous on the closed interval $[a, b]$.
II. f is bounded on the open interval (a, b).
III. If $a<a_1<b_1<b$ and $f(a_1)<0<f(b_1)$, then there exists a number c such that $a_1<c<b_1$ and $f(c)=0$.

Which of the above statements must be true?
(a) I and II
(b) I and III
(c) II and III
(d) Only III

30. Number of points, where the function $f(x)=(x^2-1)|x^2-x-2|+\sin(|x|)$ is not differentiable, is
(a) 0 (b) 1
(c) 2 (d) 3

31. Consider function $f: R-\{-1, 1\}\to R$. $f(x)=\dfrac{x}{1-|x|}$.

Then, which of the statements is incorrect?
(a) It is continuous at the origin
(b) It is not derivable at the origin
(c) The range of the function is R
(d) f is continuous and derivable in its domain

32. If the functions $f: R\to R$ and $g: R\to R$ are such that $f(x)$ is continuous at $x=\alpha$ and $f(\alpha)=a$ and $g(x)$ is discontinuous at $x=a$ but $g(f(x))$ is continuous at $x=\alpha$, where $f(x)$ and $g(x)$ are non-constant functions.
(a) $x=\alpha$ is a extremum of $f(x)$ and $x=a$ is an extremum of $g(x)$
(b) $x=\alpha$ may not be an extremum of $f(x)$ and $x=a$ is an extremum of $g(x)$
(c) $x=\alpha$ is an extremum of $f(x)$ and $x=a$ may not be an extremum of $g(x)$
(d) None of the above

33. The total number of points of non-differentiability of $f(x)=\min\left[|\sin x|, |\cos x|, \dfrac{1}{4}\right]$ in $(0, 2\pi)$ is
(a) 8 (b) 9 (c) 10 (d) 11

34. The function $f(x)=[x]^2-[x^2]$, where $[y]$ is the greatest integer less than or equal to y, is discontinuous at
(a) all integers
(b) all integers except 0 and 1
(c) all integers except 0
(d) all integers except 1

35. The function $f(x)=(x^2-1)|x^2-6x+5|+\cos|x|$ is not differentiable at
(a) –1 (b) 0 (c) 1 (d) 5

36. Let $f(x)=\begin{cases}e^{\frac{-1}{x^2}}, & \text{if } x\neq 0\\ 0, & \text{if } x=0\end{cases}$

Then, $f'(0)$ is equal to
(a) 0 (b) 1
(c) – 1 (d) doesn't exist

37. Given $f(x)=\dfrac{e^x-\cos 2x-x}{x^2}$, for $x\in R-\{0\}$

$$g(x)=\begin{cases}f(\{x\}), & \text{for } n<x<n+\dfrac{1}{2}\\ f(1-\{x\}), & \text{for } n+\dfrac{1}{2}\le x<n+1, n\in I\\ \dfrac{5}{2}, & \text{otherwise}\end{cases}$$

$\begin{cases}\text{where } \{x\} \text{ denotes}\\ \text{fractional part function,}\end{cases}$ then $g(x)$ is
(a) discontinuous at all integral values of x only
(b) continuous everywhere except for $x=0$
(c) discontinuous at $x=n+\dfrac{1}{2}, n\in I$ and at some $x\in I$
(d) continuous everywhere

38. The function $g(x)=\begin{cases}x+b, & x<0\\ \cos x, & x\ge 0\end{cases}$ cannot be made differentiable at $x=0$,
(a) if b is equal to zero (b) if b is not equal to zero
(c) if b takes any real value (d) for no value of b

39. The graph of function f contains the point $P(1, 2)$ and $Q(s, r)$. The equation of the secant line through P and Q is $y=\left(\dfrac{s^2+2s-3}{s-1}\right)x-1-s$. The value of $f'(1)$ is
(a) 2 (b) 3
(c) 4 (d) non-existent

40. Consider
$f(x)=\left[\dfrac{2(\sin x-\sin^3 x)+|\sin x-\sin^3 x|}{2(\sin x-\sin^3 x)-|\sin x-\sin^3 x|}\right], x\neq\dfrac{\pi}{2}$ for $x\in(0,\pi)$, $f(\pi/2)=3$, where [ ] denotes the greatest integer function, then
(a) f is continuous and differentiable at $x=\pi/2$
(b) f is continuous but not differentiable at $x=\pi/2$
(c) f is neither continuous nor differentiable at $x=\pi/2$
(d) None of the above

41. If $f(x+y)=f(x)+f(y)+|x|y+xy^2, \forall\ x, y\in R$ and $f'(0)=0$, then
(a) f need not be differentiable at every non-zero x
(b) f is differentiable for all $x\in R$
(c) f is twice differentiable at $x=0$
(d) None of the above

42. Let $f(x)=\max\{|x^2-2|x||, |x|\}$ and $g(x)=\min\{|x^2-2|x||, |x|\}$, then
(a) both $f(x)$ and $g(x)$ are non-differentiable at 5 points
(b) $f(x)$ is not differentiable at 5 points whether $g(x)$ is non-differentiable at 7 points
(c) number of points of non-differentiability for $f(x)$ and $g(x)$ are 7 and 5 points, respectively
(d) both $f(x)$ and $g(x)$ are non-differentiable at 3 and 5 points, respectively

43. Let $g(x)=\begin{cases}3x^2-4\sqrt{x}+1, & \text{for } x<1\\ ax+b, & \text{for } x\geq 1\end{cases}$. If $g(x)$ is the continuous and differentiable for all numbers in its domain, then
(a) $a=b=4$ (b) $a=b=-4$
(c) $a=4$ and $b=-4$ (d) $a=-4$ and $b=4$

44. Let $f(x)$ be continuous and differentiable function for all reals and $f(x+y)=f(x)-3xy+f(y)$.
If $\lim\limits_{h\to 0}\dfrac{f(h)}{h}=7$, then the value of $f'(x)$ is
(a) $-3x$ (b) 7
(c) $-3x+7$ (d) $2f(x)+7$

45. Let $[x]$ be the greatest integer function and $f(x)=\dfrac{\sin\frac{1}{4}\pi[x]}{[x]}$. Then, which one of the following does not hold good?
(a) Not continuous at any point
(b) Continuous at 3/2
(c) Discontinuous at 2
(d) Differentiable at 4/3

46. If $f(x)=\begin{cases}b([x]^2+[x])+1, \text{ for } x\geq -1\\ \sin(\pi(x+a)), \quad \text{for } x<-1\end{cases}$, where $[x]$ denotes the integral part of x, then for what values of a, b the function is continuous at $x=-1$?
(a) $a=2n+(3/2); b\in R; n\in I$
(b) $a=4n+2; b\in R; n\in I$
(c) $a=4n+(3/2); b\in R^+; n\in I$
(d) $a=4n+1; b\in R^+; n\in I$

47. If both $f(x)$ and $g(x)$ are differentiable functions at $x=x_0$, then the function defined as, $h(x)=\max\{f(x), g(x)\}$
(a) is always differentiable at $x=x_0$
(b) is never differentiable at $x=x_0$
(c) is differentiable at $x=x_0$ when $f(x_0)\neq g(x_0)$
(d) cannot be differentiable at $x=x_0$, if $f(x_0)=g(x_0)$

48. Number of points of non-differentiability of the function
$g(x)=[x^2]\{\cos^2 4x\}+\{x^2\}[\cos^2 4x]+x^2\sin^2 4x$
$+[x^2][\cos^2 4x]+\{x^2\}\{\cos^2 4x\}$ in $(-50, 50)$,
where $[\cdot]$ and $\{\cdot\}$ are greatest integer function and fractional part of x, is equal to
(a) 98
(b) 99
(c) 100
(d) 0

49. If $f(x)=\dfrac{\{x\}g(x)}{\{x\}g(x)}$ is a periodic function with period $\dfrac{1}{4}$, where $g(x)$ is a differentiable function, then (where $\{\cdot\}$ denotes fractional part of x).
(a) $g'(x)$ has exactly three roots in $\left(\dfrac{1}{4}, \dfrac{5}{4}\right)$
(b) $g(x)=0$ at $x=\dfrac{k}{4}$, where $k\in I$
(c) $g(x)$ must be non-zero function
(d) $g(x)$ must be periodic function

50. If $f\left(\dfrac{x}{y}\right)=\dfrac{f(x)}{f(y)}$ for all $x, y\in R, y\neq 0$ and $f'(x)$ exists for all x, $f(2)=4$. Then, $f(5)$ is
(a) 3 (b) 5
(c) 25 (d) None of these

Continuity and Differentiability Exercise 2 : More than One Option Correct Type Questions

51. Indicate the correct alternative, if $f(x)=\frac{x}{2}-1$, then on the interval $[0,\pi]$,

(a) $\tan(f(x))$ and $\frac{1}{f(x)}$ are both continuous

(b) $\tan(f(x))$ and $\frac{1}{f(x)}$ are both discontinuous

(c) $\tan(f(x))$ and $f^{-1}(x)$ are both continuous

(d) $\tan(f(x))$ is continuous but $\frac{1}{f(x)}$ is not continuous

52. On the interval $I=[-2,2]$, if the function

$$f(x)=\begin{cases}(x+1)\,e^{-\left(\frac{1}{|x|}+\frac{1}{x}\right)}, & x\neq 0\\ 0, & x=0\end{cases}$$ then which of the following hold good?

(a) $f(x)$ is continuous for all values of $x\in I$

(b) $f(x)$ is continuous for $x\in I-\{0\}$

(c) $f(x)$ assumes all intermediate values from $f(-2)$ to $f(2)$

(d) $f(x)$ has a maximum value equal to $3/e$

53. If $f(x)=\begin{cases}3-\left[\cot^{-1}\left(\frac{2x^3-3}{x^2}\right)\right], & \text{for } x>0\\ \{x^2\}\cos(e^{1/x}), & \text{for } x<0\end{cases}$, where $\{x\}$ and $[x]$ denote fractional part and the greatest integer function respectively, then which of the following statements does not hold good?

(a) $f(0^-)=0$

(b) $f(0^+)=0$

(c) $f(0)=0\Rightarrow$ Continuous at $x=0$

(d) Irremovable discontinuity at $x=0$

54. If $f(x)=\begin{cases}b([x]^2+[x])+1, & \text{for } x>-1\\ \sin(\pi(x+a)), & \text{for } x<-1\end{cases}$, where $[x]$ denotes the integral part of x, then for what values of a and b, the function is continuous at $x=-1$?

(a) $a=2n+\frac{3}{2}; b\in R, n\in I$

(b) $a=4n+2; b\in R, n\in I$

(c) $a=4n+\frac{3}{2}; b\in R^+, n\in I$

(d) $a=4n+1; b\in R^+, n\in I$

55. Let $[x]$ be the greatest integer function, then $f(x)=\frac{\sin\frac{1}{4}\pi[x]}{[x]}$ is

(a) not continuous at any point (b) continuous at $x=\frac{3}{2}$

(c) discontinuous at $x=2$ (d) differentiable at $x=\frac{4}{3}$

56. If $f(x)=\begin{cases}(\sin^{-1}x)^2\cos\left(\frac{1}{x}\right), & x\neq 0\\ 0, & x=0\end{cases}$, then $f(x)$ is

(a) continuous nowhere in $-1\le x\le 1$

(b) continuous everywhere in $-1\le x\le 1$

(c) differentiable nowhere in $-1\le x\le 1$

(d) differentiable everywhere in $-1\le x\le 1$

57. Let $f(x)=\cos x$ and $H(x)=\begin{cases}\min(f(t):0\le t<x), & \text{for } 0\le x\le \pi/2\\ \frac{\pi}{2}-x, & \text{for } \frac{\pi}{2}<x\le 3\end{cases}$, then

(a) $H(x)$ is continuous and derivable in $[0,3]$

(b) $H(x)$ is continuous but not derivable at $x=\frac{\pi}{2}$

(c) $H(x)$ is neither continuous nor derivable at $x=\frac{\pi}{2}$

(d) maximum value of $H(x)$ in $[0,3]$ is 1

58. If $f(x)=3(2x+3)^{2/3}+2x+3$, then

(a) $f(x)$ is continuous but not differentiable at $x=-\frac{3}{2}$

(b) $f(x)$ is differentiable at $x=0$

(c) $f(x)$ is continuous at $x=0$

(d) $f(x)$ is differentiable but not continuous at $x=-\frac{3}{2}$

59. If $f(x)=\begin{cases}\frac{x\cdot\ln(\cos x)}{\ln(1+x^2)}, & x\neq 0\\ 0, & x=0\end{cases}$, then

(a) f is continuous at $x=0$

(b) f is continuous at $x=0$ but not differentiable at $x=0$

(c) f is differentiable at $x=0$

(d) f is not continuous at $x=0$

60. Let $[x]$ denotes the greatest integer less than or equal to x. If $f(x) = [x \sin \pi x]$, then $f(x)$ is
(a) continuous at $x = 0$
(b) continuous in $(-1, 0)$
(c) differentiable at $x = 1$
(d) differentiable in $(-1, 1)$

61. The function $f(x) = [|x|] - |[x]|$, where $[x]$ denotes greatest integer function
(a) is continuous for all positive integers
(b) is discontinuous for all non-positive integers
(c) has finite number of elements in its range
(d) is such that its graph does not lie above the X-axis

62. The function $f(x) = \sqrt{1 - \sqrt{1 - x^2}}$
(a) has its domain $-1 \le x \le 1$
(b) has finite one sided derivates at the point $x = 0$
(c) is continuous and differentiable at $x = 0$
(d) is continuous but not differentiable at $x = 0$

63. Consider the function $f(x) = |x^3 + 1|$. Then,
(a) domain of $f(x) \in R$
(b) range of f is R^+
(c) f has no inverse
(d) f is continuous and differentiable for every $x \in R$

64. f is a continuous function in $[a, b]$, g is a continuous function in $[b, c]$. A function $h(x)$ is defined as
$h(x) = \begin{cases} f(x) \text{ for } x \in [a, b) \\ g(x) \text{ for } x \in (b, c] \end{cases}$. If $f(b) = g(b)$, then
(a) $h(x)$ has a removable discontinuity at $x = b$
(b) $h(x)$ may or may not be continuous in $[a, c]$
(c) $h(b^-) = g(b^+)$ and $h(b^+) = f(b^-)$
(d) $h(b^+) = g(b^-)$ and $h(b^-) = f(b^+)$

65. Which of the following function(s) has/have the same range?
(a) $f(x) = \dfrac{1}{1 + x}$
(b) $f(x) = \dfrac{1}{1 + x^2}$
(c) $f(x) = \dfrac{1}{1 + \sqrt{x}}$
(d) $f(x) = \dfrac{1}{\sqrt{3 - x}}$

66. If $f(x) = \sec 2x + \operatorname{cosec} 2x$, then $f(x)$ is discontinuous at all points in
(a) $\{n\pi, n \in N\}$
(b) $\left\{(2n \pm 1)\dfrac{\pi}{4}, n \in I\right\}$
(c) $\left\{\dfrac{n\pi}{4}, n \in I\right\}$
(d) $\left\{(2n \pm 1)\dfrac{\pi}{8}, n \in I\right\}$

67. Let $f(x) = \begin{cases} x^n \sin\left(\dfrac{1}{x^2}\right), & x \ne 0 \\ 0, & x = 0 \end{cases}, (n \in I)$, then
(a) $\lim\limits_{x \to 0} f(x)$ exists for every $n > 1$
(b) f is continuous at $x = 0$ for $n > 1$
(c) f is differentiable at $x = 0$ for every $n > 1$
(d) None of the above

68. A function is defined as $f(x) = \begin{cases} e^x, & x \le 0 \\ |x - 1|, & x > 0 \end{cases}$, then $f(x)$ is
(a) continuous at $x = 0$ (b) continuous at $x = 1$
(c) differentiable at $x = 0$ (d) differentiable at $x = 1$

69. Let $f(x) = \int_{-2}^{x} |t + 1|\, dt$, then
(a) $f(x)$ is continuous in $[-1, 1]$
(b) $f(x)$ is differentiable in $[-1, 1]$
(c) $f'(x)$ is continuous in $[-1, 1]$
(d) $f'(x)$ is differentiable in $[-1, 1]$

70. A function $f(x)$ satisfies the relation $f(x + y) = f(x) + f(y) + xy(x + y), \forall\ x, y \in R$. If $f'(0) = -1$, then
(a) $f(x)$ is a polynomial function
(b) $f(x)$ is an exponential function
(c) $f(x)$ is twice differentiable for all $x \in R$
(d) $f'(3) = 8$

71. If $f(x) = \begin{cases} 3x^2 + 12x - 1, & -1 \le x \le 2 \\ 37 - x, & 2 < x \le 3 \end{cases}$, then
(a) $f(x)$ is increasing on $[-1, 2]$
(b) $f(x)$ is continuous on $[-1, 3]$
(c) $f'(2)$ doesn't exist
(d) $f(x)$ has the maximum value at $x = 2$

72. If $f(x) = 0$ for $x < 0$ and $f(x)$ is differentiable at $x = 0$, then for $x > 0$, $f(x)$ may be
(a) x^2 (b) x (c) $-x$ (d) $-x^{3/2}$

Continuity and Differentiability Exercise 3 : Statements I and II Type Questions

■ **Directions** (Q. Nos. 73 to 82) *For the following questions, choose the correct answer from the codes* (a), (b), (c) *and* (d) *defined as follows :*

(a) Statement I is correct, Statement II is also correct; Statement II is the correct explanation of Statement I

(b) Statement I is correct, Statement II is also correct; Statement II is not the correct explanation of Statement I

(c) Statement I is correct, Statement II is incorrect

(d) Statement I is incorrect, Statement II is correct

73. **Statement I** $f(x) = \sin x + [x]$ is discontinuous at $x = 0$.

Statement II If $g(x)$ is continuous and $f(x)$ is discontinuous, then $g(x) + f(x)$ will necessarily be discontinuous at $x = a$.

74. Consider $f(x) = \begin{cases} 2\sin(a\cos^{-1} x), & \text{if } x \in (0, 1) \\ \sqrt{3}, & \text{if } x = 0 \\ ax + b, & \text{if } x < 0 \end{cases}$

Statement I If $b = \sqrt{3}$ and $a = \dfrac{2}{3}$, then $f(x)$ is continuous in $(-\infty, 1)$.

Statement II If a function is defined on an interval I and limit exists at every point of interval I, then function is continuous in I.

75. Let $f(x) = \begin{cases} \dfrac{\cos x - e^{x^2/2}}{x^3}, & x \neq 0 \\ 0, & x = 0, \text{ then} \end{cases}$

Statement I $f(x)$ is continuous at $x = 0$.

Statement II $\lim\limits_{x \to 0} \dfrac{\cos x - e^{-x^2/2}}{x^3} = -\dfrac{1}{12}$

76. **Statement I** The equation $\dfrac{x^3}{4} - \sin \pi x + \dfrac{2}{3} = 0$ has atleast one solution in $[-2, 2]$.

Statement II Let $f : [a, b] \to R$ be a function and c be a number such that $f(a) < c < f(b)$, then there is at least one number $n \in (a, b)$ such that $f(n) = c$.

77. **Statement I** Range of $f(x) = x\left(\dfrac{e^{2x} - e^{-2x}}{e^{2x} + e^{-2x}}\right) + x^2 + x^4$ is not R.

Statement II Range of a continuous even function cannot be R.

78. Let $h(x) = f_1(x) + f_2(x) + f_3(x) + \ldots + f_n(x)$, where $f_1(x), f_2(x), f_3(x), \ldots, f_n(x)$ are real valued functions of x.

Statement I $f(x) = |\cos|x|| + \cos^{-1}(\text{sgn } x) + |\ln x|$ is not differentiable at 3 points in $(0, 2\pi)$.

Statement II Exactly one function , is $f_i(x)$, $i = 1, 2, \ldots, n$ is not differentiable and the rest of the function is differentiable at $x = a$ makes $h(x)$ not differentiable at $x = a$.

79. **Statement I** $f(x) = |x| \sin x$ is differentiable at $x = 0$.

Statement II If $g(x)$ is not differentiable at $x = a$ and $h(x)$ is differentiable at $x = a$, then $g(x) \cdot h(x)$ cannot be differentiable at $x = a$.

80. **Statement I** $f(x) = |\cos x|$ is not derivable at $x = \dfrac{\pi}{2}$.

Statement II If $g(x)$ is differentiable at $x = a$ and $g(a) = 0$, then $|g(x)|$ is non-derivable at $x = a$.

81. Let $f(x) = x - x^2$ and $g(x) = \{x\}, \forall\ x \in R$, where $\{\}$ denotes fractional part function.

Statement I $f(g(x))$ will be continuous, $\forall\ x \in R$.

Statement II $f(0) = f(1)$ and $g(x)$ is periodic with period 1.

82. Let $f(x) = \begin{cases} -ax^2 - b|x| - c, & -\alpha \le x < 0 \\ ax^2 + b|x| + c, & 0 \le x \le \alpha \end{cases}$, where a, b, c are positive and $\alpha > 0$, then

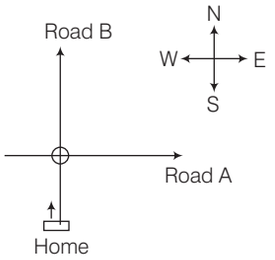
Statement I The equation $f(x) = 0$ has at least one real root for $x \in [-\alpha, \alpha]$.

Statement II Values of $f(-\alpha)$ and $f(\alpha)$ are opposite in sign.

Continuity and Differentiability Exercise 4 : Passage Based Questions

Passage I (Q. Nos. 83 to 85)

A man leaves his home early in the morning to have a walk. He arrives at a junction of roads A and B as shown in figure. He takes the following steps in later journies :



(i) 1 *km in North direction.*

(ii) *Changes direction and moves in North-East direction for* $2\sqrt{2}$ *km.*

(iii) *Changes direction and moves Southwards for distance of* 2 *km.*

(iv) *Finally, he changes the direction and moves in South-East direction to reach road A again.*

Visible/invisible path *The path traced by the man in the direction parallel to road A and road B is called invisible path, the remaining path is called visible.*

Visible points *The point about which the man changes direction are called visible points, except the point from where he changes direction last time.*

Now, if roads A and B are taken as X-axis and Y-axis, then visible point representing the graph of $y = f(x)$.

83 The value of x at which the function is discontinuous, is

(a) 2 (b) 0 (c) 1 (d) 3

84. The value of x for which fof is discontinuous, is

(a) 0 (b) 1 (c) 2 (d) 3

85. If $f(x)$ is periodic with period 3, then $f(19)$ is

(a) 2 (b) 3
(c) 19 (d) None of these

Passage II (Q. Nos. 86 to 89)

Let f *be a function that is differentiable everywhere and that has the following properties :*

(i) $f(x) > 0$ *(ii)* $f'(0) = -1$

(iii) $f(-x) = \dfrac{1}{f(x)}$ *and* $f(x+h) = f(x) \cdot f(h)$

A standard result is $\displaystyle\int \frac{f'(x)}{f(x)}dx = \log|f(x)| + C.$

86. Range of $f(x)$ is

(a) R (b) $R - \{0\}$
(c) R^+ (d) $(0, e)$

87. The range of the function $\Delta = f(|x|)$ is

(a) $[0, 1]$ (b) $[0, 1)$
(c) $(0, 1]$ (d) None of these

88. The function $y = f(x)$ is

(a) odd (b) even
(c) increasing (d) decreasing

89. If $h(x) = f'(x)$, then $h(x)$ is given by

(a) $-f(x)$ (b) $\dfrac{1}{f(x)}$ (c) $f(x)$ (d) $e^{f(x)}$

Passage III (Q. Nos. 90 to 92)

Let $y = f(x)$ *be defined in* $[a, b]$, *then*

(i) *Test of continuity at* $x = c$, $a < c < b$

(ii) *Test of continuity at* $x = a$

(iii) *Test of continuity at* $x = b$

***Case* I** *Test of continuity at* $x = c$, $a < c < b$

If $y = f(x)$ *be defined at* $x = c$ *and its value* $f(c)$ *be equal to limit of* $f(x)$ *as* $x \to c$, i.e. $f(c) = \lim\limits_{x \to c} f(x)$

or $\lim\limits_{x \to c^-} f(x) = f(c) = \lim\limits_{x \to c^+} f(x)$

or LHL $= f(c) =$ RHL

Then, $y = f(x)$ *is continuous at* $x = c$.

***Case* II** *Test of continuity at* $x = a$

If $RHL = f(a)$

Then, $f(x)$ *is said to be continuous at the end point* $x = a$.

***Case* III** *Test of continuity at* $x = b$, *if* $LHL = f(b)$

Then, $f(x)$ *is continuous at right end* $x = b$.

90. If $f(x) = \begin{cases} \sin x, & x \le 0 \\ \tan x, & 0 < x < 2\pi \\ \cos x, & 2\pi \le x < 3\pi \\ 3\pi, & x = 3\pi \end{cases}$, then $f(x)$ is discontinuous at

(a) $\dfrac{\pi}{2}, \dfrac{3\pi}{2}, 2\pi$ (b) $0, \dfrac{\pi}{2}, \pi, \dfrac{3\pi}{2}, 3\pi$

(c) $\dfrac{\pi}{2}, 2\pi$ (d) None of these

91. Number of points of discontinuity of $[2x^3 - 5]$ in $[1, 2)$ is (where $[\cdot]$ denotes the greatest integral function)

(a) 14 (b) 13
(c) 10 (d) None of these

92. Max $([x], |x|)$ is discontinuous at

(a) $x = 0$
(b) ϕ
(c) $x = n, n \in I$
(d) None of the above

Passage IV (Q. Nos. 93 to 95)

$f(x) = \cos x$ *and* $H_1(x) = min\{f(t), 0 \le t < x\}$;

$0 \le x \le \frac{\pi}{2} = \frac{\pi}{2} - x; \frac{\pi}{2} < x \le \pi$

$f(x) = \cos x$ *and* $H_2(x) = max\{f(t), 0 \le t \le x\}$;

$0 \le x \le \frac{\pi}{2} = \frac{\pi}{2} - x; \frac{\pi}{2} < x \le \pi$

$g(x) = \sin x$ *and* $H_3(x) = min\{g(t), 0 \le t \le x\}$;

$0 \le x \le \frac{\pi}{2} = \frac{\pi}{2} - x; \frac{\pi}{2} < x \le \pi$

$g(x) = \sin x$ *and* $H_4(x) = max\{g(t), 0 \le t \le x\}$;

$0 \le x \le \frac{\pi}{2} = \frac{\pi}{2} - x; \frac{\pi}{2} < x \le \pi$

93. Which of the following is true for $H_2(x)$?

(a) Continuous and derivable in $[0, \pi]$

(b) Continuous but not derivable at $x = \frac{\pi}{2}$

(c) Neither continuous nor derivable at $x = \frac{\pi}{2}$

(d) None of the above

94. Which of the following is true for $H_3(x)$?

(a) Continuous and derivable in $[0, \pi]$

(b) Continuous but not derivable at $x = \frac{\pi}{2}$

(c) Neither continuous nor derivable at $x = \frac{\pi}{2}$

(d) None of the above

95. Which of the following is true for $H_4(x)$?

(a) Continuous and derivable in $[0, \pi]$

(b) Continuous but not derivable at $x = \frac{\pi}{2}$

(c) Neither continuous nor derivable at $x = \frac{\pi}{2}$

(d) None of the above

Passage V (Q. Nos. 96 to 99)

Let $f(x)$ be a real valued function not identically zero, which satisfied the following conditions

I. $f(x + y^{2n+1}) = f(x) + (f(y))^{2n+1}, n \in N, x, y$ *are any real numbers.*

II. $f'(0) \ge 0$

96. The value of $f(1)$ is

(a) 0 (b) 1
(c) 2 (d) Not defined

97. The value of $f(x)$ is

(a) $2x$ (b) $x^2 + x + 1$
(c) x (d) None of these

98. The value of $f'(10)$ is

(a) 10 (b) 0 (c) $2n + 1$ (d) 1

99. The function $f(x)$ is

(a) odd
(b) even
(c) neither even nor odd
(d) both even as well as odd

Passage VI (Q. Nos. 100 to 101)

If $f : R \to (0, \infty)$ is a differentiable function $f(x)$ satisfying $f(x + y) - f(x - y) = f(x) \cdot \{f(y) - f(-y)\}, \forall\ x, y \in R$, $(f(y) \ne f(-y)$ *for all* $y \in R)$ *and* $f'(0) = 2010$. *Now, answer the following questions*

100. Which of the following is true for $f(x)$?

(a) $f(x)$ is one-one and into
(b) $\{f(x)\}$ is non-periodic, where $\{\cdot\}$ denotes fractional part of x
(c) $f(x) = 4$ has only two solutions
(d) $f(x) = f'(x)$ has only one solution

101. The value of $\frac{f'(x)}{f(x)}$ is

(a) 2016 (b) 2014 (c) 2012 (d) 2010

Continuity and Differentiability Exercise 5 : Matching Type Questions

102. Match the column.

	Column I		Column II
(A)	If $f(x)=\begin{cases}\sin\{x\}; & x<1\\ \cos x+a; & x\geq 1\end{cases}$, where $\{x\}$ denotes the fractional part function, such that $f(x)$ is continuous at $x=1$. If $\lvert K\rvert=\dfrac{a}{\sqrt{2}\sin\dfrac{(4-\pi)}{4}}$, then K is	(p)	1
(B)	If the function $f(x)=\dfrac{1-\cos(\sin x)}{x^2}$ is continuous at $x=0$, then $f(0)$ is	(q)	0
(C)	If $f(x)=\begin{cases}x, & x\in\theta\\ 1-x, & x\notin\theta\end{cases}$, then the values of x at which $f(x)$ is continuous, is	(r)	-1
(D)	If $f(x)=x+\{-x\}+[x]$, where $[x]$ and $\{x\}$ represent greatest integer and fractional part of x, then the values of x at which $f(x)$ is discontinuous, is	(s)	$\frac{1}{2}$

103. Match the column.

	Column I		Column II
(A)	Number of points where the function $f(x)=\begin{cases}1+\left[\cos\dfrac{\pi x}{2}\right], & 1<x\leq 2\\ 1-\{x\}, & 0\leq x<1 \text{ and } f(1)=0\\ \lvert\sin\pi x\rvert, & -1\leq x<0\end{cases}$ is continuous but non-differentiable, where $[\cdot]$ denotes greatest integer function and $\{\cdot\}$ denotes fractional part of x, is	(p)	0
(B)	If $f(x)=\begin{cases}x^2e^{1/x}, & x\neq 0\\ 0, & x=0\end{cases}$, then $f(0^-)$ is	(q)	1
(C)	The number of points at which $f(x)=\dfrac{1}{1+2/f(x)}$ is not differentiable, where $f(x)=\dfrac{1}{1+1/x}$, is	(r)	2
(D)	Number of points where tangent does not exist for the curve $y=\text{sgn}(x^2-1)$, is	(s)	3

104. Match the column.

	Column I		Column II
(A)	The number of values of x in $(0, 2\pi)$, where the function $f(x)=\dfrac{\tan x+\cot x}{2}-\left\lvert\dfrac{\tan x-\cot x}{2}\right\rvert$ is continuous but not differentiable, is	(p)	2
(B)	The number of points where the function $f(x)=\min\{1, 1+x^3, x^2-3x+3\}$ is non-derivable, is	(q)	0
(C)	The number of points where $f(x)=(x+4)^{1/3}$ is non-differentiable, is	(r)	4
(D)	Consider $f(x)=\begin{cases}\dfrac{-\pi}{2}\log\left(\dfrac{2x}{\pi}\right)+\dfrac{\pi}{2}, & 0<x\leq\dfrac{\pi}{2}\\ \sin^{-1}(\sin x), & \dfrac{\pi}{2}<x\leq\dfrac{3\pi}{2}\end{cases}$ Number of points in $\left(0,\dfrac{3\pi}{2}\right)$, where $f(x)$ is non-differentiable, is	(s)	1

105. Match the entries of the following two columns.

	Column I		Column II
(A)	$f(x)=\begin{cases}x+1, & \text{if } x<0\\ \cos x, & \text{if } x\geq 0\end{cases}$ at $x=0$ is	(p)	continuous
(B)	For every $x\in R$, the function $g(x)=\dfrac{\sin(\pi[x-\pi])}{1+[x]^2}$, where $[x]$ denotes the greatest integer function, is	(q)	differentiability
(C)	$h(x)=\sqrt{\{x\}^2}$, where $\{x\}$ denotes fractional part function for all $x\in I$, is	(r)	discontinuous
(D)	$k(x)=\begin{cases}x^{\frac{1}{\ln x}}, & \text{if } x\neq 1\\ e, & \text{if } x=1\end{cases}$ at $x=1$ is	(s)	non-derivable

106. Match the entries of the following two columns.

	Column I		Column II
(A)	$\lim\limits_{x\to\infty}\left(e^{\sqrt{x^4+1}}-e^{(x^2+1)}\right)$ is	(p)	e
(B)	For $a>0$, let $f(x)=\begin{cases}\dfrac{a^x+a^{-x}-2}{x^2}, & \text{if } x>0\\ 3\ln(a-x)-2, & \text{if } x\leq 0\end{cases}$. If f is continuous at $x=0$, then a equals	(q)	e^2
(C)	Let $L=\lim\limits_{x\to a}\dfrac{x^x-a^a}{x-a}$ and $M=\lim\limits_{x\to a}\dfrac{x^x-a^x}{x-a}(a>0)$. If $L=2M$, then the value of a is equal to	(r)	non-existent

Continuity and Differentiability Exercise 6 :
Single Integer Answer Type Questions

107. Number of points of discontinuity of $f(x) = \tan^2 x - \sec^2 x$ in $(0, 2\pi)$ is ..... .

108. Number of point(s) of discontinuity of the function $f(x) = [x^{1/x}]$, $x > 0$, (where [ ] denotes the greatest integral function) is ..... .

109. Let $f(x) = x + \cos x + 2$ and $g(x)$ be the inverse function of $f(x)$, then $g'(3)$ equals to ..... .

110. Let $f(x) = x \tan^{-1}(x^2) + x^4$. Let $f^k(x)$ denotes kth derivative of $f(x)$ w. r. t. x, $k \in N$.

If $f^{2m}(0) \neq 0$, $m \in N$, then m equals to ..... .

111. Let $f_1(x)$ and $f_2(x)$ be twice differentiable functions, where $F(x) = f_1(x) + f_2(x)$ and $G(x) = f_1(x) - f_2(x), \forall\ x \in R, f_1(0) = 2$ and $f_2(0) = 1$. If $f_1'(x) = f_2(x)$ and $f_2'(x) = f_1(x), \forall\ x \in R$, then the number of solutions of the equation $(F(x))^2 = \dfrac{9x^4}{G(x)}$ is ..... .

112. Suppose the function $f(x) - f(2x)$ has the derivative 5 at $x = 1$ and derivative 7 at $x = 2$. The derivative of the function $f(x) - f(4x) - 10x$ at $x = 1$ is equal to ..... .

113. In a ΔABC, angles A, B, C are in AP.

If $f(x) = \lim\limits_{A \to C} \dfrac{\sqrt{3 - 4\sin A \sin C}}{|A - C|}$, then $f'(x)$ is equal to ..... .

114. Let $f(x) = \begin{cases} x\dfrac{\left(\frac{3}{4}\right)^{1/x} - \left(\frac{3}{4}\right)^{-1/x}}{\left(\frac{3}{4}\right)^{1/x} + \left(\frac{3}{4}\right)^{-1/x}}, & x \neq 0 \\ 0, & x = 0 \end{cases}$

If $P = f'(0^-) - f'(0^+)$, then

$$4\left(\lim_{x \to P-} \frac{(\exp((x+2)\log 4))^{\frac{[x+1]}{4}} - 16}{4^x - 16}\right) \text{ is ..... .}$$

(where $[x]$ denotes greatest integer function.)

115. Let $f(x) = -x^3 + x^2 - x + 1$ and

$$g(x) = \begin{cases} \min(f(t)), 0 \le t \le x \text{ and } 0 \le x \le 1 \\ x - 1, \quad 1 < x \le 2 \end{cases}$$

Then, the value of $\lim\limits_{x \to 1} g(g(x))$ is..... .

116. The number of points at which the function $f(x) = (x - |x|)^2 (1 - x + |x|)^2$ is not differentiable in the interval $(-3, 4)$ is ..... .

117. If $f(x) = \begin{cases} \dfrac{\frac{\pi}{2} - \sin^{-1}(1 - \{x\}^2)\sin^{-1}(1 - \{x\})}{\sqrt{2}(\{x\} - \{x\}^3)}, & x > 0 \\ k, & x = 0 \\ \dfrac{A\sin^{-1}(1 - \{x\})\cos^{-1}(1 - \{x\})}{\sqrt{2\{x\}}(1 - \{x\})}, & x < 0 \end{cases}$

is continuous at $x = 0$, then the value of $\sin^2 k + \cos^2\left(\dfrac{A\pi}{\sqrt{2}}\right)$, is..... (where $\{\cdot\}$ denotes fractional part of x).

Continuity and Differentiability Exercise 7 :
Subjective Type Questions

118. Discuss the continuity of the function $f(x) = [[x]] - [x - 1]$, where [ ] denotes the greatest integral function.

119. Examine the continuity or discontinuity of the following :

(i) $f(x) = [x] + [-x]$ (ii) $g(x) = \lim\limits_{n \to \infty} \dfrac{x^{2n} - 1}{x^{2n} + 1}$

120. Examine the continuity and differentiability at points $x = 1$ and $x = 2$.

The function f defined by

$f(x) = \begin{cases} x[x], & 0 \le x < 2 \\ (x - 1)[x], & 2 \le x \le 3 \end{cases}$ (where $[\cdot]$ denotes the greatest integral function less than or equal to x).

121. Let f be twice differentiable function, such that $f''(x) = -f(x)$ and $f'(x) = g(x)$, $h(x) = [f(x)]^2 + [g(x)]^2$. Find $h(10)$, if $h(5) = 11$.

122. A function $f : R \to R$ satisfies the equation $f(x+y) = f(x) \cdot f(y)$ for all x, y in R and $f(x) \neq 0$ for any x in R. Let the function be differentiable at $x = 0$ and $f'(0) = 2$. Show that $f'(x) = 2f(x)$ for all x in R. Hence, determine $f(x)$.

123. A function $f : R \to R$, where R is a set of real numbers, satisfying the equation $f\left(\frac{x+y}{3}\right) = \frac{f(x)+f(y)+f(0)}{3}$ for all x, y in R. If the function is differentiable at $x = 0$, then show that it is differentiable for all x in R.

124. Let $f(x+y) = f(x) + f(y) + 2xy - 1$ for all real x, y and $f(x)$ be differentiable functions. If $f'(0) = \cos\alpha$, then prove that $f(x) > 0,\ \forall\ x \in R$.

Continuity and Differentiability Exercise 8 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

125. For every pair of continuous function $f,\ g : [0,1] \to R$ such that $\max\{f(x): x \in [0,1]\} = \max\{g(x): x \in [0,1]\}$. The correct statement(s) is/are **[More than One Correct Option, 2014]**

(a) $[f(c)]^2 + 3f(c) = [g(c)]^2 + 3g(c)$ for some $c \in [0,1]$

(b) $[f(c)]^2 + f(c) = [g(c)]^2 + 3g(c)$ for some $c \in [0,1]$

(c) $[f(c)]^2 + 3f(c) = [g(c)]^2 + g(c)$ for some $c \in [0,1]$

(d) $[f(c)]^2 = [g(c)]^2$ for some $c \in [0,1]$

126. Let $f : R \to R$ and $g : R \to R$ be respectively given by $f(x) = |x| + 1$ and $g(x) = x^2 + 1$. Define $h : R \to R$ by

$$h(x) = \begin{cases} \max\{f(x), g(x)\}, & \text{if } x \leq 0 \\ \min\{f(x), g(x)\}, & \text{if } x > 0 \end{cases}.$$

The number of points at which $h(x)$ is not differentiable is **[Integer Answer Type, 2014]**

127. Let $f(x) = \begin{cases} x^2 \left|\cos\frac{\pi}{x}\right|, & x \neq 0\ x \in R, \\ 0, & x = 0, \text{then } f \text{ is} \end{cases}$ **[One Correct Option, 2012]**

(a) differentiable both at $x = 0$ and at $x = 2$

(b) differentiable at $x = 0$ but not differentiable at $x = 2$

(c) not differentiable at $x = 0$ but differentiable at $x = 2$

(d) differentiable neither at $x = 0$ nor at $x = 2$

128. For every integer n, let a_n and b_n be real numbers. Let function $f : R \to R$ be given by

$$f(x) = \begin{cases} a_n + \sin\pi x, & \text{for } x \in [2n, 2n+1] \\ b_n + \cos\pi x, & \text{for } x \in (2n-1, 2n) \end{cases},$$

for all integers n.

If f is continuous, then which of the following hold(s) for all n? **[More than One Correct Option, 2012]**

(a) $a_{n-1} - b_{n-1} = 0$ (b) $a_n - b_n = 1$

(c) $a_n - b_{n+1} = 1$ (d) $a_{n-1} - b_n = -1$

129. Let $f : R \to R$ be a function such that $f(x+y) = f(x) + f(y),\ \forall x, y \in R$. If $f(x)$ is differentiable at $x = 0$, then **[More than One Correct Option, 2011]**

(a) $f(x)$ is differentiable only in a finite interval containing zero

(b) $f(x)$ is continuous for all $x \in R$

(c) $f'(x)$ is constant for all $x \in R$

(d) $f(x)$ is differentiable except at finitely many points

130. If $f(x) = \begin{cases} -x - \frac{\pi}{2}, & x \leq -\frac{\pi}{2} \\ -\cos x, & -\frac{\pi}{2} < x \leq 0, \text{ then} \\ x - 1, & 0 < x \leq 1 \\ \ln x, & x > 1 \end{cases}$ **[More than One Correct Option, 2011]**

(a) $f(x)$ is continuous at $x = -\frac{\pi}{2}$

(b) $f(x)$ is not differentiable at $x = 0$

(c) $f(x)$ is differentiable at $x = 1$

(d) $f(x)$ is differentiable at $x = -\frac{3}{2}$

131. For the function $f(x) = x\cos\frac{1}{x},\ x \geq 1$, **[More than One Correct Option, 2009]**

(a) for at least one x in the interval $[1, \infty)$, $f(x+2) - f(x) < 2$

(b) $\lim_{x \to \infty} f'(x) = 1$

(c) for all x in the interval $[1, \infty)$, $f(x+2) - f(x) > 2$

(d) $f'(x)$ is strictly decreasing in the interval $[1, \infty)$

132. Let $g(x) = \frac{(x-1)^n}{\log\cos^m(x-1)}; 0 < x < 2,\ m$ and n are integers, $m \neq 0,\ n > 0$ and let p be the left hand derivative of $|x-1|$ at $x = 1$. If $\lim_{x \to 1^+} g(x) = p$, then **[One Correct Option, 2008]**

(a) $n = 1, m = 1$ (b) $n = 1, m = -1$

(c) $n = 2, m = 2$ (d) $n > 2, m = n$

133. Let f and g be real valued functions defined on interval $(-1, 1)$ such that $g''(x)$ is continuous, $g(0) \neq 0$, $g'(0) = 0$, $g''(0) \neq 0$ and $f(x) = g(x)\sin x$.

Statement I $\lim_{x \to 0} [g(x)\cos x - g(0)]\operatorname{cosec} x = f''(0)$.

Statement II $f'(0) = g(0)$.

For the above question, choose the correct answer from the codes (a), (b), (c) and (d) defined as follows.

[Assertion and Reason, 2008]

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I

(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I

(c) Statement I is true; Statement II is false

(d) Statement I is false; Statement II is true

134. In the following, $[x]$ denotes the greatest integer less than or equal to x. **[Matching type Question, 2007]**

	Column I		Column II
A.	$x\|x\|$	p.	continuous in $(-1, 1)$
B.	$\sqrt{\|x\|}$	q.	differentiable in $(-1, 1)$
C.	$x + [x]$	r.	strictly increasing in $(-1, 1)$
D.	$\|x-1\| + \|x+1\|$	s.	not differentiable atleast at one point in $(-1, 1)$

135. If $f(x) = \min\{1, x^2, x^3\}$, then **[More than One Correct, 2006]**

(a) $f(x)$ is continuous everywhere

(b) $f(x)$ is continuous and differentiable everywhere

(c) $f(x)$ is not differentiable at two points

(d) $f(x)$ is not differentiable at one point

136. Let $f(x) = ||x| - 1|$, then points where, $f(x)$ is not differentiable is/are **[One Correct Option, 2005]**

(a) $0, \pm 1$ (b) ± 1

(c) 0 (d) 1

137. If f is a differentiable function satisfying $f\left(\frac{1}{n}\right) = 0, \forall$ $n \geq 1, n \in I$, then **[One Correct Option, 2005]**

(a) $f(x) = 0, x \in (0, 1]$

(b) $f'(0) = 0 = f(0)$

(c) $f(0) = 0$ but $f'(0)$ not necessarily zero

(d) $|f(x)| \leq 1, x \in (0, 1]$

138. The domain of the derivative of the functions

$$f(x) = \begin{cases} \tan^{-1} x, & \text{if } |x| \leq 1 \\ \frac{1}{2}(|x| - 1), & \text{if } |x| > 1 \end{cases}$$ is

[One Correct Option, 2002]

(a) $R - \{0\}$ (b) $R - \{1\}$

(c) $R - \{-1\}$ (d) $R - \{-1, 1\}$

139. The left hand derivative of $f(x) = [x]\sin(\pi x)$ at $x = k, k$ is an integer, is **[One Correct Option, 2001]**

(a) $(-1)^k (k-1)\pi$

(b) $(-1)^{k-1}(k-1)\pi$

(c) $(-1)^k k\pi$

(d) $(-1)^{k-1} k\pi$

140. Which of the following functions is differentiable at $x = 0$? **[One Correct Option, 2001]**

(a) $\cos(|x|) + |x|$ (b) $\cos(|x|) - |x|$

(c) $\sin(|x|) + |x|$ (d) $\sin(|x|) - |x|$

(ii) JEE Main & AIEEE

141. For $x \in R$, $f(x) = |\log 2 - \sin x|$ and $g(x) = f(f(x))$, then

(a) g is not differentiable at $x = 0$ **[2016, JEE Main]**

(b) $g'(0) = \cos(\log 2)$

(c) $g'(0) = -\cos(\log 2)$

(d) g is differentiable at $x = 0$ and $g'(0) = -\sin(\log 2)$

142. If the function $g(x) = \begin{cases} k\sqrt{x+1}, & 0 \leq x \leq 3 \\ mx + 2, & 3 < x \leq 5 \end{cases}$ is differentiable, then the value of $k + m$ is **[2015, JEE Main]**

(a) 2 (b) $\frac{16}{5}$

(c) $\frac{10}{3}$ (d) 4

143. If f and g are differentiable functions in $(0, 1)$ satisfying $f(0) = 2 = g(1)$, $g(0) = 0$ and $f(1) = 6$, then for some $c \in]0, 1[$ **[2014, JEE Main]**

(a) $2f'(c) = g'(c)$ (b) $2f'(c) = 3g'(c)$

(c) $f'(c) = g'(c)$ (d) $f'(c) = 2g'(c)$

144. If $f : R \to R$ is a function defined by $f(x) = [x]\cos\left(\frac{2x-1}{2}\right)\pi$, where $[x]$ denotes the greatest integer function, then f is **[2012 AIEEE]**

(a) continuous for every real x

(b) discontinuous only at $x = 0$

(c) discontinuous only at non-zero integral values of x

(d) continuous only at $x = 0$

Solutions

1. $f(x)=\begin{cases}\sin\dfrac{\pi x}{2}, & x<1\\ [x], & x\geq 1\end{cases}$

$f(1)=1,\ f(1^+)=\lim\limits_{h\to 0}[1+h]=1$

$f(1^-)=\lim\limits_{h\to 0}\sin\dfrac{\pi}{2}(1-h)=\lim\limits_{h\to 0}\sin\left(\dfrac{\pi}{2}-\dfrac{\pi h}{2}\right)=\lim\limits_{h\to 0}\cos\dfrac{\pi h}{2}=1$

$\therefore$ $f(x)$ is continuous at $x=1$.

2. $f(0^+)=\lim\limits_{h\to 0}\dfrac{8^h-4^h-2^h+1}{h^2}=\lim\limits_{h\to 0}\dfrac{(4^h-1)}{h}\dfrac{(2^h-1)}{h}$

$=(\log 4)(\log 2)$

$f(0^-)=\lim\limits_{h\to 0}(e^{-h}\sin(-h)+\pi(-h)+k\log 4)=k\log 4$

Since, $f(x)$ is continuous at $x=0$

$\Rightarrow$ $k\log 4=(\log 4)(\log 2)=f(0)$.

$\therefore$ $f(0)=(\log 4)(\log 2)$, when $k=\log 2$

3. $f(0^-)=\lim\limits_{x\to 0^-}\dfrac{a(1-x\sin x)+b\cos x+5}{x^2}=f(0)$

$=\lim\limits_{x\to 0^-}\dfrac{(a+b+5)+\left(-a-\dfrac{b}{2}\right)x^2+\ldots}{x^2}=3$

$\Rightarrow$ $a+b+5=0$ and $-a-\dfrac{b}{2}=3$

$\Rightarrow$ $a=-1,\ b=-4$

$\Rightarrow$ $f(0^+)=\lim\limits_{x\to 0^+}\left[1+\left(\dfrac{cx+dx^3}{x^2}\right)\right]^{1/x}$ exists.

$\Rightarrow$ $\lim\limits_{x\to 0^+}\dfrac{cx+dx^3}{x^2}=0\Rightarrow c=0$

Now, $\lim\limits_{x\to 0^+}(1+dx)^{1/x}=\lim\limits_{x\to 0^+}((1+dx)^{1/dx})^d=e^d$

So, $e^d=3\Rightarrow d=\log_e 3$

$\therefore$ $a+b+c+d=\log_e 3-5$

4. $f\left(\dfrac{\pi^+}{2}\right)=\lim\limits_{h\to 0}\pi\left[\dfrac{\pi}{2}+h\right]-1=(\pi-1)$

$f\left(\dfrac{\pi^-}{2}\right)=\lim\limits_{h\to 0}\cos^{-1}\left\{\cot\left(\dfrac{\pi}{2}-h\right)\right\}=\lim\limits_{h\to 0}\cos^{-1}\{\tan h\}=\dfrac{\pi}{2}$

$\therefore$ Jump of discontinuity $=(\pi-1)-\dfrac{\pi}{2}=\dfrac{\pi}{2}-1$

5. Consider $g(x)=f(x)-x$

$g(0)=f(0)-0=f(0)\geq 0$ $\quad[\because 0\leq f(x)\leq 1]$

$g(1)=f(1)-1\leq 0$

$\Rightarrow$ $g(0)\cdot g(1)\leq 0$

$\Rightarrow$ $g(x)=0$ has at least one root in [0, 1].

$\Rightarrow$ $f(x)=x$ for at least one root in [0, 1].

6. Here, $f(x)=\dfrac{x+1}{x-1}$, discontinuous at $x=1$

$g(x)=\dfrac{1}{x-2}$, discontinuous at $x=2$

$f(g(x))=\dfrac{g(x)+1}{g(x)-1}$, discontinuous at $g(x)=1$

$\Rightarrow$ $\dfrac{1}{x-2}=1$

$\Rightarrow$ $x=3$

$\therefore$ $(fog)(x)$ is discontinuous at $x=2$ and 3.

7. Here, $y_n(x)=\begin{cases}\dfrac{x^2\left[\dfrac{1}{(1+x^2)^n}-1\right]}{\dfrac{1}{1+x^2}-1}=(1+x^2)\cdot\left[1-\dfrac{1}{(1+x^2)^n}\right], & \text{when } x\neq 0,\ n\in N\\ 0, & \text{when } x=0, n\in N\end{cases}$

$\therefore$ $y(x)=\lim\limits_{n\to\infty}y_n(x)=\begin{cases}(1+x^2), & x\neq 0\\ 0, & x=0\end{cases}$

$\therefore$ $y(x)$ is discontinuous at $x=0$.

8. $g(0^-)=\lim\limits_{h\to 0}\dfrac{a^h-1-h\log a}{h^2}$

$=\lim\limits_{h\to 0}\dfrac{\left[1+h\log a+\dfrac{h^2}{2!}(\log a)^2+\ldots\right]-1-h\log a}{h^2}$

$=\lim\limits_{h\to 0}\left[\dfrac{(\log a)^2}{2!}\cdot 1+\dfrac{(\log a)^3}{3!}\cdot h\ldots\right]=\dfrac{(\log a)^2}{2}$

$g(0^+)=\lim\limits_{h\to 0}\dfrac{2^h a^h-h\log 2-h\log a-1}{h^2}$

$=\lim\limits_{h\to 0}\dfrac{\left[1+h\log(2a)+\dfrac{h^2}{2!}(\log(2a))^2\ldots\right]-h\log 2-h\log a-1}{h^2}$

$=\dfrac{(\log(2a))^2}{2}$

Since, $g(x)$ is continuous.

$\Rightarrow$ $\dfrac{(\log a)^2}{2}=\dfrac{(\log(2a))^2}{2}\Rightarrow(\log a)^2=(\log 2+\log a)^2$

$\Rightarrow$ $\log a=-\dfrac{1}{2}\log 2=\log 2^{-1/2}$

$\Rightarrow$ $a=\dfrac{1}{\sqrt{2}}$

9. $f(0^+)=\lim\limits_{h\to 0}\dfrac{\left(\dfrac{\pi}{2}-\sin^{-1}(1-h^2)\right)\cdot\sin^{-1}(1-h)}{\sqrt{2}(h-h^3)}$

$=\lim\limits_{h\to 0}\dfrac{(\cos^{-1}(1-h^2))\cdot\sin^{-1}(1-h)}{\sqrt{2}(1-h^2)\cdot h}=\dfrac{\pi}{2}$

$$f(0^-)=\lim_{h\to 0}\frac{\left(\frac{\pi}{2}-\sin^{-1}(1-(1-h^2))\right)\cdot\sin^{-1}(1-(1-h))}{\sqrt{2}((1-h)-(1-h)^3)}$$

$$=\lim_{h\to 0}\frac{\frac{\pi}{2}\sin^{-1}h}{\sqrt{2}(1-h)(2-h)h}=\frac{\pi}{4\sqrt{2}}$$

10. $f(x)=\begin{cases}-1+x, & -\infty<x<0\\ -1+\sin x, & 0\le x<\pi/2\\ \cos x, & \pi/2\le x<\infty\end{cases}$

$$f'(x)=\begin{cases}1, & -\infty<x<0\\ \cos x, & 0<x<\pi/2\\ -\sin x, & \pi/2<x<\infty\end{cases}$$

$f'(0^-)=1,\ f'(0^+)=1$

$\Rightarrow f(x)$ is differentiable at $x=0$

$$f'\left(\frac{\pi^-}{2}\right)=0,\quad f'(\pi/2^+)=-1$$

$\Rightarrow f(x)$ is not differentiable at $x=\frac{\pi}{2}$.

$\therefore$ Number of points of non-differentiability is 1.

11. $f(x)=\begin{cases}-\frac{1}{x}, & x\le -1\\ ax^2+b, & -1<x<1\\ \frac{1}{x}, & x\ge 1\end{cases}$

Since, function is continuous everywhere.

$\therefore$ LHL = RHL at $x=-1$

$\Rightarrow f(-1^-)=1,\ f(-1^+)=a+b$

$\Rightarrow a+b=1$ ...(i)

$f(x)$ is differentiable at $x=-1$

$$f'(x)=\begin{cases}\frac{1}{x^2}, & x<-1\\ 2ax, & -1<x<1\\ -\frac{1}{x^2}, & x>1\end{cases}$$

$f'(-1^-)=1,\ f'(-1^+)=-2a\Rightarrow -2a=1,\ a=-1/2$ ...(ii)

From Eqs. (i) and (ii), we get

$$a=-\frac{1}{2},\ b=\frac{3}{2}$$

12. $f(1^-)=A+B,\ f(1^+)=3A-B+2$

Since, continuous $A+B=3A-B+2$

$\Rightarrow 2A-2B=-2\Rightarrow A-B=-1$ ...(i)

$$f'(x)=\begin{cases}2Bx, & x<1\\ 3A, & x>1\end{cases}$$

$f'(1^+)=3A,\ f'(1^-)=2B$

$\Rightarrow 3A=2B$ ...(ii)

On solving Eqs. (i) and (ii), we get

$A=2,\ B=3$

13. $f'(1^+)=\lim_{h\to 0}\frac{f(1+h)-f(1)}{h}$

$$=\lim_{h\to 0}\frac{|1+h-1|([1+h]-(1+h))}{h}=0=\lim_{h\to 0}\frac{h(1-1-h)}{h}=0$$

$$f'(1^-)=\lim_{h\to 0}\frac{f(1-h)-f(1)}{-h}=\lim_{h\to 0}\frac{|-h|([1-h]-(1-h))}{-h}$$

$$=\lim_{h\to 0}\frac{h(0-1+h)}{-h}=1$$

$\Rightarrow f'(1^+)=0,\ f'(1^-)=1$

$\therefore f(x)$ is not differentiable at $x=1$.

14. $f'(1^-)=\lim_{h\to 0}\frac{f(1-h)-f(1)}{-h}=\lim_{h\to 0}\frac{[\cos\pi(1-h)]+1}{-h}$

$$=\lim_{h\to 0}\frac{-1+1}{-h}=0$$

$$f'(1^+)=\lim_{h\to 0}\frac{f(1+h)-f(1)}{h}$$

$$=\lim_{h\to 0}\frac{2\{1+h\}-1+1}{h}$$

$$=\lim_{h\to 0}\frac{2h}{h}=2$$

$\therefore\ f'(1^-)=0,\ f'(1^+)=2$

15. $f(x)=\begin{cases}x-3, & x<0\\ x^2-3x+2, & x\ge 0\end{cases}$

$f(|x|)=\begin{cases}|x|-3, & |x|<0 \text{ not possible}\\ |x|^2-3|x|+2, & |x|\ge 0\end{cases}$

$\Rightarrow\ g(x)=\begin{cases}x^2+3x+2, & x\le 0\\ x^2-3x+2, & x\ge 0\end{cases}$

$\Rightarrow\ g(x)$ is continuous at $x=0$.

$$g'(x)=\begin{cases}2x+3, & x\le 0\\ 2x-3, & x\ge 0\end{cases}$$

$g'(0^+)=-3,\ g'(0^-)=3$

16. $f(x)=\begin{cases}0, & 0\le x<1/2\\ 5/6, & x=1/2\\ 0, & 1/2<x<1\\ -2, & 1\le x<4/3\\ 0, & x=4/3\\ 2, & 4/3<x<3/2\\ 3, & 3/2\le x<2\\ 4, & x=2\end{cases}$

Hence, $f(x)$ is neither continuous nor differentiable at $x=\frac{1}{2}, 1, \frac{4}{3}, \frac{3}{2}, 2$.

$\therefore$ Number of points is 5.

17. Put $x=y=1$ in given rule

$\Rightarrow\ f(1)=f(1)-f(1)=0$

$\therefore\quad f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}=\lim_{h\to 0}\frac{f\left(\frac{x+h}{x}\right)}{h}$

$$= \lim_{h \to 0} \left(\frac{f\left(1 + \frac{h}{x}\right) - f(1)}{\frac{h}{x}} \right) \frac{1}{x} = \frac{f'(1)}{x} = \frac{1}{x}$$

[given, $f'(1) = 1$]

On integrating both sides, $f(x) = \log x + C$

On putting $x = 1$, we get $C = 0 \Rightarrow f(x) = \log_e x$

18. $f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$

$$= \lim_{h \to 0} \frac{f(x) + f(h) - 2xh - 1 - f(x)}{h}$$

$$f'(x) = \lim_{h \to 0} \left(-2x + \frac{f(h) - 1}{h} \right) = -2x + f'(0)$$

On integrating both sides, we get

$\Rightarrow \quad f(x) = -x^2 + f'(0)x + c$

$\Rightarrow \quad f(x) = -x^2 - (\sin\alpha)x + c \qquad [\text{given } f'(0) = -\sin\alpha]$

$\Rightarrow \quad f(0) = c \Rightarrow c = 1$

So, $f\{f'(0)\} = f\{-\sin\alpha\} = -\sin^2\alpha + \sin^2\alpha + 1$

$= 1$

19. $f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \geq \lim_{h \to 0} \frac{\log\left(\frac{x+h}{x}\right) + x + h - x}{h}$

$$= \lim_{h \to 0} \frac{\log\left(1 + \frac{h}{x}\right)}{\frac{h}{x}} \frac{1}{x} + 1 \geq \frac{1}{x} + 1 \quad \ldots(\text{i})$$

$$f'(x) = \lim_{h \to 0} \frac{f(x-h) - f(x)}{-h} \leq \lim_{h \to 0} \frac{\log\left(\frac{x-h}{x}\right) + x - h - x}{-h}$$

$$= \lim_{h \to 0} \frac{\log\left(1 - \frac{h}{x}\right)}{-h} + 1 \leq \frac{1}{x} + 1 \quad \ldots(\text{ii})$$

$\therefore$ From Eqs. (i) and (ii), we get $f'(x) = \frac{1}{x} + 1 = g(x)$

$$\Rightarrow \quad \sum_{n=1}^{100} g\left(\frac{1}{n}\right) = g\left(\frac{1}{1}\right) + g\left(\frac{1}{2}\right) + \ldots + g\left(\frac{1}{100}\right)$$

$$= (1+1) + (2+1) + (3+1) + \ldots + (100+1)$$

$$= (1 + 2 + \ldots + 100) + 100$$

$$= 5050 + 100 = 5150$$

20. Here, $\frac{d(f(x))}{dx} = e^{-x} f(x) + e^x f(-x)$

Let $\frac{d(f(x))}{dx} = g(x)$, where $g(x) = e^{-x} f(x) + e^x f(-x)$

$\therefore \quad g(-x) = e^x f(-x) + e^{-x} f(x) = g(x)$

$\Rightarrow$ $g(x)$ is even function.

Hence, $f(x)$ should be an odd function as $f(0) = 0$.

21. We have, $f(x^2) = \int_0^{x^2} t\, f(t)\, dt = x^4 + x^5 \qquad \ldots(\text{i})$

On differentiating both the sides w.r.t. x, we get

$$x^2 f(x^2) \cdot 2x = 4x^3 + 5x^4$$

$$\Rightarrow \quad f(x^2) = 2 + \frac{5}{2}x \qquad \ldots(\text{ii})$$

$$\therefore \sum_{r=1}^{12} f(r^2) = \sum_{r=1}^{12} \left(2 + \frac{5}{2}r\right) = 24 + \frac{5}{2} \cdot \frac{(12)(13)}{2} = 24 + 195 = 219$$

Hence, $\sum_{r=1}^{12} f(r^2) = 219$

22. Let $x = \frac{2}{3}$, which is rational.

$$\Rightarrow \quad h\left(\frac{2}{3}\right) = \frac{1}{3}$$

$\lim_{t \to 0} h\left(\frac{2}{3} + t\right) = 0 \Rightarrow$ Discontinuous at $x \in Q$

Let $x = \sqrt{2} \notin Q$

$h(\sqrt{2}) = 0$, consider $\sqrt{2} = 1.4142135624$

$$h(\sqrt{2}) = h\left(\frac{14142135624}{10^{10}}\right) = \frac{1}{10^{10}} \to 0$$

Hence, h is continuous for all irrational.

23. By theorem, if g and h are continuous functions on the open interval (a, b), then g/h is also continuous at all x in the open interval (a, b), where $h(x) \neq 0$.

24. $h(x) = \begin{cases} \frac{2\cos x - \sin 2x}{(\pi - 2x)^2}, & x < \frac{\pi}{2} \\ \frac{e^{-\cos x} - 1}{8x - 4\pi}, & x > \frac{\pi}{2} \end{cases}$

LHL at $x = \pi/2$

$$\text{LHL} = \lim_{h \to 0} \frac{2\sin h - \sin 2h}{4h^2} = \lim_{h \to 0} \frac{2\sin h\,(1 - \cos h)}{4h^2} = 0$$

$$\text{RHL} = \lim_{h \to 0} \frac{e^{\sin h} - 1}{8((\pi/2) + h) - 4\pi}$$

$$= \lim_{h \to 0} \frac{e^{\sin h} - 1}{8h} \cdot \frac{\sin h}{\sin h} = \frac{1}{8}$$

$\Rightarrow h(x)$ is discontinuous at $x = \pi/2$.

Irremovable discontinuity at $x = \pi/2$.

$$f\left(\frac{\pi^+}{2}\right) = 0 \text{ and } g\left(\frac{\pi^-}{2}\right) = \frac{1}{8}$$

$$\Rightarrow \quad f\left(\frac{\pi^+}{2}\right) \neq g\left(\frac{\pi^-}{2}\right)$$

25. $\lim_{x \to 0} \frac{x - e^x + 1 - (1 - \cos 2x)}{x^2} = -\frac{1}{2} - 2 = -\frac{5}{2}$

Hence, for continuity, $f(0) = -\frac{5}{2}$

$\therefore [f(0)] = -3$; $\{f(0)\} = \left\{-\frac{5}{2}\right\} = \frac{1}{2}$

Hence, $[f(0)] \cdot \{f(0)\} = -\frac{3}{2} = -1.5$

26. $f(1^+) = f(1^-) = f(1) = 2$

$f(0) = 1, \qquad f(2) = 2$

$f(2^-) = 1,$

$\Rightarrow$ f is not continuous at $x = 2$.

27. $f(2^+) = 8,\ f(2^-) = 16$

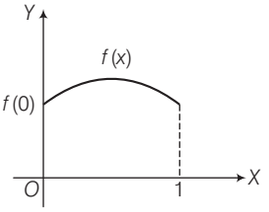
28. $g(x) = x - [x] = \{x\}$

f is continuous with $f(0) = f(1)$

$h(x) = f(g(x)) = f(\{x\})$

Let the graph of f is as shown in the figure satisfying

$$f(0) = f(1)$$



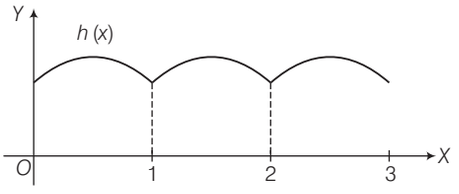
Now,

$h(0) = f(\{0\}) = f(0) = f(1)$

$h(0.2) = f(\{0.2\}) = f(0.2)$

$h(1.5) = f(\{1.5\}) = f(0.5)$ etc.

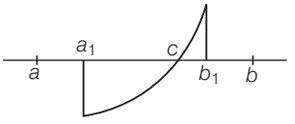
Hence, the graph of $h(x)$ will be a periodic graph as shown



$\Rightarrow h$ is continuous in R.

29. Statements I and II are false. The function $f(x) = 1/x,\ 0 < x < 1$ is a counter example.

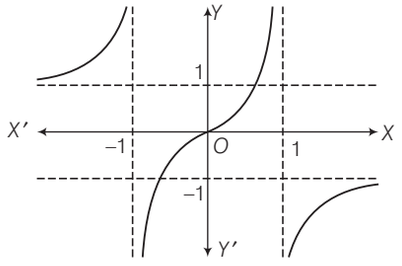
Statement III is true. Apply the intermediate value theorem to f on the closed interval $[a_1, b_1]$.



30. Since, the given function is not differentiable, at $x = 0$ and 2.

Hence, the number of points is 2.

31. $f(x) = \begin{cases} \dfrac{x}{1-x}, & \text{if } x \geq 0,\ x \neq 1 \\ \dfrac{x}{1+x}, & \text{if } x < 0,\ x \neq -1 \end{cases}$



and $f'(x) = \begin{cases} \dfrac{1}{(1-x)^2}, & \text{if } x > 0, x \neq 1 \\ \dfrac{1}{(1+x)^2}, & \text{if } x < 0,\ x \neq -1 \end{cases}$

32. $g[f(x)]$ is continuous at $x = \alpha$

$\Rightarrow \quad g[f(\alpha)] = g(a)$

Also, $\lim\limits_{x \to \alpha} g(f(x)) = g(a)$

$\Rightarrow \quad g[f(\alpha^-)] = g[f(\alpha^+)] = g(a)$

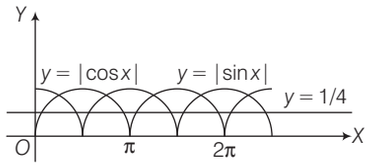
$\Rightarrow g(x)$ takes same limiting values at

$f(\alpha^-),\ f(\alpha^+)$ and $f(\alpha)$.

$\Rightarrow\ f(\alpha^-) = f(\alpha^+) \Rightarrow x = \alpha$ is an extremum of $f(x)$

and $x = a$ may not be an extremum of $g(x)$.

33. From the graph, number of points of non-differentiability = 11



34. Let n be any integer other than 1.

$$\lim_{x \to n^-} f(x) = \lim_{h \to 0} ([n-h]^2 - [(n-h)^2])$$

$$= (n-1)^2 - (n^2 - 1) = 2 - 2n$$

$$\lim_{x \to n^+} f(x) = \lim_{h \to 0} [n+h]^2 - [(n+h)^2] = n^2 - n^2 = 0$$

$\therefore$ LHL $\neq$ RHL unless $n = 1$.

Hence, $f(x)$ is discontinuous at all integral values except 1.

35. At $x = 5,\ f'(x) = \lim\limits_{x \to 5} \dfrac{\{(x-1)^2 (x+1)\,|x-5| + \cos|x|\} - \cos 5}{x-5}$

$$= \lim_{x \to 5} \frac{96\,|x-5|}{x-5} = +96, \text{ if } x > 5 \text{ and } -96, \text{ if } x < 5$$

Hence, $f'(5)$ doesn't exist.

This ambiguity doesn't occur at other points.

$\therefore f(x)$ is not differentiable at $x = 5$.

36. $f'(0^+) = \lim\limits_{x \to 0^+} \dfrac{f(x) - f(0)}{x} = \lim\limits_{x \to 0^+} \dfrac{e^{\frac{-1}{x^2}} - 0}{x} = \lim\limits_{x \to 0^+} \dfrac{1/x}{e^{1/x^2}}$

$$= \lim_{x \to 0^+} \frac{-1/x^2}{e^{1/x^2} \cdot \left(-\frac{2}{x^3}\right)} = \lim_{x \to 0^+} \frac{x}{2e^{1/x^2}} = 0$$

As, f is even, so $f'(0^-) = f'(0^+) = 0$. Thus, $f'(0) = 0$

37. $\lim\limits_{h \to 0} g(n+h) = \lim\limits_{h \to 0} \dfrac{e^h - \cos 2h - h}{h^2}$

$$= \lim_{h \to 0} \frac{e^h - h - 1}{h^2} + \lim_{h \to 0} \frac{(1 - \cos 2h)}{4h^2} \cdot 4 = \frac{1}{2} + 2 = \frac{5}{2}$$

$$\lim_{h \to 0} g(n-h) = \frac{e^{1-\{n-h\}} - \cos 2\,(1 - \{n-h\}) - (1 - \{n-h\})}{(1 - \{n-h\})^2}$$

$$= \lim_{h \to 0} \frac{e^h - \cos 2h - h}{h^2} \left[\{n-h\} = \{-h\} = 1 - h\right] = \frac{5}{2}$$

$g(n) = \dfrac{5}{2}$. Hence, $g(x)$ is continuous, $\forall\ x \in I$.

Hence, $g(x)$ is continuous, $\forall\ x \in R$.

38. $g'(0^+) = \lim\limits_{h \to 0} \dfrac{\cos h - 1}{h} = 0$

$g'(0^-) = \lim\limits_{h \to 0} \dfrac{-h + b - 1}{-h}$ for existence of limit $b = 1$

Thus, $g'(0^-) = 1$

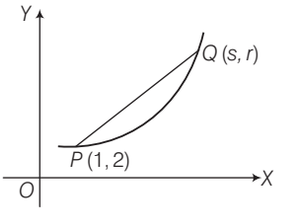
Hence, g cannot be made differentiable for no value of b.

39. By definition $f'(1)$ is the limit of the slope of the secant line when $s \to 1$.

Thus, $f'(1) = \lim_{s \to 1} \dfrac{s^2 + 2s - 3}{s - 1}$

$= \lim_{s \to 1} \dfrac{(s-1)(s+3)}{s-1}$

$= \lim_{s \to 1} (s + 3) = 4$



Aliter

By substituting $x = s$ into the equation of the secant line and cancelling by $s - 1$. Again, we get $y = s^2 + 2s - 1$.

This is $f(s)$ and its derivative is $f'(s) = 2s + 2$, so $f'(1) = 4$.

40. In the immediate neighbourhood of $x = \pi/2$, $\sin x > \sin^3 x \Rightarrow |\sin x - \sin^3 x| = \sin x - \sin^3 x$

Hence, for $x \neq \pi / 2$,

$$f(x) = \left[\frac{2(\sin x - \sin^3 x) + \sin x - \sin^3 x}{2(\sin x - \sin^3 x) - \sin x + \sin^3 x} \right]$$

$$= \frac{3\sin x - 3\sin^3 x}{\sin x - \sin^3 x} = 3$$

Hence, f is continuous and differentiable at $x = \pi/2$.

41. $f'(x) = \lim_{h \to 0} \dfrac{f(x+h) - f(x)}{h} = \lim_{h \to 0} \dfrac{f(h) + |x| h + xh^2}{h}$

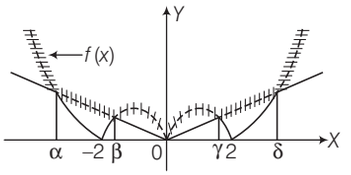
$\because \quad f(0) = 0$

Hence, $f'(x) = \lim_{h \to 0} \left[\dfrac{f(h) - f(0)}{h} + |x| + xh \right]$

$\Rightarrow \quad f'(x) = f'(0) + |x| = |x|$

42. $f(x)$ is non-differentiable at $x = \alpha, \beta, 0, \gamma, \delta$

and $g(x)$ is non-differentiable at $x = \alpha, -2, \beta, 0, \gamma, 2, \delta$.



43. We have, $g(x) = \begin{cases} 3x^2 - 4\sqrt{x} + 1, & \text{for } x < 1 \\ ax + b, & \text{for } x \geq 1 \end{cases}$

For differentiability at $x = 1$, $g'(1^+) = g'(1^-)$

$$a = 6 - \frac{4}{2\sqrt{1}}$$

$\Rightarrow \quad a = 6 - 2 = 4$

For continuity at $x = 1$, $g(1^+) = g(1^-)$

$$a + b = 3 - 4 + 1 \Rightarrow a + b = 0$$

$\Rightarrow \quad b = -4$

Hence, $a = 4$ and $b = -4$

44. $f'(x) = \lim_{h \to 0} \dfrac{f(x+h) - f(x)}{h} = \lim_{h \to 0} \dfrac{-3xh + f(h)}{h}$

$= \lim_{h \to 0} \left\{ -3x + \dfrac{f(h)}{h} \right\} = -3x + \lim_{h \to 0} \dfrac{f(h)}{h}$

$= -3x + 7$

45. $f(x) = \dfrac{\sin \dfrac{\pi[x]}{4}}{[x]}$

Obviously, continuity at $x = 3/2$

$$f(2^-) = \sin \frac{\pi}{4} = \frac{1}{\sqrt{2}}$$

At $x = 2$,

$$f(2) = \frac{\sin \dfrac{\pi}{2}}{2} = \frac{1}{2}$$

Hence, $f(x)$ is discontinuous at $x = 2$.

46. $f(-1) = b(1 - 1) + 1 = 1$

and $\lim_{h \to 0} f(-1 + h) = 1$

$\lim_{h \to 0} f(-1 - h) = \lim_{h \to 0} \sin((-1 - h + a)\pi) = -\sin \pi a$

For continuity, $\sin \pi a = -1 = \sin\left(2n\pi + \dfrac{3\pi}{2}\right)$

$\Rightarrow \quad \pi a = 2n\pi + \dfrac{3\pi}{2}$

$\Rightarrow \quad a = 2n + \dfrac{3}{2}$

Hence, $a = 2n + \dfrac{3}{2}$, $n \in I$ and $b \in R$

47. Consider the graph of $h(x) = \max(x, x^2)$ at $x = 0$ and $x = 1$

For $(d) : h(x) = \max(x^2, -x^2)$

48. Here, $g(x) = [x^2]\{\cos^2 4x\} + \{x^2\}[\cos^2 4x] + x^2 \sin^2 4x$

$$+ [x^2][\cos^2 4x] + \{x^2\}\{\cos^2 4x\}$$

$$= [x^2](\{\cos^2 4x\} + [\cos^2 4x]) + \{x^2\}([\cos^2 4x] + \{\cos^2 4x\}) + x^2 \sin^2 4x$$

$$= ([x^2] + \{x^2\})(\{\cos^2 4x\} + [\cos^2 4x]) + x^2 \sin^2 4x$$

$$= x^2 \cos^2 4x + x^2 \sin^2 4x$$

$$= x^2$$

Clearly, $g(x)$ is always differentiable.

$\therefore$ Number of points of non-differentiability is 0.

49. Here, $f(x) = \dfrac{\{x\} g(x)}{\{x\} g(x)} = 1$, when $\{x\} g(x) \neq 0$

If $f(x)$ is periodic with period $\dfrac{1}{4}$, then $\{x\} g(x) \neq 0$ with period $\dfrac{1}{4}$.

$\Rightarrow \quad g(x) = 0$ at $x = \dfrac{k}{4}$, where $k \in I$.

50. Here, $f'(x) = \lim_{h \to 0} \dfrac{f(x+h) - f(x)}{h}$

$$= \lim_{h \to 0} \frac{f\left(x\left(1 + \dfrac{h}{x}\right)\right) - f\left(\dfrac{1}{1/x}\right)}{h}$$

$$= \lim_{h \to 0} \frac{f\left(\dfrac{1 + h/x}{1/x}\right) - f\left(\dfrac{1}{1/x}\right)}{h}$$

$$= \lim_{h\to 0} \frac{\dfrac{f(1+h/x)}{f(1/x)} - \dfrac{f(1)}{f(1/x)}}{h}$$

$$= \lim_{h\to 0} \frac{f(1+h/x)-f(1)}{h/x} \cdot \frac{1}{xf\left(\dfrac{1}{x}\right)} = f'(1)\cdot\frac{1}{x}\cdot\frac{f(x)}{f(1)}$$

$\therefore \quad \dfrac{dy}{dx} = k\cdot\dfrac{y}{x}$, where $\dfrac{f'(1)}{f(1)} = k$, $f(x) = y$.

$\Rightarrow \quad \int \dfrac{dy}{y} = \int k\dfrac{dx}{x}$

$\Rightarrow \quad \log y = k\log x + \log C$

$\Rightarrow \quad \log y = \log(x^k \cdot C)$

$\Rightarrow \quad y = C\cdot x^k$

$\therefore \quad f(x) = C\cdot x^k$

Put $x = 2, y = 1$ in $f\left(\dfrac{x}{y}\right) = \dfrac{f(x)}{f(y)}$

$\Rightarrow \quad f(2) = \dfrac{f(2)}{f(1)} \Rightarrow f(1) = 1$

Also, $f(x) = C\cdot x^k$, put $x = 1$

$\Rightarrow \quad f(1) = C \Rightarrow C = 1$

$\therefore \quad f(x) = x^k$, now $f(2) = 4$

$\Rightarrow \quad f(2) = 2^k$

$4 = 2^k \Rightarrow k = 2$

$\therefore \quad f(x) = x^2 \Rightarrow f(5) = 25$

51. $\tan(f(x)) = \tan\left(\dfrac{x}{2} - 1\right), \quad x \in [0, \pi]$

$$0 \le x \le \pi \Rightarrow -1 \le \frac{x}{2} - 1 \le \frac{\pi}{2} - 1$$

$\therefore \tan(f(x))$ is continuous in $[0, \pi]$.

$\dfrac{1}{f(x)} = \dfrac{2}{x-2}$ is not defined at $x = 2 \in [0, \pi]$.

$y = \dfrac{x-2}{2} \Rightarrow f^{-1}(x) = 2x + 2$ is continuous in R.

52. $\lim\limits_{x\to 0^+} (x+1)\, e^{-\frac{2}{x}} = \lim\limits_{x\to 0^+} \dfrac{(x+1)}{e^{2/x}} = 0$

$\lim\limits_{x\to 0^-} (x+1)\, e^0 = 1$

Hence, continuous for $x \in I - \{0\}$, assumes all intermediate values from $f(-2)$ to $f(2)$ and maximum value $\dfrac{3}{e}$ at $x = 2$.

53. RHL $= \lim\limits_{x\to 0^+} \left(3 - \left[\cot^{-1}\left(\dfrac{2x^3-3}{x^2}\right)\right]\right)$

$= 3 - [\cot^{-1}(-\infty)] = 3 - 3 = 0$

LHL $= \lim\limits_{x\to 0^-} \{x^2\} \cos\left(e^{-\frac{1}{x}}\right)$

$= \lim\limits_{h\to 0} h^2 \cos\left(e^{\frac{1}{h}}\right) = 0$

and $f(0) = 0$

Hence, $f(x)$ is continuous at $x = 0$.

54. $\lim\limits_{x\to -1^+} f(x) = \lim\limits_{x\to -1^+} (b([x]^2 + [x]) + 1)$

$= \lim\limits_{h\to 0} (b([-1+h]^2 + [-1+h]) + 1)$

$= \lim\limits_{h\to 0} (b((-1)^2 - 1) + 1) = 1$

$\Rightarrow \quad b \in R$

$\lim\limits_{x\to -1^-} f(x) = \lim\limits_{x\to -1^-} \sin(\pi(x+a))$

$= \lim\limits_{h\to 0} \sin(\pi((-1-h)+a))$

$\therefore \quad \sin\pi a = -1$

$\Rightarrow \quad \pi a = 2n\pi + \dfrac{3\pi}{2} \Rightarrow a = 2n + \dfrac{3}{2}$

55. $f(x) = \begin{cases} \dfrac{\sin\frac{\pi}{4}}{1} = \dfrac{1}{\sqrt{2}}, & 1 \le x < 2 \\ \dfrac{\sin\frac{\pi}{2}}{1} = \dfrac{1}{2}, & 2 \le x < 3 \end{cases}$

Hence, $f(x)$ is continuous at $\dfrac{3}{2}$, differentiable at $\dfrac{4}{3}$ and discontinuous at 2.

56. Since, $\sin^{-1} x$ and $\cos(1/x)$ are continuous and differentiable in $x \in [-1, 1] - \{0\}$.

Now, at $x = 0$

$$f'(0^-) = \lim_{h\to 0} \frac{f(-h) - f(0)}{-h} = 0$$

$$= \lim_{h\to 0} \frac{(\sin^{-1}(-h))^2 \cos\left(-\dfrac{1}{h}\right) - 0}{-h} = 0$$

$$f'(0^+) = \lim_{h\to 0} \frac{(\sin^{-1} h)^2 \cos\left(\dfrac{1}{h}\right) - 0}{h} = 0$$

Hence, LHD = RHD. So, $f(x)$ is continuous and differentiable everywhere in $-1 \le x \le 1$.

57. $H(x) = \begin{cases} \cos x, & 0 \le x < \dfrac{\pi}{2} \\ \dfrac{\pi}{2} - x, & \dfrac{\pi}{2} < x \le 3 \end{cases}$

$$H'\left(\frac{\pi}{2}^-\right) = -\sin x = -1$$

$$H'\left(\frac{\pi}{2}^+\right) = -1$$

Hence, $H(x)$ is continuous and derivable in $[0, 3]$ and has maximum value 1 in $[0, 3]$.

58. Here, $f(x) = 3(2x+3)^{2/3} + 2x + 3$

$\Rightarrow \quad f'(x) = \dfrac{4}{(2x+3)^{1/3}} + 2$

Now, $\quad 2x + 3 \neq 0 \;\Rightarrow\; x \neq -\dfrac{3}{2}$

Hence, $f(x)$ is continuous but not differential at $x = -3/2$.

Also, $f(x)$ is differentiable and continuous at $x = 0$.

59. $f'(0^+) = \lim\limits_{h\to 0} \dfrac{h\ln(\cos h)}{h\ln(1+h^2)} = \lim\limits_{h\to 0} \dfrac{\ln(\cos h)^{1/h^2}}{\dfrac{\ln(1+h^2)}{h^2}}$

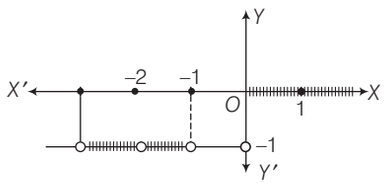
$= \lim\limits_{h\to 0} \dfrac{1}{h^2}(\cos h - 1) = -\dfrac{1}{2}$; similarly $f'(0^-) = -\dfrac{1}{2}$

Hence, f is continuous and derivable at $x = 0$.

60. $f(x) = \begin{cases} 0, & 0 < x < 1 \\ 0, & x = 0 \text{ or } 1 \text{ or } -1 \\ 0, & -1 < x < 0 \end{cases} \;\Rightarrow\; f(x) = 0$ for all in $[-1, 1]$

61. $[|x|] - |[x]| = \begin{cases} 0, & x = -1 \\ -1, & -1 < x < 0 \\ 0, & 0 \le x \le 1 \\ 0, & 1 < x \le 2 \end{cases}$

$\Rightarrow$ Range is $\{0, -1\}$. The graph is



62. $f'(0^+) = \dfrac{1}{\sqrt{2}}, f'(0^-) = -\dfrac{1}{\sqrt{2}}$;

$f(x) = \dfrac{\sqrt{x^2}}{\sqrt{1+\sqrt{1-x^2}}} = \dfrac{|x|}{\sqrt{1+\sqrt{1-x^2}}}$

63. Range is $R^+ \cup \{0\} \Rightarrow$ Option (b) is not correct.

f is not differentiable at $x = -1$

As, $\quad f(x) = \begin{cases} x^3 + 1, & \text{if } x \ge -1 \\ -(x^3+1), & \text{if } x < -1 \end{cases}$

$\Rightarrow \quad f'(x) = \begin{cases} 3x^2, & \text{if } x > -1 \\ -3x^2, & \text{if } x < -1 \end{cases}$

$f'(-1^+) = 3, f'(-1^-) = -3 \Rightarrow f$ is not differentiable at $x = -1$.

Also, f is not bijective, hence it has no inverse.

64. Given, f is continuous in $[a, b]$ ...(i)

$\Rightarrow$ g is continuous in $[b, c]$ ...(ii)

$\Rightarrow$ $f(b) = g(b)$ ...(iii)

$\Rightarrow$ $\left.\begin{matrix} h(x) = f(x) \text{ for } x \in [a, b) \\ = g(x) \text{ for } x \in (b, c] \end{matrix}\right\}$ ...(iv)

$\Rightarrow h(x)$ is continuous in $[a, b) \cup (b, c]$ [using Eqs. (i) and (ii)]

Also, $\quad f(b^-) = f(b),\ g(b^+) = g(b)$

[using Eqs. (i) and (ii)] ...(iv)

$\therefore \quad h(b^-) = f(b^-) = f(b) = g(b) = g(b^+) = h(b^+)$

[using Eqs. (iv) and (v)]

Now, verify each alternative. Of course! $g(b^-)$ and $f(b^+)$ are undefined.

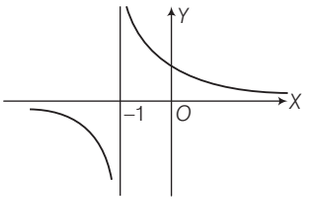
$h(b^-) = f(b^-) = f(b) = g(b) = g(b^+)$

and $\quad h(b^+) = g(b^+) = g(b) = f(b) = f(b^-)$

Hence, $\quad h(b^-) = h(b^+) = f(b) = g(b)$

and $h(b)$ is not defined.

65. (a) Domain is $R - \{-1\}$; Range = $R - \{0\}$



(b) Domain is $x \in R$; Range = $(0, 1]$

(c) Domain is $[0, \infty)$; Range = $(0, 1]$

(d) Domain is $(-\infty, 3)$; Range = $(0, \infty)$

66. $f(x) = \sec 2x + \operatorname{cosec} 2x = \dfrac{2(\sin 2x + \cos 2x)}{2\cos 2x \sin 2x}$

$= \dfrac{2(\sin 2x + \cos 2x)}{\sin 4x}$

is discontinuous, where $4x = n\pi$, $n \in I$ or $x = \dfrac{n\pi}{4}$.

Options (a) and (b) also satisfy the condition, since they are subsets of option (c).

67. $\lim\limits_{x\to 0} f(x) = \lim\limits_{x\to 0} x^n \cdot \sin\left(\dfrac{1}{x^2}\right) = 0$, if $n > 0$

and hence true for $n > 1$.

Since, $f(0) = 0$, $f(x)$ is continuous at $x = 0$.

Now, $\lim\limits_{x\to 0} \dfrac{f(x) - f(0)}{x - 0} = \lim\limits_{x\to 0} \dfrac{x^n \sin\dfrac{1}{x^2}}{x}$

$= \lim\limits_{x\to 0} x^{n-1} \sin\left(\dfrac{1}{x^2}\right) = 0$, if $n > 1$.

Hence, $f(x)$ is differentiable at $x = 0$, if $n > 1$.

68. $f(x) = \begin{cases} e^x, & x \le 0 \\ 1 - x, & 0 < x < 1 \\ x - 1, & x \ge 1 \end{cases}$

$\Rightarrow \lim\limits_{x\to 0^-} f(x) = 1, \lim\limits_{x\to 0^+} f(x) = 1$

and $\lim\limits_{x\to 1^-} f(x) = 0, \lim\limits_{x\to 1^+} f(x) = 0$

Hence, $f(x)$ is continuous at $x = 0$ and 1.

$f'(0^-) = 1$ and $f'(0^+) = -1$.

Hence, $f(x)$ is not differentiable at $x = 1$.

69. $f(x) = \int_{-2}^{x} |t+1|\, dt = -\int_{-2}^{-1}(t+1)\, dt + \int_{-1}^{x}(t+1)\, dt$

$$= \frac{1}{2} + \left(\frac{t^2}{2} + t\right)_{-1}^{x} = \frac{x^2}{2} + x + 1, \text{ for } x \geq -1$$

$f(x)$ is a quadratic polynomial.

$\therefore$ $f(x)$ is continuous as well as differentiable in $[-1, 1]$.

Also, $f'(x)$ is continuous as well as differentiable in $[-1, 1]$.

70. We have, $f(x+y) = f(x) + f(y) + xy(x+y)$

$$f(0) = 0$$

$\therefore$ $\lim_{h \to 0} \frac{f(h)}{h} = -1$

$\therefore$ $\lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$

$$= \lim_{h \to 0} \frac{f(x) + f(h) + xh(x+h) - f(x)}{h}$$

$$= \lim_{h \to 0} \frac{f(h)}{h} + \lim_{h \to 0} x(x+h) = -1 + x^2$$

$\therefore$ $f'(x) = -1 + x^2$

$\therefore$ $f(x) = \frac{x^3}{3} - x + c$

$\therefore$ $f(x)$ is a polynomial function,

$f(x)$ is twice differentiable for all $x \in R$ and

$f'(3) = 3^2 - 1 = 8$.

71. We have, $f'(x) = 6x + 12$

For $f(x)$ is increasing, $f'(x) \geq 0 \Rightarrow x \geq -2$

Hence, $f(x)$ is increasing in $[-1, 2]$

$\lim_{x \to 2^+} f(x) = 35$, $\lim_{x \to 2^-} f(x) = 35$ and $f(2) = 35$

Hence, $f(x)$ is continuous on $[-1, 3]$, $f'(2^-) = 24$ and $f'(2^+) = -1$.

Hence, $f'(2)$ doesn't exist for maximum, $f(2) = 35$

$$f(-1) = -10, \qquad f(3) = 34$$

Hence, $f(x)$ has maximum value at $x = 2$.

72. Since, $f(x) = 0$, $x < 0$ and differentiable at $x = 0$, LHD $= 0$

(function is on X-axis for $x < 0$). If $f(x)$,

(a) x^2, $x > 0$

RHD at $x = 0$,

$f'(0) = 2 \times 0 = 0$ (possible)

(d) $-x^{3/2}$, $x > 0$

RHD at $x = 0$,

$f'(0) = -3/2\, x^{1/2} = -3/2 \times 0 = 0$ (possible)

73. We know that, $\sin x$ is periodic function in $[0, 2\pi]$.

$\therefore$ $\sin x$ is continuous at $x = 0$

Now, $\lim_{x \to 0} [x]$

RHL $= \lim_{x \to 0^+} [x] = \lim_{h \to 0} [x+h] = x = 0$ $\quad [\because [x+h] = x]$

LHL $= \lim_{x \to 0^-} [x] = \lim_{h \to 0} [x-h] = (x-1)$ $\quad [\because [x-h] = (x-1)]$

$= 0 - 1 = -1$

$\therefore$ RHL $\neq$ LHL

So, $[x]$ is discontinuous at $x = 0$.

We know that, sum of continuous and discontinuous functions is discontinuous.

74. We have,

$$f(x) = \begin{cases} 2\sin(a\cos^{-1} x), & \text{if } x \in (0, 1) \\ \sqrt{3}, & \text{if } x = 0 \\ ax + b, & \text{if } x < 0 \end{cases}$$

Continuity at $x = 0$

(LHL at $x = 0$) $= \lim_{x \to 0^-} ax + b$

$$= \lim_{h \to 0} a(0-h) + b = \lim_{h \to 0} -ah + b$$

$$= b$$

(RHL at $x = 0$) $= \lim_{x \to 0^+} 2\sin(a\cos^{-1} x)$

$$= \lim_{h \to 0} 2\sin(a\cos^{-1}(0+h))$$

$$= \lim_{h \to 0} 2\sin a\cos^{-1} h$$

$$= 2\sin a\cos^{-1} h = 2\sin a\cos^{-1} 0$$

$$= 2\sin\frac{a\pi}{2}$$

$$f(0) = \sqrt{3}$$

For $f(x)$ to be continuous at $x = 0$,

LHL $=$ RHL $= f(0)$

$\therefore$ $b = 2\sin\frac{a\pi}{a} = \sqrt{3}$

$\therefore$ $b = \sqrt{3}$ and $\sin\frac{a\pi}{2} = \frac{\sqrt{3}}{2}$

$\Rightarrow$ $b = \sqrt{3}$ and $\frac{a\pi}{2} = \frac{\pi}{3}$

$\Rightarrow$ $b = \sqrt{3}$ and $a = \frac{2}{3}$

So, Statement I is correct.

Since, for $x < 0$, $f(x) = ax + b$

which is a polynomial function and will be continuous for $(-\infty, 0)$.

Again, for $x \in (0, 1)$,

$f(x) = 2\sin(a\cos^{-1} x)$, which is trigonometric function will be continuous for $x \in (0, 1)$.

$\because$ $f(x)$ is continuous in $(-\infty, 1)$.

$\therefore$ Statement II is also correct.

75. We have, $f(x) = \begin{cases} \dfrac{\cos x - e^{-\frac{x^2}{2}}}{x^3}, & x \neq 0 \\ 0, & x = 0 \end{cases}$

Clearly, $f(0) = 0$

Now consider, $\lim_{x \to 0} f(x) = \lim_{x \to 0} \frac{\cos x - e^{-\frac{x^2}{2}}}{x^3}$ $\quad \left[\frac{0}{0} \text{ form}\right]$

$$= \lim_{x \to 0} \frac{-\sin x + e^{-\frac{x^2}{2}} \cdot x}{3x^2} \qquad \left[\frac{0}{0} \text{ form}\right]$$

$$= \lim_{x \to 0} \frac{-\cos x + e^{-\frac{x^2}{2}} - e^{-\frac{x^2}{2}} \cdot x^2}{6x} \qquad \left[\frac{0}{0} \text{ form}\right]$$

$$= \lim_{x \to 0} \frac{\sin x - e^{-\frac{x^2}{2}} \cdot x - 2xe^{-\frac{x^2}{2}} + e^{-\frac{x^2}{2}}}{6}$$

$$= 0$$

Thus, $\lim_{x \to 0} f(x) = f(0)$

$\Rightarrow f$ is continuous at $x = 0$

Hence, option (c) is correct.

76. Let $f(x) = \frac{x^3}{4} - \sin \pi x + \frac{2}{3}$. Then, $f(x)$ will be continuous function. ($\because$ Sum and difference of two continuous function is continuous)

Here, $f(2) = \frac{8}{3}$ and $f(-2) = -\frac{4}{3}$ $\qquad [\because \sin n\pi = 0, \forall\ n \in Z]$

Now, as $f(-2) < 0 < f(2)$, therefore by intermediate value theorem we can say that there exists atleast one point $n \in [-2, 2]$. Such that $f(n) = 0$

Hence, $f(x) = 0$, i.e. $\frac{x^3}{4} - \sin \pi x + \frac{2}{3} = 0$ has atleast one solution in $[-2, 2]$.

Clearly, Statement II is wrong. Because for this to be true, $f(x)$ should be a continuous function (by intermediate value theorem).

Hence, option (c) is correct.

77. We have,

$$f(x) = x\left(\frac{e^{2x} - e^{-2x}}{e^{2x} + e^{-2x}}\right) + x^2 + x^4$$

$$\therefore f(-x) = (-x)\left(\frac{e^{2(-x)} - e^{-2(-x)}}{e^{2(-x)} + e^{-2(-x)}}\right) + (-x)^2 + (-x)^4$$

$$= -x\left(\frac{e^{-2x} - e^{+2x}}{e^{-2x} + e^{+2x}}\right) + x^2 + x^4$$

$$= -x\left[-\left(\frac{e^{2x} - e^{-2x}}{e^{2x} + e^{-2x}}\right)\right] + x^2 + x^4$$

$$= x\left(\frac{e^{2x} - e^{-2x}}{e^{2x} + e^{-2x}}\right) + x^2 + x^4$$

$$= f(x)$$

$\therefore f(x)$ is even function and even function can't has range equal to R.

78. $y = |\ln x|$ not differentiable at $x = 1$.

$y = |\cos|x||$ is not differentiable at $x = \frac{\pi}{2}, \frac{3\pi}{2}$.

$y = \cos^{-1}(\text{sgn } x) = \cos^{-1}(1) = 0$ differentiable, $\forall\ x \in (0, 2\pi)$.

79. $f'(0^+) = \lim_{h \to 0} \frac{h \sin h - 0}{h} = 0$

$f'(0^-) = \lim_{h \to 0} \frac{h \sin(-h) - 0}{-h} = 0$

$f(x)$ is differentiable at $x = 0$.

e.g. $x|x|$ is derivable at $x = 0$.

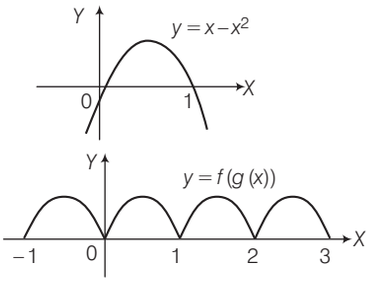
80. Consider $g(x) = x^3$ at $x = 0$, $g(0) = 0$

$|g(x)|$ is derivable at $x = 0$.

Actually nothing definite can be said. Also, for $g(x) = x - 1$ with $g(1) = 0$.

Then, $|g(x)|$ is not derivable at $x = 1$.

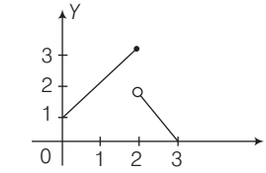
81.



82. $f(x)$ is discontinuous at $x = 0$ and $f(x) < 0, \forall\ x \in [-\alpha, 0)$ and $f(x) > 0, \forall\ x \in [0, \alpha]$.

Sol. (Q. Nos. 83 to 85)

$$f(x) = \begin{cases} x + 1, & 0 \le x \le 2 \\ -x + 3, & 2 < x < 3 \end{cases}$$



$\therefore f(x)$ is discontinuous at $x = 2$.

$$(fof)(x) = \begin{cases} x + 2, & 0 \le x \le 1 \\ -x + 2, & 1 < x \le 2 \\ -x + 4, & 2 < x < 3 \end{cases}$$

$\Rightarrow (fof)(x)$ is discontinuous at $x = 1, 2$

and $\qquad f(19) = f(3 \times 6 + 1) = f(1) = 2$

83. (a) ***84.*** (b, c) ***85.*** (a)

Sol. (Q. Nos. 86 to 89)

Since, $f(-x) = \frac{1}{f(x)}$

$\therefore$ At $x = 0$

$\Rightarrow f(0) = \frac{1}{f(0)} \Rightarrow f^2(0) = 1 \Rightarrow f(0) = +1$, as $f(x) > 0$.

$$\Rightarrow \qquad f'(x) = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h}$$

$$f'(x) = \lim_{h \to 0} \frac{f(x) \cdot f(h) - f(x)}{h}$$

$$\therefore \qquad f'(x) = f(x) \cdot \left(\lim_{h \to 0} \frac{f(h) - 1}{h}\right) = f(x) \cdot f'(0)$$

$$\Rightarrow \qquad \int \frac{f'(x)}{f(x)} = \int -1\, dx \Rightarrow \log f(x) = -x + c$$

$$f(x) = e^{-x} \cdot \lambda \text{ at } x = 0, \quad \lambda = 1 \Rightarrow f(x) = e^{-x}$$

$\Rightarrow$ Range of $f(x) \in R^+$. $\Rightarrow$ Range of $f(|x|)$ is $[0, 1]$.

$\Rightarrow f(x)$ is decreasing function

and $\qquad f'(x) = -e^{-x} = -f(x)$.

86. (c) ***87.*** (a) ***88.*** (d) ***89.*** (a)

90. $f(x)=\begin{cases}\sin x, & x\le 0\\ \tan x, & 0<x<2\pi\\ \cos x, & 2\pi\le x<3\pi\\ 3\pi, & x=3\pi\end{cases}$

$f(x)$ is discontinuous at $\frac{\pi}{2}, \frac{3\pi}{2}, 2\pi$.

91. $f(x)=[2x^3-5]$

Since $1\le x<2 \Rightarrow 1\le x^3<8$

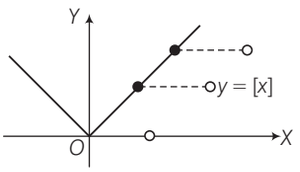
$-3\le 2x^3-5<11$

Now, $2x^3-5$ is discontinuous at integer points.

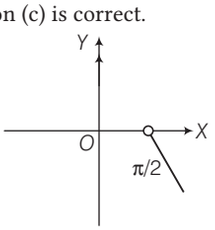
$\therefore$ $-2, -1, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10$.

Hence, number of points of discontinuity = 13

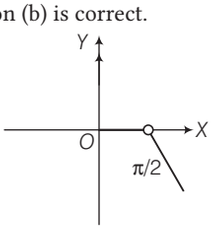
92. Max $([x], |x|)$, hence discontinuity at $x=\phi$.



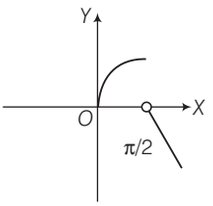
93. From figure, option (c) is correct.



94. From figure, option (b) is correct.



95. From figure, option (c) is correct.



Sol. (Q. Nos. 96 to 99)

Here, $f(x+y^{2n+1})=f(x)+(f(y))^{2n+1}$

On differentiating, we get

$f'(x+y^{2n+1})=f'(x)$

$\left[\because\ x \text{ and } y \text{ are independent, so } \frac{dy}{dx}=0\right]$

$\Rightarrow$ $f'(x)$ is constant, say $f'(x)=k$.

On integrating, we get $f(x)=kx+c$

Now, $f(0)=0 \Rightarrow c=0$ and $f(1)=1 \Rightarrow k=1$

$\therefore$ $f(x)=x \Rightarrow f'(x)=1$, for all $x\in R$

$\therefore$ $f(x)=x$ is an odd function.

96. (b) ***97.*** (c) ***98.*** (d) ***99.*** (a)

We know, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

and $f'(x)=\lim_{h\to 0}\frac{f(x-h)-f(x)}{-h}$

On adding, we get

$$2f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}+\lim_{h\to 0}\frac{f(x-h)-f(x)}{-h} \quad ...(i)$$

$$\Rightarrow \quad 2f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x-h)}{h}$$

$$\Rightarrow \quad 2f'(x)=\lim_{h\to 0} f(x)\cdot\frac{\{f(h)-f(-h)\}}{h}$$

[using $f(x+y)-f(x-y)=f(x)\{f(y)-f(-y)\}$]...(ii)

Also, $2f'(0)=\lim_{h\to 0}\left(\frac{f(h)-f(0)}{h}+\frac{f(-h)-f(0)}{-h}\right)$

[using Eq. (i)]

$$=\lim_{h\to 0}\frac{f(h)-f(-h)}{h} \quad ...(iii)$$

From Eqs. (ii) and (iii), we get

$$2f'(x)=f(x)\cdot 2f'(0) \Rightarrow \frac{f'(x)}{f(x)}=f'(0)$$

$\therefore$ $$\frac{f'(x)}{f(x)}=2010 \quad ...(iv)$$

On integrating both sides, we get

$$\log(f(x))=2010x+c, \text{ as } f(0)=1$$

$\therefore$ $$c=0 \Rightarrow f(x)=e^{2010x}$$

Thus, $\{f(x)\}$ is non-periodic. ...(v)

100. (b) ***101.*** (d)

102. (A) $\lim_{h\to 0}\sin\{1-h\}=\cos 1+a$

$\Rightarrow \lim_{h\to 0}\sin(1-h)-\cos 1=a$

$\Rightarrow a=\sin 1-\cos 1$

Now, $|K|=\frac{\sin 1-\cos 1}{\sqrt{2}\left(\sin 1\cdot\frac{1}{\sqrt{2}}-\cos 1\cdot\frac{1}{\sqrt{2}}\right)}=1 \Rightarrow K=\pm 1$

(B) $f(0)=\lim_{x\to 0}\frac{2\sin^2\left(\frac{\sin x}{2}\right)}{x^2\cdot\left(\frac{\sin x}{2}\right)^2}\cdot\left(\frac{\sin x}{2}\right)^2=\frac{1}{2}$

(C) Function should have same rule for θ and $\theta' \Rightarrow x=1-x$

$\Rightarrow$ $$x=\frac{1}{2}$$

(D) $f(x)=x+\{-x\}+[x]$

x is continuous at $x\in R$.

Check at $x=I$ (where I is integer)

$f(I^+)=2I+1$ or $f(I^-)=2I-1$

So, $f(x)$ is discontinuous at every integer, i.e. $\{1, 0, -1\}$.

103. (A) $f(x)\begin{cases} 1-1, & 1<x\le 2 \\ 0, & x=1 \\ 1-x, & 0\le x<1 \\ -\sin\pi x, & -1\le x<0 \end{cases}$

At $x=0$, $f(x)$ is not continuous and not differentiable. At $x=1$, $f(x)$ is continuous and non-differentiable. At $x=2$ and -1, $f(x)$ is continuous and differentiable.

(B) $f(0^-)=\lim\limits_{h\to 0} h^2 e^{-\frac{1}{h}}=\lim\limits_{h\to 0}\dfrac{h^2}{e^{1/h}}=0$

(C) $f(x)=\dfrac{x}{x+1}$, not defined at $x=-1$.

$$g(x)=\frac{f(x)}{f(x)+2}$$

$g(x)$ is not defined at $f(x)=-2$

$$\Rightarrow \quad \frac{x}{x+1}=-2\Rightarrow x=-\frac{2}{3}$$

Also, $x=0$ is not in domain.

$\therefore$ $f(x)$ is not differentiable at 3 points.

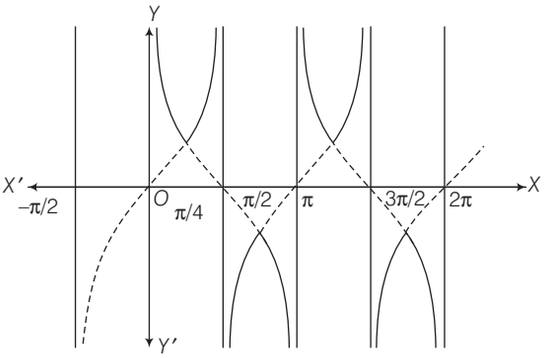
(D) $y=\operatorname{sgn}(x^2-1)=\begin{cases} 1, & x^2-1>0 \\ 0, & x^2-1=0 \\ -1, & x^2-1<0 \end{cases}=\begin{cases} 1, & |x|>1 \\ 0, & |x|=1 \\ -1, & |x|<1 \end{cases}$

$\therefore$ Tangent exists for all x.

$\therefore$ Number of points where tangent does not exists is 0.

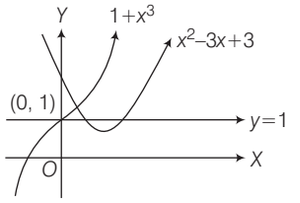
104. (A) $f(x)=\dfrac{\tan x+\cot x}{2}-\left|\dfrac{\tan x-\cot x}{2}\right|$

$$=\begin{cases}\cot x, & \tan x\ge\cot x \\ \tan x, & \cot x>\tan x\end{cases}$$



There are 4 points where the function is continuous but not differentiable in $(0, 2\pi)$.

(B) $f(x)=\min\{1, 1+x^3, x^2-3x+3\}$ can be shown as



$$\therefore \quad f(x)=\begin{cases} 1+x^3, & x\le 0 \\ 1, & 0\le x\le 1 \text{ or } x\ge 2 \\ x^2-3x+3, & 1\le x\le 2\end{cases}$$

Clearly, $f(x)$ is not differentiable at 2 points.

(C) $f(x)=(x+4)^{\frac{1}{3}}$

$$\Rightarrow f'(x)=\frac{1}{3(x+4)^{\frac{2}{3}}}$$

$\therefore$ Functions non-derivable at $x=-4$, i.e., at one point.

(D) $f(x)=\begin{cases} -\dfrac{\pi}{2}\cdot\log\left(\dfrac{2x}{\pi}\right)+\dfrac{\pi}{2}, & 0<x\le\dfrac{\pi}{2} \\ \pi-x, & \dfrac{\pi}{2}<x<\dfrac{3\pi}{2}\end{cases}$

$$f'(x)=\begin{cases}-\dfrac{\pi}{2x}, & 0<x<\dfrac{\pi}{2} \\ -1, & \dfrac{\pi}{2}<x<\dfrac{3\pi}{2}\end{cases}$$

$$f'\left(\frac{\pi^-}{2}\right)=f'\left(\frac{\pi^+}{2}\right)=-1$$

$\therefore$ $f(x)$ is differentiable for all $x\in\left(0,\dfrac{3\pi}{2}\right)$.

$\therefore$ Number of points of non-differentiable is 0.

105. (A) $Rf'(0)=\lim\limits_{h\to 0}\dfrac{\cos h-1}{h}=0$ and $Lf'(0)=\lim\limits_{h\to 0}\dfrac{-h+1-1}{-h}=-1$

Obviously,

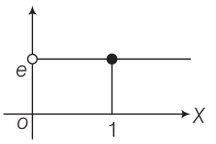
$$f(0)=f(0^-)=f(0^+)=1$$

Hence, continuous and not derivable.

(B) $g(x)=0$ for all x, hence continuous and derivable.

(C) As $0\le\{x\}<1$, hence $h(x)=\sqrt{\{x\}^2}=\{x\}$ which is discontinuous, hence non-derivable all $x\in I$.

(D) $\lim\limits_{x\to 1} x^{\frac{1}{\ln x}}=\lim\limits_{x\to 1} x^{\log_x e}=e=f(1)$



Hence, $k(x)$ is constant for all $x>0$, hence continuous and differentiable at $x=1$.

106. (A) $l=\lim\limits_{x\to\infty} e^{x^2+1}\left[e^{\sqrt{x^4+1}-(x^2+1)}-1\right]$

Consider, $\lim\limits_{x\to\infty}[\sqrt{x^4+1}-(x^2+1)]$

$$=\lim_{x\to\infty}\frac{x^4+1-(x^4+1+2x^2)}{\sqrt{x^4+1}+(x^2+1)}$$

$$=\lim_{x\to\infty}\frac{-2x^2}{x^2\left(\sqrt{1+(1/x^4)}+1+1/x^2\right)}=-1$$

Now, as $x \to \infty, \sqrt{x^4+1} - (x^2+1) \to -1$

$\infty \times \left(\frac{1}{e} - 1\right) \to -\infty$ and hence limit doesn't exist.

(B) $f(0^+) = \lim\limits_{h \to 0} \dfrac{a^{2h} - 2a^h + 1}{h^2} = \lim\limits_{h \to 0} \left(\dfrac{a^h - 1}{h}\right)^2 = \ln^2 a$

$f(0^-) = \lim\limits_{h \to 0} 3 \ln (a+h) - 2 = 3 \ln a - 2 = f(0)$

For continuous

$\ln^2 a = 3 \ln a - 2 \quad \ln^2 a - 3 \ln a + 2 = 0$

$\Rightarrow \quad (\ln a - 2)(\ln a - 1) = 0\ ;\ a = e^2$ or $a = e$

(C) $L = a^a \ln ae$

$\Rightarrow \quad M = a^a$

$\therefore \quad a^a \ln ae = 2a^a$

$\therefore \ \ln ae = 2 \Rightarrow ae = e^2 \Rightarrow a = e$

107. $\tan^2 x$ is discontinuous at $x = \dfrac{\pi}{2}, \dfrac{3\pi}{2}$

$\sec^2 x$ is discontinuous at $x = \dfrac{\pi}{2}, \dfrac{3\pi}{2}$

$\Rightarrow$ Number of discontinuities = 2

108. Let $g(x) = x^{1/x}, g'(x) = x^{1/x} \dfrac{1 - \ln x}{x^2}$

$\Rightarrow \quad g_{\max} = e^{1/e} \in (1, 2)$

$\Rightarrow \quad \lim\limits_{x \to 0} x^{1/x} = 0, \ \lim\limits_{x \to \infty} x^{1/x} = 1$

So, $\quad f(x) = \begin{cases} 0, & 0 < x < 1 \\ 1, & 1 \le x < \infty \end{cases}$

109. $f(x) = x + \cos x + 2, f(0) = 3 \Rightarrow g(3) = 0$

$g(f(x)) = x \Rightarrow g'(f(x)) \cdot f'(x) = 1$, putting $x = 0$

$g'(3) \cdot f'(0) = 1$

Now, $\quad f'(x) = 1 - \sin x \Rightarrow f'(0) = 1 \Rightarrow \quad g'(3) = 1$

110. Let $g(x) = x \tan^{-1}(x^2)$. It is an odd function.

So, $\quad g^{2m}(0) = 0.$

Let $\quad h(x) = x^4$

So, $\quad f(x) = g(x) + h(x)$

$\Rightarrow \quad f^{2m}(0) = g^{2m}(0) + h^{2m}(0)$

$= h^{2m}(0) \neq 0$

It happens when $\ 2m = 4 \Rightarrow m = 2$

111. $F(x) = 3e^x$ and $G(x) = e^{-x}$

The equation $9x^4 = (F(x))^2 G(x)$ becomes $x^4 = e^x$

Hence, number of solutions = 2

112. $y' = f'(x) - 2f'(2x)$

$y'(1) = f'(1) - 2f'(2) = 5 \quad$ ...(i)

and $\quad y'(2) = f'(2) - 2f'(4) = 7 \quad$ ...(ii)

Now, let $\quad y = f(x) - f(4x) - 10x$

$y' = f'(x) - 4f'(4x) - 10$

$y'(1) = f'(1) - 4f'(4) - 10 \quad$ ...(iii)

On substituting the value of $f'(2) = 7 + 2f'(4)$ in Eq. (i), we get

$f'(1) - 2[7 + 2f'(4)] = 5$

$f'(1) - 4f'(4) = 19$

$\Rightarrow \quad f'(1) - 4f'(4) - 10 = 9$

113. A, B, C are in AP.

$\therefore \quad 2B = A + C$ and $A + B + C = 180°$

$\therefore \quad B = 60°$

$\therefore \quad \cos B = \dfrac{1}{2} = \dfrac{a^2 + c^2 - b^2}{2ac}$

$\Rightarrow \quad a^2 + c^2 = b^2 + ac$

$\Rightarrow \quad (a - c)^2 = b^2 - ac$

or $\quad |\sin A - \sin C| = \sqrt{\sin^2 B - \sin A \sin C}$

$\Rightarrow \ 2\cos\left(\dfrac{A+C}{2}\right)\left|\sin\left(\dfrac{A-C}{2}\right)\right| = \sqrt{\dfrac{3}{4} - \sin A \sin C}$

$\Rightarrow \quad 2\left|\sin\left(\dfrac{A-C}{2}\right)\right| = \sqrt{3 - 4\sin A \sin C}$

$\therefore \ \lim\limits_{A \to C} \dfrac{\sqrt{3 - 4 \sin A \sin C}}{|A - C|} = \lim\limits_{A \to C} \dfrac{2\left|\sin\left(\dfrac{A-C}{2}\right)\right|}{|A - C|}$

$= \lim\limits_{A \to C} \left| \dfrac{\sin\left(\dfrac{A-C}{2}\right)}{\left(\dfrac{A-C}{2}\right)} \right|$

$= |1| = 1 \Rightarrow f(x) = 1$

$\therefore \quad f'(x) = 0$

114. $\text{RHD} = \lim\limits_{h \to 0} h \dfrac{\left(\left(\frac{3}{4}\right)^{1/h} - \left(\frac{3}{4}\right)^{-1/h}\right) - 0}{\left(\left(\frac{3}{4}\right)^{1/h} + \left(\frac{3}{4}\right)^{-1/h}\right) \cdot h} = -1$

$\text{LHD} = \lim\limits_{h \to 0} (-h) \dfrac{\left(\left(\frac{3}{4}\right)^{-1/h} - \left(\frac{3}{4}\right)^{1/h}\right) - 0}{\left(\left(\frac{3}{4}\right)^{-1/h} + \left(\frac{3}{4}\right)^{1/h}\right) \cdot (-h)} = 1$

$\therefore \quad P = f'(0^-) - f'(0^+) = 1 - (-1) = 2$

Now, $4 \cdot \left(\lim\limits_{x \to 2^-} \dfrac{(\exp((x+2)\log 4))^{\frac{[x+1]}{4}} - 16}{4^x - 16} \right)$

$= 4 \cdot \left[\lim\limits_{x \to 2^-} \dfrac{(4^{x+2})^{\frac{[x+1]}{4}} - 16}{4^x - 16} \right] = 4 \times \dfrac{1}{2} = 2$

115. Here, $f(x) = -x^3 + x^2 - x + 1 \Rightarrow f'(x) = -3x^2 + 2x - 1$

$\Rightarrow \quad D = 4 - 12 = -8 < 0$

$\therefore \quad f(x)$ is decreasing.

Thus, min $f(t) = f(x)$, as $f(x)$ is decreasing and $0 \le t \le x$.

$$\therefore \quad g(x)=\begin{cases}-x^3+x^2-x+1, & 0<x\le 1\\ x-1, & 1<x\le 2\end{cases}$$

$$\Rightarrow \quad \lim_{x\to 1^+} g(g(x))=\lim_{x\to 1^+} g(0^+)=1$$

$$\Rightarrow \quad \lim_{x\to 1^-} g(g(x))=\lim_{x\to 1^-} g(0^+)=1$$

$$\therefore \quad \lim_{x\to 1} g(g(x))=1$$

116. We have, $f(x)=(x-|x|)^2(1-x+|x|)^2$

$$\Rightarrow \quad f(x)=\begin{cases}(2x)^2(1-2x)^2, & x<0\\ 0, & x\ge 0\end{cases}$$

$$=\begin{cases}16x^4-16x^3+4x^2, & x<0\\ 0, & x\ge 0\end{cases}$$

Clearly, $f(x)$ is continuous as well as derivable for all $x\in R$.

$\therefore$ Number of points of non-differentiable = 0.

117. $$\text{RHL}=\lim_{h\to 0}\frac{\left(\frac{\pi}{2}-\sin^{-1}(1-h^2)\right)\sin^{-1}(1-h)}{\sqrt{2}(h-h^3)}$$

$$=\lim_{h\to 0}\frac{\cos^{-1}(1-h^2)\sin^{-1}(1-h)}{\sqrt{2}h(1-h^2)}$$

$$=\lim_{h\to 0}\frac{\sin^{-1}\sqrt{2h^2-h^4}\cdot\sin^{-1}(1-h)}{\sqrt{2}h(1+h)(1-h)}$$

$$=\lim_{h\to 0}\frac{\sin^{-1}(h\sqrt{2-h^2})\sin^{-1}(1-h)}{\sqrt{2}h(1+h)(1-h)}$$

$$=\lim_{h\to 0}\frac{1}{\sqrt{2}}\cdot\frac{\sin^{-1}(h\sqrt{2-h^2})}{h\cdot\sqrt{2-h^2}}\cdot\frac{\sqrt{2-h^2}}{1+h}\cdot\frac{\sin^{-1}(1-h)}{(1-h)}$$

$$=\frac{1}{\sqrt{2}}\cdot\sqrt{2}\cdot\frac{\sin^{-1}(1)}{1}=\frac{\pi}{2}\Rightarrow k=\frac{\pi}{2} \qquad \ldots(i)$$

$$\text{LHL}=\lim_{h\to 0}\frac{A\sin^{-1}(1-(1-h))\cdot\cos^{-1}(1-(1-h))}{\sqrt{2(1-h)}\cdot(1-(1-h))}$$

$$=\lim_{h\to 0}\frac{A\cdot\sin^{-1}(h)\cdot\cos^{-1}(h)}{\sqrt{2(1-h)}\cdot h}=\frac{A\cdot\pi/2}{\sqrt{2}}=\frac{A\pi}{2\sqrt{2}}$$

$$\Rightarrow \quad \frac{A\pi}{2\sqrt{2}}=\frac{\pi}{2}\Rightarrow A=\sqrt{2}$$

Hence, $\sin^2 k+\cos^2\left(\frac{A\pi}{\sqrt{2}}\right)=\sin^2\left(\frac{\pi}{2}\right)+\cos^2(\pi)=1+1=2$.

118. $f(x)=[[x]]-[x-1]$

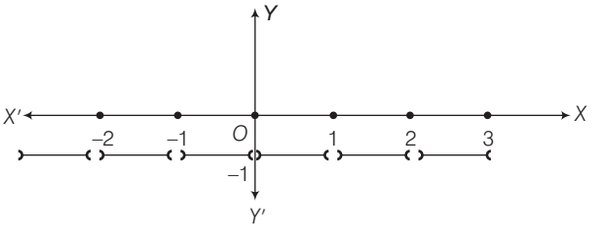
or $f(x)=[x]-[x]+1$

or $f(x)=1$, which is constant function and which is continuous for all real numbers.

119. (i) $f(x)=[x]+[-x]=\begin{cases}x-x, & x\in \text{integers}\\ [x]-1-[x], & x\notin \text{integers}\end{cases}$

$$\therefore\ f(x)=\begin{cases}0, & x\in \text{integers}\\ -1, & x\notin \text{integers}\end{cases}$$

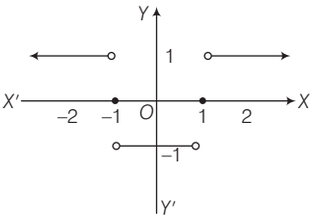
which shows the graph of $f(x)$ as shown in figure.



Thus, $f(x)$ is discontinuous at $x\in$ integers.

(ii) $g(x)=\lim_{n\to\infty}\frac{x^{2n}-1}{x^{2n}+1}=\begin{cases}-1, & |x|<1\\ 0, & |x|=1\\ 1, & |x|>1\end{cases}$

which can be shown as in the figure.



Thus, $g(x)$ is discontinuous at $x=\pm 1$.

120. $f(x)=\begin{cases}x[x], & 0\le x<2\\ (x-1)[x], & 2\le x\le 3\end{cases}$

To check continuity at $x=1$

RHL (at $x=1$) $=\lim_{h\to 0}(1+h)[1+h]=1$

LHL (at $x=1$) $=\lim_{h\to 0}(1-h)[1-h]=0$

Hence, the function is discontinuous at $x=1$.

To check continuity at $x=2$

RHL (at $x=2$) $=\lim_{h\to 0}(2+h-1)[2+h]=2$

LHL (at $x=2$) $=\lim_{h\to 0}(2-h)[2-h]=2\Rightarrow f(2)=(2-1)[2]=2$

Hence, the function is continuous at $x=2$.

To check differentiability at $x=2$

$$\text{RHD (at } x=2)=\lim_{h\to 0}\frac{f(2+h)-f(2)}{h}$$

$$=\lim_{h\to 0}\frac{(2+h-1)[2+h]-2}{h}$$

$$=\lim_{h\to 0}\frac{(1+h)2-2}{h}=2$$

$$\text{LHD (at } x=2)=\lim_{h\to 0}\frac{(2-h)[2-h]-2}{-h}$$

$$\Rightarrow \lim_{h\to 0}\frac{2-h-2}{-h}=1$$

which shows $f(x)$ is not differentiable at $x=2$.

Also, $f(x)$ is not differentiable at $x=1$, as $f(x)$ at $x=1$ is not continuous.

121. Differentiating both the sides, we get

$$h'(x) = 2f(x)\cdot f'(x) + 2g(x)\cdot g'(x)$$

$$h'(x) = 2f(x)\cdot g(x) + 2g(x)\cdot f''(x)$$

[as $g(x) = f'(x)$, $g'(x) = f''(x)$]

$$h'(x) = 2f(x)\cdot g(x) - 2g(x)\cdot f(x) \qquad [\because f''(x) = -f(x)]$$

$$h'(x) = 0$$

$\therefore$ $h(x)$ must be constant function.

Given, $h(5) = 11$

Hence, $h(10) = 11$

122. Given that,

$$f(x+y) = f(x)\cdot f(y) \text{ for all } x \in R \qquad \text{...(i)}$$

On putting $x = y = 0$ in Eq. (i), we get

$$f(0)\{f(0) - 1\} = 0$$

$\Rightarrow$ $f(0) = 0$ or $f(0) = 1$

If $f(0) = 0$, then

$$f(x) = f(x+0) = f(x)\cdot f(0)$$

$\Rightarrow$ $f(x) = 0$ for all $x \in R$

which is not true, so $f(0) = 1$

$$\therefore \quad f'(x) = \lim_{h\to 0}\frac{f(x+h) - f(x)}{h}$$

$$= \lim_{h\to 0}\frac{f(x)\cdot f(h) - f(x)}{h} \qquad \text{[from Eq. (i)]}$$

$$= \lim_{h\to 0} f(x)\left\{\frac{f(h)-1}{h}\right\}$$

$$= f(x)\cdot f'(0)$$

$$= 2f(x) \qquad \text{[given } f'(0) = 2\text{]}$$

or $\dfrac{f'(x)}{f(x)} = 2$

On integrating both the sides, we get $\log_e f(x) = 2x + C$

At $x = 0$, $f(0) = 1$

Hence, $\log f(1) = 2(0) + C$

$\Rightarrow$ $\log 1 = 0 + C$

$\Rightarrow$ $C = 0$

$\Rightarrow$ $\log_e f(x) = 2x + 0$

$\therefore$ $f(x) = e^{2x}$

123. Since, $f(x)$ is differentiable at $x = 0$.

$$\Rightarrow \quad \lim_{h\to 0}\frac{f(0+h) - f(0)}{h} = p \text{ (say)} \qquad \text{...(i)}$$

Then, $f'(x) = \lim_{h\to 0}\dfrac{f(x+h) - f(x)}{h}$

or $f'(x) = \lim_{h\to 0}\dfrac{f\left\{\frac{3x+3h}{3}\right\} - f\left(\frac{3x+3\cdot 0}{3}\right)}{h}$

or $f'(x) = \lim_{h\to 0}\dfrac{f(3x) + f(3h) + f(0) - f(3x) - f(0) - f(0)}{3h}$

or $f'(x) = \lim_{h\to 0}\dfrac{f(3h) - f(0)}{3h}$

$$\left[\text{using } f\left(\frac{x+y}{3}\right) = \frac{f(x) + f(y) + f(0)}{3}\right]$$

or $f'(x) = f'(0)$ or $f'(x) = p$ (let) [from Eq. (i)]

$\therefore$ $f(x) = px + q$

which shows $f(x)$ is differentiable for all x in R.

124. We have,

$$f'(x) = \lim_{h\to 0}\frac{f(x+h) - f(x)}{h}$$

$$= \lim_{h\to 0}\frac{f(x) + f(h) + 2hx - 1 - f(x)}{h}$$

[using given definition]

$$= \lim_{h\to 0}\left\{2x + \frac{f(h) - 1}{h}\right\}$$

Now, substituting $x = y = 0$ in the given functional relation, we get

$$f(0) = f(0) + f(0) + 0 - 1$$

$\Rightarrow$ $f(0) = 1$

$$\therefore \quad f'(x) = 2x + \lim_{h\to 0}\frac{f(h) - f(0)}{h}$$

$$= 2x + f'(0)$$

$\Rightarrow$ $f'(x) = 2x + \cos\alpha$

On integrating, $f(x) = x^2 + x\cos\alpha + C$

Here, at $x = 0$, $f(0) = 1$

$\therefore$ $1 = C \Rightarrow f(x) = x^2 + x\cos\alpha + 1$

It is a quadratic in x with discriminant,

$$D = \cos^2\alpha - 4 < 0$$

and coefficient of $x^2 = 1 > 0$

$\therefore$ $f(x) > 0, \ \forall\ x \in R$

125. **Plan** If a continuous function has values of opposite sign inside an interval, then it has a root in that interval.

$$f, g : [0, 1] \to R$$

We take two cases.

***Case* I** Let f and g attain their common maximum value at p.

$\Rightarrow$ $f(p) = g(p)$,

where $p \in [0,1]$

***Case* II** Let f and g attain their common maximum value at different points.

$\Rightarrow$ $f(a) = M$ and $g(b) = M$

$\Rightarrow$ $f(a) - g(a) > 0$ and $f(b) - g(b) < 0$

$\Rightarrow f(c) - g(c) = 0$ for some $c \in [0,1]$ as f and g are continuous functions.

$\Rightarrow f(c) - g(c) = 0$ for some $c \in [0,1]$ for all cases. ...(i)

Option (a) $\Rightarrow f^2(c) - g^2(c) + 3[f(c) - g(c)] = 0$

which is true from Eq. (i).

Option (d) $\Rightarrow f^2(c) - g^2(c) = 0$, which is true from Eq. (i).

Now, if we take $f(x) = 1$ and $g(x) = 1$, $\forall x \in [0,1]$

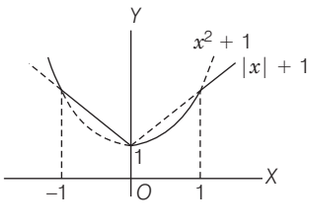
Options (b) and (c) does not hold.

Hence, options (a) and (d) are correct.

126. **Plan**

(i) In these type of questions, we draw the graph of the function.

(ii) The points at which the curve taken a sharp turn, are the points of non-differentiability. Curve of $f(x)$ and $g(x)$ are



$h(x)$ is not differentiable at $x = \pm 1$ and 0.
As, $h(x)$ take sharp turns at $x = \pm 1$ and 0.

Hence, number of points of non-differentiability of $h(x)$ is 3.

127. **Plan** To check differentiability at a point we use RHD and LHD at a point and if RHD =LHD, then $f(x)$ is differentiable at the point.

Description of Situation

As, $$R\{f'(x)\}=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$$

and $$L\{f'(x)\}=\lim_{h\to 0}\frac{f(x-h)-f(x)}{-h}$$

To check differentiable at $x=0$,

$$R\{f'(0)\}=\lim_{h\to 0}\frac{f(0+h)-f(0)}{h}$$

$$=\lim_{h\to 0}\frac{h^2\left|\cos\frac{\pi}{h}\right|-0}{h}=\lim_{h\to 0}h\cdot\left|\cos\frac{\pi}{h}\right|=0$$

$$L\{f'(0)\}=\lim_{h\to 0}\frac{f(0-h)-f(0)}{-h}=\lim_{h\to 0}\frac{h^2\left|\cos\left(-\frac{\pi}{h}\right)\right|-0}{-h}=0$$

So, $f(x)$ is differentiable at $x=0$.

To check differentiability at $x=2$,

$$R\{f'(2)\}=\lim_{h\to 0}\frac{f(2+h)-f(2)}{h}$$

$$=\lim_{h\to 0}\frac{(2+h)^2\left|\cos\left(\frac{\pi}{2+h}\right)\right|-0}{h}=\lim_{h\to 0}\frac{(2+h)^2\cdot\cos\left(\frac{\pi}{2+h}\right)}{h}$$

$$=\lim_{h\to 0}\frac{(2+h)^2\cdot\sin\left(\frac{\pi}{2}-\frac{\pi}{2+h}\right)}{h}$$

$$=\lim_{h\to 0}\frac{(2+h)^2\cdot\sin\left(\frac{\pi h}{2(2+h)}\right)}{h\cdot\frac{\pi}{2(2+h)}}\cdot\frac{\pi}{2(2+h)}=\pi$$

and $$L\{f'(2)\}=\lim_{h\to 0}\frac{f(2-h)-f(2)}{-h}$$

$$=\lim_{h\to 0}\frac{(2-h)^2\cdot\left|\cos\frac{\pi}{2-h}\right|-2^2\cdot\left|\cos\frac{\pi}{2}\right|}{-h}$$

$$=\lim_{h\to 0}\frac{(2-h)^2\left(-\cos\frac{\pi}{2-h}\right)-0}{-h}$$

$$=\lim_{h\to 0}\frac{-(2-h)^2\cdot\sin\left(\frac{\pi}{2}-\frac{\pi}{2-h}\right)}{h}$$

$$=\lim_{h\to 0}\frac{(2-h)^2\cdot\sin\left(-\frac{\pi h}{2(2-h)}\right)}{h\times\frac{-\pi}{2(2-h)}}\times\frac{-\pi}{2(2-h)}=-\pi$$

Thus, $f(x)$ is differentiable at $x=0$ but not differentiable at $x=2$.

128. $f(2n)=a_n$, $f(2n^+)=a_n$

$$f(2n^-)=b_n+1 \Rightarrow a_n-b_n=1$$

$$f(2n+1)=a_n \Rightarrow f\{(2n+1)^-\}=a_n$$

$$f\{(2n+1)^+\}=b_{n+1}-1$$

$\Rightarrow$ $a_n=b_{n+1}-1$ or $a_n-b_{n+1}=-1$

or $a_{n-1}-b_n=-1$

129. $f(x+y)=f(x)+f(y)$, as $f(x)$ is differentiable at $x=0$.

$\Rightarrow$ $f'(0)=k$ ...(i)

Now, $$f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$$

$$=\lim_{h\to 0}\frac{f(x)+f(h)-f(x)}{h}=\lim_{h\to 0}\frac{f(h)}{h}\quad\left[\frac{0}{0}\text{form}\right]$$

$$\left[\begin{array}{l}\text{given, } f(x+y)=f(x)+f(y),\ \forall\ x, y\\ \therefore\quad f(0)=f(0)+f(0),\\ \text{when}\quad x=y=0\ \Rightarrow\ f(0)=0\end{array}\right]$$

Using L'Hospital's rule,

$$\lim_{h\to 0}\frac{f'(h)}{1}=f'(0)=k \quad ...(ii)$$

$\Rightarrow$ $f'(x)=k$, integrating both sides, we get

$f(x)=kx+C$, as $f(0)=0 \Rightarrow C=0$

$\therefore$ $f(x)=kx$

$\therefore f(x)$ is continuous for all $x\in R$ and $f'(x)=k$, i.e. constant for all $x\in R$. Hence, (b) and (c) are correct.

130. We have, $$f(x)=\begin{cases}-x-\frac{\pi}{2}, & x\le-\frac{\pi}{2}\\ -\cos x, & -\frac{\pi}{2}<x\le 0\\ x-1, & 0<x\le 1\\ \log x, & x>1\end{cases}$$

Continuity at $x=-\frac{\pi}{2}$, $f\left(-\frac{\pi}{2}\right)=-\left(-\frac{\pi}{2}\right)-\frac{\pi}{2}=0$

$$\text{RHL}=\lim_{h\to 0}-\cos\left(-\frac{\pi}{2}+h\right)=0$$

$\therefore$ Continuous at $x=\left(-\frac{\pi}{2}\right)$.

Continuity at $x=0 \Rightarrow f(0)=-1$

$$\text{RHL}=\lim_{h\to 0}(0+h)-1=-1$$

$\therefore$ Continuous at $x=0$. Continuity at $x=1$, $f(1)=0$

$$\text{RHL}=\lim_{h\to 0}\log(1+h)=0$$

$\therefore$ Continuous at $x=1$

$$f'(x)=\begin{cases}-1, & x\le-\frac{\pi}{2}\\ \sin x, & -\frac{\pi}{2}<x\le 0\\ 1, & 0<x\le 1\\ \frac{1}{x}, & x>1\end{cases}$$

Differentiable at $x = 0$, LHD = 0, RHD = 1
$\therefore$ Not differentiable at $x = 0$
Differentiable at $x = 1$, LHD = 1, RHD = 1
$\therefore$ Differentiable at $x = 1$.
Also, for $x = -\frac{3}{2} \Rightarrow f(x) = -\cos x$
$\therefore$ Differentiable at $x = -\frac{3}{2}$

131. Given, $f(x) = x\cos\frac{1}{x}$, $x \geq 1$

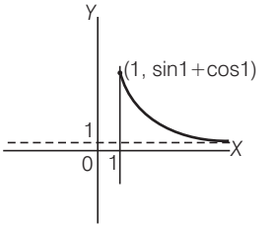
$\Rightarrow \quad f'(x) = \frac{1}{x}\sin\frac{1}{x} + \cos\frac{1}{x}$

$\Rightarrow \quad f''(x) = -\frac{1}{x^3}\cos\left(\frac{1}{x}\right)$

Now $\lim\limits_{x\to\infty} f'(x) = 0 + 1 = 1 \Rightarrow$ Option (b) is correct.

Now, $x \in [1, \infty) \Rightarrow \frac{1}{x} \in (0, 1] \Rightarrow f''(x) < 0$

Option (d) is correct.
As, $f'(1) = \sin 1 + \cos 1 > 1$
$f'(x)$ is strictly decreasing and $\lim\limits_{x\to\infty} f'(x) = 1$
So, graph of $f'(x)$ is shown as below



Now, in $[x, x+2]$, $x \in [1, \infty)$, $f(x)$ is continuous and differentiable so by LMVT, $f'(x) = \frac{f(x+2) - f(x)}{2}$
As, $f'(x) > 1$
For all $x \in [1, \infty)$

$\Rightarrow \quad \frac{f(x+2) - f(x)}{2} > 1 \quad \Rightarrow \quad f(x+2) - f(x) > 2$

For all $x \in [1, \infty)$.

132. Given, $g(x) = \frac{(x-1)^n}{\log\cos^m(x-1)}$; $0 < x < 2$, $m \neq 0$, n are integers
and $|x-1| = \begin{cases} x-1, & x \geq 1 \\ 1-x, & x < 1 \end{cases}$

The left hand derivative of $|x-1|$ at $x = 1$ is $p = -1$.
Also, $\lim\limits_{x\to 1^+} g(x) = p = -1$

$\Rightarrow \quad \lim\limits_{h\to 0} \frac{(1+h-1)^n}{\log\cos^m(1+h-1)} = -1$

$\Rightarrow \quad \lim\limits_{h\to 0} \frac{h^n}{\log\cos^m h} = -1 \Rightarrow \lim\limits_{h\to 0} \frac{h^n}{m\log\cos h} = -1$

$\Rightarrow \quad \lim\limits_{h\to 0} \frac{n\cdot h^{n-1}}{m\frac{1}{\cos h}(-\sin h)} = -1$ [using L'Hospital's rule]

$\Rightarrow \quad \lim\limits_{h\to 0}\left(-\frac{n}{m}\right)\cdot\frac{h^{n-2}}{\left(\frac{\tan h}{h}\right)} = -1 \Rightarrow \left(\frac{n}{m}\right)\lim\limits_{h\to 0}\frac{h^{n-2}}{\left(\frac{\tan h}{h}\right)} = 1$

$\Rightarrow \quad n = 2$ and $\frac{n}{m} = 1$

$\therefore \quad m = n = 2$

133. We have, $\lim\limits_{x\to 0}\frac{g(x)\cos x - g(0)}{\sin x}$ $\left[\frac{0}{0}\text{ form}\right]$

$= \lim\limits_{x\to 0}\frac{g'(x)\cos x - g(x)\sin x}{\cos x} = 0$

Statement I
Since, $f(x) = g(x)\sin x$
$f'(x) = g'(x)\sin x + g(x)\cos x$
and $f''(x) = g''(x)\sin x + 2g'(x)\cos x - g(x)\sin x$
$\Rightarrow \quad f''(0) = 0$
Thus, $\lim\limits_{x\to 0}[g(x)\cos x - g(0)]\,\text{cosec}\, x = 0 = f''(0)$
$\Rightarrow$ Statement I is true.
Statement II $f'(x) = g'(x)\sin x + g(x)\cos x \Rightarrow f'(0) = g(0)$
Statement II is not a correct explanation of Statement I.

134. Match the Columns

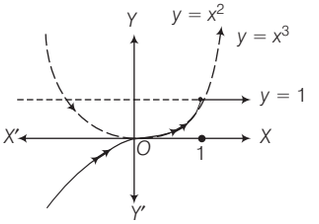
A. $x|x|$ is continuous, differentiable and strictly increasing in $(-1, 1)$.

B. $\sqrt{|x|}$ is continuous in $(-1, 1)$ and not differentiable at $x = 0$.

C. $x + [x]$ is strictly increasing in $(-1, 1)$ and discontinuous at $x = 0$
$\Rightarrow$ not differentiable at $x = 0$.

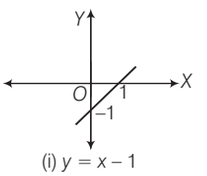
D. $|x-1| + |x+1| = 2$ in $(-1, 1)$
$\Rightarrow$ The function is continuous and differentiable in $(-1, 1)$.

135. Here, $f(x) = \min\{1, x^2, x^3\}$ which could be graphically shown as

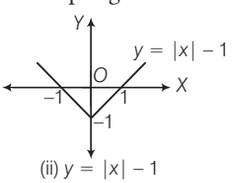


$\Rightarrow f(x)$ is continuous for $x \in R$ and not differentiable at $x = 1$ due to sharp edge. Hence, (a) and (d) are correct answers.

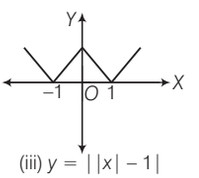
136. Using graphical transformation. As, we know that, the function is not differentiable at sharp edges.



(i) $y = x - 1$



(ii) $y = |x| - 1$



(iii) $y = ||x| - 1|$

In function, $y = ||x| - 1|$, we have 3 sharp edges at $x = -1, 0, 1$.
Hence, $f(x)$ is not differentiable at $\{0, \pm 1\}$.

137. Given, $f(1) = f\left(\frac{1}{2}\right) = f\left(\frac{1}{3}\right) = \ldots = \lim_{n \to \infty} f\left(\frac{1}{n}\right) = 0$

as $f\left(\frac{1}{n}\right) = 0$; $n \in$ integers and $n \geq 1$.

$\Rightarrow \lim_{n \to \infty} f\left(\frac{1}{n}\right) = 0$

$\Rightarrow f(0) = 0$

Since, there are infinitely many points in neighbourhood of $x = 0$.

$\therefore f(x) = 0$

$\Rightarrow f'(x) = 0 \Rightarrow f'(0) = 0$

Hence, $f(0) = f'(0) = 0$

138. Given, $f(x) = \begin{cases} \frac{1}{2}(-x-1), & \text{if } x < -1 \\ \tan^{-1} x, & \text{if } -1 \leq x \leq 1 \\ \frac{1}{2}(x-1), & \text{if } x > 1 \end{cases}$

$f(x)$ is discontinuous at $x = -1$ and $x = 1$.

$\therefore$ Domain of $f'(x) \in R - \{-1, 1\}$

139. Given, $f(x) = [x] \sin \pi x$

If x is just less than k, $[x] = k - 1$

$\Rightarrow f(x) = (k-1) \sin \pi x$.

LHD of $f(x) = \lim_{x \to k} \frac{(k-1)\sin \pi x - k \sin \pi k}{x - k}$

$= \lim_{x \to k} \frac{(k-1)\sin \pi x}{x-k}$,

$= \lim_{h \to 0} \frac{(k-1)\sin \pi (k-h)}{-h}$ [where $x = k - h$]

$= \lim_{h \to 0} \frac{(k-1)(-1)^{k-1} \cdot \sin h\pi}{-h} = (-1)^k (k-1)\pi$

140. RHD of $\sin(|x|) - |x| = \lim_{h \to 0} \frac{\sin h - h}{h} = 1 - 1 = 0 [\because f(0) = 0]$

LHD of $\sin(|x|) - |x|$

$= \lim_{h \to 0} \frac{\sin|-h| - |-h|}{-h}$

$= \lim_{h \to 0} \frac{\sin h - h}{-h} = 0$

Therefore, (d) is the answer.

141. We have, $f(x) = |\log 2 - \sin x|$ and $g(x) = f(f(x)),\ x \in R$

Note that, for $x \to 0$, $\log 2 > \sin x$

$\therefore f(x) = \log 2 - \sin x$

$\Rightarrow g(x) = \log 2 - \sin(f(x))$

$= \log 2 - \sin(\log 2 - \sin x)$

Clearly, $g(x)$ is differentiable at $x = 0$ as $\sin x$ is diferentiable.

Now, $g'(x) = -\cos(\log 2 - \sin x)(-\cos x)$

$= \cos x \cdot \cos(\log 2 - \sin x)$

$\Rightarrow g'(0) = 1 \cdot \cos(\log 2)$

142. Since, $g(x)$ is differentiable $\Rightarrow g(x)$ must be continuous.

$\therefore g(x) = \begin{cases} k\sqrt{x+1}, & 0 \leq x \leq 3 \\ mx + 2, & 3 < x \leq 5 \end{cases}$

At $x = 3$, RHL $= 3m + 2$

and at $x = 3$, LHL $= 2k$

$\therefore 2k = 3m + 2$ ...(i)

Also, $g'(x) = \begin{cases} \frac{k}{2\sqrt{x+1}}, & 0 \leq x < 3 \\ m, & 3 < x \leq 5 \end{cases}$

$\therefore L\{g'(3)\} = \frac{k}{4}$ and $R\{g'(3)\} = m$

$\Rightarrow \frac{k}{4} = m$, i.e. $k = 4m$ ...(ii)

On solving Eqs. (i) and (ii), we get

$k = \frac{8}{5}, m = \frac{2}{5}$

$\Rightarrow k + m = 2$

143. Given, $f(0) = 2 = g(1)$, $g(0) = 0$ and $f(1) = 6$

f and g are differentiable in (0, 1).

Let $h(x) = f(x) - 2g(x)$ ...(i)

$h(0) = f(0) - 2g(0) = 2 - 0 = 2$

and $h(1) = f(1) - 2g(1) = 6 - 2(2) = 2$

$\Rightarrow h(0) = h(1) = 2$

Hence, using Rolle's theorem,

$h'(c) = 0$, such that $c \in (0, 1)$

Differentiating Eq. (i) at c, we get

$\Rightarrow f'(c) - 2g'(c) = 0$

$\Rightarrow f'(c) = 2g'(c)$

144. **Given** A function $f : R \to R$ defined by

$f(x) = [x] \cos \pi\left(x - \frac{1}{2}\right)$, where [] denotes the greatest integer function.

To discuss The continuity of function f.

Now, $\cos x$ is continuous, $\forall x \in R$.

$\Rightarrow \cos \pi\left(x - \frac{1}{2}\right)$ is also continuous, $\forall x \in R$.

Hence, the continuity of f depends upon the continuity of $[x]$.

Since, $[x]$ is discontinuous, $\forall x \in I$.

So, we should check the conitnuity of f at $x = n, \forall n \in I$.

LHL at $x = n$ is given by

$f(n^-) = \lim_{x \to n^-} f(x)$

$= \lim_{x \to n^-} [x] \cos \pi\left(x - \frac{1}{2}\right) = (n-1) \cos \frac{(2n-1)\pi}{2} = 0$

RHL at $x = n$ is given by

$f(n^+) = \lim_{x \to n^+} f(x) = \lim_{x \to n^+} [x] \cos \pi\left(x - \frac{1}{2}\right)$

$= (n) \cos \frac{(2n-1)\pi}{2} = 0$

Also, value of the function at $x = n$ is

$f(n) = [n] \cos \pi\left(n - \frac{1}{2}\right) = (n) \cos \frac{(2n-1)\pi}{2} = 0$

$\therefore f(n^+) = f(n^-) = f(n)$

Hence, f is continuous at $x = n, \forall n \in I$.

Session 1

Derivative as the Rate of Change, Velocity and Acceleration in Rectilinear Motion

Derivative as the Rate of Change

If a variable quantity y is some function of time t, i.e. $y = f(t)$, then small change in time Δt have a corresponding change Δy in y.

Thus, the average rate of change $= \dfrac{\Delta y}{\Delta t}$

When limit $\Delta t \to 0$ is applied, the rate of change becomes instantaneous and we get the rate of change of y with respect to the instant t.

i.e. $$\lim_{\Delta t \to 0} \frac{\Delta y}{\Delta t} = \frac{dy}{dt}$$

Hence, it is clear that **the rate of change of any variable with respect to some other variable is the derivative of first variable with respect to other variable.**

The differential coefficient of y with respect to x i.e. $\dfrac{dy}{dx}$ is nothing but the rate of increase of y relative to x.

Example 1 ***If the radius of a circle is increasing at a uniform rate of 2 cm/s, then find the rate of increase of area of circle, at the instant when the radius is 20 cm.***

Sol. Given, $\dfrac{dr}{dt} = 2$ cm/s [where, r is radius and t is time]

Now, area of circle is given by $A = \pi r^2$

Differentiating it with respect to time t, we get

$$\frac{dA}{dt} = 2\pi r \frac{dr}{dt} \Rightarrow \frac{dA}{dt} = 2\pi \cdot 20 \cdot 2 \text{ cm}^2/\text{s}$$

$$\Rightarrow \frac{dA}{dt} = 80\,\pi \text{ cm}^2/\text{s}$$

Thus, the rate of change of area of circle with respect to time is 80π cm^2/s.

Example 2 On the curve $x^3 = 12y$, find the interval at which the abscissa changes at a faster rate than the ordinate.

Sol. Given, $x^3 = 12y$

Differentiating it with respect to y, we get

$$3x^2 \frac{dx}{dy} = 12 \Rightarrow \frac{dx}{dy} = \frac{12}{3x^2}$$

In the interval, at which the abscissa changes at a faster rate than the ordinate, we must have

$$\left|\frac{dx}{dy}\right| > 1 \quad \text{or} \quad \left|\frac{12}{3x^2}\right| > 1$$

or $$\frac{4}{x^2} > 1 \Rightarrow \frac{4 - x^2}{x^2} > 0, \text{ when } x \neq 0$$

$\Rightarrow$ $$4 - x^2 > 0\,;\, x \neq 0 \Rightarrow x^2 - 4 < 0;\, x \neq 0$$

$\Rightarrow$ $$(x-2)(x+2) < 0\,;\, x \neq 0$$

Using number line rule, we have $-2 < x < 2; x \neq 0$

Thus, $x \in (-2, 2) - \{0\}$ is the required interval at which abscissa changes at a faster rate than the ordinate.

Velocity and Acceleration in Rectilinear Motion

The velocity of a moving particle is defined as the rate of change of its displacement with respect to time and the acceleration is defined as the rate of change of its velocity with respect to time.

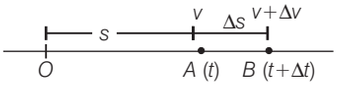

Figure 7.1

Let a particle A move rectilinearly as shown in figure. Let s be the displacement from a fixed point O along the path at time t ; s is considered to be positive on right of the point O and negative on the left of it.

Also, Δs is positive when s increases, i.e. when the particle moves towards right.

Thus, if Δs be the increment in s in time Δt, then average velocity in this interval is

$$\text{Average velocity} = \frac{\Delta s}{\Delta t}$$

and the instantaneous velocity, i.e. velocity at time t is

$$v = \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t} = \frac{ds}{dt}$$

If the velocity varies, then there is change of velocity Δv in time Δt. Hence, the acceleration at time t is

$$\text{Acceleration } (a) = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}$$

Example 3 If the displacement of a particle is given by $s = \left(\frac{1}{2}t^2 + 4\sqrt{t}\right)$ m. Find the velocity and acceleration at $t = 4$ seconds.

Sol. We have, the displacement of particle is given by,

$$s = \left(\frac{1}{2}t^2 + 4\sqrt{t}\right) \text{ m}$$

As, we know velocity $v = \frac{ds}{dt} = \left(t + \frac{2}{\sqrt{t}}\right)$ m/s ...(i)

and acceleration $a = \frac{d^2s}{dt^2} = \frac{dv}{dt} = \left(1 - \frac{1}{t^{3/2}}\right)$ m/s ...(ii)

Now, velocity when $t = 4$, is $v = \left(4 + \frac{2}{\sqrt{4}}\right)$ m/s [from Eq. (i)]

$\Rightarrow$ $v = 5$ m/s

and acceleration when $t = 4$, is $a = \left(1 - \frac{1}{4^{3/2}}\right)$ m/s^2 [from Eq. (i)]

$\Rightarrow$ $a = \left(1 - \frac{1}{8}\right)$ m/s^2 $\Rightarrow$ $a = \frac{7}{8}$ m/s^2

Example 4 ***If*** $s = \frac{1}{2}t^3 - 6t$, ***then find the acceleration at time when the velocity tends to zero.***

Sol. We have the displacement s is given by, $s = \frac{1}{2}t^3 - 6t$

Now, velocity $v = \frac{ds}{dt} = \left(\frac{3t^2}{2} - 6\right)$ ...(i)

and acceleration, $a = \frac{dv}{dt} = \frac{d^2s}{dt^2} = (3t)$ ...(ii)

To find acceleration, when velocity $\to 0$

Now, when velocit y $\to 0$, then $\frac{3t^2}{2} - 6 = 0$ [from Eq. (i)]

$\Rightarrow$ $t^2 = 4 \Rightarrow t = 2$

Thus, acceleration when velocity tends to zero, is

$a = 3t = 6$ [from Eq. (ii)]

Example 5 ***If*** r ***is the radius,*** S ***the surface area and*** V ***the volume of a spherical bubble, prove that***

(i) $\frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}$ (ii) $\frac{dV}{dS} \propto r$.

Sol. (i) Since, $V = \frac{4}{3}\pi r^3$

$\therefore$ $\frac{dV}{dt} = \frac{4}{3}\pi \cdot 3r^2 \frac{dr}{dt} = 4\pi r^2 \frac{dr}{dt}$ ...(i)

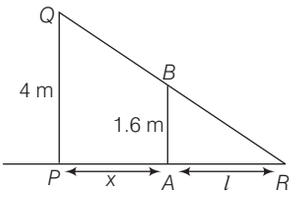
(ii) We know, $S = 4\pi r^2$ $\Rightarrow$ $\frac{dS}{dt} = 8\pi r \frac{dr}{dt}$ ...(ii)

Thus, $\frac{dV}{dS} = \frac{dV/dt}{dS/dt} = \frac{1}{2} \cdot r$ [from Eqs. (i) and (ii)]

$\Rightarrow$ $\frac{dV}{dS} = \frac{1}{2}r$ or $\frac{dV}{dS} \propto r$

Example 6 A man who is 1.6 m tall walks away from a lamp which is 4 m above ground at the rate of 30 m/min. How fast is the man's shadow lengthening?

Sol. Let $PQ = 4$ m be the height of lamp and $AB = 1.6$ m be height of man. Let the end of shadow is R and it is at a distance of l from A when the man is at a distance of x from PQ, at some instance.



Since, ΔPQR and ΔABR are similar, we have

$$\frac{PQ}{AB} = \frac{PR}{AR} \Rightarrow \frac{4}{1.6} = \frac{x + l}{l}$$

$\Rightarrow$ $2x = 3l$ $\Rightarrow$ $2\frac{dx}{dt} = 3\frac{dl}{dt}$ $\left[\text{given} \frac{dx}{dt} = 30 \text{ m/min}\right]$

$\therefore$ $\frac{dl}{dt} = \frac{2}{3} \cdot 30$ m/min $= 20$ m/min (lengthening)

Example 7 If x and y are the sides of two squares such that $y = x - x^2$, find the rate of change of the area of the second square with respect to the first square.

Sol. Given, x and y are sides of two squares, thus the area of two squares are x^2 and y^2.

We have to obtain $\frac{d(y^2)}{d(x^2)} = \frac{2y\frac{dy}{dx}}{2x} = \frac{y}{x} \cdot \frac{dy}{dx}$ ...(i)

The given curve is $y = x - x^2$

$\Rightarrow$ $\frac{dy}{dx} = 1 - 2x$ ...(ii)

Thus, $\frac{d(y^2)}{d(x^2)} = \frac{y}{x}(1 - 2x)$ [from Eqs. (i) and (ii)]

or $\frac{d(y^2)}{d(x^2)} = \frac{(x - x^2)(1 - 2x)}{x}$

$\Rightarrow$ $\frac{d(y^2)}{d(x^2)} = 2x^2 - 3x + 1$

Exercise for Session 1

1. The surface area of a spherical bubble is increasing at the rate of 2 cm^2/s. Find the rate at which the volume of the bubble is increasing at the instant, if its radius is 6 cm.

2. A particle moves along the curve $y = \frac{2}{3}x^3 + 1$. Find the point on the curve at which y-coordinate is changing twice as fast as x-coordinate.

3. The area of an expanding rectangle is increasing at the rate of 48 cm^2/s. The length of rectangle is always equal to square of the breadth. At which rate the length is increasing at the instant when the breadth is 4 cm?

4. An edge of a variable cube is increasing at the rate of 10 cm/s. How fast the volume of the cube is increasing when the edge is 5 cm long?

5. An air-force plane is ascending vertically at the rate of 100 km/h. If the radius of the earth is r km, how fast is the area of the earth, visible from the plane, increasing at 3 min after it started ascending?

   Note Visible area $A = \frac{2\pi r^2 h}{r + h}$, where h is the height of the plane above the earth.

6. Sand is pouring from the pipe at the rate of 12 cm^3/s. The falling sand forms a cone on the ground in such a way that the height of the cone is always one-sixth of the radius of the base. How fast is the height of the sand cone increasing when the height is 4 cm?

7. Water is dripping out from a conical funnel, at the uniform rate of 2 cm^3/s, through a tiny hole at the vertex of the bottom. When the slant height of the water is 4 cm, find the rate of decrease of the slant height of the water, if the vertical angle of funnel is 120°.

8. From a cylindrical drum containing oil and kept vertical, the oil leaking at the rate of 10 cm^3/s. If the radius of the drum is 10 cm and height is 50 cm, then find the rate at which level of oil is changing when oil level is 20 cm.

9. A kite is 120 m high and 130 m of string is out. If the kite is moving away horizontally at the rate of 52 m/s, find the rate at which the string is being paid out.

10. A ladder 13 m long leans against a wall. The foot of the ladder is pulled along the ground away from the wall, at the rate of 1.5 m/s. How fast is the angle θ between the ladder and the ground changing when the foot of the ladder is 12 m away from the wall?

11. Water is running into a conical vessel, 15 cm deep and 5 cm in radius, at the rate of 0.1 cm^3/s. When the water is 6 cm deep, find at what rate is
    (a) the water level rising?
    (b) the water surface area increasing?
    (c) the wetted surface of the vessel increasing?

12. Height of a tank in the form of an inverted cone is 10 m and radius of its circular base is 2 m. The tank contains water and it is leaking through a hole at its vertex at the rate of 0.02 m^3/s. Find the rate at which the water level changes and the rate at which the radius of water surface changes when height of water level is 5 m.

13. At what points of the ellipse $16x^2 + 9y^2 = 400$ does the ordinate decreases at the same rate at which the abscissa increases?

14. A satellite travels in a circular orbit of radius R. If its x-coordinate decreases at the rate of 2 units/s at the point (a, b), how fast is the y-coordinate changing?

15. The ends of a rod AB which is 5 m long moves along two grooves OX, OY which are at right angles. If A moves at a constant speed of $\frac{1}{2}$ m/s, what is the speed of B, when it is 4 m from O?

Session 2

Differential and Approximation, Geometrical Meaning of Δx, Δy, dx and dy

Differential and Approximation

We are familiar with the symbol dy/dx representing derivative of y w.r.t. x.

Now, we shall give meaning to the symbols dx and dy such that the symbol dy/dx represents the **quotient of dy and dx**.

Let $y = f(x)$ be a function of x.

Let Δx denotes small change in x and let the corresponding change in y be Δy.

Then, $$\lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{dy}{dx} \Rightarrow \frac{\Delta y}{\Delta x} = \frac{dy}{dx} \text{ (approx)}$$

$$\Rightarrow \frac{\Delta y}{\Delta x} = \frac{dy}{dx} + \varepsilon, \text{ where } \varepsilon \to 0 \text{ as } \Delta x \to 0$$

$$\Rightarrow \Delta y = \frac{dy}{dx} \cdot \Delta x + \varepsilon \cdot \Delta x \quad \ldots(i)$$

Now, Δy consists of two parts. The part $\varepsilon \cdot \Delta x$ is very small and hence negligible. The part $\frac{dy}{dx} \cdot \Delta x$ is called **principal part of Δy** and is denoted by dy and is called **differential of y.**

Thus, $$dy = \frac{dy}{dx} \cdot \Delta x \quad \ldots(ii)$$

$$\Rightarrow dx = \frac{dy}{dy} \cdot \Delta x$$

$$= (1)\Delta x = \Delta x \quad \ldots(iii)$$

From Eqs. (ii) and (iii), we get

$$dy = \frac{dy}{dx} \cdot dx$$

$\Rightarrow$ (Differential of y) = (Differential coefficient of y w.r.t. x) $\cdot$ (Differential of x)

$$\Rightarrow \frac{\text{Differential of } y}{\text{Differential of } x} = \text{(Differential coefficient of } y \text{ w.r.t. } x)$$

From Eq. (i), $$\Delta y = \frac{dy}{dx} \cdot \Delta x \text{ (approx)}$$

$$\Rightarrow \Delta y = dy \text{ (approx)}$$

Hence, approximately

$$dy = \Delta y = (y + \Delta y) - y = f(x + \Delta x) - f(x)$$

$$\Rightarrow \frac{dy}{dx} \cdot dx = f(x + \Delta x) - f(x) \text{ (approx)}$$

$$\boxed{f(x + \Delta x) - f(x) = f'(x) \cdot \Delta x \text{ (approx)}}$$

Errors

Definition of Absolute Error

Δx or dx is called absolute error in x.

Definition of Relative Error

$\frac{\Delta x}{x}$ or $\frac{dx}{x}$ is called relative error in x.

Definition of Percentage Error

$\left(\frac{\Delta x}{x}\right) \cdot 100$ or $\left(\frac{dx}{x}\right) \cdot 100$ is called percentage error in x.

Geometrical Meaning of Δx, Δy, dx and dy

Let us take a point $A(x, y)$ on the curve $y = f(x)$, where $f(x)$ is differentiable real function.

Let $B(x + \Delta x, y + \Delta y)$ be a neighbouring point on the curve, where Δx denotes a small change in x and Δy is the corresponding change in y.

From the figure, it is clear that if Δx and Δy are sufficiently small quantities, then

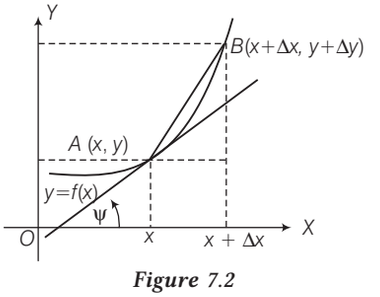


Figure 7.2

$$\frac{\Delta y}{\Delta x} = \tan \psi \cong \frac{dy}{dx} = f'(x)$$

Hence, approximate change in the value of y, called its differential, is given by $\Delta y = f'(x) \cdot \Delta x$

Example 8 Use differential to approximate $\sqrt{101}$.

Sol. Let $f(x)=\sqrt{x}$, then $f'(x)=\dfrac{1}{2\sqrt{x}}$.

Now, let $x=100$ and $\Delta x=1$, so that $x+\Delta x=101$

Then, by definition $f(x+\Delta x)-f(x)=f'(x)\cdot\Delta x$, we get

$$\sqrt{101}-\sqrt{100}=f'(\sqrt{100})\cdot 1$$

$$\sqrt{101}=\sqrt{100}+\frac{1}{2\sqrt{100}}\cdot 1$$

$$=10+\frac{1}{20}=10.05$$

Example 9 ***Use differential to approximate*** $(66)^{1/3}$.

Sol. Let $f(x)=(x)^{1/3}$

Then, $f'(x)=\dfrac{1}{3x^{2/3}}$

Now, let $x=64$, $\Delta x=2$, so that $x+\Delta x=66$

Then, by definition $f(x+\Delta x)-f(x)=f'(x)\cdot\Delta x$

$$\Rightarrow\quad f(66)-f(64)=f'(64)\cdot(2)$$

$$\Rightarrow\quad (66)^{1/3}-(64)^{1/3}=\frac{1}{3(64)^{2/3}}\times 2$$

$$\Rightarrow\quad (66)^{1/3}=4+\frac{2}{48}=\frac{97}{24}=4.0416$$

Example 10 If the radius of a circle increases from 5 cm to 5.1 cm, find the increase in area.

Sol. Let r be the radius of the circle. Then, $r=5$ cm and $r+dr=5.1$ cm, so that $dr=0.1$ cm.

Let A denotes the areas of the circle.

Then, $A=\pi r^2\ \therefore\ \dfrac{dA}{dr}=2\pi r$

$\therefore$ At $r=5$, $\dfrac{dA}{dr}=10\pi$

Now, $dA=\dfrac{dA}{dr}\cdot dr=10\pi\times(0.1)=\pi\ \text{cm}^2$

$\therefore$ Increase in area $=\pi\ \text{cm}^2$

Example 11 Find the approximate value of $\tan^{-1}(0.999)$ using differential.

Sol. Let $f(x)=\tan^{-1}x$

Then, $f'(x)=\dfrac{1}{1+x^2}$

Now, let $x=1$ and $\Delta x=-0.001$. So that $x+\Delta x=0.999$

Then, by definition,

$f(x+\Delta x)-f(x)=f'(x)\cdot\Delta x$, we get

$$f(0.999)-f(1)=f'(1)\cdot(-0.001)$$

$$\Rightarrow\quad \tan^{-1}(0.999)=\tan^{-1}(1)-(0.001)\cdot\frac{1}{1+1^2}$$

$$=\frac{\pi}{4}-0.0005=\frac{1}{4}\times\frac{22}{7}-0.0005=0.7852$$

Example 12 ***The time*** T ***of oscillation of a simple pendulum of length*** l ***is given by*** $T=2\pi\cdot\sqrt{\dfrac{l}{g}}$.

Find percentage error in T ***corresponding to***

(i) an increase of 2% in the value of l.

(ii) decrease of 2% in the value of l.

Sol. (i) We have, $T=2\pi\cdot\sqrt{\dfrac{l}{g}}$

$$\Rightarrow\quad \log T=\log 2+\log\pi+\frac{1}{2}\log l-\frac{1}{2}\log g$$

Differentiating w.r.t. l, we get

$$\frac{1}{T}\frac{dT}{dl}=0+0+\frac{1}{2l}-0\ \Rightarrow\ \frac{dT}{T}=\frac{1}{2}\frac{dl}{l}$$

$$\therefore\quad \frac{dT}{T}\times 100=\frac{1}{2}\left(\frac{dl}{l}\times 100\right)=\frac{1}{2}(2)\%=1\%$$

$$\left[\because \frac{dl}{l}\times 100=2\%\right]$$

Percentage error in $T=1\%$.

(ii) We have, $\dfrac{dT}{T}=\dfrac{1}{2}\dfrac{dl}{l}$

$$\Rightarrow\ \frac{dT}{T}\times 100=\frac{1}{2}\left(\frac{dl}{l}\times 100\right)=\frac{1}{2}(-2)\%=-1\%$$

[$\because$ decrease in $l=2\%$]

Percentage error in $T=-1\%$.

Example 13 ***In an acute*** ΔABC, ***if sides*** a ***and*** b ***are constants and the base angles*** A ***and*** B ***vary, show that*** $\dfrac{dA}{\sqrt{a^2-b^2\sin^2A}}=\dfrac{dB}{\sqrt{b^2-a^2\sin^2B}}$.

Sol. $\dfrac{a}{\sin A}=\dfrac{b}{\sin B}$ or $b\sin A=a\sin B$

$$\Rightarrow\quad b\cos A\,dA=a\cos B\,dB$$

$$\Rightarrow\quad \frac{dA}{a\cos B}=\frac{dB}{b\cos A}$$

$$\Rightarrow\quad \frac{dA}{a\sqrt{1-\sin^2B}}=\frac{dB}{b\sqrt{1-\sin^2A}}$$

$$\Rightarrow\quad \frac{dA}{a\sqrt{1-\dfrac{b^2\sin^2A}{a^2}}}=\frac{dB}{b\sqrt{1-\dfrac{a^2\sin^2B}{b^2}}}$$

$$\Rightarrow\quad \frac{dA}{\sqrt{a^2-b^2\sin^2A}}=\frac{dB}{\sqrt{b^2-a^2\sin^2B}}$$

Exercise for Session 2

1. Use differential to approximate $\sqrt{51}$.
2. Use differential to approximate $\log(9.01)$. (Given, $\log 3 = 1.0986$)
3. If the error committed in measuring the radius of a circle is 0.01%, find the corresponding error in calculating the area.
4. The pressure p and the volume V of a gas are connected by the relation $pV^{1/4} = a$ (constant). Find the percentage increase in pressure corresponding to a decrease of $\left(\frac{1}{2}\right)\%$ in volume.
5. If in a ΔABC, the side c and the angle C remain constant, while the remaining elements are changed slightly. Using differential, show that $\frac{da}{\cos A} + \frac{db}{\cos B} = 0$.
6. If a ΔABC, inscribed in a fixed circle, is slightly varied in such a way as to have its vertices always on the circle, show that $\frac{da}{\cos A} + \frac{db}{\cos B} + \frac{dc}{\cos C} = 0$.

Session 3

Slope of Tangent and Normal, Equation of Tangent, Equation of Normal

Slope of Tangent and Normal

Slope of Tangent

Let $y = f(x)$ be a continuous curve and let $P(x_1, y_1)$ be a point on it.

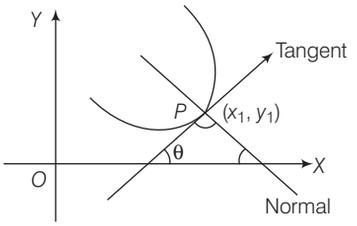

Figure 7.3

Then, $\left(\frac{dy}{dx}\right)_{(x_1, y_1)}$ **is the slope of tangent to the curve $y = f(x)$ at a point $P(x_1, y_1)$.**

$\Rightarrow \quad \left(\frac{dy}{dx}\right)_P = \tan\theta =$ Slope of tangent at P

where, θ is the angle which the tangent at $P(x_1, y_1)$ forms with the positive direction of X-axis as shown in the figure.

Remarks

(i) **Horizontal tangent** If tangent is parallel to X-axis, then

$$\theta = 0° \Rightarrow \tan\theta = 0$$

$$\therefore \quad \left(\frac{dy}{dx}\right)_{(x_1, y_1)} = 0$$

(ii) **Vertical tangent** If tangent is perpendicular to X-axis or parallel to Y-axis, then

$$\theta = 90° \Rightarrow \tan\theta = \infty \quad \text{or} \quad \cot\theta = 0$$

$$\therefore \quad \left(\frac{dx}{dy}\right)_{(x_1, y_1)} = 0$$

Slope of Normal

We know that the normal to the curve at $P(x_1, y_1)$ is a line perpendicular to tangent at $P(x_1, y_1)$ and passes through P.

$\therefore$ **Slope of the normal at**

$$P = -\frac{1}{\text{Slope of the tangent at } P}$$

$$\Rightarrow \text{ Slope of normal at } P(x_1, y_1) = -\frac{1}{\left(\frac{dy}{dx}\right)_{(x_1, y_1)}}$$

$$\text{or} \quad \text{Slope of normal at } P(x_1, y_1) = -\left(\frac{dx}{dy}\right)_{(x_1, y_1)}$$

Remarks

(i) **Horizontal normal** If normal is parallel to X-axis, then

$$-\left(\frac{dx}{dy}\right)_{(x_1, y_1)} = 0 \text{ or } \left(\frac{dx}{dy}\right)_{(x_1, y_1)} = 0$$

(ii) **Vertical normal** If normal is perpendicular to X-axis or parallel to Y-axis, then $-\left(\frac{dy}{dx}\right)_{(x_1, y_1)} = 0$

Example 14 ***Find the slopes of the tangent and normal to the curve $x^3 + 3xy + y^3 = 2$ at (1, 1).***

Sol. Given equation of curve is $x^3 + 3xy + y^3 = 2$.

Differentiating it w.r.t. x, we get

$$3x^2 + 3x\frac{dy}{dx} + 3y + 3y^2\frac{dy}{dx} = 0$$

$$\Rightarrow \quad \frac{dy}{dx} = -\frac{(3x^2 + 3y)}{(3x + 3y^2)} \quad \Rightarrow \quad \frac{dy}{dx} = -\frac{(x^2 + y)}{(x + y^2)}$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(1,1)} = -\left(\frac{2}{2}\right) = -1$$

$$\therefore \quad \text{Slope of tangent at } (1,1) = \left(\frac{dy}{dx}\right)_{(1,1)} = -1$$

$$\text{and slope of normal at } (1,1) = -\frac{1}{\left(\frac{dy}{dx}\right)_{(1,1)}} = \frac{-1}{-1} = 1$$

Example 15 ***Find the point on the curve $y = x^3 - 3x$ at which tangent is parallel to X-axis.***

Sol. Let the point at which tangent is parallel to X-axis be $P(x_1, y_1)$.

Then, it must lie on curve.

Therefore, we have $y_1 = x_1^3 - 3x_1$ ...(i)

Differentiating $y = x^3 - 3x$ w.r.t. x, we get

$$\frac{dy}{dx} = 3x^2 - 3 \quad \Rightarrow \quad \left(\frac{dy}{dx}\right)_{(x_1, y_1)} = 3x_1^2 - 3$$

Since, the tangent is parallel to X-axis.

$$\therefore \quad \left(\frac{dy}{dx}\right)_{(x_1,\, y_1)} = 0 \;\Rightarrow\; 3x_1^2 - 3 = 0$$

$$\Rightarrow \quad x_1 = \pm 1 \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

When $x_1 = 1$, then $y_1 = 1 - 3 = -2$

When $x_1 = -1$, then $y_1 = -1 + 3 = 2$

$\therefore$ Points at which tangent is parallel to X-axis are $(1, -2)$ and $(-1, 2)$.

Example 16 Find the point on the curve $y = x^3 - 2x^2 - x$ at which the tangent line is parallel to the line $y = 3x - 2$.

Sol. Let $P(x_1, y_1)$ be the required point.

Then, we have $\quad y_1 = x_1^3 - 2x_1^2 - x_1 \qquad \text{...(i)}$

Differentiating the curve $y = x^3 - 2x^2 - x$ w.r.t. x, we get

$$\frac{dy}{dx} = 3x^2 - 4x - 1 \;\Rightarrow\; \left(\frac{dy}{dx}\right)_{(x_1,\, y_1)} = 3x_1^2 - 4x_1 - 1$$

Since, tangent at (x_1, y_1) is parallel to the line $y = 3x - 2$.

$\therefore$ Slope of the tangent at $P(x_1, y_1)$ = Slope of the line

$$y = 3x - 2 \;\Rightarrow\; \left(\frac{dy}{dx}\right)_{(x_1,\, y_1)} = 3$$

$$\Rightarrow \quad 3x_1^2 - 4x_1 - 1 = 3 \;\Rightarrow\; 3x_1^2 - 4x_1 - 4 = 0$$

$$\Rightarrow \quad (x_1 - 2)(3x_1 + 2) = 0 \;\Rightarrow\; x_1 = 2, -2/3 \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

When $x_1 = 2$, then

$$y_1 = 8 - 8 - 2 \;\Rightarrow\; y_1 = -2$$

When $\quad x_1 = -2/3$, then $y_1 = x_1^3 - 2x_1^2 - x_1$

$$\Rightarrow \quad y_1 = \frac{-8}{27} - \frac{8}{9} + \frac{2}{3} \;\Rightarrow\; y_1 = \frac{-14}{27}$$

Thus, the point at which tangent is parallel to $y = 3x - 2$ are $(2, -2)$ and $\left(-\frac{2}{3}, -\frac{14}{27}\right)$.

Example 17 *In which of the following cases, the function $f(x)$ has a vertical tangent at $x = 0$?*

(i) $f(x) = x^{1/3}$ (ii) $f(x) = \text{sgn } x$

(iii) $f(x) = x^{2/3}$ (iv) $f(x) = \sqrt{|x|}$

(v) $f(x) = \begin{cases} 0, \text{ if } x < 0 \\ 1, \text{ if } x \geq 0 \end{cases}$

Sol. **Vertical Tangent**

Concept $y = f(x)$ has a vertical tangent at the points $x = x_0$, if

$$\lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h} = \infty \text{ or } -\infty \text{ but not both.}$$

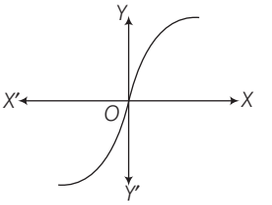
Here, the functions $f(x) = x^{1/3}$ and $f(x) = \text{sgn } x$ both have a vertical tangent at $x = 0$, but $f(x) = x^{2/3}, f(x) = \sqrt{|x|}$ and $f(x) = \begin{cases} 0, \text{ if } x < 0 \\ 1, \text{ if } x \geq 0 \end{cases}$ have no vertical tangent.

Explanation

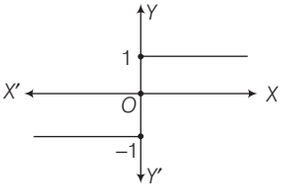
(i) $f(x) = x^{1/3}$

$$\left.\begin{aligned} f'(0^+) &= \lim_{h \to 0} \frac{h^{1/3}}{h} = \frac{1}{h^{2/3}} \to \infty \\ f'(0^-) &= \lim_{h \to 0} \frac{(-h)^{1/3}}{-h} = \frac{1}{(-h)^{2/3}} = \frac{1}{h^{2/3}} \to \infty \end{aligned}\right\}$$

$\Rightarrow$ $f(x)$ has a vertical tangent at $x = 0$.



(ii) $f(x) = \text{sgn } x = \begin{cases} 1, \text{ if } x > 0 \\ 0, \text{ if } x = 0 \\ -1, \text{ if } x < 0 \end{cases}$



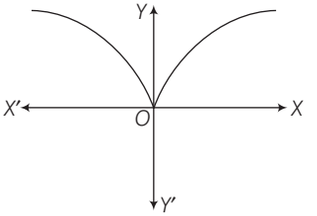
$$\left.\begin{aligned} f'(0^+) &= \lim_{h \to 0} \frac{1 - 0}{h} \to \infty \\ f'(0^-) &= \lim_{h \to 0} \frac{-1}{-h} \to \infty \end{aligned}\right\}$$

$\Rightarrow$ $f(x)$ has a vertical tangent at $x = 0$.

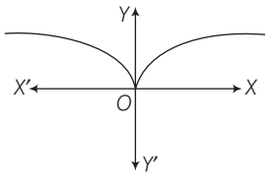
(iii) $f(x) = x^{2/3}$

$$\left.\begin{aligned} f'(0^+) &= \lim_{h \to 0} \frac{h^{2/3}}{h} \to \infty \\ f'(0^-) &= \lim_{h \to 0} \frac{(-h)^{2/3}}{-h} = -\frac{1}{h^{1/3}} \to -\infty \end{aligned}\right\}$$

$\Rightarrow$ No vertical tangent at $x = 0$.



(iv) $f(x) = \sqrt{|x|} = \begin{cases} \sqrt{x}, \text{ if } x \geq 0 \\ \sqrt{-x}, \text{ if } x < 0 \end{cases}$

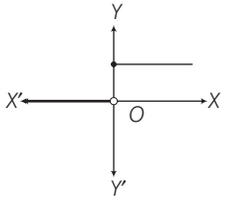


$$\left.\begin{aligned} f'(0^+) &= \lim_{h \to 0} \frac{\sqrt{h} - 0}{h} \to \infty \\ f'(0^-) &= \lim_{h \to 0} \frac{\sqrt{h}}{-h} \to -\infty \end{aligned}\right\}$$

$\Rightarrow$ No vertical tangent at $x = 0$.

(v) $f(x) = \begin{cases} 0, \text{ if } x < 0 \\ 1, \text{ if } x \geq 0 \end{cases}$

$$\left.\begin{aligned} f'(0^+) &= \lim_{h \to 0} \frac{1-1}{h} = 0 \\ f'(0^-) &= \lim_{h \to 0} \frac{0-1}{h} \to -\infty \end{aligned}\right\}$$



$\Rightarrow$ No vertical tangent at $x = 0$.

Equation of Tangent

Let $y = f(x)$ be the equation of curve and point (x_1, y_1) be any point on the curve. Let PT be the tangent at point (x_1, y_1).

Since, tangent is a line passing through the point $P(x_1, y_1)$ and having slope $m = \left(\frac{dy}{dx}\right)_{(x_1, y_1)}$, therefore by coordinate geometry, the equation of tangent is

$$\boldsymbol{y - y_1 = m(x - x_1) \Rightarrow y - y_1 = \left(\frac{dy}{dx}\right)_{(x_1, y_1)} \cdot (x - x_1).}$$

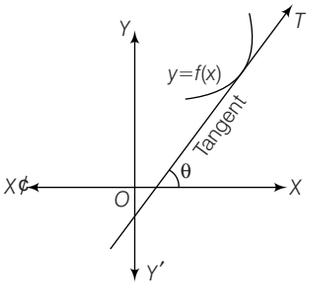


Figure 7.4

Tangent from External Point

If a point $P(a, b)$ does not lie on the curve $y = f(x)$, then the equation of all possible tangents to the curve $y = f(x)$, passing through (a, b), can be found by solving for the point of contact Q.

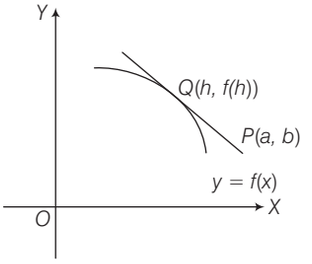

Figure 7.5

Then, $f'(h) = \dfrac{f(h) - b}{h - a}$

and equation of tangent is

$$\boldsymbol{y - b = \frac{f(h) - b}{h - a} \cdot (x - a)}$$

Example 18 Find value of c such that line joining points $(0, 3)$ and $(5, -2)$ becomes tangent to $y = \dfrac{c}{x+1}$.

Sol. Equation of line joining $A(0, 3)$ and $B(5, -2)$ is $x + y = 3$.

Solving the line and curve, we get

$$3 - x = \frac{c}{x+1}$$

$\Rightarrow$ $x^2 - 2x + (c - 3) = 0$ ...(i)

For tangency, roots of this equation must be equal.

Hence, discriminant of quadratic equation = 0.

$\Rightarrow$ $4 = 4(c - 3) \Rightarrow c = 4$

Hence, required value of c is 4.

Equation of Normal

We know that normal to curve at any point is a straight line passes through that point and is perpendicular to the tangent to the curve at that point.

Since, the slope of tangent at $P(x_1, y_1) = \left(\frac{dy}{dx}\right)_{(x_1, y_1)}$

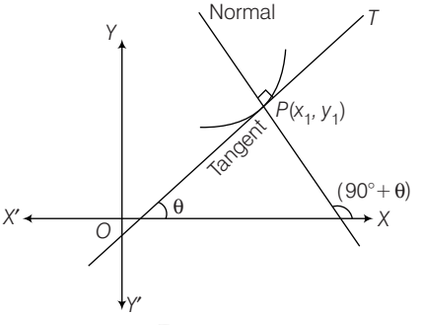

Figure 7.6

Now, as normal is perpendicular to the tangent.

$\therefore$ Slope of normal at $P(x_1, y_1) = \dfrac{-1}{\left(\dfrac{dy}{dx}\right)_{(x_1, y_1)}}$

Hence, from coordinate geometry equation of normal is

$$y - y_1 = -\frac{1}{\left(\dfrac{dy}{dx}\right)_{(x_1, y_1)}}(x - x_1)$$

or $$y - y_1 = -\left(\frac{dx}{dy}\right)_{(x_1, y_1)}(x - x_1)$$

Example 19 Find the equation of tangent and normal to the curve $2y = 3 - x^2$ at (1,1).

Sol. The equation of given curve is,

$$2y = 3 - x^2 \quad \text{...(i)}$$

Differentiating Eq. (i) w.r.t. x, we get

$$2\left(\frac{dy}{dx}\right) = -2x \Rightarrow \frac{dy}{dx} = -x$$

$$\Rightarrow \left(\frac{dy}{dx}\right)_{(1,1)} = -1 \quad \text{...(ii)}$$

Now, the equation of tangent at (1, 1) is,

$$\Rightarrow \frac{y-1}{x-1} = \left(\frac{dy}{dx}\right)_{(1,1)} \Rightarrow \frac{y-1}{x-1} = -1$$

$$\Rightarrow y - 1 = -x + 1$$

$$\Rightarrow y + x = 2 \quad \text{[required equation of tangent]}$$

and the equation of the normal at (1, 1) is,

$$\frac{y-1}{x-1} = -\frac{1}{(dy/dx)_{(1,1)}} = 1$$

$$\therefore y - x = 0 \quad \text{[required equation of normal]}$$

Example 20 ***Find the equation of tangent and normal to the parabola*** $y^2 = 4ax$ ***at the point*** $(at^2, 2at)$.

Sol. The equation of given curve is,

$$y^2 = 4ax \quad \text{...(i)}$$

Differentiating Eq. (i) w.r.t. x, we get $2y\dfrac{dy}{dx} = 4a$

$$\Rightarrow \left(\frac{dy}{dx}\right)_{(at^2, 2at)} = \frac{4a}{4at} = \frac{1}{t} \quad \text{...(ii)}$$

Now, the equation of tangent at $(at^2, 2at)$ is

$$\frac{y - 2at}{x - at^2} = \left(\frac{dy}{dx}\right)_{(at^2, 2at)} = \frac{1}{t} \quad \text{[using Eq. (ii)]}$$

$$\Rightarrow (y - 2at)t = x - at^2$$

$$\Rightarrow yt - 2at^2 = x - at^2 \Rightarrow yt = x + at^2$$

[required equation of tangent]

and the equation of normal at $(at^2, 2at)$ is,

$$\frac{y - 2at}{x - at^2} = -\frac{1}{\left(\dfrac{dy}{dx}\right)_{(at^2, 2at)}} = -t \quad \text{[using Eq. (ii)]}$$

$$\Rightarrow y - 2at = -xt + at^3$$

$$\Rightarrow y + xt = 2at + at^3 \text{ [required equation of normal]}$$

Example 21 ***Find the point on the curve*** $y - e^{xy} + x = 0$ ***at which we have vertical tangent.***

Sol. The equation of given curve is,

$$y - e^{xy} + x = 0 \quad \text{...(i)}$$

Differentiating Eq. (i) w.r.t. x, we get

$$\frac{dy}{dx} - e^{xy}\left\{1 \cdot y + x \cdot \frac{dy}{dx}\right\} + 1 = 0$$

$$\Rightarrow \frac{dy}{dx}(1 - xe^{xy}) = -1 + y \cdot e^{xy}$$

$$\Rightarrow \frac{dy}{dx} = \frac{-1 + y \cdot e^{xy}}{1 - xe^{xy}} \quad \text{...(ii)}$$

Let at point (x_1, y_1) on the curve, we have a vertical tangent (i.e. a tangent parallel to Y-axis). Then,

$$\left(\frac{dy}{dx}\right)_{(x_1, y_1)} = \infty \text{ or } \left(\frac{dx}{dy}\right)_{(x_1, y_1)} = 0$$

$$\Rightarrow \frac{1 - x_1 e^{x_1 y_1}}{-1 + y_1 e^{x_1 y_1}} = 0 \Rightarrow 1 - x_1 e^{x_1 y_1} = 0$$

$$\Rightarrow x_1 e^{x_1 y_1} = 1,$$

which is possible only if $x_1 = 1$ and $y_1 = 0$.

Thus, the required point is (1, 0).

Remarks

For standard curves students are advised to use direct method of finding equation of tangent.

For the curve of the form

$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$, replace

x^2 by xx_1; $2x$ by $x + x_1$;

y^2 by yy_1; $2y$ by $y + y_1$

and xy by $\dfrac{xy_1 + x_1 y}{2}$

Then, equation of tangent is,

$axx_1 + h(xy_1 + yx_1) + byy_1 + g(x + x_1) + f(y + y_1) + c = 0$

e.g.

(i) Find equation of tangent to the curve $2y = x^2 + 3$ at (x_1, y_1).

Sol. On replacing $2y$ by $y + y_1$ and x^2 by xx_1, we get

$(y + y_1) = xx_1 + 3$, which is the required equation of tangent.

(ii) Find equation of tangent to the curve $y^2 = 4ax$ at $(at^2, 2at)$.

Sol. Clearly, the equation of curve $y^2 = 4ax$ is a standard equation of curve, therefore on replacing y^2 by yy_1 and $2x$ by $x + x_1$,

we can get the equation of tangent. Thus, the required equation is given by

$$yy_1 = 2a(x + x_1)$$

where $(x_1, y_1) = (at^2, 2at)$

Hence, the required equation of tangent is

$$y(2at) = 2a(x + at^2) \Rightarrow yt = x + at^2$$

(iii) Find the equation of tangent, at point $P(x_1, y_1)$, to the curve

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Sol. Clearly, the equation of curve $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is a standard equation of curve, therefore equation of the tangent can be obtained by replacing x^2 *by* xx_1 and y^2 *by* yy_1.

i.e. $$\frac{xx_1}{a^2} + \frac{yy_1}{b^2} = 1$$

Some Important Points Regarding Tangent and Normal

1. If a curve passes through the origin, then the equation of the tangent at the origin can be directly written by equating the lowest degree terms appearing in the equation of the curve to zero.

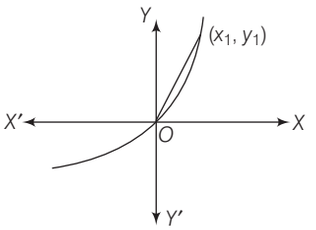

Figure 7.7

Proof Let the equation of the curve be

$$a_1x + b_1y + a_2x^2 + b_2xy + c_2y^2 = 0 \quad \ldots(i)$$

Tangent $$y - 0 = \lim_{\substack{x_1 \to 0 \\ y_1 \to 0}} \frac{y_1}{x_1}(x - 0)$$

Now, Eq. (i) becomes

$$a_1 + b_1\frac{y_1}{x_1} + a_2x_1 + b_2\frac{y_1}{x_1}\cdot x_1 + c_2\frac{y_1}{x_1}\cdot y_1 = 0 \quad \ldots(ii)$$

at $x_1 \to 0$ and $y_1 \to 0, \frac{y_1}{x_1} \to m$

From Eq. (ii), $a_1 + b_1m = 0 \quad \left[\because\ m = -\frac{a_1}{b_1}\right]$

Hence, tangent is $y = -\frac{a_1}{b_1}x$

$\Rightarrow \quad a_1x + b_1y = 0$

e.g.

(i) Equation of tangent at origin, to the curve $x^2 + y^2 + 2gx + 2fy = 0$ is $gx + fy = 0$.

(ii) Equation of tangent at origin to the curve $x^3 + y^3 - 3x^2y + 3xy^2 + x^2 - y^2 = 0$ is $x^2 - y^2 = 0$.

(iii) Equation of tangent at origin, to the curve $x^3 + y^3 - 3xy = 0$ is $xy = 0$.

2. If the curve is $x^4 + y^4 = x^2 + y^2$, then the equation of the tangent would be $x^2 + y^2 = 0$ which would indicate that the origin is an isolated point on the graph.

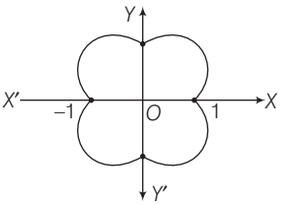

Figure 7.8

3. Same line could be the tangent as well as normal to a given curve at a given point.

e.g. In $x^3 + y^3 - 3xy = 0$ [folium of descartes]

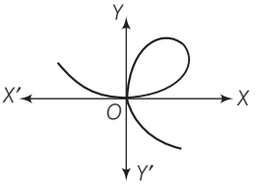

Figure 7.9

The line pair $xy = 0$ is both the tangent as well as normal at $x = 0$.

4. Some common parametric coordinates on a curve

(i) For $x^{2/3} + y^{2/3} = a^{2/3}$, take parametric coordinate $x = a\cos^3\theta$ and $y = a\sin^3\theta$.

(ii) For $\sqrt{x} + \sqrt{y} = \sqrt{a}$, take $x = a\cos^4\theta$ and $y = a\sin^4\theta$.

(iii) For $\frac{x^n}{a^n} + \frac{y^n}{b^n} = 1$, take $x = a(\cos\theta)^{2/n}$ and $y = b(\sin\theta)^{2/n}$.

(iv) For $c^2(x^2 + y^2) = x^2y^2$, take $x = c\sec\theta$ and $y = c\,\mathrm{cosec}\,\theta$.

(v) For $y^2 = x^3$, take $x = t^2$ and $y = t^3$.

Example 22 ***Find the sum of the intercepts on the axes of coordinates by any tangent to the curve*** $\sqrt{x} + \sqrt{y} = 2$.

Sol. Here, equation of curve is $\sqrt{x} + \sqrt{y} = 2$.

Whose parametric coordinates are given by,

$$\sqrt{x} = 2\cos^2\theta$$

and $\sqrt{y} = 2\sin^2\theta$

i.e. $x = 4\cos^4\theta$

and $y = 4\sin^4\theta$

$\therefore \quad \dfrac{dy}{dx} = \dfrac{4 \times 4\sin^3\theta \cdot \cos\theta}{4 \times 4\cos^3\theta(-\sin\theta)} = -\tan^2\theta$

Now, equation of tangent is $\dfrac{y - 4\sin^4\theta}{x - 4\cos^4\theta} = -\tan^2\theta$

$\therefore$ x-intercept, $\left|4\cos^4\theta + \dfrac{4\sin^4\theta}{\tan^2\theta}\right| = 4\cos^2\theta$

and y-intercept, $\left|4\sin^4\theta + \dfrac{4\sin^4\theta}{\tan^2\theta}\right| = 4\sin^2\theta$

Hence, the sum of intercepts made on the axes of coordinates is,

$$4\cos^2\theta + 4\sin^2\theta = 4$$

Example 23 T***he*** tangent, represented by the graph of the function $y = f(x)$, at the point with abscissa $x = 1$ form an angle of $\pi/6$, at the point $x = 2$ form an angle of $\pi/3$ and at the point $x = 3$ form an angle of $\pi/4$. T***hen,*** find the value of,

$$\int_1^3 f'(x)\, f''(x)\, dx + \int_2^3 f''(x)\, dx.$$

Sol. Given, at $x = 1$, $\dfrac{dy}{dx} = \tan \pi/6 = 1/\sqrt{3}$

or at $x = 1$, $f'(1) = \tan \pi/6 = 1/\sqrt{3}$

Also, at $x = 2$, $f'(2) = \tan \pi/3 = \sqrt{3}$

and at $x = 3$, $f'(3) = \tan \pi/4 = 1$

Then, $\int_1^3 f'(x)\, f''(x)\, dx + \int_2^3 f''(x)\, dx$

$= \int_{f'(1)}^{f'(3)} t\, dt + (f'(x))_2^3$

[putting $f'(x) = t \Rightarrow f''(x)\, dx = dt$]

$= \dfrac{1}{2}(t^2)_{f'(1)}^{f'(3)} + \{f'(3) - f'(2)\}$

$= \dfrac{1}{2}\{(f'(3))^2 - (f'(1))^2\} + \{f'(3) - f'(2)\}$

$= \dfrac{1}{2}\left\{(1)^2 - \left(\dfrac{1}{\sqrt{3}}\right)^2\right\} + \{1 - \sqrt{3}\} = \dfrac{1}{2}\left(1 - \dfrac{1}{3}\right) + (1 - \sqrt{3})$

$= \dfrac{4}{3} - \sqrt{3} = \dfrac{4 - 3\sqrt{3}}{3}$

Example 24 Find the equation for family of curves for which the length of normal is equal to the radius vector.

Sol. Let $P(x, y)$ be the point on the curve.

OP = radius vector $= \sqrt{x^2 + y^2}$

PN = length of normal

Now, $\tan\phi = -\dfrac{1}{\left(\dfrac{dy}{dx}\right)}$ and $PN = \dfrac{y}{\sin\phi}$

It is given $OP = PN$

$\Rightarrow \quad \sqrt{x^2 + y^2} = y\sqrt{1 + \left(\dfrac{dy}{dx}\right)^2}$

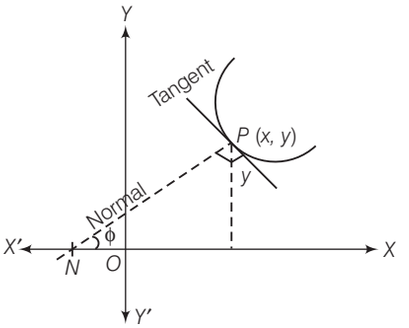

Figure 7.10

$\Rightarrow \quad x^2 + y^2 = y^2\left[1 + \left(\dfrac{dy}{dx}\right)^2\right]$

$\Rightarrow \quad x^2 = y^2\left(\dfrac{dy}{dx}\right)^2 \Rightarrow \dfrac{dy}{dx} = \pm\dfrac{x}{y}$

or $y\, dy = \pm\, x\, dx$

Integrating both the sides, we get

$y^2 = \pm\, x^2 + C$, which is the required family of curves.

Example 25 ***Find the condition that the line*** $x\cos\alpha + y\sin\alpha = p$ ***may touch the curve*** $\left(\dfrac{x}{a}\right)^m + \left(\dfrac{y}{b}\right)^m = 1$.

Sol. Given equation of curve is $\left(\dfrac{x}{a}\right)^m + \left(\dfrac{y}{b}\right)^m = 1$

Differentiating the equation of curve w.r.t. x, we get

$$m\left(\frac{x}{a}\right)^{m-1} \cdot \frac{1}{a} + m\left(\frac{y}{b}\right)^{m-1} \cdot \frac{1}{b} \cdot \frac{dy}{dx} = 0$$

On simplifying, we get $\dfrac{dy}{dx} = \dfrac{-b^m x^{m-1}}{a^m y^{m-1}}$

Now, at any point $P(x_1, y_1)$ on the curve,

slope of tangent $= \left(\dfrac{dy}{dx}\right)_{(x_1, y_1)} = \dfrac{-b^m x_1^{m-1}}{a^m y_1^{m-1}}$

$\therefore$ Equation of tangent at P is, $y - y_1 = \dfrac{-b^m x_1^{m-1}}{a^m y_1^{m-1}}(x - x_1)$

$\Rightarrow \quad \dfrac{yy_1^{m-1}}{b^m} - \dfrac{y_1^m}{b^m} = -\dfrac{xx_1^{m-1}}{a^m} + \dfrac{x_1^m}{a^m}$

i.e. $\dfrac{x}{a}\left(\dfrac{x_1}{a}\right)^{m-1} + \dfrac{y}{b}\left(\dfrac{y_1}{b}\right)^{m-1} = \left(\dfrac{x_1}{a}\right)^m + \left(\dfrac{y_1}{b}\right)^m = 1$

Since, P lies on the curve, therefore the equation of tangent at $P(x_1, y_1)$ on the curve is,

$$\frac{x}{a}\left(\frac{x_1}{a}\right)^{m-1}+\frac{y}{b}\left(\frac{y_1}{b}\right)^{m-1}=1 \quad \text{...(i)}$$

Also, we have $x\cos\alpha + y\sin\alpha = p$ ...(ii)

If Eq. (ii) is the equation of tangent, then coefficients of Eqs. (i) and (ii) must be proportional for point (x_1, y_1).

i.e. $$\frac{\cos\alpha}{\frac{1}{a}\left(\frac{x_1}{a}\right)^{m-1}}=\frac{\sin\alpha}{\frac{1}{b}\left(\frac{y_1}{b}\right)^{m-1}}=\frac{p}{1}$$

This gives $$\frac{x_1}{a}=\left(\frac{a\cos\alpha}{p}\right)^{\frac{1}{m-1}}, \frac{y_1}{b}=\left(\frac{b\sin\alpha}{p}\right)^{\frac{1}{m-1}}$$

Since, point $P(x_1, y_1)$ lies on the curve.

Therefore, we have $\left(\frac{x_1}{a}\right)^m+\left(\frac{y_1}{b}\right)^m=1$

i.e. $$\left(\frac{a\cos\alpha}{p}\right)^{\frac{m}{m-1}}+\left(\frac{b\sin\alpha}{p}\right)^{\frac{m}{m-1}}=1$$

i.e. $$(a\cos\alpha)^{\frac{m}{m-1}}+(b\sin\alpha)^{\frac{m}{m-1}}=p^{\frac{m}{m-1}},$$

which is the required condition.

Example 26 If tangent and normal to the curve $y=2\sin x+\sin 2x$ are drawn at $P\left(x=\frac{\pi}{3}\right)$, then area of the quadrilateral formed by the tangent, the normal at P and the coordinate axes is

(a) $\frac{\pi}{3}$ (b) 3π

(c) $\frac{\pi\sqrt{3}}{2}$ (d) None of these

Sol. Here, $\frac{dy}{dx}=0$ at $\left(x=\frac{\pi}{3}, y=\frac{3\sqrt{3}}{2}\right)$

$\Rightarrow$ Tangent at $x=\frac{\pi}{3}$ is parallel to X-axis.

$\Rightarrow$ Equation of tangent is, $y=\frac{3\sqrt{3}}{2}$

Also, equation of normal is, $x=\frac{\pi}{3}$

Now, area of quadrilateral $=\frac{\pi}{3}\cdot\frac{3\sqrt{3}}{2}=\frac{\pi\sqrt{3}}{2}$ sq unit

Hence, (c) is the correct answer.

Example 27 *The* ***maximum value of the sum of the intercepts made by any tangent to the curve*** $(a\sin^2\theta, 2a\sin\theta)$ ***with the axes is***

(a) $2a$ (b) $a/4$ (c) $a/2$ (d) a

Sol. The curve is $(a\sin^2\theta, 2a\sin\theta) \Rightarrow x=a\sin^2\theta, y=2a\sin\theta$

Now, the equation of any tangent to the curve is,

$$\frac{y-2a\sin\theta}{x-a\sin^2\theta}=\frac{1}{\sin\theta} \Rightarrow y\sin\theta = x+a\sin^2\theta$$

$$\Rightarrow \quad \frac{x}{-a\sin^2\theta}+\frac{y}{a\sin\theta}=1$$

$\Rightarrow$ Sum of intercepts $= a(\sin^2\theta+\sin\theta)$

$$=a\left\{\left(\sin\theta+\frac{1}{2}\right)^2-\frac{1}{4}\right\}$$

Which is maximum, when $\sin\theta=1$

i.e. $(\text{Sum of intercept})_{\max}=2a$

Hence, (a) is the correct answer.

Example 28 ***If*** $g(x)$ ***is a curve which is obtained by the reflection of*** $f(x)=\frac{e^x-e^{-x}}{2}$ ***by the line*** $y=x$, ***then***

(a) $g(x)$ has more than one tangent parallel to X-axis

(b) $g(x)$ has more than one tangent parallel to Y-axis

(c) $y=-x$ is a tangent to $g(x)$ at $(0, 0)$

(d) $g(x)$ has no extremum

Sol. As $g(x)$ is a curve, obtained by the reflection of $f(x)=\frac{e^x-e^{-x}}{2}$ on $y=x$.

so $g(x)$ is inverse of $f(x)$

$\therefore \quad g(x)=\log(x+\sqrt{1+x^2})=f^{-1}(x)$

$$\Rightarrow \quad g'(x)=\frac{1}{x+\sqrt{1+x^2}}\cdot\left(1+\frac{2x}{2\sqrt{1+x^2}}\right)$$

$$=\frac{1}{\sqrt{1+x^2}}\neq 0, \forall\, x\in R$$

$\Rightarrow g(x)$ has no tangent parallel to X-axis. Also, $g'(x)$ is always defined, $\forall\, x\in R$.

$\Rightarrow g(x)$ has no tangent parallel to Y-axis.

Since $g'(x)>0\ \forall x\in R$,

therefore $g(x)$ doesn't have any extremum.

Hence, (d) is the correct answer.

Exercise for Session 3

1. If the line $ax + by + c = 0$ is normal to the $xy + 5 = 0$, then a and b have

(a) same sign (b) opposite sign

(c) cannot be discussed (d) None of these

2. The equation of tangent drawn to the curve $y^2 - 2x^3 - 4y + 8 = 0$ from the point (1, 2) is given by

(a) $y - 2(1 \pm \sqrt{2}) = \pm 2\sqrt{3}\,(x - 2)$ (b) $y - 2(1 \pm \sqrt{3}) = \pm 2\sqrt{2}\,(x - 2)$

(c) $y - 2(1 \pm \sqrt{3}) = \pm 2\sqrt{3}\,(x - 2)$ (d) None of these

3. The equation of the tangents to the curve $(1 + x^2)y = 1$ at the points of its intersection with the curve $(x + 1)y = 1$, is given by

(a) $x + y = 1, y = 1$ (b) $x + 2y = 2, y = 1$

(c) $x - y = 1, y = 1$ (d) None of these

4. The tangent lines for the curve $y = \int_0^x 2|t|\,dt$ which are parallel to the bisector of the first coordinate angle, is given by

(a) $y = x + \frac{3}{4}, y = x - \frac{1}{4}$ (b) $y = -x + \frac{1}{4}, y = -x + \frac{3}{4}$

(c) $x + y = 2, x - y = 1$ (d) None of these

5. The equation of normal to $x + y = x^y$, where it intersects X-axis, is given by

(a) $x + y = 1$ (b) $x - y - 1 = 0$

(c) $x - y + 1 = 0$ (d) None of these

6. The equation of normal at any point θ to the curve $x = a\cos\theta + a\theta\sin\theta, y = a\sin\theta - a\theta\cos\theta$ is always at a distance of

(a) $2a$ unit from origin (b) a unit from origin

(c) $\frac{1}{2}a$ unit from origin (d) None of these

7. If the tangent at (x_0, y_0) to the curve $x^3 + y^3 = a^3$ meets the curve again at (x_1, y_1), then $\frac{x_1}{x_0} + \frac{y_1}{y_0}$ is equal to

(a) a (b) $2a$

(c) 1 (d) None of these

8. The area bounded by the axes of reference and the normal to $y = \log_e x$ at $(1, 0)$, is

(a) 1 sq unit (b) 2 sq units

(c) $\frac{1}{2}$ sq unit (d) None of these

9. If $\frac{x}{a} + \frac{y}{b} = 2$ touches the curve $\frac{x^n}{a^n} + \frac{y^n}{b^n} = 2$ at the point (α, β), then

(a) $\alpha = a^2, \beta = b^2$ (b) $\alpha = a, \beta = b$

(c) $\alpha = -2a, \beta = 4b$ (d) $\alpha = 3a, \beta = -2b$

10. The equation of tangents to the curve $y = \cos(x + y)$, $-2\pi \le x \le 2\pi$ that are parallel to the line $x + 2y = 0$, is

(a) $x + 2y = \frac{\pi}{2}$ and $x + 2y = -\frac{3\pi}{2}$ (b) $x + 2y = \frac{\pi}{2}$ and $x + 2y = \frac{3\pi}{2}$

(c) $x + 2y = 0$ and $x + 2y = \pi$ (d) None of these

Session 4

Angle of Intersection of Two Curves, Length of Tangent, Subtangent, Normal and Subnormal

Angle of Intersection of Two Curves

The angle of intersection of two curves is defined as the angle between the tangents to the two curves at their point of intersection.

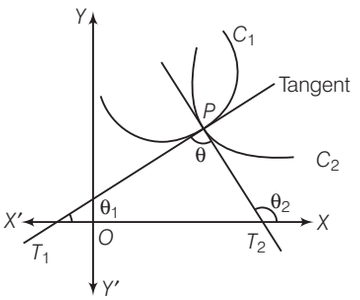

Figure 7.11

Let C_1 and C_2 be two curves having equations $y = f(x)$ and $y = g(x)$, respectively.

Let PT_1 and PT_2 be tangents to the curves C_1 and C_2 at their point of intersection.

Let θ be the angle between the two tangents PT_1 and PT_2 and θ_1 and θ_2 are the angles made by tangents with the positive direction of X-axis in anti-clockwise sense.

Then,
$$m_1 = \tan\theta_1 = \left(\frac{dy}{dx}\right)_{C_1}$$
$$m_2 = \tan\theta_2 = \left(\frac{dy}{dx}\right)_{C_2}$$

From the figure it follows, $\theta = \theta_2 - \theta_1$

$$\Rightarrow \quad \tan\theta = \tan(\theta_2 - \theta_1) = \frac{\tan\theta_2 - \tan\theta_1}{1 + \tan\theta_2 \tan\theta_1}$$

$$\Rightarrow \quad \tan\theta = \left|\frac{\left(\frac{dy}{dx}\right)_{C_1} - \left(\frac{dy}{dx}\right)_{C_2}}{1 + \left(\frac{dy}{dx}\right)_{C_1}\left(\frac{dy}{dx}\right)_{C_2}}\right|$$

Angle of intersection of these curves is defined as acute angle between the tangents.

Orthogonal Curves If the angle of intersection of two curves is a right angle, then the two curves are said to be orthogonal and the curves are called orthogonal curves.

$\therefore$ If the curves are orthogonal, then $\theta = \pi/2$

$$\Rightarrow \quad 1 + \left(\frac{dy}{dx}\right)_{C_1}\left(\frac{dy}{dx}\right)_{C_2} = 0$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{C_1}\left(\frac{dy}{dx}\right)_{C_2} = -1$$

Condition for Two Curves to Touch

If two curves touch each other, then

$$\theta = 0$$

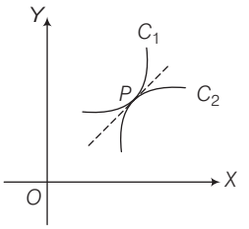

Figure 7.12

$$\Rightarrow \quad \tan\theta = 0$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{C_1} - \left(\frac{dy}{dx}\right)_{C_2} = 0$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{C_1} = \left(\frac{dy}{dx}\right)_{C_2}$$

Example 29 ***Find the angle of intersection of the curves*** $y = x^2$ ***and*** $y = 4 - x^2$.

Sol. For the intersection points of the given curves, consider

$$x^2 = 4 - x^2$$

$$\Rightarrow \quad x = \pm\sqrt{2}$$

Now, at $x = \sqrt{2}$, $\frac{dy}{dx}$ for first curve $= 2x|_{\text{at } x=\sqrt{2}} = 2\sqrt{2}$

While at $x = \sqrt{2}$,

$\frac{dy}{dx}$ for second curve $= -2x|_{at\ x=\sqrt{2}} = -2\sqrt{2}$

Hence, if θ_1 is the acute angle of intersection of the curves, then

$$\tan\theta_1 = \left|\frac{2\sqrt{2}-(-2\sqrt{2})}{1+2\sqrt{2}(-2\sqrt{2})}\right| = \left|\frac{4\sqrt{2}}{-7}\right|$$

$$\therefore \quad \theta_1 = \tan^{-1}\left(\frac{4\sqrt{2}}{7}\right) \qquad ...(i)$$

Again, at $x=-\sqrt{2}$,

$$\left(\frac{dy}{dx}\right) \text{ for first curve} = -2\sqrt{2}$$

and $$\left(\frac{dy}{dx}\right) \text{ for second curve} = 2\sqrt{2}$$

Hence, if θ_2 is the acute angle of intersection of the curves, then

$$\tan\theta_2 = \left|\frac{-2\sqrt{2}-2\sqrt{2}}{1+(-2\sqrt{2})(2\sqrt{2})}\right|$$

$$\therefore \quad \theta_2 = \tan^{-1}\left(\frac{4\sqrt{2}}{7}\right) \qquad ...(ii)$$

From Eqs. (i) and (ii) the two acute angles are equal.

Example 30 ***Find the acute angle between the curves*** $y=|x^2-1|$ ***and*** $y=|x^2-3|$ ***at their points of intersection when*** $x>0$.

Sol. For the intersection of the given curves,

$$|x^2-1| = |x^2-3| \Rightarrow (x^2-1)^2 = (x^2-3)^2$$

$$\Rightarrow \quad (x^2-1)^2-(x^2-3)^2 = 0$$

$$\Rightarrow \quad [(x^2-1)-(x^2-3)][(x^2-1)+(x^2-3)] = 0$$

$$\Rightarrow \quad 2[2x^2-4] = 0 \Rightarrow 2x^2 = 4 \Rightarrow x = \pm\sqrt{2}$$

Neglecting $x=-\sqrt{2}$, as $x>0$

Now, we have, point of intersection as $x=\sqrt{2}$.

Here, $y=|x^2-1|=(x^2-1)$ in the neighbourhood of $x=\sqrt{2}$ and $y=-(x^2-3)$ in the neighbourhood of $x=\sqrt{2}$.

Now, at $x=\sqrt{2}$, $\frac{dy}{dx}$ for first curve

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{C_1} = 2x = 2\sqrt{2}$$

and $\frac{dy}{dx}$ for second curve $\left(\frac{dy}{dx}\right)_{C_2} = -2x = -2\sqrt{2}$

Hence, if θ is angle between them, then

$$\tan\theta = \left|\frac{2\sqrt{2}-(-2\sqrt{2})}{1+2\sqrt{2}(-2\sqrt{2})}\right| = \left|\frac{4\sqrt{2}}{-7}\right| = \left(\frac{4\sqrt{2}}{7}\right)$$

$$\therefore \quad \theta = \tan^{-1}\left(\frac{4\sqrt{2}}{7}\right)$$

Example 31 Find the angle of intersection of curves, $y=[|\sin x|+|\cos x|]$ and $x^2+y^2=5$, where $[\cdot]$ denotes the greatest integral function.

Sol. We know that, $1 \le |\sin x| + |\cos x| \le \sqrt{2}$

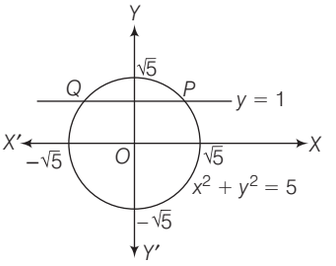
$$\therefore \quad y = [|\sin x| + |\cos x|] = 1$$

Let P and Q be the points of intersection of given curves.

Clearly, the given curves meet at points where $y=1$, so we get $x^2+1=5$

$$\Rightarrow \quad x = \pm 2$$

Now, we have $P(2, 1)$ and $Q(-2, 1)$



Differentiating $x^2+y^2=5$ w.r.t. x, we get

$$2x + 2y\frac{dy}{dx} = 0$$

$$\Rightarrow \quad \frac{dy}{dx} = -\frac{x}{y}$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(2,\,1)} = -2$$

and $$\left(\frac{dy}{dx}\right)_{(-2,\,1)} = 2$$

Clearly, the slope of line $y=1$ is zero and the slope of the tangents at P and Q are (-2) and (2), respectively.

Thus, the angle of intersection is $\tan^{-1}(2)$.

Length of Tangent, Subtangent, Normal and Subnormal

Length of Tangent The length of the segment PT, i.e. the portion of the tangent intercepted between the point of contact and X-axis is called the length of tangent.

Subtangent and its Length The projection of the segment PT along X-axis is called the subtangent. Here, ST is the length of subtangent.

Length of Normal The length of segment PN, i.e. the portion of the normal intercepted between the point on the curve and X-axis is called the length of normal.

Subnormal and its Length

The projection of the segment PN along X-axis is called the subnormal. Here, SN is the length of sub normal.

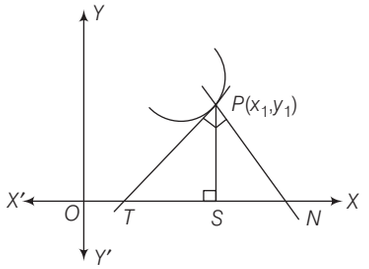


Figure 7.13

From the figure, if PT makes an angle θ with X-axis, then

$$\tan\theta = \left(\frac{dy}{dx}\right)_{(x_1,\,y_1)}$$

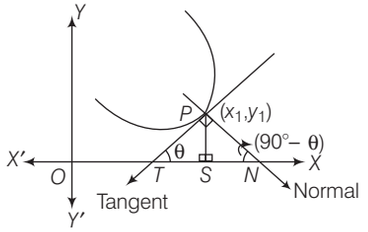

Figure 7.14

Also, we have $\dfrac{ST}{PS} = \cot\theta \Rightarrow ST = PS\cot\theta$

or **subtangent** $= ST = \left| y_1 \left(\dfrac{dx}{dy}\right)_{(x_1,\,y_1)} \right|$

Similarly, $\dfrac{SN}{PS} = \cot(90^\circ - \theta)$

$\Rightarrow$ Subnormal $= SN = PS\tan\theta$

$\Rightarrow$ **Subnormal** $= SN = \left| y_1 \left(\dfrac{dy}{dx}\right)_{(x_1,\,y_1)} \right|$

Now, **length of tangent**

$$= PT = \left| \sqrt{y_1^2 + y_1^2 \left(\frac{dx}{dy}\right)^2_{(x_1,\,y_1)}} \right|$$

$$\Rightarrow \quad PT = \left| y_1 \sqrt{1 + \left(\frac{dx}{dy}\right)^2_{(x_1,\,y_1)}} \right|$$

and **length of normal** $= PN = \left| \sqrt{y_1^2 + y_1^2 \left(\dfrac{dy}{dx}\right)^2_{(x_1,\,y_1)}} \right|$

$$\Rightarrow \quad PN = \left| y_1 \sqrt{1 + \left(\frac{dy}{dx}\right)^2_{(x_1,\,y_1)}} \right|$$

Example 32 ***Show that for the curve $y = be^{x/a}$, the subtangent is of constant length and the subnormal varies as the square of ordinate.***

Sol. The equation of given curve is $y = be^{x/a}$

Let us consider a point (x_1, y_1) on the curve.

Then, we have $y_1 = be^{x_1/a}$ ...(i)

Differentiating the curve $y = be^{x/a}$ w.r.t. x, we get

$$\frac{dy}{dx} = be^{x/a}\cdot\frac{1}{a}$$

$$\therefore \quad \left(\frac{dy}{dx}\right)_{(x_1,\,y_1)} = \frac{b}{a}e^{x_1/a} \qquad \text{...(ii)}$$

Thus, the length of subtangent $= \left| y_1 \left(\dfrac{dx}{dy}\right)_{(x_1,\,y_1)} \right|$

$$= \left| y_1 \cdot \frac{a}{be^{x_1/a}} \right| = \left| be^{x_1/a} \cdot \frac{a}{be^{x_1/a}} \right|$$

$= a$ (constant) [using Eqs. (i) and (ii)]

$\Rightarrow$ Subtangent is of constant length a.

Again, length of subnormal $= \left| y_1 \left(\dfrac{dy}{dx}\right)_{(x_1,\,y_1)} \right|$

$$= \left| be^{x_1/a} \cdot \frac{be^{x_1/a}}{a} \right| = \frac{1}{a}(be^{x_1/a})^2 = \frac{1}{a}y^2$$ [using Eq. (i)]

Therefore, subnormal varies as the square of ordinate.

Example 33 ***Find the length of tangent, subtangent, normal and subnormal to $y^2 = 4ax$ at $(at^2, 2at)$.***

Sol. The equation of given curve is

$$y^2 = 4ax \qquad \text{...(i)}$$

Differentiating Eq. (i) w.r.t. x, we get

$$2y\frac{dy}{dx} = 4a$$

$$\Rightarrow \quad \left[\frac{dy}{dx}\right]_{(at^2,\,2at)} = \frac{4a}{4at} = \frac{1}{t} \qquad \text{...(ii)}$$

Now, the length of tangent at $(at^2, 2at)$ is

$$= y_1\sqrt{1 + \left(\frac{dx}{dy}\right)^2_{(x_1,\,y_1)}} = 2at\sqrt{1 + t^2}$$ [using Eq. (ii)]

length of normal at $(at^2, 2at)$ is

$$= y_1\sqrt{1 + \left(\frac{dy}{dx}\right)^2_{(x_1,\,y_1)}} = 2at\sqrt{1 + 1/t^2} = 2a\sqrt{t^2 + 1}$$

length of subtangent is

$$\frac{y_1}{\left[\dfrac{dy}{dx}\right]_{(x_1,\,y_1)}} = \frac{2at}{1/t} = 2at^2$$

and length of subnormal is

$$y_1\left[\frac{dy}{dx}\right]_{(x_1,\ y_1)} = 2at \cdot \frac{1}{t} = 2a$$

Example 34 Find the equation of tangent and normal, the length of subtangent and subnormal of the circle $x^2 + y^2 = a^2$ at the point (x_1, y_1).

Sol. The equation of given curve is,

$$x^2 + y^2 = a^2 \qquad ...(i)$$

Differentiating Eq. (i) w.r.t. x, we get

$$2x + 2y\frac{dy}{dx} = 0$$

$$\Rightarrow \qquad \left(\frac{dy}{dx}\right)_{(x_1,\ y_1)} = -\frac{x_1}{y_1} \qquad ...(ii)$$

Thus, the equation of tangent is,

$$y - y_1 = \left[\frac{dy}{dx}\right]_{(x_1,\ y_1)}(x - x_1)$$

$$\Rightarrow \qquad y - y_1 = -\frac{x_1}{y_1}(x - x_1) \qquad \text{[from Eq. (ii)]}$$

$$\Rightarrow \qquad yy_1 - y_1^2 = -xx_1 + x_1^2$$

$$\Rightarrow \qquad xx_1 + yy_1 = x_1^2 + y_1^2$$

$$\Rightarrow \qquad xx_1 + yy_1 = a^2 \qquad \text{[using Eq. (i) as } (x_1, y_1) \text{ lies on } x^2 + y^2 = a^2 \Rightarrow x_1^2 + y_1^2 = a^2\text{]}$$

While the equation of normal is,

$$y - y_1 = \frac{y_1}{x_1}(x - x_1)$$

$$\Rightarrow \qquad x_1y - x_1y_1 = xy_1 - x_1y_1 \Rightarrow xy_1 - x_1y = 0$$

The length of subtangent $= \left|y_1 \cdot \left(\frac{dx}{dy}\right)_{(x_1,\ y_1)}\right|$

$$= \left|y_1 \cdot \left(\frac{-y_1}{x_1}\right)\right| \qquad \text{[using Eq. (ii)]}$$

$\Rightarrow$ The length of subtangent $= \left|\frac{y_1^2}{x_1}\right|$

While the length of subnormal $= \left|y_1 \cdot \left(\frac{dy}{dx}\right)_{(x_1,\ y_1)}\right|$

$$= \left|y_1\left(-\frac{x_1}{y_1}\right)\right| = |x_1|$$

Example 35 If the relation between subnormal SN and subtangent ST on the curve, $by^2 = (x + a)^3$ is $p(SN) = q(ST)^2$, then find the value of $\frac{p}{q}$.

Sol. The equation of given curve is $by^2 = (x + a)^3$

Differentiating both the sides w.r.t. x, we get

$$2by\frac{dy}{dx} = 3(x + a)^2 \cdot 1$$

$$\Rightarrow \qquad \frac{dy}{dx} = \frac{3}{2}\frac{(x + a)^2}{by}$$

$\therefore$ Length of subnormal

$$\Rightarrow \qquad SN = y\frac{dy}{dx} = \frac{3}{2} \cdot \frac{(x + a)^2}{b} \qquad ...(i)$$

and Length of subtangent

$$\Rightarrow \qquad ST = y\frac{dx}{dy} = \frac{2by^2}{3(x + a)^2} \qquad ...(ii)$$

$$\because \qquad \frac{p}{q} = \frac{(ST)^2}{(SN)} \qquad \text{[given]}$$

$$\therefore \qquad \frac{p}{q} = \frac{(2by^2)^2 \cdot 2b}{\{3(x + a)^2\}^2 \cdot 3(x + a)^2} \qquad \text{[using Eqs. (i) and (ii)]}$$

$$= \frac{8b}{27} \cdot \frac{\{(x + a)^3\}^2}{(x + a)^6} = \frac{8b}{27} \qquad \text{[using, } by^2 = (x + a)^3\text{]}$$

$$\therefore \qquad \frac{p}{q} = \frac{8b}{27}$$

Example 36 ***If the length of subnormal is equal to length of subtangent at any point*** $(3, 4)$ ***on the curve*** $y = f(x)$ ***and the tangent at (3, 4) to*** $y = f(x)$ ***meets the coordinate axes at A and B, then maximum area of the*** ΔOAB ***where O is origin, is***

(a) $\frac{45}{2}$ (b) $\frac{49}{2}$ (c) $\frac{25}{2}$ (d) $\frac{81}{2}$

Sol. Length of subnormal = Length of subtangent

$$\Rightarrow \qquad \frac{dy}{dx} = \pm 1$$

If $\frac{dy}{dx} = 1$, then equation of tangent is,

$$y - 4 = x - 3 \Rightarrow y - x = 1$$

$\therefore$ Area of $\Delta OAB = \frac{1}{2} \times 1 \times 1 = \frac{1}{2}$ ...(i)

If $\frac{dy}{dx} = -1$, then equation of tangent is,

$$y - 4 = -x + 3 \Rightarrow x + y = 7$$

$\therefore$ Area of $\Delta OAB = \frac{1}{2} \times 7 \times 7 = \frac{49}{2}$ ...(ii)

Clearly, maximum area $= \frac{49}{2}$

Hence, (b) is the correct answer.

Exercise for Session 4

1. The angle of intersection of $y = a^x$ and $y = b^x$, is given by

(a) $\tan\theta = \left|\frac{\log(ab)}{1-\log(ab)}\right|$ (b) $\tan\theta = \left|\frac{\log(a/b)}{1+\log a \log b}\right|$

(c) $\tan\theta = \left|\frac{\log(a/b)}{1-\log(a/b)}\right|$ (d) None of these

2. The angle between the curves $x^2 + 4y^2 = 32$ and $x^2 - y^2 = 12$, is

(a) $\frac{\pi}{3}$ (b) $\frac{\pi}{4}$ (c) $\frac{\pi}{6}$ (d) $\frac{\pi}{2}$

3. If $ax^2 + by^2 = 1$ cuts $a'x^2 + b'y^2 = 1$ orthogonally, then

(a) $\frac{1}{a} - \frac{1}{a'} = \frac{1}{b} - \frac{1}{b'}$ (b) $\frac{1}{a} + \frac{1}{a'} = \frac{1}{b} + \frac{1}{b'}$

(c) $\frac{1}{a} + \frac{1}{b} = \frac{1}{a'} + \frac{1}{b'}$ (d) None of these

4. The length of subtangent to the curve, $y = e^{x/a}$, is

(a) $2a$ (b) a (c) $a/2$ (d) $a/4$

5. The length of normal to the curve $x = a(\theta + \sin\theta)$, $y = a(1 - \cos\theta)$, at $\theta = \frac{\pi}{2}$ is

(a) $2a$ (b) a (c) $\sqrt{2}a$ (d) $2\sqrt{2}a$

6. The length of tangent to the curve $y = x^3 + 3x^2 + 4x - 1$ at a point $x = 0$, is

(a) $\frac{1}{4}$ (b) $\frac{\sqrt{17}}{4}$ (c) $\frac{3}{4}$ (d) $\frac{\sqrt{15}}{4}$

7. The possible values of p such that the equation $px^2 = \log x$ has exactly one solution, are

(a) R (b) R^+ (c) $(-\infty, 0] \cup \left\{\frac{1}{2e}\right\}$ (d) $[0, \infty)$

8. If curve $y = 1 - ax^2$ and $y = x^2$ intersect orthogonally then a is

(a) $\frac{1}{2}$ (b) $\frac{1}{3}$ (c) 2 (d) 3

9. The length of tangent to the curve $x = a\left(\cos t + \log\tan\frac{t}{2}\right)$, $y = a(\sin t)$, is

(a) ax (b) ay (c) a (d) xy

10. The lines tangent to the curves $y^3 - `x^2y + 5y - 2x = 0$ and $x^4 - x^3y^2 + 5x + 2y = 0$ at the origin intersect at an angle θ equal to

(a) $\frac{\pi}{6}$ (b) $\frac{\pi}{4}$ (c) $\frac{\pi}{3}$ (d) $\frac{\pi}{2}$

Session 5

Rolle's Theorem, Lagrange's Mean Value Theorem

Rolle's Theorem

The theorem was named after the French Mathematician Michel Rolle (1652–1719). Who first gave it in his book *Methode pour resoudre lesegalites* (1691).

Statement

Let f be a real-valued function defined on the closed interval $[a, b]$ such that

(i) $f(x)$ is continuous in the closed interval $[a, b]$

(ii) $f(x)$ is differentiable in the open interval $]a, b[$ and

(iii) $f(a) = f(b)$

Then, there is atleast one value c of x in open interval $]a, b[$ for which $f'(c) = 0$.

Analytical Proof

Now, Rolle's theorem is valid for a function such that

(i) $f(x)$ is continuous in the closed interval $[a, b]$

(ii) $f(x)$ is differentiable in open interval $]a, b[$ and

(iii) $f(a) = f(b)$

So, generally two cases arise in such circumstances.

***Case* I** $f(x)$ is constant in the interval $[a, b]$, then $f'(x) = 0$ for all $x \in [a, b]$.

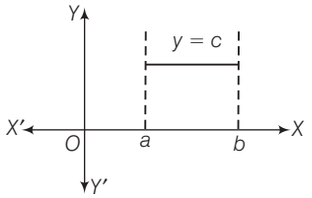

***Figure* 7.15**

Hence, Rolle's theorem follows and we can say, $f'(c) = 0$, where $a < c < b$

***Case* II** $f(x)$ is not constant in the interval $[a, b]$ and since $f(a) = f(b)$.

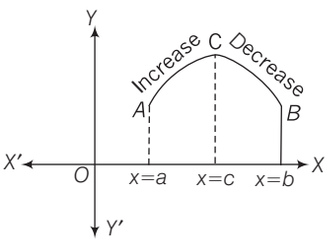

***Figure* 7.16**

The function should either increase or decrease when x assumes values slightly greater than a.

Now, let $f(x)$ increases for $x > a$.

Since, $f(a) = f(b)$, hence the function increase at some value $x = c$ and decrease upto $x = b$.

Clearly, at $x = c$ function has maximum value.

Now, let h be a small positive quantity, then from definition of maximum value of the function,

$$f(c + h) - f(c) < 0$$

and $$f(c - h) - f(c) < 0$$

$\therefore$ $$\frac{f(c + h) - f(c)}{h} < 0$$

and $$\frac{f(c - h) - f(c)}{-h} > 0$$

So, $$\lim_{h \to 0} \frac{f(c + h) - f(c)}{h} \leq 0$$

and $$\lim_{h \to 0} \frac{f(c - h) - f(c)}{-h} \geq 0 \quad \text{...(i)}$$

But, if $$\lim_{h \to 0} \frac{f(c + h) - f(c)}{h} \neq \lim_{h \to 0} \frac{f(c - h) - f(c)}{-h}$$

Then, Rolle's theorem cannot be applied because in such case,

$$\text{RHD at } x = c \neq \text{LHD at } x = c.$$

Hence, $f(x)$ is not differentiable at $x = c$, which contradicts the condition of Rolle's theorem.

$\therefore$ Only one possible solution arises, when

$$\lim_{h \to 0} \frac{f(c + h) - f(c)}{h} = \lim_{h \to 0} \frac{f(c - h) - f(c)}{-h} = 0$$

which implies that, $f'(c) = 0$ where $a < c < b$.

Hence, Rolle's theorem is proved.

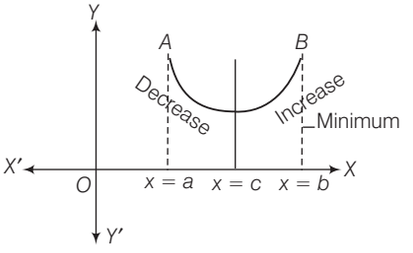

***Figure* 7.17**

Similarly, the case where $f(x)$ decreases in the interval $a < x < c$ and then increases in the interval $c < x < b$, $f'(c) = 0$, but when $x = c$, the minimum value of $f(x)$ exists in the interval $[a, b]$.

Geometrical Proof

Consider the portion AB of the curve $y = f(x)$, lying between $x = a$ and $x = b$, such that

(i) it goes continuously from A to B

(ii) it has tangent at every point between A and B

(iii) ordinate of A = ordinate of B

From the figure, it is clear that $f(x)$ **increases in the interval** AC_1, which implies that $f'(x) > 0$ in this region and decreases in the interval C_1B which implies $f'(x) < 0$ in this region. Now, **since there is unique tangent to be drawn on the curve lying in between A and B and since each of them has a unique slope, i.e. unique value of $f'(x)$.**

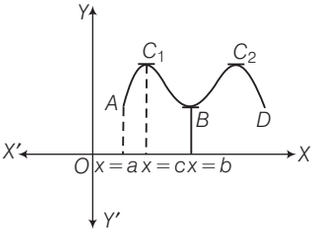

Figure 7.18

So, due to continuity and differentiability of the function $f(x)$ in the region A to B, there is a point $x = c$, where $f'(c)$ should be zero.

Hence, $f'(c) = 0$, where $a < c < b$

Thus, Rolle's theorem is proved.

Remarks

Generally, two types of problems are formulated on Rolle's theorem.

(i) To check the applicability of Rolle's theorem to a given function on a given interval

(ii) To verify Rolle's theorem for a given function in a given interval.

In both the types of problems, first we check whether $f(x)$ satisfies the conditions of Rolle's theorem or not.

Some Important Results Regarding Rolle's Theorem

(i) A polynomial function is everywhere continuous and differentiable.

(ii) The exponential function, sine and cosine functions are everywhere continuous and differentiable.

(iii) Logarithmic functions is continuous and differentiable in its domain.

(iv) $\tan x$ is not continuous and differentiable at $x = \pm\pi/2, \pm 3\pi/2, \pm 5\pi/2, \ldots\ldots$

(v) $|x|$ is not differentiable at $x = 0$.

(vi) If $f'(x)$ tends to $\pm\infty$ as $x \to k$, then $f(x)$ is not differentiable at $x = k$.

e.g. If $f(x) = (2x - 1)^{1/2}$, then $f'(x) = \dfrac{1}{\sqrt{2x - 1}}$ is such that as

$$x \to \left(\frac{1}{2}\right)^{+} \quad \Rightarrow \quad f'(x) \to \infty$$

So, $f(x)$ is not differentiable at $x = 1/2$.

Example 37 Verify Rolle's theorem for the function $f(x) = x^3 - 3x^2 + 2x$ in the interval $[0, 2]$.

Sol. Here, we observe that

(a) $f(x)$ is polynomial and since polynomials are always continuous, so $f(x)$ is continuous in the interval $[0, 2]$.

(b) $f'(x) = 3x^2 - 6x + 2$, which exists for all $x \in (0, 2)$. So, $f(x)$ is differentiable for all $x \in (0, 2)$ and

(c) $f(0) = 0$, $f(2) = 2^3 - 3 \cdot (2)^2 + 2(2) = 0$

$\therefore \quad f(0) = f(2)$

Thus, all the conditions of Rolle's theorem are satisfied.

So, there must exists some $c \in (0, 2)$ such that $f'(c) = 0$

$\Rightarrow \quad f'(c) = 3c^2 - 6c + 2 = 0 \Rightarrow c = 1 \pm \dfrac{1}{\sqrt{3}}$.

Where, $c = 1 \pm \dfrac{1}{\sqrt{3}} \in (0, 2)$, thus Rolle's theorem is verified.

Example 38 If $ax^2 + bx + c = 0$, $a, b, c \in R$, then find the condition that this equation would have at least one root in (0, 1).

Sol. Let $f'(x) = ax^2 + bx + c$

Integrating both sides, we get

$$f(x) = \frac{ax^3}{3} + \frac{bx^2}{2} + cx + d$$

$$\Rightarrow \quad f(0) = d \text{ and } f(1) = \frac{a}{3} + \frac{b}{2} + c + d$$

Now, for Rolle's theorem to be applicable, we should have

$$f(0) = f(1)$$

$$\Rightarrow \quad d = \frac{a}{3} + \frac{b}{2} + c + d$$

$$\Rightarrow \quad 2a + 3b + 6c = 0$$

Here, the required condition is $2a + 3b + 6c = 0$.

Example 39 If $f(x)$ and $g(x)$ are continuous functions in $[a, b]$ and they are differentiable in (a, b), then prove that there exists $c \in (a, b)$ such that

$$\begin{vmatrix} f(a) & f(b) \\ g(a) & g(b) \end{vmatrix} = (b - a) \begin{vmatrix} f(a) & f'(c) \\ g(a) & g'(c) \end{vmatrix}$$

Sol. Consider a function, $\phi(x) = f(a)\,g(x) - f(x)\,g(a)$ for all $x \in [a, b]$.

As, $\phi(x)$ is continuous and differentiable on (a, b).

$$\therefore \quad \phi'(c) = \frac{\phi(b) - \phi(a)}{b - a} \text{ for some } c \in (a, b). \qquad \text{...(i)}$$

Now, as $\phi(x) = f(a)\,g(x) - f(x)\,g(a)$

$$\therefore \quad \phi'(x) = f(a)\,g'(x) - f'(x)\,g(a)$$

$$\Rightarrow \quad \phi'(c) = f(a)\,g'(c) - f'(c)\,g(a)$$

$$\Rightarrow \quad \phi'(c) = \begin{vmatrix} f(a) & f'(c) \\ g(a) & g'(c) \end{vmatrix}$$

Also, $$\phi(b) = f(a)\,g(b) - f(b)\,g(a) = \begin{vmatrix} f(a) & f(b) \\ g(a) & g(b) \end{vmatrix}$$

and $$\phi(a) = f(a)\,g(a) - f(a)\,g(a) = 0$$

$\therefore$ Eq. (i) reduces to;

$$\begin{vmatrix} f(a) & f'(c) \\ g(a) & g'(c) \end{vmatrix} = \frac{1}{(b-a)} \begin{vmatrix} f(a) & f(b) \\ g(a) & g(b) \end{vmatrix}$$

or $$\begin{vmatrix} f(a) & f(b) \\ g(a) & g(b) \end{vmatrix} = (b-a) \begin{vmatrix} f(a) & f'(c) \\ g(a) & g'(c) \end{vmatrix}$$

Example 40 Use Rolle's theorem to find the condition for the polynomial equation $f(x) = 0$ to have a repeated real roots. Hence, or otherwise prove that the equation;

$1 + \frac{x}{1!} + \frac{x^2}{2!} + \ldots + \frac{x^n}{n!} = 0$, cannot have repeated roots.

Sol. By Rolle's theorem, we can say that between any two roots of a polynomial there is always a root of its derivative. Thus, if α is a repeated root of a polynomial $f(x)$, then there must be a root of $f'(x)$ in the interval.

$$\Rightarrow \quad f'(\alpha) = 0$$

i.e. $f(\alpha) = f'(\alpha) = 0$, for α to be a repeated root.

Let $\phi(x) = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \ldots + \frac{x^n}{n!}$ has a repeated root α.

$$\Rightarrow \quad \phi(\alpha) = 0$$

and $$\phi'(\alpha) = 0$$

$$\Rightarrow \quad 1 + \frac{\alpha}{1!} + \frac{\alpha^2}{2!} + \ldots + \frac{\alpha^n}{n!} = 0$$

and $$1 + \alpha + \frac{\alpha^2}{2!} + \ldots + \frac{\alpha^{n-1}}{(n-1)!} = 0$$

Solving above equations, we get

$$\frac{\alpha^n}{n!} = 0$$

or $\alpha = 0$, thus 0 is the repeated root of $\phi(x) = 0$.

But, 0 doesn't satisfy $\phi(x)$.

$\therefore$ There is no repeated root of $\phi(x) = 0$.

Example 41 Let $f(x)$ and $g(x)$ be differentiable functions such that $f'(x)g(x) \neq f(x)g'(x)$ for any real x. Show that between any two real solutions of $f(x) = 0$, there is atleast one real solution of $g(x) = 0$.

Sol. Let a, b be the solutions of $f(x) = 0$.

Suppose $g(x)$ is not equal to zero for any x belonging to $[a, b]$.

Now, consider $h(x) = f(x) / g(x)$

Since, $g(x)$ is not equal to zero, therefore

$h(x)$ is differentiable and continuous in $[a, b]$.

Also, $h(a) = h(b) = 0$

[as $f(a) = 0$ and $f(b) = 0$ but $g(a)$ and $g(b) \neq 0$]

Applying Rolle's theorem for $h(x)$ in $[a, b]$, we get

$h'(c) = 0$ for some c belonging to (a, b)

$$\Rightarrow \quad f(c)g'(c) = f'(c)g(c), \text{ for some } c \in (a, b).$$

This gives the contradiction. **Hence proved**.

Example 42 Consider the function $f(x) = \begin{cases} x \sin\frac{\pi}{x}, & \text{for } x > 0 \\ 0, & \text{for } x = 0 \end{cases}$, then the number of points in (0, 1), where the derivative $f'(x)$ tends to zero is

(a) 0 (b) 1 (c) 2 (d) infinite ***[IIT 2010]***

Sol. $f(x)$ tends to zero at points, where $\sin\frac{\pi}{x} = 0$

i.e. $\frac{\pi}{x} = k\pi$, $k = 1, 2, 3, 4, \ldots$

Hence, $x = \frac{1}{k}$.

Also, $$f'(x) = \sin\frac{\pi}{x} - \frac{\pi}{x}\cos\frac{\pi}{x}, \quad \text{if } x \neq 0$$

Since, the function has a derivative at any interior point of the interval (0, 1), also continuous in [0, 1] and $f(0) = f(1)$, therefore Rolle's theorem is applicable to any one of the intervals $\left[\frac{1}{2}, 1\right], \left[\frac{1}{3}, \frac{1}{2}\right], \ldots, \left[\frac{1}{k+1}, \frac{1}{k}\right]$.

Hence, there exists some c in each of these intervals, where $f'(c) = 0 \Rightarrow$ Infinite points.

Hence, (d) is the correct answer.

Lagrange's Mean Value Theorem

First Form

If a function $f(x)$,

(i) is continuous in the closed interval $[a, b]$ and

(ii) is differentiable in the open interval $]a, b[$

Then, there is at least one value $c \in (a, b)$, such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

Proof Consider the function,

$$\phi(x) = f(x) - \frac{f(b) - f(a)}{b - a}\, x$$

Since, $f(x)$ is continuous in $[a, b]$.

$\therefore$ $\phi(x)$ is also continuous in $[a, b]$.

Since, $f'(x)$ exists in (a, b), therefore $\phi'(x)$ also exists in (a, b) and

$$\phi'(x) = f'(x) - \frac{f(b) - f(a)}{b - a} \qquad ...(i)$$

Also, we have $\phi(a) = \phi(b)$.

Thus, $\phi(x)$ satisfies all the conditions of Rolle's theorem.

$\therefore$ There is atleast one value of c of x between a and b, such that $\phi'(c) = 0$

On substituting $x = c$ in Eq. (i), we get

$$f'(c) = \frac{f(b) - f(a)}{b - a}, \text{ which proves the theorem.}$$

Second Form

If we write $b = a + h$, then $c = a + \theta h$, where $0 < \theta < 1$.

$[\because \ a < c < b]$

Thus, the mean value theorem can be stated as follows:

If (i) $f(x)$ is continuous in closed interval $[a, a + h]$.

(ii) $f'(x)$ exists in the open interval $]a, a + h[$, then there exists at least one number θ $(0 < \theta < 1)$, such that $f(a + h) = f(a) + hf'(a + \theta h)$

Geometrical Interpretation of Lagrange's Theorem

Let A, B be the points on the curve $y = f(x)$ corresponding to $x = a$ and $x = b$, so that $A = [a, f(a)]$ and $B = [b, f(b)]$

Now, slope of chord $AB = \dfrac{f(b) - f(a)}{b - a}$

The slope of the chord $AB = f'(c)$, the slope of the tangent to the curve at $x = c$.

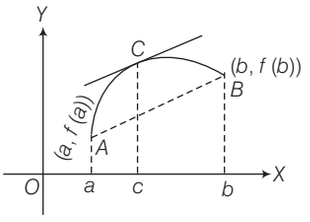

Figure 7.19

Hence, the Lagrange's mean value theorem asserts that if a curve has a tangent at each of its points, then there is a point c on this curve in between A and B, the tangent at which is parallel to the chord AB.

Example 43 ***Find*** c ***of the Lagrange's mean value theorem for which*** $f(x) = \sqrt{25 - x^2}$ ***in*** $[1, 5]$ **.**

Sol. It is clear that $f(x)$ has a definite and unique value for each $x \in [1, 5]$.

Thus, for every point in the interval $[1, 5]$ the value of $f(x)$ is equal to the limit of $f(x)$.

So, $f(x)$ is continuous in the interval $[1, 5]$.

Also, $f'(x) = \dfrac{-x}{\sqrt{25 - x^2}}$, which clearly exists for all x in open interval $(1, 5)$

Hence, $f(x)$ is differentiable in $(1, 5)$.

So, there must be a value $c \in (1, 5)$ such that,

$$f'(c) = \frac{f(5) - f(1)}{5 - 1} = \frac{0 - \sqrt{24}}{4} = \frac{-\sqrt{6}}{2}$$

But $\quad f'(c) = \dfrac{-c}{\sqrt{25 - c^2}}$

$$\therefore \quad \frac{-c}{\sqrt{25 - c^2}} = \frac{-\sqrt{6}}{2} \ \Rightarrow \ 4c^2 = 6(25 - c^2)$$

$$\Rightarrow \quad c = \pm\sqrt{15}$$

Clearly, $c = \sqrt{15} \in (1, 5)$. So, for $c = \sqrt{15}$ Lagrange's theorem is satisfied.

Example 44 ***Let*** $f(x)$ ***and*** $g(x)$ ***be differentiable for*** $0 \le x \le 2$ ***such that*** $f(0) = 2, g(0) = 1$ ***and*** $f(2) = 8$***. Let there exists a real number c in [0, 2] such that*** $f'(c) = 3g'(c)$***, then the value of*** $g(2)$ ***must be***

(a) 2 (b) 3 (c) 4 (d) 5

Sol. As $f(x)$ and $g(x)$ are continuous and differentiable in $[0, 2]$, therefore there exists atleast one value 'c' such that

$$\frac{f'(c)}{g'(c)} = \frac{f(2) - f(0)}{g(2) - g(0)} \Rightarrow \frac{8 - 2}{g(2) - 1} = 3$$

$$\Rightarrow \quad g(2) - 1 = 2 \ \Rightarrow \ g(2) = 3$$

Hence, (b) is the correct answer.

Example 45 ***If*** $f(x) = \log_e x$, $g(x) = x^2$ ***and*** $c \in (4, 5)$, ***then*** $c \log\left(\dfrac{4^{25}}{5^{16}}\right)$ ***is equal to***

(a) $c \log_e 5 - 8$ (b) $2(c^2 \log_e 4 - 8)$

(c) $2(c^2 \log_e 5 - 8)$ (d) $c \log_e 4 - 8$

Sol. Let $\phi(x) = x^2 (\log_e 4) - 16 \log_e x$, which is continuous in $[4, 5]$ and differentiable in $(4, 5)$.

Then, by Lagrange's theorem, we get

$$\frac{\phi(5) - \phi(4)}{5 - 4} = \phi'(c), \text{ for some } c \in (4, 5)$$

Now, $$\phi(5) - \phi(4) = \log_e\left(\frac{4^{25}}{5^{16}}\right)$$

Also, $$\phi'(c) = \frac{2}{c}(c^2 \log_e 4 - 8)$$

$$\therefore \quad \phi'(c) = \frac{\phi(5) - \phi(4)}{5 - 4}$$

$$\Rightarrow \quad \frac{2}{c}(c^2 \log_e 4 - 8) = \log_e\left(\frac{4^{25}}{5^{16}}\right)$$

or $$c \log\left(\frac{4^{25}}{5^{16}}\right) = 2(c^2 \log 4 - 8)$$

Hence, (b) is the correct answer.

Example 46 *If* $0 < a < b < \frac{\pi}{2}$ *and* $f(a,b) = \frac{\tan b - \tan a}{b - a}$, *then*

(a) $f(a, b) \geq 2$ (b) $f(a, b) > 1$

(c) $f(a, b) \leq 1$ (d) None of these

Sol. Consider the function $f(x) = \tan x$, defined on $[a, b]$ such that $a, b \in \left(0, \frac{\pi}{2}\right)$.

Applying Lagrange's mean value theorem, we have

$$f'(c) = \frac{f(b) - f(a)}{b - a} \text{ for some } c \in (a, b)$$

$$\Rightarrow \quad \sec^2 c = \frac{\tan b - \tan a}{b - a}$$

$$\Rightarrow \quad f(a, b) = \sec^2 c$$

$$\Rightarrow \quad f(a, b) > 1 \qquad [\because \sec^2 c > 1 \text{ as } c \in (0, \pi/2)]$$

Hence, (b) is the correct answer.

Example 47 In $[0, 1]$ Lagrange's mean value theorem is not applicable to *[IIT JEE 2003]*

(a) $f(x) = \begin{cases} \frac{1}{2} - x, & x < \frac{1}{2} \\ \left(\frac{1}{2} - x\right)^2, & x \geq \frac{1}{2} \end{cases}$

(b) $f(x) = \begin{cases} \frac{\sin x}{x}, & x \neq 0 \\ 1, & x = 0 \end{cases}$

(c) $f(x) = x|x|$

(d) $f(x) = |x|$

Sol. For the function $f(x)$ given in option (a), we have (LHD at $x = 1/2) = -1$ and (RHD at $x = 1/2) = 0$.

So, it is not differentiable at $x = 1/2 \in (0, 1)$.

$\therefore$ Lagrange's mean value theorem is not applicable.

Hence, (a) is the correct answer.

Example 48 Let $f(x)$ satisfy the requirements of Lagrange's mean value theorem in $[0, 2]$. If $f(0) = 0$ and $|f'(x)| \leq 1/2$ for all $x \in [0, 2]$, then

(a) $f(x) \leq 2$ (b) $|f(x)| \leq 2x$

(c) $|f(x)| \leq 1$ (d) $f(x) = 3$, for atleast one $x \in [0, 2]$

Sol. Let $x \in (0, 2)$. Since, $f(x)$ satisfies the requirements of Lagrange's mean value theorem in $[0, 2]$. So, it also satisfies in $[0, x]$. Consequently, there exists $c \in (0, x)$ such that

$$f'(c) = \frac{f(x) - f(0)}{x - 0} \Rightarrow f'(c) = \frac{f(x)}{x}$$

$$\Rightarrow \quad \left|\frac{f(x)}{x}\right| = |f'(c)| \leq 1/2 \qquad [\because |f'(x)| \leq 1/2]$$

$$\Rightarrow \quad |f(x)| \leq \frac{x}{2}$$

$$\Rightarrow \quad |f(x)| \leq 1 \qquad [\because x \in (0, 2), \ \therefore x \leq 2]$$

Hence, (c) is the correct answer.

Example 49 Let $f : [2, 7] \to [0, \infty)$ be a continuous and differentiable function. T*hen,* the value of $(f(7) - f(2)) \frac{(f(7))^2 + (f(2))^2 + f(2) \cdot f(7)}{3}$ is (where $c \in (2, 7)$)

(a) $3f^2(c) f'(c)$ (b) $5f^2(c) \cdot f(c)$

(c) $5f^2(c) \cdot f'(c)$ (d) None of these

Sol. Let $g(x) = f^3(x) \Rightarrow g'(x) = 3f^2(x) \cdot f'(x)$

$\because \quad f : [2, 7] \to [0, \infty) \quad \therefore \quad g : [2, 7] \to [0, \infty)$

Using Lagrange's mean value theorem on $g(x)$, we get

$$g'(c) = \frac{g(7) - g(2)}{5}, \ c \in (2, 7)$$

$$\Rightarrow 3f^2(c) f'(c) = \frac{f^3(7) - f^3(2)}{5}$$

$$\Rightarrow 5f^2(c) \cdot f'(c) = \frac{(f(7) - f(2))(f^2(7) + f^2(2) + f(7) \cdot f(2))}{3}$$

Hence, (c) is the correct answer.

Example 50 T*he* ***equation*** $\sin x + x \cos x = 0$ ***has atleast one root in the interval .***

(a) $\left(-\frac{\pi}{2}, 0\right)$ (b) $(0, \pi)$ (c) $\left(-\frac{\pi}{2}, \frac{3\pi}{2}\right)$ (d) None of these

Sol. Consider the function given by,

$$f(x) = \int (\sin x + x\cos x)\, dx = x\sin x$$

we observe that $f(0) = f(\pi) = 0$

$\therefore$ 0 and π are two roots of $f(x) = 0$.

Consequently, $f'(x) = 0$, i.e. $\sin x + x\cos x = 0$ has at least one root in $(0, \pi)$.

Hence, (b) is the correct answer.

Example 51 Between any two real roots of the equation $e^x \sin x - 1 = 0$, the equation $e^x \cos x + 1 = 0$ has

(a) at least one root (b) at most one root

(c) exactly one root (d) no root

Sol. Let $f(x) = e^{-x} - \sin x$ and α and β be two roots of the equation $e^x \sin x - 1 = 0$ such that $\alpha < \beta$.

Then, $e^{\alpha}\sin\alpha = 1$ and $e^{\beta}\sin\beta = 1$

$\Rightarrow$ $e^{-\alpha} - \sin\alpha = 0$ and $e^{-\beta} - \sin\beta = 0$ ...(i)

Clearly, $f(x)$ is continuous on $[\alpha, \beta]$ and differentiable on (α, β). Also, $f(\alpha) = f(\beta) = 0$ [using Eq. (i)]

$\therefore$ By Rolle's theorem there exists $c \in (\alpha, \beta)$ such that

$$f'(c) = 0$$

$\Rightarrow$ $-e^{-c} - \cos c = 0$

$\Rightarrow$ $e^c \cos c + 1 = 0$

$\Rightarrow$ $x = c$ is root of $e^x \cos x + 1 = 0$; where $c \in (\alpha, \beta)$

Hence, (a) is the correct answer.

Exercise for Session 5

1. If $f(x) = x^{\alpha}\log x$ and $f(0) = 0$, then the value of 'α' for which Rolle's theorem can be applied in [0, 1], is

(a) -2 (b) -1

(c) 0 (d) $\frac{1}{2}$

2. If a, b, c are non-zero real numbers such that $\int_0^1 (1+\cos^8 x)(ax^2 + bx + c)\, dx$

$= \int_0^2 (1+\cos^8 x)(ax^2 + bx + c)\, dx = 0$, then the equation $ax^2 + bx + c = 0$ will have

(a) one root between 0 and 1 and another between 1 and 2

(b) both the roots between 0 and 1

(c) both the roots between 1 and 2

(d) None of the above

3. Let $n \in N$, if the value of c prescribed in Rolle's theorem for the function $f(x) = 2x\,(x-3)^n$ on [0, 3] is $\frac{3}{4}$, then n is equal to

(a) 1 (b) 3

(c) 5 (d) 7

4. If $f(x) > x\,; \forall\, x \in R$. Then, the equation $f(f(x)) - x = 0$, has ***[IIT]***

(a) atleast one real root

(b) more than one real root

(c) no real root if $f(x)$ is a polynomial and one real root if $f(x)$ is not a polynomial

(d) no real root

5. If $f(x)$ is twice differentiable function such that $f(a) = 0, f(b) = 2, f(c) = -1, f(d) = 2, f(e) = 0$, where $a < b < c < d < e$, then the minimum number of zeroes of $g(x) = (f'(x))^2 + f''(x)\cdot f(x)$ in the interval $[a, e]$, is ***[IIT]***

(a) 4 (b) 5

(c) 6 (d) 7

Session 6

Application of Cubic Functions

Application of Cubic Functions

The cubic function $y = ax^3 + bx^2 + cx + d$ will have

1. One real and two imaginary roots
(always monotonic), $\forall\ x \in R$

Condition $f'(x) \geq 0$ or $f'(x) \leq 0$ together with either $f'(x) = 0$ has no root (i.e. $D < 0$) or $f'(x) = 0$ has a root $x = \alpha$, then $f(\alpha) = 0$.

e.g. $y = x^3 - 2x^2 + 5x + 4$

$y' = 3x^2 - 4x + 5 \qquad [D < 0]$

$y = (x-2)^3 \ \Rightarrow\ y' = 3(x-2)^2 = 0$

$\Rightarrow \quad x = 2$, also $f(2) = 0$ gives $x = 2, y(2) = 0$

In this case, if $f'(x) = 0$ has a root $x = \alpha$ and $f(\alpha) = 0$ this would mean $f(x) = 0$ has repeated roots, which is dealt with separately.

2. Exactly one root and non-monotonic

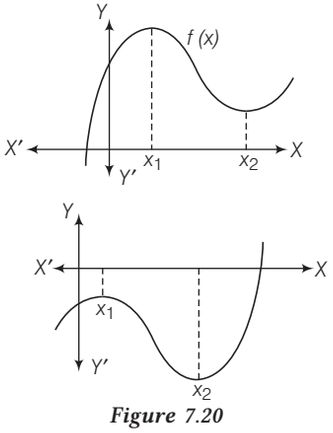

Figure 7.20

$f(x_1) \cdot f(x_2) > 0$

where x_1 and x_2 are the roots of $f'(x) = 0$

3. Two coincident and One different $f(x_1) \cdot f(x_2) = 0$

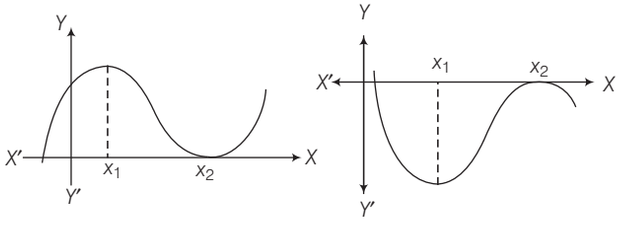

Figure 7.21

where x_1 and x_2 are the roots of $f'(x) = 0$

4. All three distinct real roots

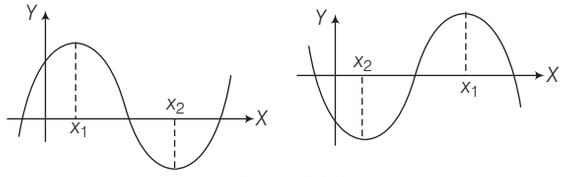

Figure 7.22

$f(x_1) \cdot f(x_2) < 0$

where x_1 and x_2 are the roots of $f'(x) = 0$

5. All the three roots are coincident

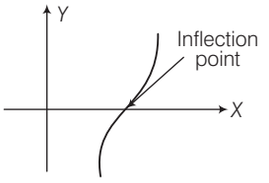

Figure 7.23

$f'(x) \geq 0 \quad$ or $\quad f'(x) \leq 0$

and $\quad f(\alpha) = 0$

where α is a root of $f'(x) = 0$

e.g. $y = (x-1)^3$

Remarks

(i) Graph of every cubic polynomial must have exactly one point of inflection.

(ii) In case (4), if $f(a)$, $f(b)$, $f(c)$ and $f(d)$ alternatively change sign.

Example 52 If the cubic function $f(x) = x^3 + px + q$ has 3 distinct real roots, then prove that $4p^3 + 27q^2 < 0$.

Sol. $f'(x) = 3x^2 + p = 3x^2 + 0 \cdot x + p$

Now, we have $x_1 + x_2 = 0$ and $x_1 x_2 = \frac{p}{3}$, where x_1, x_2 are roots of $f'(x) = 0$

According to given condition, we have

$(x_1^3 + px_1 + q)(x_2^3 + px_2 + q) < 0$

$\Rightarrow \quad x_1^3 \cdot x_2^3 + px_1^3 x_2 + qx_1^3 + p^2 x_1 x_2 + px_1 x_2^3 + qx_2^3 + pqx_1 + q^2 + pqx_2 < 0$

$\Rightarrow (x_1 x_2)^3 + px_1 x_2 (x_1^2 + x_2^2) + q(x_1^3 + x_2^3) + pq(x_1 + x_2) + p^2 x_1 x_2 + q^2 < 0$

$\Rightarrow (x_1 x_2)^3 + px_1 x_2 \{(x_1 + x_2)^2 - 2x_1 x_2\} + q\{(x_1 + x_2)^3 - 3(x_1 x_2)(x_1 + x_2)\} + pq(x_1 + x_2) + p^2 x_1 x_2 + q^2 < 0$

$$\Rightarrow \quad \frac{p^3}{27} + \frac{p^2}{3}\left\{-\frac{2p}{3}\right\} + p^2\left\{\frac{p}{3}\right\} + q^2 < 0$$

$$\Rightarrow \quad 4p^3 + 27q^2 < 0$$

Example 53 ***If*** $f(x)$ ***is a polynomial of degree 5 with real coefficients such that*** $f(|x|)=0$ ***has 8 real roots, then*** $f(x)=0$ ***has***

(a) 4 real roots

(b) 5 real roots

(c) 3 real roots

(d) nothing can be said

Sol. Given that $f(|x|)=0$ has 8 real roots.

$\Rightarrow$ $f(x)=0$ has 4 positive roots.

Since, $f(x)$ is a polynomial of degree 5, $f(x)$ cannot have even number of real roots.

$\Rightarrow f(x)$ has all the five roots real, in which four positive and one root is negative.

Hence, (b) is the correct answer.

Example 54 If the function $f(x)=x^3-9x^2+24x+c$ has three real and distinct roots α, β and γ, then the value of $[\alpha]+[\beta]+[\gamma]$ are

(a) 5, 6

(b) 6, 7

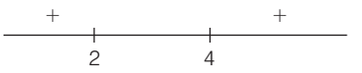
(c) 7, 8

(d) None of the above

Sol. Take $y = x^3 - 9x^2 + 24x$

$$\Rightarrow \quad \frac{dy}{dx} = 3x^2 - 18x + 24 = 3(x^2 - 6x + 8)$$

$$= 3(x-2)(x-4)$$



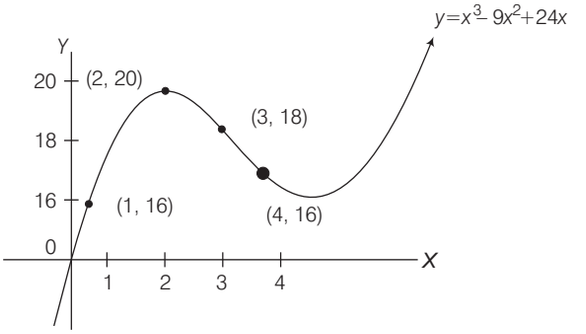
for three real roots of

$f(x) = x^3 - 9x^2 + 24x + c, f(2)f(4) < 0$

$\therefore \ (c+20)(c+16) < 0$

$c \in (-20, -16)$

Now, if $c \in (-20, -18)$, $\alpha \in (1,2), \beta \in (2,3)$, $\gamma \in (4,5)$



$\Rightarrow \quad [\alpha]+[\beta]+[\gamma]=7$

If $\quad c \in (-18, -16)$

$\Rightarrow \quad \alpha \in (1,2), \beta \in (3,4), \gamma \in (4,5)$

$\Rightarrow \quad [\alpha]+[\beta]+[\gamma]=8$

Hence, (c) is the correct answer.

Exercise for Session 6

1. Find all the possible values of the parameter a, so that $x^3 - 3x + a = 0$ has three real and distinct roots.

2. $f(x)$ is a polynomial of degree 4 with real coefficients such that $f(x)=0$ is satisfied by $x = 1, 2, 3$ only, then $f'(1)\cdot f'(2)\cdot f'(3)$ is equal to

   (a) 0 (b) 2

   (c) –1 (d) None of these

3. If the function $f(x) = |x^2 + a|x| + b|$ has exactly three points of non-differentiability, then which of the following can be true?

   (a) $b = 0, a < 0$ (b) $b < 0, a \in R$

   (c) $b > 0, a \in R$ (d) All of these

4. If the equation $e^{||x|-2|+b} = 2$ has four solutions, then b lies in

   (a) (log 2, – log2) (b) (log2 – 2 , log2)

   (c) (– 2, log2) (d) (0, log2)

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *Number of integral value(s) of k for which the equation $4x^2 - 16x + k = 0$ has one root lie between 1 and 2 and other root lies between 2 and 3, is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. (*c*) Here, $f(1)\cdot f(2) < 0$

$\Rightarrow \quad (k-12)(k-16) < 0$

$\Rightarrow \quad 12 < k < 16$ ...(i)

Also, $f(2)\cdot f(3) < 0$

$\Rightarrow \quad (k-16)(k-12) < 0 \Rightarrow 12 < k < 16$ ...(ii)

From Eqs. (i) and (ii), we get

$k = \{13, 14, 15\}$

$\therefore$ Number of integral values of $k = 3$

● **Ex. 2** *Let a, b, c∈ R such that two of them are equal and satisfy* $\begin{vmatrix} 2a & b & c \\ b & c & 2a \\ c & 2a & b \end{vmatrix} = 0$, *then equation* $24ax^2 + 4bx + c = 0$ *has*

(a) at least one root in $(0, 1/2)$
(b) at least one root in $(-1/2, 1/2)$
(c) at least one root in $(-1, 0)$
(d) at least two roots in $(0, 2)$

Sol. (*a*) Given determinant is

$$2a(bc - 4a^2) - b(b^2 - 2ac) + c(2ab - c^2) = 0$$

$\Rightarrow \quad 6abc - 8a^3 - b^3 - c^3 = 0$

or $\quad (2a + b + c)[(2a - b)^2 + (b - c)^2 + (c - 2a)^2] = 0$

$\Rightarrow \quad 2a + b + c = 0$ ...(i)
$[\because b \neq c]$

Let $f(x) = 8ax^3 + 2bx^2 + c\ x \Rightarrow f'(x) = 24ax^2 + 4bx + c$

Here, $f(0) = 0$ and $f(1/2) = a + b/2 + c/2 = \dfrac{2a + b + c}{2}$

$\therefore \quad f(1/2) = 0$ [using Eq. (i)]

So, $f(x)$ satisfy Rolle's theorem and hence $f'(x) = 0$ must have at least one root in $(0, 1/2)$.

● **Ex. 3** *The set of values of 'a' for which the equation* $\log_e(a\log_e x) = \log_e x$ *has more than one solution is*

(a) $(1, \infty)$ (b) (e, ∞) (c) $(0, e)$ (d) $(1, e)$

Sol. (*b*) Here, $\log_e(a\log_e x) = \log_e x$

$\Rightarrow \quad a\log_e x = e^{\log_e x} \Rightarrow a\log_e x = x$

If we put $a = e$, then $\log_e x = x/e$ will have only one solution at $x = e$.

$[\because$ the line $y = \dfrac{x}{e}$ is tangent to the curve $y = \log_e x$ at $x = e]$

$\Rightarrow \log_e x = \dfrac{x}{a}$ has more than one solution for $a \in (e, \infty)$.

● **Ex. 4** *The tangent to the hyperbola* $y = \dfrac{x+9}{x+5}$ *passing through the origin is*

(a) $x + 25y = 0$ (b) $5x + y = 0$
(c) $5x - y = 0$ (d) $x - 25y = 0$

Sol. (*a*) Here, $y = 1 + \dfrac{4}{x+5} \Rightarrow (dy/dx)$ at $(x_1, y_1) = -\dfrac{4}{(x_1+5)^2}$

Now, equation of tangent, is

$$y - \left(1 + \frac{4}{x_1 + 5}\right) = -\frac{4}{(x_1+5)^2}(x - x_1)$$

Since, it passes through $(0, 0)$, therefore

$$-1 - \frac{4}{x_1 + 5} = \frac{4x_1}{(x_1+5)^2}$$

$\Rightarrow \quad -(x_1+5)^2 - 4(x_1+5) = 4x_1$

$\Rightarrow \quad (x_1+5)^2 + 4(x_1+5) + 4x_1 = 0$

$\Rightarrow \quad x_1^2 + 18x_1 + 45 = 0$

$\Rightarrow \quad (x_1+15)(x_1+3) = 0 \Rightarrow x_1 = -15$ or -3

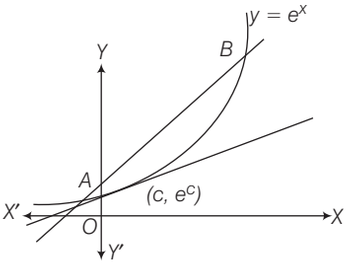
So, equation of tangents are

$$x + 25y = 0 \text{ or } x + y = 0$$

● **Ex. 5** *The tangent to the curve* $y = e^x$ *drawn at the point* (c, e^c) *intersects the line joining the points* $(c-1, e^{c-1})$ *and* $(c+1, e^{c+1})$ ***[IIT JEE 2007]***

(a) on the left of $x = c$ (b) on the right of $x = c$
(c) at no point (d) at all points

Sol. (*a*) Slope of the line joining the points $(c - 1, e^{c-1})$ and $(c + 1, e^{c+1})$ is equal to $\dfrac{e^{c+1} - e^{c-1}}{2} > e^c$



$\Rightarrow$ Tangent to the curve $y = e^x$ will intersect the given line to the left of the line $x = c$.

Aliter

The equation of the tangent to the curve $y = e^x$ at (c, e^c) is

$$y - e^c = e^c (x - c) \quad \ldots(i)$$

Equation of the line joining the given points is

$$y - e^{c-1} = \frac{e^c (e - e^{-1})}{2} [x - (c - 1)] \quad \ldots(ii)$$

Eliminating y from Eqs. (i) and (ii), we get

$$[x - (c - 1)] [2 - (e - e^{-1})] = 2e^{-1}$$

or $$x - c = \frac{e + e^{-1} - 2}{2 - (e - e^{-1})} < 0$$

$\Rightarrow$ $$x < c$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

● ***Ex. 6*** *The coordinate of the point(s) on the graph of the function,* $f(x) = \frac{x^3}{3} - \frac{5x^2}{2} + 7x - 4$ *where the tangent drawn cuts-off intercepts from the coordinate axes which are equal in magnitude but opposite in sign, is*

(a) $\left(2, \frac{8}{3}\right)$ (b) $\left(3, \frac{7}{2}\right)$

(c) $\left(1, \frac{5}{6}\right)$ (d) None of these

Sol. (a, b) Since, intercepts are equal in magnitude but opposite in sign, therefore

$$\left[\frac{dy}{dx}\right]_P = 1$$

Now, $\frac{dy}{dx} = x^2 - 5x + 7 = 1$

$\Rightarrow$ $x^2 - 5x + 6 = 0$

$\therefore$ $x = 2$ or 3

● ***Ex. 7*** *Let* $f : [0, 1] \to R$ *be a differentiable function with non-increasing derivative such that* $f(0) = 0$, $f'(1) > 0$, *then*

(a) $f(1) \geq f'(1)$

(b) $f'(c) \neq 0$ for any $c \in (0, 1)$

(c) $f(1/2) > f(1)$

(d) None of the above

Sol. (a, b) By Lagrange's mean value theorem,

$$\frac{f(1) - f(0)}{1 - 0} = f'(c), c \in (0, 1)$$

$\because f'(x)$ is non-increasing.

$\therefore$ $f'(c) \geq f'(1)$

$\Rightarrow$ $f'(c) > 0 [\because f'(1) > 0]$

Also, $f(1) = f(1) - f(0) = f'(c) \geq f'(1)$

$\therefore$ $f(1) \geq f'(1)$.

● ***Ex. 8*** *If* $f(x)$ *is continuous and derivable,* $\forall\, x \in R$ *and* $f'(c) = 0$ *for exactly* 2 *real values of 'c', then the number of real and distinct values of 'd' for which* $f(d) = 0$ *can be*

(a) 1 (b) 2 (c) 3 (d) 4

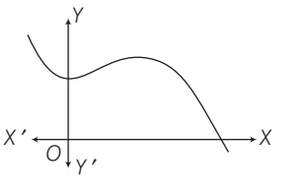
Sol. (a, b, c) If $f'(x) = 0$ has n real roots, then

$f(x) = 0$ has atmost $(n + 1)$ real roots.

Now, if $f'(c) = 0$ for exactly 2 real values of c.

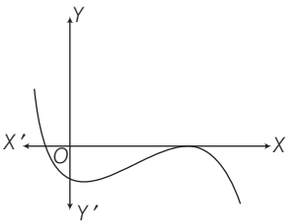
Then, following cases may arise

(a)



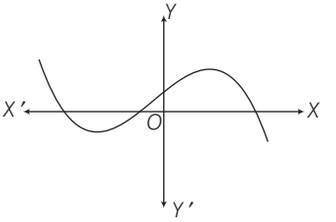
$\Rightarrow$ $f(x) = 0$ have 1 real root.

(b)



$\Rightarrow$ $f(x) = 0$ has 2 real roots.

(c)



$\Rightarrow$ $f(x) = 0$ has 3 real roots.

● ***Ex. 9*** *Which of the following statements are true, where* $\phi(x)$ *is a polynomial?*

(a) Between any two roots of $\phi(x)=0$ there exists at least one root of $\phi'(x)+\lambda\phi(x)=0$

(b) Between any two roots of $\phi(x)=0$ there exists at least one root of $x\phi'(x)+\lambda\phi(x)=0$

(c) Between any two roots of $\phi(x)=0$ there exists at least one root of $(x^2+1)\phi'(x)+\phi(x)=0$

(d) Between any two roots of $\phi(x)=0$ there exists at least one root of $\phi'(x)+x\phi(x)=0$

Sol. (c, d) If α and β are the consecutive roots of $\phi(x)=0$, then $\phi'(\alpha)\cdot\phi'(\beta)\le 0$

Let $\phi(x)=(x-1)(x-2)$

$\phi'(x)=2x-3$

$\therefore\quad \phi'(x)+\lambda\phi(x)=0$

$\Rightarrow\quad (2x-3)+\lambda(x-1)(x-2)=0$

Must have at least one root $\in(\alpha,\beta)$.

Similarly, $(x^2+1)\phi'(x)+\phi(x)=0$

and $\phi'(x)+x\phi(x)=0$ has at least one root $\in(\alpha,\beta)$.

● ***Ex. 10*** *Let* $f(x)$ *be twice differentiable function such that* $f''(x)<0$ *in* $[0,2]$. *Then,*

(a) $f(0)+f(2)=2f(c), 0<c<2$

(b) $f(0)+f(2)=2f(1)$

(c) $f(0)+f(2)>2f(1)$

(d) $f(0)+f(2)<2f(1)$

Sol. (a, d) By intermediate mean value theorem, we get

$$\frac{f(0)+f(2)}{2}=f(c),\quad 0<c<2 \qquad ...(i)$$

By Lagrange's mean value theorem, we get

$$f(1)-f(0)=f'(c_1),\quad 0<c_1<1 \qquad ...(ii)$$

$$f(2)-f(1)=f'(c_2),\quad 1<c_2<2 \qquad ...(iii)$$

On subtracting Eq. (ii) from Eq. (iii), we get

$$f(2)+f(0)-2f(1)=f'(c_2)-f'(c_1) \qquad ...(iv)$$

Again, by Lagrange's mean value theorem, we get

$$f''(c_3)=\frac{f'(c_2)-f'(c_1)}{c_2-c_1},\ \text{for some } c_3\in(c_1,c_2)$$

$\Rightarrow\quad f'(c_2)-f'(c_1)=(c_2-c_1)f''(c_3)<0\quad [f''(x)<0]$ ...(v)

From Eqs. (iv) and (v), we get

$$f(2)+f(0)-2f(1)<0\ \Rightarrow\ f(0)+f(2)<2f(1)$$

JEE Type Solved Examples :
Statements I and II Type Questions

■ **Directions** (Q. Nos. 11 to 13) *For the following questions, choose the correct answers from the option* (*a*), (*b*), (*c*) *and* (*d*) *defined as follows*

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I

(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I

(c) Statement I is true, Statement II is false

(d) Statement I is false, Statement II is true

● ***Ex. 11*** **Statement I** *The tangent at* $x=1$ *to the curve* $y=x^3-x^2-x+2$ *again meets the curve at* $x=-2$.

Statement II *When an equation of a tangent solved with the curve, repeated roots are obtained at the point of tangency.*

Sol. (*d*) When $x=1$, then $y=1$. Also, $y'=3x^2-2x-1$

$\Rightarrow\quad y'\big|_{x=1}=0\ \Rightarrow$ equation of tangent is $y=1$.

Solving $x^3-x^2-x+2=1$

or $\quad x^3-x^2-x+1=0$, we get $x=-1,1$

$\therefore$ The tangent meets the curve again at $x=-1$.

$\therefore$ Statement I is false and Statement II is true.

● ***Ex. 12*** **Statement I** *The ratio of length of tangent to length of normal is inversely proportional to the ordinate of the point of tengency at the curve* $y^2=4ax$.

Statement II *Length of normal and tangent to a curve*

$$y=f(x)\ is\ \left|y\sqrt{1+m^2}\right|\ and\ \left|\frac{y\sqrt{1+m^2}}{m}\right|,$$

where $m=\dfrac{dy}{dx}$.

Sol. (*a*) Let the slope of the tangent be denoted by $\tan\psi$ and the length of tangent $= y\ \text{cosec}\ \psi$.

Then, length of normal $= y\sec\psi$

$$\therefore\quad \frac{\text{Length of tangent}}{\text{Length of normal}}=\cot\psi\propto\frac{1}{y}$$

$\therefore$ Statement I is true.

$$\text{Length of normal}=\left|y\sqrt{1+\left(\frac{dy}{dx}\right)^2}\right|$$

$$= \left| y\sqrt{1+m^2} \right|$$

$$\text{Length of tangent} = \left| y\sqrt{1+\left(\frac{dx}{dy}\right)^2} \right| = \left| \frac{y\sqrt{1+m^2}}{m} \right|$$

$\therefore$ Statement II is true and explain Statement I.

● ***Ex. 13*** **Statement I** *Tangent drawn at the point* $(0, 1)$ *to the curve* $y = x^3 - 3x + 1$ *meets the curve thrice at one point only.*

Statement II *Tangent drawn at the point* $(1, -1)$ *to the curve* $y = x^3 - 3x + 1$ *meets the curve at one point only.*

Sol. (c) $\frac{dy}{dx} = 3x^2 - 3$

Statement I $\left(\frac{dy}{dx}\right)_{\text{at } (0,\,1)} = -3$

$\therefore$ Equation of the tangent is $y - 1 = -3(x - 0)$

i.e. $y = -3x + 1$

Now, $-3x + 1 = x^3 - 3x + 1 \Rightarrow x = 0$

$\therefore$ The tangent meets the curve at one point only.

$\therefore$ Statement I is true.

Statement II $\left(\frac{dy}{dx}\right)_{\text{at } (1,\,-1)} = 0$

$\therefore$ Equation of the tangent is $y + 1 = 0(x - 1)$

i.e. $y = -1$

Now, $-1 = x^3 - 3x + 1$

$\Rightarrow$ $x^3 - 3x + 2 = 0$

$\Rightarrow$ $(x - 1)(x^2 + x - 2) = 0$

$\Rightarrow$ The tangent meets the curve at two points.

$\therefore$ Statement II is false.

JEE Type Solved Examples : Passage Based Questions

Passage I (Ex. Nos. 14 to 18)

Let $f(x) = x^3 + ax^2 + bx + c$ *be the given cubic polynomial and* $f(x) = 0$ *be the corresponding cubic equation, where* $a, b, c \in R$. *Now,* $f'(x) = 3x^2 + 2ax + b$

Let $D = 4a^2 - 12b = 4(a^2 - 3b)$ *be the discriminant of the equation* $f'(x) = 0$.

● ***Ex. 14*** *If* $D = 4(a^2 - 3b) < 0$, *then*

(a) $f(x)$ has all real roots
(b) $f(x)$ has one real and two imaginary roots
(c) $f(x)$ has repeated roots
(d) None of the above

● ***Ex. 15*** *If* $D = 4(a^2 - 3b) > 0$ *and* $f(x_1) \cdot f(x_2) > 0$, *where* x_1, x_2 *are the roots of* $f(x)$, *then*

(a) $f(x)$ has all real and distinct roots
(b) $f(x)$ has three real roots but one of the roots would be repeated
(c) $f(x)$ would have just one real root
(d) None of the above

● ***Ex. 16*** *If* $D = 4(a^2 - 3b) > 0$ *and* $f(x_1) \cdot f(x_2) < 0$, *where* x_1, x_2 *are the roots of* $f(x)$, *then*

(a) $f(x)$ has all real and distinct roots
(b) $f(x)$ has three real roots but one of the roots would be repeated
(c) $f(x)$ would have just one real root
(d) None of the above

● ***Ex. 17*** *If* $D = 4(a^2 - 3b) > 0$ *and* $f(x_1) \cdot f(x_2) = 0$, *where* x_1, x_2 *are the roots of* $f(x)$, *then*

(a) $f(x)$ has all real and distinct roots
(b) $f(x)$ has three real roots but one of the roots would be repeated
(c) $f(x)$ would have just one real root
(d) $f(x)$ has three real roots but all are same

● ***Ex. 18*** *If* $D = 4(a^2 - 3b) = 0$, *then*

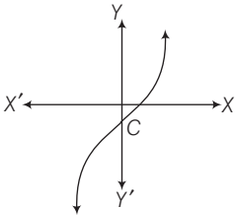
(a) $f(x)$ has all real and distinct roots
(b) $f(x)$ has three real roots but one of the roots would be repeated
(c) $f(x)$ would have just one real root
(d) None of the above

■ ***Sol.*** (Ex. Nos. 14 to 18)

Case I If $D < 0 \Rightarrow f'(x) > 0, \forall\ x \in R$

That means $f(x)$ would be an increasing function of x.

Also, $\lim_{x \to \infty} f(-x) = -\infty$ and $\lim_{x \to \infty} f(x) = \infty$



The graph of $f(x)$ would look like as shown in this figure.

It is clear that the graph of $f(x)$ would intersect the X-axis only once.

That means we would have just one real root (say x_0).

***Case* II** Clearly, $x_0 > 0$, if $c < 0$ and $x_0 < 0$, if $c > 0$.

If $D > 0$, $f'(x) = 0$ would have two real roots (say x_1 and x_2, let $x_1 < x_2$).

$\Rightarrow$ $f'(x) = 3(x - x_1)(x - x_2)$

Clearly, $f'(x) < 0,\ x \in (x_1, x_2)$

$f'(x) > 0,\ x \in (-\infty, x_1)\ (x_2, \infty)$

That means $f(x)$ would increase in $(-\infty, x_1)$ and (x_2, ∞) and would decrease in (x_1, x_2). Hence, $x = x_1$ would be a point of local maxima and $x = x_2$ would be a point of local minima. Thus, the graph of $y = f(x)$ could have these five possibilities.

Thus, the following results are obtained from the above graphs

(a) $f(x_1) \cdot f(x_2) > 0$, $f(x) = 0$ would have just one real root.

(b) $f(x_1) \cdot f(x_2) < 0$, $f(x) = 0$ would have three real and distinct roots.

(c) $f(x_1) \cdot f(x_2) = 0$, $f(x) = 0$ would have three real roots about one of the roots would be repeated.

***Case* III** If $D = 0$, $f'(x) = 3(x - x_1)^2$, where x_1 is root of $f'(x) = 0$

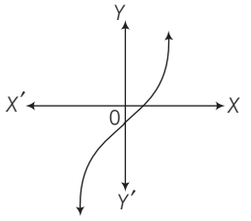
$\Rightarrow$ $f(x) = (x - x_1)^3 + k$

$\therefore$ $f(x) = 0$ has three real roots, if $k = 0$

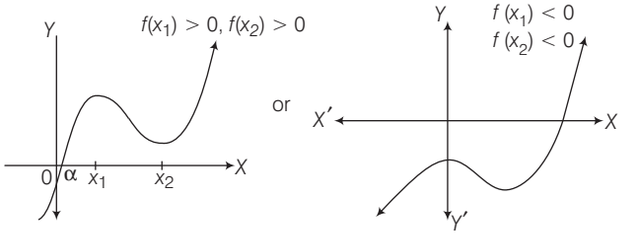
$f(x) = 0$ have one real root, if $k \neq 0$.

14. (*b*) Here, $f(x) = 0$ and $D < 0$

$\Rightarrow f'(x) > 0,\ \forall x \in R$



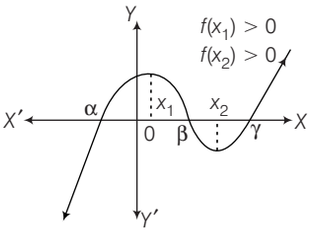
15. (*c*) Here, $f(x) = 0$ with one real root $x = \alpha$ and other two imaginary roots.



From both graph, $f(x_1)\ f(x_2) > 0$

$\therefore$ $f(x)$ would have one real roots.

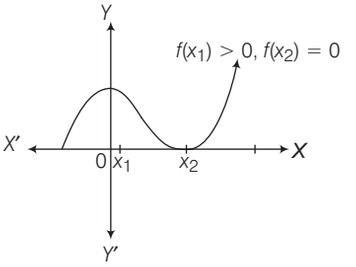
16. (*a*) Here, $f(x) = 0$ with three distinct root α, β, γ.



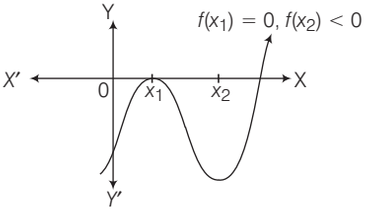
From graph, $f(x_1)\ f(x_2) < 0$

$\therefore$ $f(x)$ has real and distinct roots.

17. (*b*) Here, $f(x) = 0$ with three roots $x = \alpha, x_2$ (x_2 being repeated root).



18. (*b*) Here, $f(x) = 0$ with three real roots $x = x_1, \alpha$ (x_1 being repeated root).



Passage II (Ex. Nos. 19 to 21)

■ *If $y = f(x)$ is a curve and if there exists two points $A(x_1, f(x_1))$ and $B(x_2, f(x_2))$ on it such that $f'(x_1) = -\dfrac{1}{f'(x_2)} = \dfrac{f(x_2) - f(x_1)}{x_2 - x_1}$, then the tangent at x_1 is normal at x_2 for that curve. Now, answer the following questions.*

● ***Ex. 19*** *Number of such lines on the curve $y = \sin x$ is*

(a) 1 (b) 0 (c) 2 (d) infinite

Sol. (*b*) Let $f(x) = y = \sin x$

Then, $f'(x) = \dfrac{dy}{dx} = \cos x$

$\therefore$ $\cos x_1 = -\dfrac{1}{\cos x_2} = \dfrac{\sin x_2 - \sin x_1}{x_2 - x_1}$

i.e. $\cos x_1 \cos x_2 = -1$

$\therefore$ $\sin x_1 = \sin x_2 = 0$

$\therefore$ There is no solution.

● **Ex. 20** *Number of such lines on the curve* $y = |\ln x|$ *is*

(a) 1 (b) 2 (c) 0 (d) infinite

Sol. (*c*) $f(x) = y = |\ln x|$

$$\therefore \quad f'(x_1) = -\frac{1}{f'(x_2)} = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$$

$$\Rightarrow \quad \frac{\ln x_1}{x_1 |\ln x_1|} = -\frac{x_2 |\ln x_2|}{\ln x_2} = \frac{|\ln x_2| - |\ln x_1|}{x_2 - x_1} \qquad ...(i)$$

$\Rightarrow \ln x_1 \cdot \ln x_2 < 0$

Let $0 < x_1 < 1$, then $1 < x_2$ and $x_1 \cdot x_2 = 1$

From Eq. (i), we get

$$-\frac{1}{x_1} = -x_2 = \frac{\ln x_2 + \ln x_1}{x_2 - x_1} = \frac{\ln x_1 x_2}{x_2 - x_1} = 0,$$

which is not possible.

∴ There is no solution.

● **Ex. 21** *Number of such lines on the curve* $y^2 = x^3$, *is*

(a) 1 (b) 2
(c) 3 (d) 0

Sol. (*b*) We know that, $y^2 = x^3$

$$\therefore \quad y = \sqrt{x^3} \text{ or } -\sqrt{x^3}$$

$$2y\frac{dy}{dx} = 3x^2$$

$$\frac{3x_1^2}{2y_1} = -\frac{2y_2}{3x_2^2} \Rightarrow \frac{9}{4}x_1^2 x_2^2 = -y_1 y_2$$

$$\therefore \quad y_1 y_2 < 0$$

Let $y_1 = \sqrt{x_1^3}$ and $y_2 = -\sqrt{x_2^3}$

Thus, $$\frac{3x_1^2}{2\sqrt{x_1^3}} = -\frac{2\sqrt{x_2^3}}{3x_2^2} = \frac{-\sqrt{x_2^3} - \sqrt{x_1^3}}{x_2 - x_1}$$

$$\Rightarrow \quad \frac{3\sqrt{x_1}}{2} = \frac{2}{3\sqrt{x_2}} = \frac{\sqrt{x_2^3} + \sqrt{x_1^3}}{x_1 - x_2}$$

$$\Rightarrow \quad \sqrt{x_1 x_2} = \frac{4}{9}$$

and $$3x_1\sqrt{x_1} - 3\sqrt{x_1}\,x_2 = 2\sqrt{x_2^3} + 2\sqrt{x_1^3}$$

$$\Rightarrow \quad 3(\sqrt{x_1})^3 - \frac{3 \times 16}{81\sqrt{x_1}} = 2 \cdot \frac{64}{729\sqrt{x_1^3}} + 2\sqrt{x_1^3}$$

$$\Rightarrow \quad 3x_1^3 - \frac{16}{27}x_1 = \frac{128}{729} + 2x_1^3$$

$$\Rightarrow \quad x_1^3 - \frac{16}{27}x_1 = \frac{128}{729}$$

$$\Rightarrow \quad 739x_1^3 - 432x_1 - 12 = 0$$

Consider, $h(t) = 729x^3 - 432t - 128$

$$h'(t) = 3 \times 729t^2 - 432 = 0$$

Gives $$t = \pm\frac{4}{9}$$

$$h\left(-\frac{4}{9}\right) = 0$$

∴ There are two distinct solutions of

$$729x_1^3 - 432x_1 - 128 = 0.$$

Passage III (Ex. Nos. 22 and 23)

■ *Let* $f(x) = \int_0^x (|t-1| - |t+2| + t - 2)\,dt$, *such that* $f''(a) \neq 1$. *If vectors* $a\hat{\mathbf{i}} - b^2\hat{\mathbf{j}}$ *and* $\hat{\mathbf{i}} + 3b\hat{\mathbf{j}}$ *are parallel for at least one* a, *then*

● **Ex. 22** *Number of integral values of 'b' can be*

(a) 5 (b) 10
(c) 11 (d) 13

● **Ex. 23** *Maximum value of* $(1 - 8b - b^2)$ *is*

(a) 4 (b) 8
(c) 12 (d) 16

Sol. (Ex. Nos. 22 and 23) Here, $f(x) = \int_0^x (|t-1| - |t+2| + t - 2)\,dt$

$$\Rightarrow \quad f'(x) = |x-1| - |x+2| + x - 2$$

or $$f'(x) = \begin{cases} x+1, & x < -2 \\ -x-3, & -2 \le x \le 1 \\ x-5, & x > 1 \end{cases}$$

Clearly, $f''(a) \neq 1$ only when $a \in [-2, 1]$ ...(i)

Since, vectors are parallel.

$$\therefore \quad \frac{a}{1} = \frac{-b^2}{3b} \Rightarrow b^2 + 3ab = 0 \qquad ...(ii)$$

Let $g(a) = b^2 + 3ab$ must have atleast one root in $[-2, 1]$.

$$\therefore \quad g(-2) \cdot g(1) \le 0$$

$$\Rightarrow \quad (b^2 - 6b)(b^2 + 3b) \le 0$$

$$\Rightarrow \quad b^2(b-6)(b+3) \le 0$$

$$\therefore \quad b \in [-3, 6] \cup \{0\}$$

$\Rightarrow$ Number of integral values of 'b' can be 11.

Now, let $h(b) = 1 - 8b - b^2$

$$h'(b) = -8 - 2b = 0$$

$$\Rightarrow \quad b = -4$$

∴ $h(b)$ is decreasing, when $b > -4$

$$\Rightarrow \quad (h(b)_{\max}) \text{ at } b = -3$$

$$\therefore \quad (h(-3))_{\max} = 16$$

22. (*c*)

23. (*d*)

JEE Type Solved Examples :
Matching Type Questions

● ***Ex. 24*** *Match the statements of Column* I *with values of Column* II.

	Column I		Column II
(A)	The sides of a triangle vary slightly in such a way that its circumradius remains constant, if $\frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}+1=\lvert m\rvert$, then the value of m is	(p)	1
(B)	If the length of subtangent to the curve $x^2y^2=16$ at the point $(-2, 2)$ is $\lvert k\rvert$, then the value of k is	(q)	–1
(C)	If the curve $y=2e^{2x}$ intersects the Y-axis at an angle $\cot^{-1}\lvert(8n-4)/3\rvert$, then the value of n is	(r)	2
(D)	If the area of a triangle formed by normal at the point (1, 0) on the curve $x=e^{\sin y}$ with axes is $\lvert 2t+1\rvert/6$ sq units, then the value of t is	(s)	–2

Sol. (A) → (p, q); (B) → (r, s); (C) → (r, q); (D) → (p, s)

(A) We know that in any ΔABC,

$$\frac{a}{\sin A}=\frac{b}{\sin B}=\frac{c}{\sin C}=2R$$

$$\Rightarrow \quad a=2R\sin A, b=2R\sin B, c=2R\sin C$$

$$\Rightarrow \quad \frac{da}{dA}=2R\cos A, \frac{db}{dB}=2R\cos B, \frac{dc}{dC}=2R\cos C$$

$$\Rightarrow \quad \frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}=2R(dA+dB+dC)$$

Also, $A+B+C=\pi$

$\therefore \quad dA+dB+dC=0$

Hence, $\frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}=0$

or $\frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}+1=1$

$$\Rightarrow \quad \lvert m\rvert=1\Rightarrow m=\pm 1$$

(B) We have, $x^2y^2=16$

$$\Rightarrow \quad 2x^2y\frac{dy}{dx}+2xy^2=0 \quad \Rightarrow \quad \frac{dy}{dx}=-y/x$$

Length of subtangent $=\left\lvert y\frac{dx}{dy}\right\rvert=\left\lvert -y\frac{x}{y}\right\rvert=\lvert x\rvert$

$\Rightarrow$ Length of subtangent = 2

$\therefore \quad k=\pm 2$

(C) We have $y=2e^{2x}$, which intersect Y-axis at (0, 2)

Now, $\frac{dy}{dx}=4e^{2x}$

$\therefore \quad \left(\frac{dy}{dx}\right)_{(0,2)}=4$

$\therefore$ Angle of intersection with Y-axis

$$=\frac{\pi}{2}-\tan^{-1}4=\cot^{-1}4$$

Hence $\left\lvert\frac{8n-4}{3}\right\rvert=4, \ n=2$ or -1

(D) We have, $x=e^{\sin y}$

$$\Rightarrow \quad \frac{dx}{dy}=\cos y\, e^{\sin y}$$

Slope of normal at (1, 0) = -1

Equation of normal is $x+y=1$

Area of triangle $=\frac{1}{2}$

$$\therefore \quad \frac{\lvert 2t+1\rvert}{6}=\frac{1}{2}$$

$$\Rightarrow \quad t=1, -2$$

● ***Ex. 25*** *Match the statements of Column* I *with values of Column* II.

	Column I		Column II
(A)	Rolle's theorem in $[-1, 1]$ does not hold, if	(p)	$f(x)=\begin{cases}\left(\frac{1}{2}-x\right)^2, & x>\frac{1}{2}\\ \left(\frac{1}{2}-x\right), & x\le\frac{1}{2}\end{cases}$
(B)	LMVT in $[0, 1]$ does not hold, if	(q)	$f(x)=\lvert x\rvert$
(C)	Rolle's theorem in $[0, 1]$ does not hold, if	(r)	$f(x)=\begin{cases}1, & 0\le x<\frac{1}{2}\\ 2, & \frac{1}{2}\le x\le 1\end{cases}$
		(s)	$f(x)=\log\lvert x\rvert$
		(t)	$f(x)=x^2+x+1$

Sol. (A) → (p,q,r,s,t); (B) → (p, r, s); (C) → (p,r,s,t)

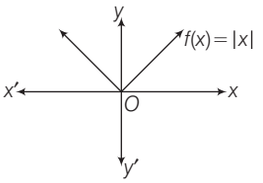
(p) $$f(x)=\begin{cases}\left(\frac{1}{2}-x\right)^2, & x>\frac{1}{2}\\ \left(\frac{1}{2}-x\right), & x\le\frac{1}{2}\end{cases}$$

$$\therefore\quad f'(x)=\begin{cases}-2\left(\frac{1}{2}-x\right), & x>\frac{1}{2}\\ -1, & x\le\frac{1}{2}\end{cases}$$

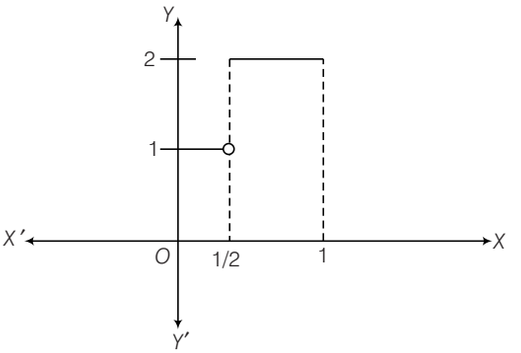
$$f'\left(\frac{1}{2}^{+}\right)\neq f'\left(\frac{1}{2}^{-}\right)$$

$\Rightarrow f(x)$ is not differentiable at $x=\frac{1}{2}$.

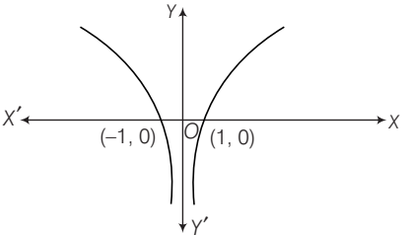
(q) $f(x)=|x|$ is not differential at $x=0$.



(r) $$f(x)=\begin{cases}1, & 0\le x<\frac{1}{2}\\ 2, & \frac{1}{2}\le x<1\end{cases}$$



$\Rightarrow f(x)$ is discontinuous at $x=\frac{1}{2}$.



$f(x)=\log|x|$ is discontinuous at $x=0$.

(t) $f(x)=x^2+x+1$

$\Rightarrow\quad f(-1)=1$

and $\quad f(1)=3$

$\Rightarrow\quad f(-1)\neq f(1)$

JEE Type Solved Examples :
Single Integer Answer Type Questions

● ***Ex. 26*** *Suppose that $f(0)=-3$ and $f'(x)\le 5$ for all values of x. Then, the largest value which $f(2)$ can assume is ..... .*

Sol. (7) Using LMVT in [0, 2]

$$\frac{f(2)-f(0)}{2-0}=f'(c)\qquad [\text{where } c\in(0,2)]$$

$$\Rightarrow\quad \frac{f(2)+3}{2}\le 5$$

$$\Rightarrow\quad f(2)\le 7$$

● ***Ex. 27*** *Let C be the curve $y=x^3$ (where x assumes all real values). The tangent at A meets the curve again at B. If the gradient at B is k times the gradient at A, then k is equal to ..... .*

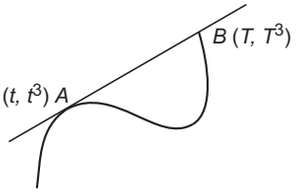
Sol. (4) $\quad \frac{dy}{dx}=3x^2=3t^2$ at 'A'

$$\therefore\quad 3t^2=\frac{T^3-t^3}{T-t}=T^2+Tt+t^2$$

$$\Rightarrow\quad T^2+Tt-2t^2=0$$

$$\Rightarrow\quad (T-t)(T+2t)=0$$

$$\Rightarrow\quad T=t \text{ or } T=-2t\qquad [T=t \text{ is not possible}]$$



Now, $\quad m_A=\frac{t^3}{t}=t^2;\ m_B=T^2$

$$\Rightarrow \quad \frac{m_B}{m_A} = \frac{T^2}{t^2} = \frac{4t^2}{t^2} \qquad [\text{using } T = -2t]$$

$$\therefore \quad k = 4$$

● ***Ex. 28*** *Consider the two graphs $y = 2x$ and $x^2 - xy + 2y^2 = 28$. The absolute value of the tangent of the angle between the two curves at the points where they meet, is ..... .*

Sol. (2) $y = 2x,\ x^2 - xy + 2y^2 = 28$

Solving the point of intersection are $(2, 4)$ and $(-2, -4)$.

For 1st curve, $\quad \frac{dy}{dx} = 2 = m_1 \qquad ...(i)$

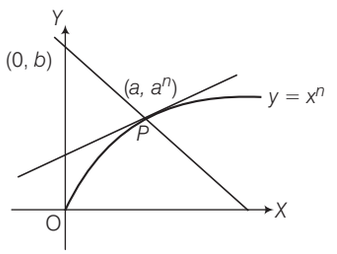
For 2nd curve, $\quad \frac{dy}{dx} = \frac{y - 2x}{4y - x} \Rightarrow m_2 = 0 \qquad ...(ii)$

$$\therefore \quad \tan\theta = 2$$

● ***Ex. 29*** *At the point $P(a, a^n)$ on the graph of $y = x^n$ $(n \in N)$ in the first quadrant a normal is drawn. The normal intersects the Y-axis at the point (0, b). If $\lim_{a \to 0} b = \frac{1}{2}$, then n equals ..... .*

Sol. (2) $y = x^n \Rightarrow \frac{dy}{dx} = n\,x^{n-1} = na^{n-1}$ at $p(a, a^n)$

Slope of normal $= -\frac{1}{na^{n-1}}$



Equation of normal is $y - a^n = -\frac{1}{na^{n-1}}(x - a)$

Put $x = 0$ to get y-intercept , then $y = a^n + \frac{1}{na^{n-2}}$

Hence, $\quad b = a^n + \frac{1}{na^{n-2}}$

Now, $\quad \lim_{a \to 0} b = \begin{cases} 0, & \text{if } n < 2 \\ \frac{1}{2}, & \text{if } n = 2 \\ \infty, & \text{if } n > 2 \end{cases} \Rightarrow \lim_{a \to 0} b = \frac{1}{2}, \text{ if } n = 2$

● ***Ex. 30*** *The maximum possible integral value of $\frac{\beta - \alpha}{\tan^{-1}\beta - \tan^{-1}\alpha}$, where $0 < \alpha < \beta < \sqrt{3}$ is*

Sol. (3) Let $f(x) = \tan^{-1}x,\ 0 < \alpha < \beta < \sqrt{3}$.

Then, by using LMVT, $\quad \frac{\tan^{-1}\beta - \tan^{-1}\alpha}{\beta - \alpha} = \frac{1}{1 + c^2}$,

where $0 < \alpha < c < \beta < \sqrt{3}$

So, $\quad \frac{1}{4} < \frac{1}{1 + c^2} < \frac{1}{1}$

$$\Rightarrow \quad \frac{1}{4} < \frac{\tan^{-1}\beta - \tan^{-1}\alpha}{\beta - \alpha} < 1$$

or $\quad 1 < \frac{\beta - \alpha}{\tan^{-1}\beta - \tan^{-1}\alpha} < 4$

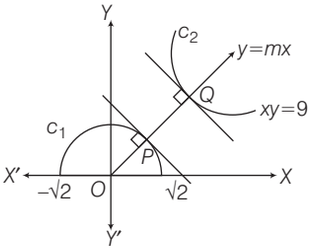
$\therefore$ Maximum possible integral value is 3.

● ***Ex. 31*** *Let P be a point on the curve $c_1 : y = \sqrt{2 - x^2}$ and Q be a point on the curve $c_2 : xy = 9$, both P and Q be in the first quadrant. If d denotes the minimum distance between P and Q, then d^2 is, ...*

Sol. (8) Here, c_1 is a semi-circle and c_2 is a rectangular hyperbola. PQ will be minimum if the normal at P on semi-circle is also a normal at Q on $xy = 9$.

Let the normal at P be $y = mx\ (m > 0)$. ...(i)

Solving with $xy = 9$



$$mx^2 = 9 \Rightarrow x = 3/\sqrt{m}$$

$$\Rightarrow \quad y = 9\sqrt{m}/3$$

$$\therefore \quad Q(3/\sqrt{m}, 3\sqrt{m})$$

Differentiating $xy = 9 \Rightarrow x\,dy/dx + y = 0$

$$\Rightarrow \quad dy/dx = -y/x$$

$$\therefore \quad |dy/dx|_Q = -\frac{3\sqrt{m}\sqrt{m}}{3} = -m$$

Now, tangent at P and Q must be parallel.

$$\therefore \quad -m = -1/m \Rightarrow m^2 = 1 \Rightarrow m = 1$$

$\therefore$ Normal at P and Q is $y = x$

Now, we get $P(1, 1)$ and $Q(3, 3)$.

$$\therefore \quad (PQ)^2 = d^2 = 4 + 4 = 8$$

Subjective Type Questions

● **Ex. 32** *If the line* $x\cos\alpha + y\sin\alpha = P$ *is the normal to the curve* $(x+a)y = c^2$*, then show that*

$$\alpha \in \left(2n\pi + \frac{\pi}{2}, (2n+1)\pi\right) \cup \left(2n\pi + \frac{3\pi}{2}, (2n+2)\pi\right).$$

Sol. Here, $y = \dfrac{c^2}{x+a} \Rightarrow \dfrac{dy}{dx} = -\dfrac{c^2}{(x+a)^2}$

Slope of normal is $\dfrac{(x+a)^2}{c^2} > 0$ for all x.

$\because$ $x\cos\alpha + y\sin\alpha = P$ is normal

$\therefore$ $-\dfrac{\cos\alpha}{\sin\alpha} > 0 \Rightarrow \cot\alpha < 0$

i.e. α lies in II or IV quadrant.

So, $\alpha \in \left(2n\pi + \dfrac{\pi}{2}, (2n+1)\pi\right) \cup \left(2n\pi + \dfrac{3\pi}{2}, (2n+2)\pi\right)$

● **Ex. 33** *Find the total number of parallel tangents of* $f_1(x) = x^2 - x + 1$ *and* $f_2(x) = x^3 - x^2 - 2x + 1$.

Sol. Here, $f_1(x) = x^2 - x + 1$

and $f_2(x) = x^3 - x^2 - 2x + 1$

$\Rightarrow$ $f_1'(x_1) = 2x_1 - 1$

and $f_2'(x_2) = 3x_2^2 - 2x_2 - 2$

Let the tangents drawn to the curves $y = f_1(x)$ and $y = f_2(x)$ at $(x_1, f_1(x_1))$ and $(x_2, f_2(x_2))$ respectively are parallel.

$\therefore$ $2x_1 - 1 = 3x_2^2 - 2x_2 - 2$ or $2x_1 = 3x_2^2 - 2x_2 - 1$

Which is possible for infinite numbers of ordered pairs.

$\therefore$ It will have infinite number of parallel tangents.

● **Ex. 34** *Find the point on the curve* $3x^2 - 4y^2 = 72$*, which is nearest to the line* $3x + 2y + 1 = 0$.

Sol. Slope of the given line $3x + 2y + 1 = 0$ is $(-3/2)$.

Let us locate the point (x_1, y_1) on the curve at which the tangent is parallel to the given line.

Differentiating the curve both sides with respect to x, we get

$$6x - 8y\frac{dy}{dx} = 0$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(x_1, y_1)} = \frac{3x_1}{4y_1} = \frac{-3}{2} \qquad [\because \text{parallel to } 3x + 2y = 1]$$

Also, the point (x_1, y_1) lies on $3x^2 - 4y^2 = 72$

$\therefore$ $3x_1^2 - 4y_1^2 = 72$

$$\Rightarrow \quad 3\frac{x_1^2}{y_1^2} - 4 = \frac{72}{y_1^2} \Rightarrow 3(4) - 4 = \frac{72}{y_1^2} \quad \left[\text{as } \frac{x_1}{y_1} = -2\right]$$

$$\Rightarrow \quad y_1^2 = 9 \Rightarrow y_1 = \pm 3$$

Required points are $(-6, 3)$ and $(6, -3)$.

Distance of $(-6, 3)$ from the given line

$$= \frac{|-18 + 6 + 1|}{\sqrt{13}} = \frac{11}{\sqrt{13}}$$

and distance of $(6, -3)$ from the given line

$$= \frac{|18 - 6 + 1|}{\sqrt{13}} = \frac{13}{\sqrt{13}} = \sqrt{13}$$

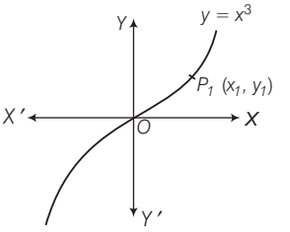
Thus, $(-6, 3)$ is the required point.

● **Ex. 35** *Tangent at a point* P_1 *(other than* $(0, 0)$*) on the curve* $y = x^3$ *meets the curve again at* P_2*. The tangent at* P_2 *meets the curve at* P_3 *and so on, show that the abscissa of* $P_1, P_2, P_3, \ldots, P_n$*, form a GP. Also, find the ratio of* $\dfrac{ar(\Delta P_1P_2P_3)}{ar(\Delta P_2P_3P_4)}$.

Sol. Let $P_1(x_1, y_1)$ be a point on the curve.

$$y = x^3 \qquad \ldots(i)$$

Then, we have $y_1 = x_1^3$ ...(ii)



Now, $\dfrac{dy}{dx} = 3x^2$

$\therefore$ Slope of the tangent at $P_1 = m_1 = 3x_1^2$

$\therefore$ Equation of the tangent at $P_1(x_1, y_1)$ is

$y - x_1^3 = 3x_1^2(x - x_1)$ or $y = 3x_1^2x - 2x_1^3$ ...(iii)

Solving Eqs. (i) and (iii), we get

$$x^3 - 3x_1^2x + 2x_1^3 = 0$$

i.e. $(x - x_1)\cdot(x^2 + xx_1 - 2x_1^2) = 0$

i.e. $(x - x_1)(x - x_1)(x + 2x_1) = 0$

$\therefore$ $x = x_1$ (neglecting) or $x = -2x_1$

$\therefore$ $x_2 = -2x_1, y_2 = x_2^3 = -8x_1^3$

$\therefore$ $P_2(x_2, y_2) = (-2x_1, -8x_1^3)$

Now, we find P_3, the point where the tangent, at P_2 meets the curve.

Slope of the tangent at $P_2 = \left(\dfrac{dy}{dx}\right)_{(x_2, y_2)}$

$$= 3x_2^2 = 3\cdot 4x_1^2 = 12x_1^2$$

$\therefore$ Equation of tangent at P_2 is,

$$y - x_2^3 = 3x_2^2(x - x_2) \qquad \text{...(iv)}$$

To get, $P_3 = (x_3, y_3)$, solve Eqs. (i) and (iv), we get

$P_3 = (x_3, y_3) = (-2x_2, -8x_2^3) = (4x_1, 64x_1^3)$ and so on.

$\therefore$ Abscissa of $P_1, P_2, P_3, \ldots$ are given by $x_1, -2x_1, 4x_1, -8x_1, \ldots$, which forms an GP with common ratio $= -2$.

Now, $$\text{a}\,(\Delta P_1P_2P_3) = \frac{1}{2}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}$$

$$\Rightarrow \quad \text{ar}\,(\Delta P_1P_2P_3) = \frac{1}{2}\begin{vmatrix} x_1 & x_1^3 & 1 \\ -2x_1 & -8x_1^3 & 1 \\ 4x_1 & 64x_1^3 & 1 \end{vmatrix}$$

$$\Rightarrow \quad \text{ar}\,(\Delta P_1P_2P_3) = \frac{x_1^4}{2}\begin{vmatrix} 1 & 1 & 1 \\ -2 & -8 & 1 \\ 4 & 64 & 1 \end{vmatrix}$$

Similarly, $$\text{ar}\,(\Delta\, P_2P_3P_4) = \frac{1}{2}\begin{vmatrix} x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \\ x_4 & y_4 & 1 \end{vmatrix}$$

$$\Rightarrow \quad \text{ar}\,(\Delta\, P_2P_3P_4) = \frac{1}{2}\begin{vmatrix} -2x_1 & -8x_1^3 & 1 \\ 4x_1 & 64x_1^3 & 1 \\ -8x_1 & -512x_1^3 & 1 \end{vmatrix}$$

$$\Rightarrow \quad \text{ar}\,(\Delta\, P_2P_3P_4) = 8x_1^4\begin{vmatrix} 1 & 1 & 1 \\ -2 & -8 & 1 \\ 4 & 64 & 1 \end{vmatrix}$$

$$\therefore \quad \frac{\text{ar}\,(\Delta\, P_1P_2P_3)}{\text{ar}\,(\Delta\, P_2P_3P_4)} = \frac{1}{16}$$

● ***Ex. 36*** *Determine all polynomial $P(x)$ with rational coefficient so that for all x with $|x| \le 1$;*

$$P(x) = P\left(\frac{-x + \sqrt{3 - 3x^2}}{2}\right).$$

Sol. Here, $P(x) = P\left(\dfrac{-x + \sqrt{3 - 3x^2}}{2}\right)$ for $|x| \le 1$ ...(i)

Let $x = 0 \Rightarrow P(0) = P(\sqrt{3}/2)$

Which shows, $P(x) - P(0)$ is divisible by $x\left(x - \dfrac{\sqrt{3}}{2}\right)$.

Since, $P(x) - P(0)$ has rational coefficients and $\dfrac{\sqrt{3}}{2}$ is one of the roots.

$\therefore$ $-\dfrac{\sqrt{3}}{2}$ is also a root of $P(x) - P(0)$.

Thus, $x\left(x - \dfrac{\sqrt{3}}{2}\right)\left(x + \dfrac{\sqrt{3}}{2}\right) = x^3 - \dfrac{3}{4}x = \dfrac{4x^3 - 3x}{4}$ is factor of $P(x) - P(0)$.

$\therefore$ $P(x) = P(0) + (3x - 4x^3)\,P_1(x)$ for $|x| \le 1$ ...(ii)

As, $P(x) = P\left(\dfrac{-x + \sqrt{3 - 3x^2}}{2}\right)$

$$\Rightarrow \quad 3\left(\frac{-x + \sqrt{3 - 3x^2}}{2}\right) - 4\left(\frac{-x + \sqrt{3 - 3x^2}}{2}\right) = 3x - 4x^3$$

$$\therefore \quad P_1(x) = P_1\left(\frac{-x + \sqrt{3 - 3x^2}}{2}\right)$$

$\therefore$ $P_1(x) = P_1(0) + (3x - 4x^3)\,P_2(x)$ [using Eq. (ii)]

$\Rightarrow$ $P(x) = P(0) + (3x - 4x^3)\,(P_1(0)) + (3x - 4x^3)P_2(x))$

$= P(0) + (3x - 4x^3)\,P_1(0) + (3x - 4x^3)^2\,P_2(x)$

Thus, in general,

$$P(x) = a_0 + a_1(3x - 4x^3) + a_2\,(3x - 4x^3)^2 + \ldots + (3x - 4x^3)^k \cdot k\,(x)$$

Where $k\,(x)$ is a polynomial with rational coefficient.

● ***Ex. 37*** *Let $f(x) = (x - a)\,(x - b)\,(x - c), a < b < c$. Show that $f'(x) = 0$ has two roots one belonging to (a, b) and other belonging to (b, c).*

Sol. Here, $f(x)$ being a polynomial, is continuous and differentiable for all real values of x.

We also have, $f(a) = f(b) = f(c)$

If we apply Rolle's theorem to $f(x)$ in $[a, b]$ and $[b, c]$ we observe that $f'(x) = 0$ would have atleast one root in (a, b) and atleast one root in (b, c).

But $f'(x) = 0$ is a polynomial of degree two, hence $f'(x) = 0$ cannot have more than two roots.

It implies that exactly one root of $f'(x) = 0$ would lie in (a, b) and exactly one root of $f'(x) = 0$ would lie in (b, c).

● ***Ex. 38*** *If at each point of the curve $y = x^3 - ax^2 + x + 1$, the tangents is inclined at an acute angle with the positive direction of the X-axis, then find the interval of a.*

Sol. As, $y = x^3 - ax^2 + x + 1$ and the tangent is inclined at an acute angle with the positive direction of X-axis.

$$\therefore \quad \frac{dy}{dx} \ge 0 \;\Rightarrow\; 3x^2 - 2ax + 1 \ge 0, \text{ for all } x \in R$$

[we know, $ax^2 + bx + c \ge 0$ for all $x \in R$ $\Rightarrow a > 0$ and $D \le 0$]

$\Rightarrow$ $(2a)^2 - 4(3)(1) \le 0 \;\Rightarrow\; 4\,(a^2 - 3) \le 0$

$\Rightarrow$ $(a - \sqrt{3})(a + \sqrt{3}) \le 0 \quad \therefore \; -\sqrt{3} \le a \le \sqrt{3}$

● ***Ex. 39*** *Show that there is no cubic curve for which the tangent lines at two distinct points coincide.*

Sol. Suppose $y \equiv ax^3 + bx^2 + cx + d = 0\,(a \ne 0)$ be a cubic curve.

We assume that (x_1, y_1) and $(x_2, y_2), (x_1 < x_2)$ are two distinct points on the curve at which tangents coincide.

Then, by mean value theorem, there exists $x_3\,(x_1 < x_3 < x_2)$ such that

$$\frac{y_2 - y_1}{x_2 - x_1} = y'(x_3)$$

Since, tangent x_1, x_2, x_3 are solutions of equation

$$3ax^2 + 2bx + c = M$$

But, it is a quadratic and thus cannot have more than two roots. Therefore, no such cubic is possible.

● ***Ex. 40*** *The tangent at a point P to the rectangular hyperbola $xy = c^2$ meets the lines $x - y = 0, x + y = 0$ at Q and R, Δ_1 is the area of the Δ OQR, where O is the origin. The normal at P meets the X-axis at M and Y-axis at N. If Δ_2 is the area of the ΔOMN, show that Δ_2 varies inversely as the square of Δ_1.*

Sol. Tangent at $P(x_1, y_1)$ is $xy_1 + yx_1 = 2c^2$

The point of intersection of this line with $x - y = 0$ is given by,

$$x(x_1 + y_1) = 2c^2, \text{ i.e. } x = 2c^2/(x_1 + y_1)$$

$$\therefore \quad Q \text{ is} \left(\frac{2c^2}{x_1 + y_1}, \frac{2c^2}{x_1 + y_1}\right)$$

The point of intersection of the tangent with $x + y = 0$ is given by,

$$x(y_1 - x_1) = 2c^2, \quad x = \frac{2c^2}{y_1 - x_1}$$

$$\therefore \quad R \text{ is} \left(\frac{2c^2}{y_1 - x_1}, \frac{2c^2}{x_1 - y_1}\right)$$

Now, $\Delta_1 = \frac{1}{2}\{a_1b_2 - a_2b_1\} = \frac{1}{2}\{-a_1a_2 - a_2a_1\} = -a_1a_2$

$$\Delta_1 = \frac{4c^4}{x_1^2 - y_1^2}$$

The normal at (x_1, y_1) is $y - y_1 = \frac{x_1}{y_1}(x - x_1)$

Intersection with $y = 0$ is given by, $x - x_1 = -\frac{y_1^2}{x_1}$

$$\Rightarrow \quad x = \frac{x_1^2 - y_1^2}{x_1} \qquad \therefore \text{ M is} \left(\frac{x_1^2 - y_2^2}{x_1}, 0\right)$$

intersection with $x = 0$ is given by $\quad y - y_1 = -\frac{x_1^2}{y_1}$

$$\Rightarrow \quad y = \frac{y_1^2 - x_1^2}{y_1}. \qquad \therefore N \text{ is} \left(0, \frac{y_1^2 - x_1^2}{y_1}\right)$$

Now, $\Delta_2 = \frac{1}{2}\frac{(x_1^2 - y_1^2)}{x_1} \cdot \frac{(y_1^2 - x_1^2)}{y_1}$

$$= -\frac{1}{2}\frac{(x_1^2 - y_1^2)^2}{x_1y_1} = -\frac{1}{2}\frac{(x_1^2 - y_1^2)^2}{c^2}$$

$$\therefore \quad \Delta_1^2 \Delta_2 = \frac{16c^8}{(x_1^2 - y_1^2)^2}\left(-\frac{1}{2}\right)\frac{(x_1^2 - y_1^2)^2}{c^2} = -8c^6 = \text{constant}$$

$$\Rightarrow \quad \Delta_2 \propto \frac{1}{\Delta_1^2}$$

or Δ_2 varies inversely as the square of Δ_1.

● ***Ex. 41*** *If the function of $f : [0, 4] \to R$ is differentiable, then show that*

(i) $(f(4))^2 - (f(0))^2 = 8 f'(a) f(b)$ for some $a, b \in (0, 4)$.

(ii) $\int_0^4 f(t)\, dt = 2\{\alpha f(\alpha^2) + \beta f(\beta^2)\}$ for some $0 < \alpha, \beta < 2$.

[IIT JEE 2003]

Sol. (i) Here, f is differentiable $\Rightarrow f$ is also continuous.

Now, by Lagrange's mean value theorem, there exist $a \in (0, 4)$ such that

$$f'(a) = \frac{f(4) - f(0)}{4 - 0} = \frac{f(4) - f(0)}{4} \qquad \ldots(i)$$

Also, by intermediate mean value theorem, there exists $b \in (0, 4)$ such that

$$f(b) = \frac{f(4) + f(0)}{2} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$f'(a)\, f(b) = \frac{f(4) - f(0)}{4} \times \frac{f(4) + f(0)}{2}$$

$$f'(a)\, f(b) = \frac{(f(4))^2 - (f(0))^2}{8}$$

$$\Rightarrow (f(4))^2 - (f(0))^2 = 8 f'(a) f(b) \text{ for some, } a, b \in (0, 4)$$

(ii) Putting $t = z^2$, we have

$$\int_0^4 f(t)\, dt = \int_0^2 2z\, f(z^2)\, dz$$

Consider the function $\phi(t)$ given by,

$$\phi(t) = \int_0^t 2z\, f(z^2)\, dz;\ t \in [0, 2]$$

Clearly, $\phi(t)$ being an integral function of a continuous function, is continuous and differentiable on $[0, 2]$.

$\therefore$ By Lagrange's mean value theorem, there exists $c \in (0, 2)$ such that $\frac{\phi(2) - \phi(0)}{2 - 0} = \phi'(c)$

$$\Rightarrow \frac{\int_0^2 2z\, f(z^2)\, dz - \int_0^0 2z\, f(z^2)\, dz}{2 - 0} = 2cf(c^2)$$

[using $\phi'(t) = 2t\, f(t^2)$]

$$\Rightarrow \quad \int_0^2 2z\, f(z^2)\, dz = 4cf(c^2) \qquad \ldots(i)$$

Also, by intermediate mean value theorem for $c \in (0, 2)$, there exist $\alpha, \beta \in (0, 2)$ such that

$$\frac{\phi'(\alpha) + \phi'(\beta)}{2} = \phi'(c), \text{ where } 0 < \alpha < c < \beta < 2$$

$$\Rightarrow \quad 2\alpha f(\alpha^2) + 2\beta\, f(\beta^2) = 2\{2c\, f(c^2)\} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$\int_0^2 2z\, f(z^2)\, dz = 2\alpha\, f(\alpha^2) + 2\beta\, f(\beta^2),$$

for some $0 < \alpha, \beta < 2$

$$\Rightarrow \int_0^4 f(t)\, dt = 2(\alpha\, f(\alpha^2) + \beta\, f(\beta^2)),$$

for some $0 < \alpha, \beta < 2$

dy/dx as Rate Measurer and Tangents, Normals Exercise 1 : Single Option Correct Type Questions

1. Consider the cubic equation $f(x) = x^3 - nx + 1 = 0$ where $n \geq 3, n \in N$, then $f(x) = 0$ has
(a) at least one root in $(0, 1)$ (b) at least one root in $(1, 2)$
(c) at least one root in $(-1, 0)$ (d) data insufficient

2. If the normal to $y = f(x)$ at $(0, 0)$ is given by $y - x = 0$, then $\lim_{x \to 0} \dfrac{x^2}{f(x^2) - 20f(9x^2) + 2f(99x^2)}$ is
(a) $1/19$ (b) $-1/19$ (c) $1/2$ (d) does not exist

3. Tangent to a curve intersects the Y-axis at a point. A line perpendicular to this tangent through P passes through another point $(1, 0)$. The differential equation of the curve is
(a) $y\dfrac{dy}{dx} - x\left(\dfrac{dy}{dx}\right)^2 = 1$ (b) $x\dfrac{d^2y}{dx^2} + \left(\dfrac{dy}{dx}\right)^2 = 1$
(c) $y\dfrac{dy}{dx} + x = 1$ (d) None of these

4. The number of points in the rectangle $\{(x, y) : |x| \leq 9, |y| \leq 3\}$ which lie on the curve $y^2 = x + \sin x$ and at which the tangent to the curve is parallel to X-axis, is
(a) 3 (b) 2 (c) 4 (d) None of these

5. If $a, b, c, d \in R$ such that $\dfrac{a + 2c}{b + 3d} = -\dfrac{4}{3}$, then the equation $ax^3 + bx^2 + cx + d = 0$ has
(a) at least one root in $(-1, 0)$ (b) at least one root in $(0, 1)$
(c) no root in $(-1, 1)$ (d) no root in $(0, 2)$

6. If $3(a + 2c) = 4(b + 3d) \neq 0$, then the equation $ax^3 + bx^2 + cx + d = 0$ will have
(a) no real solution
(b) at least one real root in $(-1, 0)$
(c) at least one real root in $(0, 1)$
(d) None of the above

7. Let $f(x)$ be a differentiable function in the interval $(0, 2)$, then the value of $\int_0^2 f(x)\,dx$
(a) $f(c)$ where $c \in (0, 2)$ (b) $2f(c)$, where $c \in (0, 2)$
(c) $f'(c)$, where $c \in (0, 2)$ (d) None of these

8. Let $f(x)$ be a fourth differentiable function such that $f(2x^2 - 1) = 2xf(x), \forall\ x \in R$, then $f^{iv}(0)$ is equal to (where $f^{iv}(0)$ represents fourth derivative of $f(x)$ at $x = 0$)
(a) 0 (b) 1
(c) -1 (d) data insufficient

9. The curve $x + y - \ln(x + y) = 2x + 5$ has a vertical tangent at the point (α, β). Then, $\alpha + \beta$ is equal to
(a) -1 (b) 1 (c) 2 (d) -2

10. Let $y = f(x)$, $f : R \to R$ be an odd differentiable function such that $f'''(x) > 0$ and
$g(\alpha, \beta) = \sin^8 \alpha + \cos^8 \beta + 2 - 4\sin^2 \alpha \cos^2 \beta$.
If $f''(g(\alpha, \beta)) = 0$, then $\sin^2 \alpha + \sin^2 \beta$ is equal to
(a) 0 (b) 1 (c) 2 (d) 3

11. A polynomial of 6th degree $f(x)$ satisfies $f(x) = f(2 - x), \forall\ x \in R$, if $f(x) = 0$ has 4 distinct and 2 equal roots, then sum of the roots of $f(x) = 0$ is
(a) 4 (b) 5 (c) 6 (d) 7

12. Let a curve $y = f(x)$, $f(x) \geq 0, \forall\ x \in R$ has property that for every point P on the curve length of subnormal is equal to abscissa of P. If $f(1) = 3$, then $f(4)$ is equal to
(a) $-2\sqrt{6}$ (b) $2\sqrt{6}$ (c) $3\sqrt{5}$ (d) None of these

13. If a variable tangent to the curve $x^2y = c^3$ makes intercepts, a, b on X and Y-axes respectively, then the value of a^2b is
(a) $27c^3$ (b) $\dfrac{4}{27}c^3$
(c) $\dfrac{27}{4}c^3$ (d) $\dfrac{4}{9}c^3$

14. Let $f(x) = \begin{vmatrix} 1 & 1 & 1 \\ 3 - x & 5 - 3x^2 & 3x^3 - 1 \\ 2x^2 - 1 & 3x^5 - 1 & 7x^8 - 1 \end{vmatrix}$. Then, the equation $f(x) = 0$ has
(a) no real root
(b) atmost one real root
(c) at least two real roots
(d) exactly one real root in $(0, 1)$ and no other real root

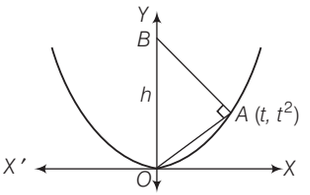
15. The graphs $y = 2x^3 - 4x + 2$ and $y = x^3 + 2x - 1$ intersect at exactly 3 distinct points. The slope of the line passing through two of these points is
(a) equal to 4 (b) equal to 6
(c) equal to 8 (d) not unique

16. In which of the following functions Rolle's theorem is applicable?
(a) $f(x) = \begin{cases} x, & 0 \leq x < 1 \\ 0, & x = 1 \end{cases}$ on $[0, 1]$
(b) $f(x) = \begin{cases} \dfrac{\sin x}{x}, & -\pi \leq x < 0 \\ 0, & x = 0 \end{cases}$ on $[-\pi, 0]$

(c) $f(x) = \dfrac{x^2 - x - 6}{x - 1}$ on $[-2, 3]$

(d) $f(x) = \begin{cases} \dfrac{x^3 - 2x^2 - 5x + 6}{x - 1}, & \text{if } x \neq 1 \\ -6, & \text{if } x = 1 \end{cases}$ on $[-2, 3]$

17. The figure shows a right triangle with its hypotenuse OB along the Y-axis and its vertex A on the parabola $y = x^2$.



Let h represents the length of the hypotenuse which depends on the x-coordinate of the point A. The value of $\lim\limits_{t \to 0} (h)$ is equal to

(a) 0 (b) 1/2 (c) 1 (d) 2

18. Number of positive integral value(s) of 'a' for which the curve $y = a^x$ intersects the line $y = x$ is

(a) 0 (b) 1 (c) 2 (d) more than 2

19. If $f(x) = 4 - \left(\dfrac{1}{2} - x\right)^{2/3}$, $g(x) = \begin{cases} \dfrac{\tan [x]}{x}, & x \neq 0 \\ 1, & x = 0 \end{cases}$

$h(x) = \{x\}$, $k(x) = 5^{\log_2 (x+3)}$, where $[x]$ and $\{x\}$ denote the greatest integer and fraction part function, then in $[0, 1]$, Lagrange's mean value theorem is not applicable to

(a) f, g, h (b) h, k (c) f, g (d) g, h, k

20. If the function $f(x) = x^4 + bx^2 + 8x + 1$ has a horizontal tangent and a point of inflection for the same value of x, then the value of b is equal to

(a) -1 (b) 1 (c) 6 (d) -6

21. Coffee is coming out from a conical filter, with height and diameter both are 15 cm into a cylindrical coffee pot with a diameter 15 cm. The rate at which coffee comes out from the filter into the pot is 100 cu cm/min.

The rate (in cm/min) at which the level in the pot is rising at the instance when the coffee in the pot is 10 cm, is

(a) $\dfrac{9}{16\pi}$ (b) $\dfrac{25}{9\pi}$ (c) $\dfrac{5}{3\pi}$ (d) $\dfrac{16}{9\pi}$

22. A horse runs along a circle with a speed of 20 km/h. A lantern is at the centre of the circle. A fence is there along the tangent to the circle at the point at which the horse starts. The speed with which the shadow of the horse moves along the fence at the moment when it covers 1/8 of the circle (in km/h) is

(a) 20 (b) 40 (c) 30 (d) 60

23. Water runs into an inverted conical tent at the rate of 20 cu ft/min and leaks out at the rate of 5 cu ft/min. The height of the water is three times the radius of the water's surface. The radius of the water surface is increasing when the radius is 5 ft, is

(a) $\dfrac{1}{5\pi}$ ft/min (b) $\dfrac{1}{10\pi}$ ft/min (c) $\dfrac{1}{15\pi}$ ft/min (d) None of these

24. Let $f(x) = x^3 - 3x^2 + 2x$. If the equation $f(x) = k$ has exactly one positive and one negative solution, then the value of k equals

(a) $-\dfrac{2\sqrt{3}}{9}$ (b) $-\dfrac{2}{9}$

(c) $\dfrac{2}{3\sqrt{3}}$ (d) $\dfrac{1}{3\sqrt{3}}$

25. The x-intercept of the tangent at any arbitrary point of the curve $\dfrac{a}{x^2} + \dfrac{b}{y^2} = 1$ is proportional to

(a) square of the abscissa of the point of tangency
(b) square root of the abscissa of the point of tangency
(c) cube of the abscissa of the point of tangency
(d) cube root of the abscissa of the point of tangency

26. If $f(x)$ is continuous and differentiable over $[-2, 5]$ and $-4 \leq f'(x) \leq 3$ for all x in $(-2, 5)$, then the greatest possible value of $f(5) - f(-2)$ is

(a) 7 (b) 9
(c) 15 (d) 21

27. A curve is represented parametrically by the equations $x = t + e^{at}$ and $y = -t + e^{at}$, where $t \in R$ and $a > 0$. If the curve touches the axis of x at the point A, then the coordinates of the point A are

(a) (1, 0) (b) $(1/e, 0)$
(c) $(e, 0)$ (d) $(2e, 0)$

28. At any two points of the curve represented parametrically by $x = a(2\cos t - \cos 2t)$, $y = a(2\sin t - \sin 2t)$, the tangents are parallel to the axis of x corresponding to the values of the parameter t differing from each other by

(a) $2\pi / 3$ (b) $3\pi / 4$ (c) $\pi / 2$ (d) $\pi / 3$

29. Let $F(x) = \int_{\sin x}^{\cos x} e^{(1 + \sin^{-1}(t))^2}\, dt$ on $\left[0, \dfrac{\pi}{2}\right]$, then

(a) $F''(c) = 0$ for all $c \in \left(0, \dfrac{\pi}{2}\right)$

(b) $F''(c) = 0$ for some $c \in \left(0, \dfrac{\pi}{2}\right)$

(c) $F'(c) = 0$ for some $c \in \left(0, \dfrac{\pi}{2}\right)$

(d) $F(c) \neq 0$ for all $c \in \left(0, \dfrac{\pi}{2}\right)$

30. If $f'(1) = 1$ and $\frac{d}{dx}(f(2x)) = f'(x), \forall\ x > 0$. If $f'(x)$ is differentiable, then there exists a number $c \in (2, 4)$ such that $f''(c)$ is equal to
(a) $-1/4$
(b) $-1/8$
(c) $1/4$
(d) $1/8$

31. Let $f(x)$ and $g(x)$ be two functions which are defined and differentiable for all $x \geq x_0$. If $f(x_0) = g(x_0)$ and $f'(x) > g'(x)$ for all $x > x_0$, then
(a) $f(x) < g(x)$ for some $x > x_0$
(b) $f(x) = g(x)$ for some $x > x_0$
(c) $f(x) > g(x)$ only for some $x > x_0$
(d) $f(x) > g(x)$ for all $x > x_0$

32. The range of values of m for which the line $y = mx$ and the curve $y = \frac{x}{x^2 + 1}$ enclose a region, is
(a) $(-1, 1)$ (b) $(0, 1)$
(c) $[0, 1]$ (d) $(1, \infty)$

33. Let S be a square with sides of length x. If we approximate the change in size of the area of S by $h \cdot \left.\frac{dA}{dx}\right|_{x = x_0}$, when the sides are changed from x_0 to $x_0 + h$, then the absolute value of the error in our approximation, is
(a) h^2 (b) $2hx_0$ (c) x_0^2 (d) h

34. Consider $f(x) = \int_1^x \left(t + \frac{1}{t}\right) dt$ and $g(x) = f'(x)$ for $x \in \left[\frac{1}{2}, 3\right]$. If P is a point on the curve $y = g(x)$ such that the tangent to this curve at P is parallel to a chord joining the points $\left(\frac{1}{2}, g\left(\frac{1}{2}\right)\right)$ and $(3, g(3))$ of the curve, then the coordinates of the point P are
(a) can't be found out (b) $\left(\frac{7}{4}, \frac{65}{28}\right)$
(c) $(1, 2)$ (d) $\left(\sqrt{\frac{3}{2}}, \frac{5}{\sqrt{6}}\right)$

dy/dx as Rate Measurer & Tangents, Normals Exercise 2 : More than One Option Correct Type Questions

35. For the curve represented parametrically by the equation, $x = 2\log(\cot t) + 1$ and $y = \tan t + \cot t$, then
(a) tangent at $t = \frac{\pi}{4}$ is parallel to X-axis
(b) normal at $t = \frac{\pi}{4}$ is parallel to Y-axis
(c) tangent at $t = \frac{\pi}{4}$ is parallel to $y = x$
(d) normal at $t = \frac{\pi}{4}$ is parallel to $y = x$

36. Consider the curve $f(x) = x^{1/3}$, then
(a) the equation of tangent at $(0, 0)$ is $x = 0$
(b) the equation of normal at $(0, 0)$ is $y = 0$
(c) normal to the curve does not exist at $(0, 0)$
(d) $f(x)$ and its inverse meet at exactly 3 points

37. The angle at which the curve $y = ke^{kx}$ intersects Y-axis is
(a) $\tan^{-1}(k^2)$ (b) $\cot^{-1}(k^2)$
(c) $\sin^{-1}\left(\frac{1}{\sqrt{1 + k^4}}\right)$ (d) $\sec^{-1}(\sqrt{1 + k^4})$

38. Let $f(x) = 8x^3 - 6x^2 - 2x + 1$, then
(a) $f(x) = 0$ has no root in $(0, 1)$
(b) $f(x) = 0$ has at least one root in $(0, 1)$
(c) $f'(c)$ vanishes for some $c \in (0, 1)$
(d) None of the above

39. If $f(0) = f(1) = f(2) = 0$ and function $f(x)$ is twice differentiable in $(0, 2)$ and continuous in $[0, 2]$, then which of the following is/are definitely true?
(a) $f''(c) = 0; \forall\ c \in (0, 2)$
(b) $f'(c) = 0$; for at least two $c \in (0, 2)$
(c) $f'(c) = 0$; for exactly one $c \in (0, 2)$
(d) $f''(c) = 0$; for at least one $c \in (0, 2)$

40. Equation $\frac{1}{(x + 1)^3} - 3x + \sin x = 0$ has
(a) no real root
(b) two real and distinct roots
(c) exactly one negative root
(d) exactly one root between -1 and ∞

41. If f is an odd continuous function in $[-1, 1]$ and differentiable in $(-1, 1)$, then
(a) $f'(A) = f(1)$ for some $A \in (-1, 0)$
(b) $f'(B) = f(1)$ for some $B \in (0, 1)$
(c) $n(f(A))^{n-1} f'(A) = (f(1))^n$ for some $A \in (-1, 0), n \in N$
(d) $n(f(B))^{n-1} f'(B) = (f(1))^n$ for some $B \in (0, 1), n \in N$

42. The parabola $y = x^2 + px + q$ intersects the straight line $y = 2x - 3$ at a point with abscissa 1. If the distance between the vertex of the parabola and the X-axis is least, then
(a) $p = 0$ and $q = -2$
(b) $p = -2$ and $q = 0$

(c) least distance between the vertex of the parabola and X-axis is 2
(d) least distance between the vertex of the parabola and X-axis is 1

43. The abscissa of the point on the curve $\sqrt{xy} = a + x$, the tangent at which cuts off equal intersects from the coordinate axes, is $(a > 0)$

(a) $\frac{a}{\sqrt{2}}$ (b) $-\frac{a}{\sqrt{2}}$ (c) $a\sqrt{2}$ (d) $-a\sqrt{2}$

44. If the side of a triangle vary slightly in such a way that its circumradius remains constant, then $\frac{da}{\cos A} + \frac{db}{\cos B} + \frac{dc}{\cos C}$ is equal to

(a) $6R$ (b) $2R$
(c) 0 (d) $2R\,(dA + dB + dC)$

45. Let $f(x)$ satisfy the requirements of Lagrange's mean value theorem in $[0, 1]$, $f(0) = 0$ and $f'(x) \le 1 - x, \forall\ x \in (0, 1)$, then

(a) $f(x) \ge x$ (b) $|f(x)| \ge 1$
(c) $f(x) \le x(1 - x)$ (d) $f(x) \le 1/4$

46. For function $f(x) = \frac{\ln x}{x}$, which of the following statements are true?

(a) $f(x)$ has horizontal tangent at $x = e$
(b) $f(x)$ cuts the X-axis only at one point
(c) $f(x)$ is many-one function
(d) $f(x)$ has one vertical tangent

47. Equation of a line which is tangent to both the curves $y = x^2 + 1$ and $y = -x^2$ is

(a) $y = \sqrt{2}\,x + \frac{1}{2}$ (b) $y = \sqrt{2}\,x - \frac{1}{2}$
(c) $y = -\sqrt{2}\,x + \frac{1}{2}$ (d) $y = -\sqrt{2}\,x - \frac{1}{2}$

48. Let $F(x) = (f(x))^2 + (f'(x))^2$, $F(0) = 6$ where $f(x)$ is thrice differentiable function such that $|f(x)| \le 1$ for all $x \in [-1, 1]$, then choose the correct statement(s).

(a) There is at least one point in each of the intervals $(-1, 0)$ and $(0, 1)$ where $|f'(x)| \le 2$
(b) There is at least one point in each of the intervals $(-1, 0)$ and $(0, 1)$ where $F(x) \le 5$
(c) There is no point of local maxima of $F(x)$ in $(-1, 1)$
(d) For some $c \in (-1, 1)$, $F(c) \ge 6$, $F'(c) = 0$ and $F''(c) \le 0$

49. If the Rolle's theorem is applicable to the function f defined by

$$f(x) = \begin{cases} ax^2 + b, & |x| \le 1 \\ 1, & |x| = 1 \\ \frac{c}{|x|}, & |x| > 1 \end{cases}$$

in the interval $[-3, 3]$, then which of the following alternative(s) is/are correct?

(a) $a + b + c = 2$ (b) $|a| + |b| + |c| = 3$
(c) $2a + 4b + 3c = 8$ (d) $4a^2 + 4b^2 + 5c^2 = 15$

dy/dx as Rate Measurer & Tangents, Normals Exercise 3 : Statements I and II Type Questions

■ **Directions** (Q. Nos. 50 to 56) *For the following questions, choose the correct answer from the options (a), (b), (c) and (d) defined as follows*

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I
(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I
(c) Statement I is true, Statement II is false
(d) Statement I is false, Statement II is true

50. **Statement I** If $g(x)$ is a differentiable function $g(1) \ne 0$, $g(-1) \ne 0$ and Rolle's theorem is not applicable to $f(x) = \frac{x^2 - 1}{g(x)}$ in $[-1, 1]$, then $g(x)$ has atleast one root in $(-1, 1)$.

Statement II If $f(a) = f(b)$, then Rolle's theorem is applicable for $x \in (a, b)$.

51. **Statement I** Shortest distance between $|x| + |y| = 2$ and $x^2 + y^2 = 16$ is $4 - \sqrt{2}$.

Statement II Shortest distance between the two smooth curves lies along the common normal.

52. **Statement I** If $\alpha_1, \alpha_2, \alpha_3, \ldots, \alpha_n$ are the n real roots of a polynomial equation of nth degree with real coefficients such that sum of the roots taken $r\,(1 \le r \le n)$ at a time is positive, then all the roots are positive.

Statement II The number of times sign of coefficients change while going left to right of a polynomial equation is the number of maximum positive roots.

53. **Statement I** Tangents at two distinct points of a cubic polynomial cannot coincide.

Statement II If $P(x)$ is a polynomial of degree $n\,(n \ge 2)$, then $P'(x) + k$ cannot hold for n or more distinct values of x.

54. **Statement I** For $f(x)=\begin{cases}\frac{1}{2}-x, & x<\frac{1}{2}\\ \left(\frac{1}{2}-x\right)^2, & x\geq\frac{1}{2}\end{cases}$, mean value theorem is applicable in the interval $[0, 1]$.

Statement II For application of mean value theorem, $f(x)$ must be continuous in $[0, 1]$ and differentiable in $(0, 1)$.

55. Let $f(x)=\ln(2+x)-\frac{2x+2}{x+3}$.

Statement I The function $f(x)=0$ has a unique solution in the domain of $f(x)$.

Statement II If $f(x)$ is continuous in $[a, b]$ and is strictly monotonic in (a, b), then f has a unique root in (a, b).

56. Consider the polynomial function

$$f(x)=\frac{x^7}{7}-\frac{x^6}{6}+\frac{x^5}{5}-\frac{x^4}{4}+\frac{x^3}{3}-\frac{x^2}{2}+x$$

Statement I The equation $f(x)=0$ cannot have two or more roots.

Statement II Rolle's theorem is not applicable for $y=f(x)$ on any interval $[a, b]$, where $a, b\in R$.

dy/dx as Rate Measurer & Tangents, Normals Exercise 4 : Passage Based Questions

Passage I (Q. Nos. 57 to 59)

We say an equation $f(x)=g(x)$ is consistent, if the curves $y=f(x)$ and $y=g(x)$ touch or intersect at at least one point. If the curves $y=f(x)$ and $y=g(x)$ do not intersect or touch, then the equation $f(x)=g(x)$ is said to be inconsistent, i.e. has no solution.

57. The equation $\cos x+\cos^{-1}x=\sin x+\sin^{-1}x$ is

(a) consistent and has infinite number of solutions
(b) consistent and has finite number of solutions
(c) inconsistent
(d) None of the above

58. The equation $\sin x=x^2+x+1$ is

(a) consistent and has infinite number of solutions
(b) consistent and has finite number of solutions
(c) inconsistent
(d) consistent and has unique solution

59. Among the following equations, which is consistent in $(0, \pi/2)$?

(a) $\sin x+x^2=0$ (b) $\cos x=x$
(c) $\tan x=x$ (d) All of these

Passage II (Q. Nos. 60 to 62)

To find the point of contact $P\equiv(x_1, y_1)$ of a tangent to the graph of $y=f(x)$ passing through origin O, we equate the slope of tangent to $y=f(x)$ at P to the slope of OP. Hence, we solve the equation $f'(x_1)=\frac{f(x_1)}{x_1}$ to get x_1 and y_1.

60. The equation $|\ln mx|=px$, where m is a positive constant, has a single root for

(a) $0<p<\frac{m}{e}$ (b) $p<\frac{e}{m}$
(c) $0<p<\frac{e}{m}$ (d) $p>\frac{m}{e}$

61. The equation $|\ln mx|=px$, where m is a positive constant, has exactly two roots for

(a) $p=\frac{m}{e}$ (b) $p=\frac{e}{m}$
(c) $0<p\leq\frac{e}{m}$ (d) $0<p\leq\frac{m}{e}$

62. The equation $|\ln mx|=px$, where m is a positive constant, has exactly three roots for

(a) $p<\frac{m}{e}$ (b) $0<p<\frac{m}{e}$
(c) $0<p<\frac{e}{m}$ (d) $p<\frac{e}{m}$

Passage III (Q. Nos. 63 to 64)

Consider the family of circles: $x^2+y^2-3x-4y-c_i=0$, $c_i\in N$ $(i=1, 2, 3, \ldots, n)$.
Also, let all circles intersects X-axis at integral points only and $c_1<c_2<c_3<c_4\ldots<c_n$. A point (x, y) is said to be integral point, if both coordinates x and y are integers.

63. If circle $x^2+y^2-3x-4y-(c_2-c_1)=0$ and circle $x^2+y^2=r^2$ have only one common tangent, then

(a) $r=1/2$
(b) tangent passes through $(10, 0)$
(c) $(3, 4)$ lies outside the circle $x^2+y^2=r^2$
(d) $c_2=2r+c_1$

64. The ellipse $4x^2+9y^2=36$ and hyperbola $a^2x^2-y^2=4$ intersect orthogonally, then the equation of circle through the points of intersection of two conics is

(a) $x^2+y^2=(c_5)^2$ (b) $x^2+y^2=\frac{c_4}{7}$
(c) $x^2+y^2=c_3-2c_1$ (d) $x^2+y^2=c_7/14$

dy/dx as Rate Measurer & Tangents, Normals Exercise 5 : Matching Type Questions

65. Match the statements of Column I with values of Column II.

	Column I		Column II
(A)	The equation $x \log x = 3 - x$ has at least one root in	(p)	(0, 1)
(B)	If $27a + 9b + 3c + d = 0$, then the equation $4ax^3 + 3bx^2 + 2cx + d = 0$ has at least one root in	(q)	(1, 3)
(C)	If $c = \sqrt{3}$ and $f(x) = x + \frac{1}{x}$, then interval of x in which LMVT is applicable for $f(x)$ is	(r)	(0, 3)
(D)	If $c = \frac{1}{2}$ and $f(x) = 2x - x^2$, then the interval of x in which LMVT is applicable for $f(x)$, is	(s)	(− 1, 1)

66. Match the statements of Column I with values of Column II.

	Column I		Column II
(A)	A circular plate is expanded by heat from radius 5 cm to 5.06 cm. Approximate increase in area is	(p)	4
(B)	If an edge of a cube increases by 1%, then percentage increase in volume is	(q)	$0.6\,\pi$
(C)	If the rate of decrease of $\frac{x^2}{2} - 2x + 5$ is twice the rate of decrease of x, then x is equal to (rate of decrease is non-zero)	(r)	3
(D)	Rate of increase in area of equilateral triangle of side 15 cm, when each side is increasing at the rate of 0.1 cm/s, is	(s)	$\frac{3\sqrt{3}}{4}$

dy/dx as Rate Measurer & Tangents, Normals Exercise 6 : Single Integer Answer Type Questions

67. A point is moving along the curve $y^3 = 27x$. The interval in which the abscissa changes at slower rate than ordinate, is (a, b). Then, $(a + b)$ is ..... .

68. The slope of the curve $2y^2 = ax^2 + b$ at $(1, -1)$ is -1. Then, $(a - b)$ is ..... .

69. Let $f(1) = -2$, $f'(x) \geq 4.2$ for $1 \leq x \leq 6$. The smallest possible value of $f(6) - 16$ is ..... .

70. Let $f(x) = \begin{cases} -x^2, & \text{for } x < 0 \\ x^2 + 8, & \text{for } x \geq 0 \end{cases}$. Then, the absolute value of x-intercept of the line that is tangent to the graph of $f(x)$, is ..... .

71. The tangent to the graph of the function $y = f(x)$ at that point with abscissa, $x = a$ forms with the X- axis at an angle of $\frac{\pi}{3}$ and the point with abscissa at $x = b$ at an angle $\frac{\pi}{4}$, then the value of $\left| \int_a^b f'(x) \cdot f''(x)\, dx \right|$ is ..... .

72. Two curves $C_1 : y = x^2 - 3$ and $C_2 : y = kx^2,\ k \in R$ intersect each other at two different points. The tangent drawn to C_2 at one of the points of intersection $A(a, y_1), (a > 0)$ meets C_1 again at $B(1, y_2)$.
The value of a is ..... .

73. Consider the function $f(x) = 8x^2 - 7x + 5$ on the interval $[-6, 6]$. The value of c that satisfies the conclusion of the mean value theorem, is ..... .

74. Suppose that f is differentiable for all x and that $f'(x) \leq 2$ for all x. If $f(1) = 2$ and $f(4) = 8$, then $f(2)$ has the value equal to ..... .

75. Suppose a, b and c are positive integers with $a < b < c$ such that $1/a + 1/b + 1/c = 1$. The value of $(a + b + c - 5)$ is ..... .

Subjective Type Questions

76. Show that a tangent to an ellipse whose segment intercepted by the axes is the shortest, is divided at the point of tangency into two parts respectively, is equal to the semi-axes of the ellipse.

77. Tangents are drawn from the origin to the curve $y = \sin x$. Prove that points of contact lie on $y^2 = \dfrac{x^2}{1+x^2}$.

78. If f is a continuous function with $\int_0^x f(t)\,dt \to \infty$ as $|x| \to \infty$, then show that every line $y = mx$ intersects the curve $y^2 + \int_0^x f(t)\,dt = 2$.

79. Find the equation of the straight line which is a tangent at one point and normal at another point to the curve $y = 8t^3 - 1,\ x = 4t^2 + 3$.

80. Let a curve $y = f(x)$ passes through (1, 1), at any point P on the curve tangent and normal are drawn to intersect the X-axis at Q and R, respectively. If $QR = 2$, find the equation of all such possible curves.

81. Show that the angle between the tangent at any point P and the line joining P to the origin 'O' is the same at all points of the curve $\log(x^2 + y^2) = c\,\tan^{-1}(y/x)$, where c is constant.

82. If the equation of two curves are $y^2 = 4ax$ and $x^2 = 4ay$

(i) Find the angle of intersection of two curves.
(ii) Find the equation of common tangents to these curves.

83. A straight line intersects the three concentric circles at A, B, C. If the distance of the line from the centre of the circles is 'P', prove that the area of the triangle formed by the tangents to the circle at A, B, C is $\left(\dfrac{1}{2P}\cdot AB\cdot BC\cdot CA\right)$.

84. Find the equation of all possible curves such that length of intercept made by any tangent on X-axis is equal to the square of x-coordinate of the point of tangency. Given that the curve passes through $(2, 1)$.

85. The tangent to the curve $y = x - x^3$ at a point P meets the curve again at Q. Prove that one point of trisection of PQ lies on the Y-axis. Find the locus of the other points of trisection.

86. Determine all the curves for which the ratio of the length of the segment intercepted by any tangent on the Y-axis to the length of the radius vector is constant.

87. If t be a real number satisfying $2t^3 - 9t^2 + 30 - a = 0$, then the values of the parameter a for which the equation $x + \dfrac{1}{x} = t$ gives six real and distinct values of x.

dy/dx as Rate Measurer & Tangents, Normals Exercise 8 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

88. The slope of the tangent to the curve $(y - x^5)^2 = x(1 + x^2)^2$ at the point (1, 3) is **[Integer Type Question 2014]**

89. Let $f(x) = 2 + \cos x$, for all real x.

Statement I For each real t, there exists a point c in $[t, t + \pi]$, such that $f'(c) = 0$. Because
Statement II $f(t) = f(t + 2\pi)$ for each real t. **[Assertion and Reason 2007]**

(a) Statement I is correct, Statement II is also correct; Statement II is the correct explanation of Statement I
(b) Statement I is correct, Statement II is also correct; Statement II is not the correct explanation of Statement I
(c) Statement I is correct; Statement II is incorrect
(d) Statement I is incorrect; Statement II is correct

90. If $|f(x_1) - f(x_2)| \le (x_1 - x_2)^2, \forall x_1, x_2 \in R$. Find the equation of tangent to the curve $y = f(x)$ at the point (1, 2). **[Analytical Descriptive 2005]**

91. The point(s) on the curve $y^3 + 3x^2 = 12y$, where the tangent is vertical, is (are) **[One Correct Option 2002]**

(a) $\left(\pm\dfrac{4}{\sqrt{3}}, -2\right)$ (b) $\left(\pm\sqrt{\dfrac{11}{3}}, 0\right)$ (c) (0, 0) (d) $\left(\pm\dfrac{4}{\sqrt{3}}, 2\right)$

92. If the normal to the curve $y = f(x)$ at the point (3, 4) makes an angle $\frac{3\pi}{4}$ with the positive X-axis, then $f'(3)$ is equal to **[One Correct Option 2000]**

(a) −1 (b) −3/4 (c) 4/3 (d) 1

(ii) JEE Main & AIEEE

93. The normal to the curve $y(x-2)(x-3) = x+6$ at the point where the curve intersects the Y-axis passes through the point **[2017 JEE Main]**

(a) $\left(\frac{1}{2}, \frac{1}{3}\right)$ (b) $\left(-\frac{1}{2}, -\frac{1}{2}\right)$ (c) $\left(\frac{1}{2}, \frac{1}{2}\right)$ (d) $\left(\frac{1}{2}, -\frac{1}{3}\right)$

94. The normal to the curve $x^2 + 2xy - 3y^2 = 0$ at (1,1) **[2015 JEE Main]**

(a) does not meet the curve again
(b) meets in the curve again the second quadrant
(c) meets the curve again in the third quadrant.
(d) meets the curve again in the fourth quadrant

Answers

Exercise for Session 1

1. 6 cm^3/s **2.** (1, 5/3) and (−1, 1/3)

3. 8 cm/s **4.** 750 cm^3/s **5.** $\frac{200\,\pi r^3}{(r+5)^2}$ km^2/h

6. $\frac{1}{48\,\pi}$ cm/s **7.** $-\frac{1}{3\pi}$ cm/s **8.** $\frac{1}{10\pi}$ cm/s

82. (i) $Q = \tan^{-1}\left(\frac{3}{4}\right)$ (ii) $x + y = a = 0$
84. Possible curve are $y = \frac{x}{2(x-1)}$ or $y = \frac{3x}{2(1+x)}$.
85. $y = x - 5x^3$ **86.** $(y + \sqrt{x^2 + y^2})\, x^{k-1} = c_1$
87. No real value **88.** 8 **89.** (b) **90.** $y - 2 = 0$
91. (d) **92.** (d) **93.** (c) **94.** (d)

Solutions

1. Here, $f(x) = x^3 - nx + 1$

$f(0) = 1$ and $f(1) = 1 - n + 1 = 2 - n$

$\because \quad n \geq 3$

$\therefore \quad f(1) < 0$ and also we have, $f(0) > 0$

$\therefore$ $f(x)$ must have at least one real root in $(0, 1)$.

2. Given, slope of normal to $y = f(x)$ is 1.

$$\Rightarrow \quad \left(-\frac{1}{f'(x)}\right)_{(0,\,0)} = 1$$

$$\Rightarrow \quad f'(0) = -1 \qquad \text{...(i)}$$

Now, $\lim\limits_{x\to 0} \dfrac{x^2}{f(x^2) - 20f(9x^2) + 2f(99x^2)}$

$$= \lim_{x\to 0} \frac{2x}{f'(x^2)\cdot 2x - 20f'(9x^2)\cdot 18x + 2f'(99x^2)\cdot(198x)}$$

[using L' Hospital's rule]

$$= \lim_{x\to 0} \frac{1}{f'(x^2) - 180f'(9x^2) + f'(99x^2)\cdot(198)}$$

$$= \frac{1}{f'(0) - 180\cdot f'(0) + 198\cdot f'(0)}$$

$$= \frac{1}{-1 + 180 - 198}$$

$$= -\frac{1}{19}$$

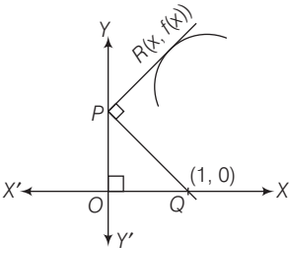
3. The equation of the tangent at the point $R(x, f(x))$ is

$$Y - f(x) = f'(x)(X - x) \qquad \text{...(i)}$$

The point of intersection on Y-axis, is $P(0, f(x) - x f'(x))$.

The slope of line perpendicular to tangent at R, is

$$m_{PQ} = \frac{(f(x) - xf'(x)) - 0}{0 - 1} \qquad \text{...(ii)}$$



$$\therefore \quad f'(x)\cdot m_{PQ} = -1$$

$$\Rightarrow \quad f'(x)\cdot\frac{(f(x) - xf'(x))}{-1} = -1$$

$$\Rightarrow \quad f(x)f'(x) - x(f'(x))^2 = 1$$

4. Here, $y^2 = x + \sin x$

$$\Rightarrow \quad 2y\,dy/dx = 1 + \cos x$$

For horizontal tangent, $dy/dx = 0$

$$\therefore \quad \cos x = -1 \Rightarrow x = (2n+1)\pi$$

Since, $y^2 = x + \sin x$ and $|y| \leq 3$

$$\Rightarrow \quad 0 \leq x \leq 9$$

$$\Rightarrow \quad 0 \leq (2n+1)\pi \leq 9$$

$$\therefore \quad n = 0 \Rightarrow x = \pi$$

$$\Rightarrow \quad y^2 = \pi \text{ or } y = \pm\sqrt{\pi}$$

Thus, points are $(\pi, \sqrt{\pi})$ and $(\pi, -\sqrt{\pi})$.

$\therefore$ Number of points is 2.

5. Here, $\dfrac{a + 2c}{b + 3d} = -\dfrac{4}{3}$

$$\Rightarrow \quad 3a + 6c = -4b - 12d$$

$$\Rightarrow \quad 3a + 4b + 6c + 12d = 0$$

or $$\frac{a}{4} + \frac{b}{3} + \frac{c}{2} + d = 0 \qquad \text{...(i)}$$

Consider, $f(x) = \dfrac{ax^4}{4} + \dfrac{bx^3}{3} + \dfrac{cx^2}{2} + dx$

Then, $f(0) = 0 = f(1)$ [using Eq. (i)] ...(ii)

$\therefore$ $f(x)$ satisfy the condition of Rolle's theorem in $[0, 1]$.

Hence, $f'(x) = 0$ has at least one solution in $(0, 1)$.

6. Let $f(x) = \dfrac{ax^4}{4} + \dfrac{bx^3}{3} + \dfrac{cx^2}{2} + dx$,

which is continuous and differentiable.

Also, $$f(0) = 0,\ f(-1) = \frac{a}{4} - \frac{b}{3} + \frac{c}{2} - d$$

$$= \frac{1}{4}(a + 2c) - \frac{1}{3}(b + 3d) = 0$$

So, according to Rolle's theorem, there exists at least one root of $f'(x) = 0$ in $(-1, 0)$.

7. Let us consider $g(t) = \int_0^t f(x)\,dx$

Applying LMVT in $(0, 2)$, we get

$$\frac{g(2) - g(0)}{2 - 0} = g'(c), \text{ where } c \in (0, 2)$$

$$\Rightarrow \quad \int_0^2 f(x)\,dx = 2f(c), \text{ where } c \in (0, 2)$$

8. Replace x by $-x$

$\Rightarrow$ $x[f(x) + f(-x)] = 0 \Rightarrow$ $f(x)$ is an odd function.

$\Rightarrow$ $f^{iv}(x)$ is also odd $\Rightarrow$ $f^{iv}(0) = 0$

9. Given, $x + y - \ln(x + y) = 2x + 5$

$$\Rightarrow \quad 1 + \frac{dy}{dx} - \frac{1}{x + y}\left(1 + \frac{dy}{dx}\right) = 2$$

$$\Rightarrow \quad \frac{dy}{dx} = \frac{x + y + 1}{x + y - 1}$$

$$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(\alpha,\,\beta)} = \frac{\alpha + \beta + 1}{\alpha + \beta - 1} = \infty, \text{ when } \alpha + \beta = 1$$

10. Since, $f''(x)$ is odd function.

$\therefore \quad g(\alpha, \beta) = 0$

$\Rightarrow \quad (\sin^4 \alpha - 1)^2 + (\cos^4 \beta - 1)^2 + 2(\sin^2 \alpha - \cos^2 \beta)^2 = 0$

$\Rightarrow \quad \sin^2 \alpha + \sin^2 \beta = 1$

11. Let α be the root of $f(x) = 0$.

$\Rightarrow \quad f(\alpha) = f(2 - \alpha) = 0$

$\therefore \quad f(x)$ has 4 distinct and 2 equal roots.

$\therefore$ Sum of the roots $= 6$

12. Given, $y\dfrac{dy}{dx} = x$

$\Rightarrow \quad y\,dy = x\,dx \Rightarrow \; y^2 = x^2 + c$

$\because \quad f(1) = 3$

$\therefore \quad 9 = 1 + c \;\Rightarrow\; c = 8 \;\Rightarrow\; y^2 = x^2 + 8$

$\Rightarrow \quad f(x) = \sqrt{x^2 + 8}$

$\Rightarrow \quad f(4) = \sqrt{16 + 8} = 2\sqrt{6}$

13. Given, $x^2y = c^3$

$\Rightarrow \quad x^2\dfrac{dy}{dx} + 2xy = 0$

$\Rightarrow \quad \dfrac{dy}{dx} = -\dfrac{2y}{x}$

Equation of tangent at (x, y), is $Y - y = -\dfrac{2y}{x}(X - x)$

$Y = 0$, gives $X = \dfrac{3x}{2} = a$

and $X = 0$, gives $Y = 3y = b$

Now, $a^2b = \dfrac{9x^2}{4} \cdot 3y = \dfrac{27}{4}x^2y = \dfrac{27}{4}c^3$

14. Clearly, $f(0) = f(1) = 0$ and $f(x)$ is a polynomial of degree 10.

Therefore, by LMVT, we must have at least one root in $(0, 1)$.

Since, the degree of $f(x)$ is even.

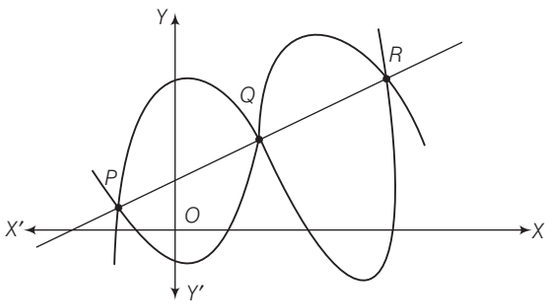
$\therefore$ It has at least two real roots.

15. Let (x_1, y_1) and (x_2, y_2) be two intersect points.

Given, $y = x^3 + 2x - 1$ and $y = 2x^3 - 4x + 2$

$\therefore \quad y_1 = 2x_1^3 - 4x_1 + 2$ ...(i)

and $2y_1 = 2x_1^3 + 4x_1 - 2$ ...(ii)



Subtracting Eq. (i) from Eq. (ii), we get

$y_1 = 8x_1 - 4$ ...(iii)

Similarly, $y_2 = 8x_2 - 4$ ...(iv)

Now, from Eqs. (iii) and (iv), we get $y_2 - y_1 = 8(x_2 - x_1)$

$\therefore \quad \dfrac{y_2 - y_1}{x_2 - x_1} = 8$

16. (a) Discontinuous at $x = 1$, therefore not applicable.

(b) Discontinuous at $x = 0$, therefore not applicable.

(c) Discontinuity at $x = 1 \;\Rightarrow$ not applicable.

(d) Note that $x^3 - 2x^2 - 5x + 6 = (x - 1)(x^2 - x - 6)$.

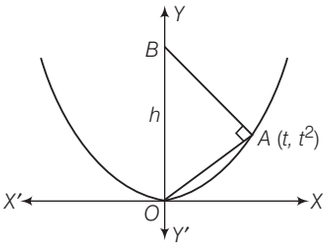
Hence, $f(x) = x^2 - x - 6$, if $x \neq 1$ and $f(1) = -6$

$\Rightarrow \; f$ is continuous at $x = 1$.

So, $f(x) = x^2 - x - 6$ is continuous throughout the interval $[-2, 3]$.

Also, note that $f(-2) = f(3) = 0$. Hence, Rolle's theorem is applicable.

17. Let $A = (t, t^2)$. Then, $m_{OA} = t, m_{AB} = -\dfrac{1}{t}$



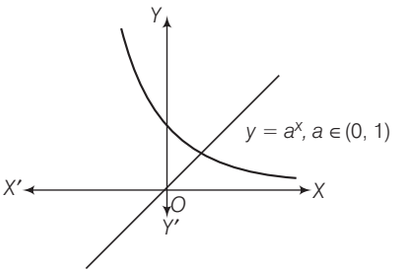
Equation of AB, $y - t^2 = -\dfrac{1}{t}(x - t)$

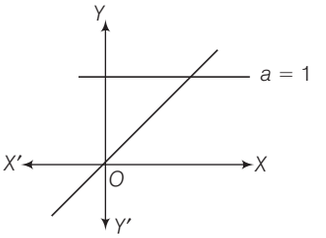
Putting $x = 0$

$\Rightarrow \quad h = t^2 + 1$

Now, $\lim\limits_{t \to 0}(h) = \lim\limits_{t \to 0}(1 + t^2) = 1$

18. For $0 < a \leq 1$, the line always intersects $y = a^x$



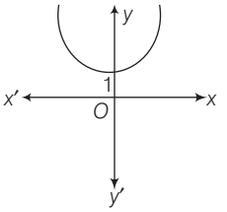


For $a > 1$, say $a = e$. Consider $f(x) = e^x - x$, $f'(x) = e^x - 1$

$f'(x) > 0$ for $x > 0$ and $f'(x) < 0$ for $x < 0$

$\therefore$ $f(x)$ is increasing $(\uparrow)$ for $x > 0$

and decreasing $(\downarrow)$ for $x < 0$



$y = e^x$ always lies above $y = x$, i.e. $e^x - x \geq 1$ for $a > 1$

Hence, the line $y = x$ intersect when $a \in (0, 1]$.

19. $\because$ f is not differentiable at $x = \frac{1}{2}$,

g is not continuous in $[0, 1]$ at $x = 0$ and 1,

and h is not continuous in $[0, 1]$ at $x = 1$

$$k(x) = (x+3)^{\ln_2 5} = (x+3)^p, \text{ where } 2 < p < 3$$

$\therefore$ None of these, f, g, h follows Lagrange's mean value theorem.

20. $f'(x) = 0$ and $f''(x) = 0$ for the same $x = x_1$ [say]

Now, $f'(x) = 4x^3 + 2bx + 8$

$$f'(x_1) = 2[2x_1^3 + bx_1 + 4] = 0 \quad \ldots(i)$$

$$f''(x_1) = 2[6x_1^2 + b] = 0 \quad \ldots(ii)$$

From Eq. (ii), $b = -6x_1^2$

Substituting this value of b in Eq. (i), we get

$$2x_1^3 + (-6x_1^3) + 4 = 0$$

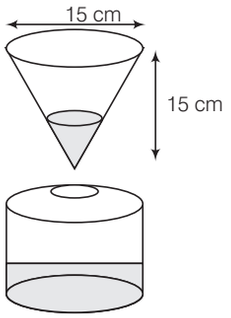
$$\Rightarrow \quad 4x_1^3 = 4$$

$$\Rightarrow \quad x_1 = 1$$

Hence, $b = -6$

21. For a cylindrical pot, $V = \pi r^2 h$

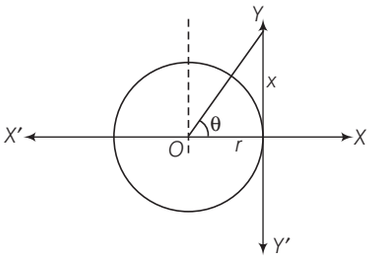
$$\Rightarrow \quad \frac{dV}{dt} = \pi\left[r^2\frac{dh}{dt} + h\cdot 2r\frac{dr}{dt}\right] \qquad \left[r = \text{constant}, \frac{dr}{dt} = 0\right]$$



$$\Rightarrow \quad 100 = \pi r^2\frac{dh}{dt} \Rightarrow 100 = \pi\cdot\frac{225}{4}\cdot\frac{dh}{dt} \qquad \left[\because\ r = \frac{15}{2}\text{ cm}\right]$$

$$\Rightarrow \quad \frac{dh}{dt} = \frac{400}{225\pi} = \frac{16}{9\pi}\text{ cm/min}$$

22. $\tan\theta = x/r \ \Rightarrow \ x = r\tan\theta$

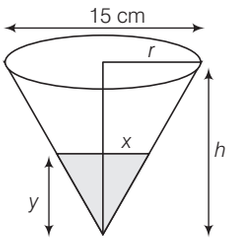


$$\Rightarrow \quad dx/dt = r\sec^2\theta\,(d\theta/dt) = r\,\omega\sec^2\theta = v\sec^2\theta$$

when, $\theta = 2\pi/8$, $dx/dt = v\sec^2(\pi/4) = 2$ $v = 40$ km/h.

23. $\frac{dV}{dt} = 15$, $h = 3r$, $V = \frac{1}{3}\pi x^2 y$, $\frac{dx}{dt} = ?$, when $x = 5$

$$\frac{x}{y} = \frac{r}{h} = \frac{1}{3} \ \Rightarrow V = \frac{2}{3}\pi r^2 3x = \pi x^3$$



$$\frac{dV}{dt} = 3\pi x^2\frac{dx}{dt}$$

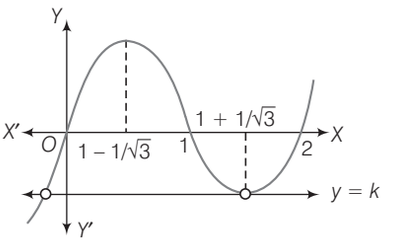
$$\Rightarrow \quad 15 = 3\pi\cdot 25\frac{dx}{dt}$$

$$\Rightarrow \quad \frac{dx}{dt} = \frac{1}{5\pi}$$

24. Given, $f(x) = x(x^2 - 3x + 2)$

$\Rightarrow f(x) = x(x-2)(x-1)$

Graph of $y = f(x)$ is shown as



Now, for exactly one positive and one negative solution of the equation $f(x) = K$

We should have, $k = f\left(1 + \frac{1}{\sqrt{3}}\right)$

$$\left[\because\ -\frac{1}{\sqrt{3}} \text{ and } 1 + \frac{1}{\sqrt{3}} \text{ are the roots of } f'(x) = 0\right]$$

$$\therefore \quad k = \underbrace{\left(1 + \frac{1}{\sqrt{3}}\right)}_{x}\underbrace{\left(\frac{1}{\sqrt{3}} - 1\right)}_{x-2}\underbrace{\left(\frac{1}{\sqrt{3}}\right)}_{x-1}$$

$$= \left(\frac{1}{3} - 1\right)\left(\frac{1}{\sqrt{3}}\right) = -\frac{2}{3\sqrt{3}}$$

$$= -\frac{2\sqrt{3}}{3}$$

25. We have, $\frac{a}{x^2}+\frac{b}{y^2}=1$

$$\Rightarrow \quad -\frac{2a}{x^3}-\frac{2b}{y^3}\frac{dy}{dx}=0 \Rightarrow \frac{dy}{dx}=-\frac{ay^3}{bx^3} \quad \ldots(i)$$

Equation of tangent is $Y-y=-\frac{ay^3}{bx^3}(X-x)$

For x-intercept, put $Y=0$

$$\therefore \quad X=\frac{bx^3}{ay^2}+x$$

$$\Rightarrow \quad X=x\left[\frac{bx^2+ay^2}{ay^2}\right]=x\left[\frac{x^2y^2}{ay^2}\right]=\frac{x^3}{a}$$

[using Eq. (i)]

$\Rightarrow$ x-intercept is proportional to cube of abscissa.

26. Using LMVT in $[-2, 5]$, we get

$$-4\le\frac{f(5)-f(-2)}{7}\le 3$$

$$\Rightarrow \quad -28\le f(5)-f(-2)\le 21$$

27. Given, $x=t+e^{at}$, $y=-t+e^{at}$

$$\Rightarrow \quad \frac{dx}{dt}=1+ae^{at}, \ \frac{dy}{dt}=-1+ae^{at}, \ \frac{dy}{dx}=\frac{-1+ae^{at}}{1+ae^{at}}$$

At the point A, $y=0$ and $\frac{dy}{dx}=0$ for some $t=t_1$

$$\therefore \quad ae^{at_1}=1 \quad \ldots(i)$$

Also, $0=-t_1+e^{at_1}$

$$\therefore \quad e^{at_1}=t_1 \quad \ldots(ii)$$

Putting this value in Eq. (i), we get

$$at_1=1 \Rightarrow t_1=\frac{1}{a}$$

Now from Eq. (i), $ae=1$

$$\Rightarrow \quad a=\frac{1}{e}$$

Hence, $x_A=t_1+e^{at_1}=e+e=2e$

$$\Rightarrow \quad A\equiv(2e, 0)$$

28. Given, $x=a(2\cos t-\cos 2t)$, $y=a(2\sin t-\sin 2t)$

$$\therefore \quad \frac{dy}{dx}=\frac{\cos t-\cos 2t}{\sin 2t-\sin t}=0$$

$$\Rightarrow \quad \cos 2t=\cos t$$

$$\Rightarrow \quad \cos 2t=\cos(2\pi-t)$$

$$\Rightarrow \quad t=2\pi/3$$

29. $F'(x)=e^{(1+\sin^{-1}(\cos x))^2}\cdot(-\sin x)-e^{(1+x)^2}\cdot\cos x$

$$\therefore \quad F'(0)=0-e=-e$$

and $F'\left(\frac{\pi}{2}\right)=-e-0=-e$

Hence, Rolle's theorem is applicable for the function $F'(x)$.

So, there exists c in $\left(0, \frac{\pi}{2}\right)$ for which $F''(c)=0$ as

Rolle's theorem is applicable for $F'(x)$ in $\left[0, \frac{\pi}{2}\right]$.

Also, $F(0)=\int_0^1 f(t)\,dt$ and $F\left(\frac{\pi}{2}\right)=\int_1^0 f(t)\,dt$

Hence, $F(0)$ and $F\left(\frac{\pi}{2}\right)$ have opposite signs.

$$\Rightarrow \quad F(c)=0 \text{ for some } c\in\left(0, \frac{\pi}{2}\right)$$

30. Given, $f'(1)=1, 2\cdot f'(2x)=f'(x)$

Put $x=1$, $f'(2)=\frac{f'(1)}{2}=\frac{1}{2}$

and $f'(4)=\frac{1}{2}f'(2)=\frac{1}{4}$

Applying LMVT for $y=f'(x)$ in $[2, 4]$, we get

$$f''(c)=\frac{f'(4)-f'(2)}{2}=\frac{\frac{1}{4}-\frac{1}{2}}{2}=-\frac{1}{8}$$

31. Consider $\phi(x)=f(x)-g(x)\Rightarrow\phi'(x)=f'(x)-g'(x)>0$.

Clearly, $\phi(x)$ is also continuous and derivable in $[x_0, x]$.

Using LMVT for $\phi(x)$ in $[x_0, x]$, we get

$$\phi'(c)=\frac{\phi(x)-\phi(x_0)}{x-x_0}$$

Since, $\phi'(x)=f'(x)-g'(x)>0$ for all $x>x_0$

$$\therefore \quad \phi'(c)>0$$

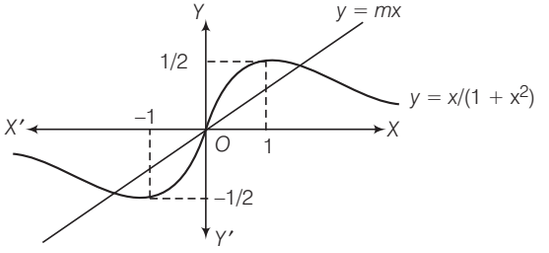
Hence, $\phi(x)-\phi(x_0)>0$

$$\Rightarrow \quad \phi(x)>\phi(x_0)$$

$$\Rightarrow \quad \phi(x)>0 \quad [\because \phi(x_0)=f(x_0)-g(x_0)=0]$$

$$\Rightarrow \quad f(x)-g(x)>0$$

32. Solving, $mx=\frac{x}{x^2+1} \Rightarrow x^2+1=\frac{1}{m}$ or $x=0$



$$\Rightarrow \quad x^2=\frac{1}{m}-1>0 \text{ for a region}$$

$$\Rightarrow \quad \frac{m-1}{m}<0 \Rightarrow m\in(0, 1)$$

Remark

For $m=0$ or 1, the line does not enclose a region.

33. $\because$ Side $=x$

$$\therefore \text{Area } A=x^2 \Rightarrow \frac{dA}{dx}=2x. \text{ So, } \left\{\left(\frac{dA}{dx}\right)_{x=x_0}\times h\right\}=2x_0h$$

The exact change in the area of S when x is changed from x_0 to x_0+h, is

$$(x_0+h)^2-x_0^2=x_0^2+2x_0h+h^2-x_0^2=2x_0h+h^2$$

The difference between the exact change and the approximate change is $2x_0h+h^2-2x_0h=h^2$

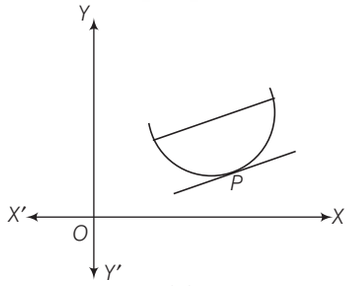
34. $f(x)=\int_1^x\left(t+\frac{1}{t}\right)dt \Rightarrow f'(x)=x+\frac{1}{x}$

$\therefore \quad g(x)=x+\frac{1}{x}$

For $x\in\left[\frac{1}{2},3\right]$,

$g\left(\frac{1}{2}\right)=2+\frac{1}{2}=\frac{5}{2},\ g(3)=3+\frac{1}{3}=\frac{10}{3}$

Let $P\equiv(c,\ g(c)),\ c\in\left[\frac{1}{2},3\right]$



By LMVT, $g'(c)=\frac{g(3)-g\left(\frac{1}{2}\right)}{3-\frac{1}{2}}$

$\therefore \quad 1-\frac{1}{c^2}=\frac{\frac{10}{3}-\frac{5}{2}}{3-\frac{1}{2}}$

$\Rightarrow \quad c^2=\frac{3}{2}$

$\Rightarrow \quad c=\sqrt{\frac{3}{2}}$

$\therefore \quad g(c)=\sqrt{\frac{3}{2}}+\frac{1}{\sqrt{\frac{3}{2}}}=\frac{5}{\sqrt{6}}$

Thus, $P\equiv\left(\sqrt{\frac{3}{2}},\frac{5}{\sqrt{6}}\right)$

35. Here, $\frac{dx}{dt}=\frac{2(-\operatorname{cosec}^2 t)}{\cot t}$

$\Rightarrow \quad \left.\frac{dx}{dt}\right|_{\text{at } t=\frac{\pi}{4}}=-4$

and $\frac{dy}{dt}=\sec^2 t-\operatorname{cosec}^2 t$

$\Rightarrow \quad \left.\frac{dy}{dt}\right|_{\text{at } t=\frac{\pi}{4}}=0$

$\therefore \quad \frac{dy}{dx}=0$

Hence, tangent is parallel to X-axis and its normal is parallel to Y-axis.

36. Here, $f'(x)=\frac{1}{3x^{2/3}}$

$\Rightarrow f'(0)\to\infty$ and tangent is vertical at $x=0$.

Equation of tangent at $(0,\ 0)$ is $x=0$.

Equation of normal is $y=0$.

Now, $f(x)=f^{-1}(x) \Rightarrow x^{1/3}=x^3$

$\Rightarrow \quad x^9=x \Rightarrow x=0,\ 1,\ -1$

37. Here, $\frac{dy}{dx}=k^2\,e^{kx}$

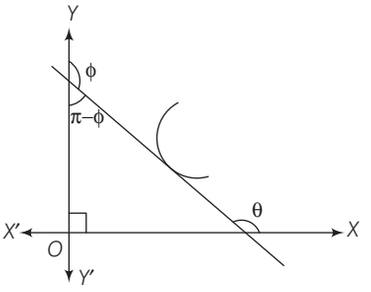
$\Rightarrow \left(\frac{dy}{dx}\right)_{x=0}=k^2=\tan\theta$, where θ is angle made by X- axis.

Let ϕ be the angle made by Y-axis.

$\therefore \quad \tan\theta=\tan\left(\frac{3\pi}{2}-\phi\right)=\cot\phi$

$\Rightarrow \quad \cot\phi=k^2 \Rightarrow \phi=\cot^{-1}k^2$

$\Rightarrow \quad \phi=\sin^{-1}\left(\frac{1}{\sqrt{1+k^4}}\right)$



38. As, $f(x)$ is continuous in $[0,\ 1]$ and differentiable in $(0,\ 1)$ and $f(0)=f(1)=1$.

$\therefore$ By Rolle's theorem, there must exist at least one $x=c\in(0,\ 1)$ such that $f'(c)=0$

$\therefore f'(c)$ vanishes for some $c\in(0,\ 1)$.

Now, $f(0)=1$, $f(1/2)=-\frac{1}{2}$ and $f(1)=1$

$\therefore$ By intermediate value theorem, $f(x)$ must have one root belongs to $\left(0,\frac{1}{2}\right)$ and other in the interval $\left(\frac{1}{2},1\right)$.

39. Here, $f(0)=f(1)$ and f is continuous in $[0,\ 1]$ and derivable in $(0,\ 1)$.

$\therefore f'(c_1)=0$ for at least one $c_1\in(0,\ 1)$

Similarly, as $f(1)=f(2)$

$\therefore\ f'(c_2)=0$ for at least one $c_2\in(1,\ 2). \Rightarrow f'(c_1)=f'(c_2)$

$\Rightarrow f''(c)=0$ for at least one $c\in(c_1,\ c_2)$.

40. Let $f(x)=\frac{1}{(x+1)^3}-3x+\sin x$

Domain of f is $(-\infty,-1)\cup(-1,\infty)$.

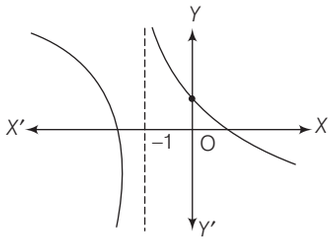
$$f'(x)=-3\left[\frac{1}{(x+1)^4}+1\right]+\cos x \Rightarrow f'(x)<0$$

$\Rightarrow f$ is decreasing.

Also, $\lim\limits_{x\to-1^+}f(x)\to\infty,\quad \lim\limits_{x\to-1^-}f(x)\to-\infty$

and $\lim\limits_{x\to\infty}f(x)\to-\infty,\quad \lim\limits_{x\to-\infty}f(x)\to\infty$

$\Rightarrow f(x) = 0$ has exactly two roots.



41. Clearly, $f(-1) = -f(1)$ and $f(0) = 0$. For (a) and (b) apply LMVT for the function $f(x)$ in $(-1, 0)$ and $(0, 1)$, respectively. For (d) apply LMVT for $(f(x))^n$ in $(0, 1)$.

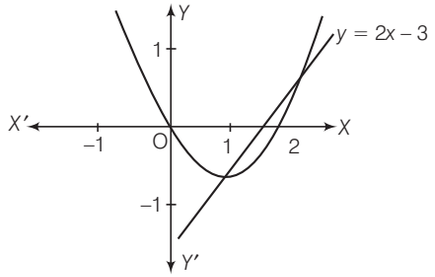
42. When $x = 1$, $y = -1$ [from the line]

Thus, it must lie on the parabola $y = x^2 + px + q$

$\Rightarrow -1 = 1 + p + q \Rightarrow p + q = -2$

$\therefore$ Now, distance of the vertex of the parabola from the X-axis is

$$d = f\left(-\frac{p}{2}\right) = \frac{p^2}{4} - \frac{p^2}{2} + q = q - \frac{p^2}{4}$$



Substituting $q = -2 - p$, we get

$$d = -2 - p - \frac{p^2}{4}$$

Now, take $g(p) = -2 - p - \frac{p^2}{4}$

So, $g'(p) = -1 - \frac{p}{2} = 0 \Rightarrow p = -2$

Hence, $q = 0$

Note that least distance of the vertex from X-axis is 1.

43. Given, $\sqrt{xy} = a + x \Rightarrow xy = a^2 + x^2 + 2ax$

$$\Rightarrow y = \frac{a^2}{x} + x + 2a$$

$$\Rightarrow \frac{dy}{dx} = -\frac{a^2}{x^2} + 1 = -1$$

$$\Rightarrow 2x^2 = a^2$$

$$\Rightarrow x = \pm\frac{a}{\sqrt{2}}$$

44. Given, $\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} = 2R$ [say]

$\therefore$ $da = 2R\cos A\, dA$, $db = 2R\cos B\, dB$,

$dc = 2R\cos C\, dC$

$$\therefore \frac{da}{\cos A} + \frac{db}{\cos B} + \frac{dc}{\cos C} = 2R(dA + dB + dC) \quad \ldots(i)$$

Also, $A + B + C = \pi$

So, $dA + dB + dC = 0$ ...(ii)

From Eqs. (i) and (ii), we get

$$\frac{da}{\cos A} + \frac{db}{\cos B} + \frac{dc}{\cos C} = 0$$

45. $\frac{f(x) - f(0)}{x - 0} = f'(c) \le 1 - x$ for some $c \in (0, 1)$.

$\Rightarrow f(x) \le x(1 - x) \le 1/4$

46. Here, $f(x) = \frac{\ln x}{x}$ ...(i)

$\therefore$ Domain is R^+.

$\because$ $$f'(x) = \frac{x \cdot \frac{1}{x} - \ln x}{x^2} = \frac{1 - \ln x}{x^2}$$

(a) For horizontal tangent, $f'(x) = 0$

$\Rightarrow \ln x = 1 \Rightarrow x = e$ [true]

(b) If $f(x)$ intersects the X-axis.

$$\frac{\ln x}{x} = 0 \Rightarrow x = 1$$ [true]

(c) $f'(x)$ is positive, if $x \in (0, e)$ and $f'(x)$ is negative, if $x \in (e, \infty)$

$\therefore$ $f(x)$ is not monotonic.

$\therefore$ $f(x)$ is many-one.

(d) For vertical tangent, $f'(x) = \infty$ [true]

$$\Rightarrow \frac{1 - \ln x}{x^2} = \infty \Rightarrow \frac{x^2}{1 - \ln x} = 0$$

$\Rightarrow x = 0$ which is not in the domain of $f(x)$. [false]

47. Let the tangent line be $y = ax + b$

The equation for its intersection with the upper parabola is

$$x^2 + 1 = ax + b$$

$$\Rightarrow x^2 - ax + (1 - b) = 0$$

This has a double root when $a^2 - 4(1 - b) = 0$

or $$a^2 + 4b = 4$$

For the lower parabola, $ax + b = -x^2$

$$\Rightarrow x^2 + ax + b = 0$$

This has a double root when $a^2 - 4b = 0$

On subtracting these two equations, we get $8b = 4$ or $b = \frac{1}{2}$

On adding these equations, we get $2a^2 = 4$ or $a = \pm\sqrt{2}$

The tangent lines are $y = \sqrt{2}\,x + \frac{1}{2}$ and $y = -\sqrt{2}\,x + \frac{1}{2}$

48. For some $\alpha \in (0, 1)$, $|f'(\alpha)| = \left|\frac{f(1) - f(0)}{1 - 0}\right| \le |f(1)| + |f(0)|$

$$\Rightarrow |f'(\alpha)| \le 1 + 1 = 2$$

Similarly, for some $\beta \in (-1, 0)$, $|f'(\beta)| \le 2$

Also, $F(x) = (f(x))^2 + (f'(x))^2$

$$\Rightarrow F(\alpha) = (f(\alpha))^2 + (f'(\alpha))^2 \le 1 + 4 \le 5$$

Similarly, $F(\beta) \le 5$ for some $\beta \in (-1, 0)$

As, $F(0) = 6$, so there must be a point of local maxima for $F(x)$ in $(-1, 1)$ and at the point of maxima, say $x = c$,

$$F(c) \geq 6 \Rightarrow F'(c) = 0 \text{ and } F''(c) \leq 0$$

49. As, Rolle's theorem is applicable, the function should be continuous and differentiable in $[-3, 3]$.

So, at $x = 1$ it is continuous

$$\Rightarrow \quad \lim_{x \to 1^-} f(x) = \lim_{x \to 1^+} f(x) = f(1)$$

$$\Rightarrow \quad a + b = c = 1 \qquad \text{...(i)}$$

Since, differentiable at $x = 1$, therefore

$$f'(1^+) = f'(1^-)$$

$$\Rightarrow \quad \lim_{h \to 0} \frac{\frac{c}{1+h} - 1}{h} = 2a$$

$$\Rightarrow \quad 2a = \lim_{h \to 0} \frac{c - 1 - h}{h(h+1)} \text{ exists only when } c = 1$$

$$\Rightarrow \quad 2a = \lim_{h \to 0} \frac{-1}{(1+h)} = -1$$

$$\therefore \quad a = -1/2 \text{ and } c = 1 \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$b = 3/2 \qquad \text{...(iii)}$$

$$\therefore \quad a + b + c = 2 \qquad \text{...(iv)}$$

$$|a| + |b| + |c| = 3 \qquad \text{...(v)}$$

$$2a + 4b + 3c = 8 \qquad \text{...(vi)}$$

$$4a^2 + 4b^2 + 5c^2 = 15 \qquad \text{...(vii)}$$

50. **Statement I** As, $f(-1) = f(1)$ and Rolle's theorem is not applicable, then it implies that $f(x)$ is either discontinuous or $f'(x)$ does not exist at at least one point in $(-1, 1)$.

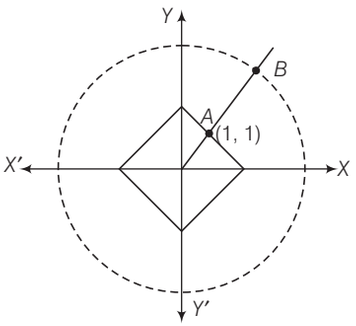
$\Rightarrow$ $g(x) = 0$ for at at least one value of x in $(-1, 1)$.

Statement II is false. Consider the example in Statement I.

51. Common normal is $y = x$

Solving, $y = x$ with $x + y = 2$, we get $A(1, 1)$

and with $x^2 + y^2 = 16$, we get $B(2\sqrt{2}, 2\sqrt{2})$



The shortest distance between the given curves is $AB = 4 - \sqrt{2}$.

But as the curves are not smooth, check at slope points. The coordinates in 1st quadrant are (2, 0) and (4, 0) and here distance = 2.

$\therefore$ $4 - \sqrt{2}$ is not the shortest.

52. If $P(x) = 0$ is a polynomial equation, then $P(-x) = 0$ has no positive root.

$\Rightarrow$ $P(x) = 0$ cannot have negative roots.

53. Let $A(a, P(a))$, $B(b, P(b))$, then slope of $AB = P'(a) = P'(b)$ from LMVT there exists $c \in (a, b)$, where $P'(c) =$ slope of AB.

54.
$$f(x) = \begin{cases} \frac{1}{2} - x, & x < \frac{1}{2} \\ \left(\frac{1}{2} - x\right)^2, & x \geq \frac{1}{2} \end{cases}$$

$$\Rightarrow f'(x) = \begin{cases} -1, & x < \frac{1}{2} \\ 2\left(\frac{1}{2} - x\right)(-1), & x > \frac{1}{2} \end{cases}$$

Left hand derivative at $x = 1/2$ is (-1) and right hand derivative at $x = 1/2$ is 0, so the function is not differentiable at $x = 1/2$.

55. $f(x) = \ln(2 + x) - \dfrac{2x + 2}{x + 3}$ is continuous in $[-2, \infty)$.

$$f'(x) = \frac{1}{x+2} - \frac{4}{(x+3)^2} = \frac{(x+3)^2 - 4(x+2)}{(x+2)(x+3)^2}$$

$$= \frac{x^2 + 2x + 1}{(x+2)(x+3)^2} = \frac{(x+1)^2}{(x+2)(x+3)^2} > 0$$

$$[f'(x) = 0 \text{ at } x = -1]$$

$\Rightarrow$ f is increasing in $(-2, \infty)$.

Also, $\lim_{x \to -2^+} f(x) \to -\infty$

and $\lim_{x \to \infty} f(x) \to \infty$ $\Rightarrow$ unique root.

56. Let $f(x) = 0$ has two roots say $x = r_1$ and $x = r_2$, where $r_1, r_2 \in [a, b]$.

$$\Rightarrow \quad f(r_1) = f(r_2)$$

Hence, there must exist some $c \in (r_1, r_2)$, where $f'(c) = 0$

But $f'(x) = x^6 - x^5 + x^4 - x^3 + x^2 - x + 1$

for $x \geq 1$, $f'(x) = (x^6 - x^5) + (x^4 - x^3) + (x^2 - x) + 1 > 0$

for $x \leq 1$, $f'(x) = (1 - x) + (x^2 - x^3) + (x^4 - x^5) + x^6 > 0$

Hence, $f'(x) > 0$ for all x.

$\therefore$ Rolle's theorem fails.

$\Rightarrow$ $f(x) = 0$ cannot have two or more roots.

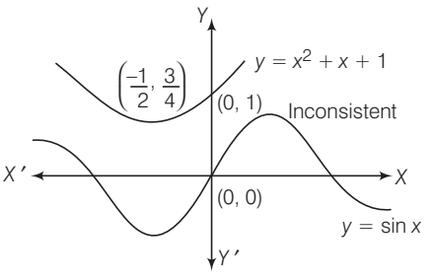
57. Let $f(x) = \cos x - \sin x + \cos^{-1} x - \sin^{-1} x$, $x \in [-1, 1]$

$\because$ $f(-1)\, f(1) < 0$

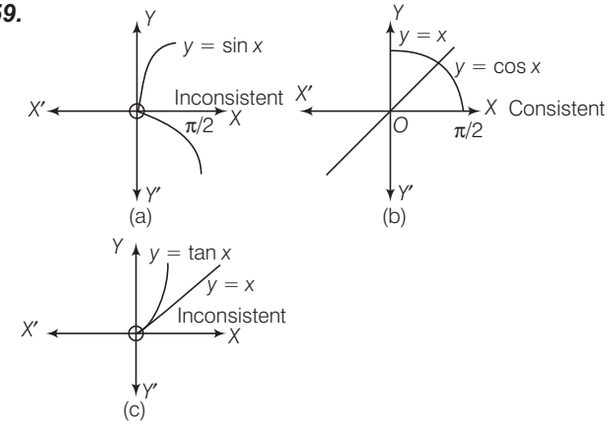
$\therefore$ There exists at least one $c \in (-1, 1)$ such that $f(c) = 0$.

Hence, the curves $y = \cos x + \cos^{-1} x$ and $y = \sin x + \sin^{-1} x$ intersect each other at at least one point.

58. Given, $\sin x = x^2 + x + 1 = \left(x + \dfrac{1}{2}\right)^2 + \dfrac{3}{4}$



59.

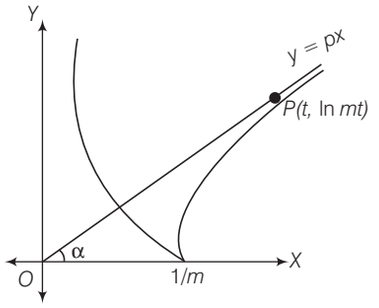


Sol. (Q. Nos. 60 to 62)

Slope of tangent at P = Slope of OP

$$\Rightarrow \quad \frac{1}{t} = \frac{\ln mt}{t}$$

$$\Rightarrow \quad t = \frac{e}{m}$$



$$\Rightarrow \quad P \equiv \left(\frac{e}{m}, 1\right)$$

$$\Rightarrow \quad \tan\alpha = p = \frac{m}{e}$$

60. $p > m/e$ **61.** $p = m/e$

62. $0 < p < m/e$

63. Putting $y = 0$, we get $x^2 - 3x - c_i = 0$

As roots are integers and $D = 9 + 4c_i$ must be perfect square, therefore $9 + 4c_i = (2\lambda + 1)^2$, $\lambda \in I$.

$$\Rightarrow \quad c_i = \lambda^2 + \lambda - 2$$

$$\Rightarrow \quad c_k = k(k+3), \quad k = 1, 2, 3, \ldots$$

$$\therefore \quad c_1 = 4, c_2 = 10, \ldots$$

$$\Rightarrow \quad x^2 + y^2 - 3x - 4y - (c_2 - c_1) = 0$$

or $\quad x^2 + y^2 - 3x - 4y - 6 = 0$

and $x^2 + y^2 = r^2$ will touch each other, if

$$\sqrt{9/4 + 4} = |r - \sqrt{9/4 + 10}|$$

$$\Rightarrow \quad |r - 7/2| = 5/2$$

$$\Rightarrow \quad r = 6$$

$\therefore$ Common tangent is $3x + 4y - 30 = 0$ and passes through $(10, 0)$.

64. An ellipse and hyperbola intersect orthogonally.

They must be confocal $\Rightarrow$ $a = 2$

Let point $P(\alpha, \beta)$ lies on both the curves, then

$$4\alpha^2 + 9\beta^2 = 36 \quad \ldots(i)$$

and $\quad 4\alpha^2 - \beta^2 = 4 \quad \ldots(ii)$

On adding Eqs. (i) and (ii), we get

$$8\alpha^2 + 8\beta^2 = 40$$

$$\Rightarrow \quad \alpha^2 + \beta^2 = 5$$

or $\quad x^2 + y^2 = \frac{c_7}{14}$, as $c_7 = 70$.

65. (A) $f'(x) = \log x - \frac{3}{x} + 1$

$$\Rightarrow \quad f(x) = (x-3)\log x + c$$

$$\Rightarrow \quad f(1) = f(3)$$

(B) $f'(x) = 4ax^3 + 3bx^2 + 2cx + d$

$$\Rightarrow \quad f(x) = ax^4 + bx^3 + cx^2 + dx + e$$

$$\Rightarrow \quad f(0) = f(3) \qquad [\because 27a + 9b + 3c + d = 0]$$

(C) $\frac{f(b) - f(a)}{b - a} = f'(\sqrt{3}) = \frac{2}{3}$

$$\Rightarrow \quad \frac{ab - 1}{ab} = \frac{2}{3}$$

(D) $\frac{f(b) - f(a)}{b - a} = f'\left(\frac{1}{2}\right) = 1$

$$\Rightarrow \quad a + b = 1$$

66. (A) Here, $r = 5$ cm, $\Delta r = 0.06$

$$\because \quad A = \pi r^2,$$

$$\therefore \quad dA = 2\pi r\, dr = 2\pi r \cdot \Delta r = 10\pi \times 0.06 = 0.6\,\pi$$

(B) $v = x^3$, $dv = 3x^2\, dx$

$$\frac{dv}{v} \times 100 = 3\frac{dx}{x} \times 100 = 3 \times 1 = 3$$

(C) $(x-2)\frac{dx}{dt} = 2\frac{dx}{dt} \Rightarrow x = 4$

(D) $A = \frac{\sqrt{3}}{4}x^2$

$$\frac{dA}{dt} = \frac{\sqrt{3}}{2} \cdot x \cdot \frac{dx}{dt}$$

$$= \frac{\sqrt{3}}{2} \cdot 15 \cdot \frac{1}{10} = \frac{3\sqrt{3}}{4}\ \text{cm}^2/\text{s}$$

67. $\because \left|\frac{dx}{dt}\right| < \left|\frac{dy}{dt}\right| \Rightarrow \left|\frac{dy}{dx}\right| > 1$

and $\quad 3y^2 \cdot \frac{dy}{dx} = 27$ or $\frac{dy}{dx} = \frac{9}{y^2}$

$$\therefore \quad \frac{9}{y^2} > 1 \Rightarrow y^2 < 9$$

$$\Rightarrow \quad -3 < y < 3 \Rightarrow -27 < y^3 < 27$$

$$\Rightarrow \quad -27 < 27x < 27 \Rightarrow -1 < x < 1$$

$$\therefore \quad x \in (-1, 1) \Rightarrow a + b = 0$$

68. Here, $4y\dfrac{dy}{dx} = 2ax$

$\therefore \quad \left.\dfrac{dy}{dx}\right|_{(1,\,-1)} = \dfrac{-a}{2} = -1$

$\Rightarrow \quad a = 2$

Also, $2y^2 = ax^2 + b$ at $(1, -1)$ is

$2 = a + b$

$\Rightarrow \quad b = 0$

$\therefore \quad a - b = 2$

69. Using LMVT, for some $c \in (1, 6)$, we get

$$f'(c) = \frac{f(6) - f(1)}{5}$$

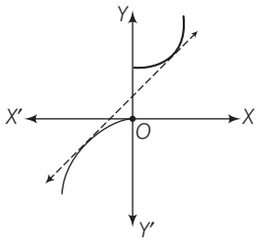
$$= \frac{f(6) + 2}{5} \geq 4.2$$

$\Rightarrow \quad f(6) \geq 19$

$\Rightarrow \quad f(6) - 16 \geq 3$

$\therefore$ Least value of $f(6) - 16 = 3$

70. Let $y = mx + c$ be a tangent to $f(x)$.



For, $x \geq 0$, intersection point is given by

$mx + c = x^2 + 8 \qquad [\because\ y = x^2 + 8, \text{ for } x \geq 0]$

$\Rightarrow \quad x^2 - mx + (8 - c) = 0$

For line to be tangent, $D = 0$

$\therefore \quad m^2 = 4(8 - c) \qquad \ldots(i)$

Again, for $x < 0$

$mx + c = -x^2 \qquad [\because\ y = -x^2, \text{ for } x < 0]$

$\Rightarrow \quad x^2 + mx + c = 0$

Now, $D = 0$

$\Rightarrow \quad m^2 = 4c \qquad \ldots(ii)$

From Eqs. (i) and (ii), we get

$c = 4, m = 4$

$\therefore$ Tangent is $y = 4x + 4$

Putting $y = 0$, we get

$x = -1$

$\therefore$ Absolute value of x-intercept is 1.

71. Here, $f'(a) = \sqrt{3}$ and $f'(b) = 1$

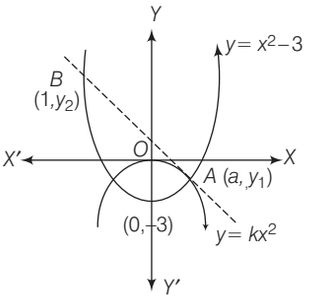
$$\therefore \quad \left|\int_a^b f'(x)\cdot f''(x)\,dx\right| = \left|\left(\frac{(f'(x))^2}{2}\right)_a^b\right| = \frac{1}{2}\left|(f'(b))^2 - (f'(a))^2\right|$$

$$= \frac{1}{2}|1 - 3| = 1$$

72. Point $A(a, y_1)$ lies on C_1 and C_2.

$\therefore \quad y_1 = a^2 - 3$ and $y_1 = ka^2$.

$\Rightarrow \quad a^2 - 3 = ka^2 \qquad \ldots(i)$



Now, $y = kx^2$

$\Rightarrow \quad \dfrac{dy}{dx} = 2kx$

$\therefore \quad \left(\dfrac{dy}{dx}\right)_{(a,\,y_1)} = 2ka = \dfrac{y_2 - y_1}{1 - a}$

But, $y_2 = 1 - 3 = -2$

$\therefore \quad 2ka = \dfrac{-2 - (a^2 - 3)}{1 - a}$

$\Rightarrow \quad 2ka = \dfrac{1 - a^2}{1 - a} = 1 + a$

$\Rightarrow \quad 2ak = 1 + a \qquad \ldots(ii)$

Substituting $k = \dfrac{a^2 - 3}{a^2}$ from Eq. (i) in Eq. (ii), we get

$$\frac{2a(a^2 - 3)}{a^2} = 1 + a$$

$\Rightarrow \quad 2a^2 - 6 = a + a^2$

$\Rightarrow \quad a^2 - a - 6 = 0$

$\Rightarrow \quad a = 3, -2$

$\therefore \quad a = 3 \qquad [\because\ -2 \text{ is rejected as } a > 0]$

73. $f'(c) = 16c - 7 = \dfrac{f(6) - f(-6)}{12}$

$$= \frac{(8\cdot 36 - 7\cdot 6 + 5) - (8\cdot 36 + 7\cdot 6 + 5)}{12}$$

$$= -\frac{2\cdot 7\cdot 6}{12} = -7$$

$\Rightarrow \ 16c = 0 \ \Rightarrow \ c = 0$

74. Using LMVT for f in $[1, 2]$, we get, for some $c \in (1, 2)$

$$\frac{f(2) - f(1)}{2 - 1} = f'(c) \leq 2$$

$$f(2) - f(1) \leq 2$$

$\Rightarrow \quad f(2) \leq 4 \qquad \ldots(i)$

Again, using LMVT in $[2, 4]$, we get, for some $d \in (2, 4)$

$\Rightarrow \quad \dfrac{f(4) - f(2)}{4 - 2} = f'(d) \leq 2$

$\therefore \quad f(4)-f(2)\le 4, \quad 8-f(2)\le 4, \quad 4\le f(2)$

$\Rightarrow \quad f(2)\ge 4 \qquad ...(ii)$

From Eqs. (i) and (ii), we get $f(2)=4$

75. As, a, b and c are positive integers.

We must have $\frac{1}{a}<1$, so $a>1$. $\left[\text{similarly, } \frac{1}{b}<1, \frac{1}{c}<1\right]$

Since, $\frac{1}{a}>\frac{1}{b}>\frac{1}{c}$

$\Rightarrow \quad \frac{1}{a}>\frac{1}{3} \Rightarrow a<3 \Rightarrow a=2$

$\therefore \quad \frac{1}{a}+\frac{1}{b}+\frac{1}{c}=1 \Rightarrow \frac{1}{b}+\frac{1}{c}=\frac{1}{2}$, where $2<b<c$.

Similarly, $\frac{1}{b}>\frac{1}{4}$, so $b<4 \Rightarrow b=3$

Now, $\frac{1}{a}+\frac{1}{b}+\frac{1}{c}=1$

$\Rightarrow \quad \frac{1}{2}+\frac{1}{3}+\frac{1}{c}=1$

$\Rightarrow \quad c=6$

$\therefore \quad (a+b+c-5)=2+3+6-5=6$

76. Equation of ellipse is $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$

Equation of tangent at $(a\cos\theta, b\sin\theta)$ is

$$\frac{x}{a}\cos\theta+\frac{y}{b}\sin\theta=1$$

Intercept on the X-axis $=(a\sec\theta)$

Intercept on the Y-axis $=(b\operatorname{cosec}\theta)$

Length of intercept of the tangent by the axes

$$=\sqrt{a^2\sec^2\theta+b^2\operatorname{cosec}^2\theta}$$

Let $l=a^2\sec^2\theta+b^2\operatorname{cosec}^2\theta$

$\Rightarrow \quad \frac{dl}{d\theta}=2a^2\sec^2\theta\tan\theta-2b^2\operatorname{cosec}^2\theta\cot\theta$

Now, $\frac{dl}{d\theta}=0$

$\Rightarrow \quad a^2\sin^4\theta=b^2\cos^4\theta \Rightarrow \frac{a}{b}=\cot^2\theta$

$\Rightarrow \quad \sin^2\theta=\frac{b}{a+b}, \ \cos^2\theta=\frac{a}{a+b}$

Distance between $(a\sec\theta, 0)$ and point of tangency $(a\cos\theta, b\sin\theta)$ is

$$=\sqrt{a^2(\sec\theta-\cos\theta)^2+b^2\sin^2\theta}$$

$$=\sqrt{a^2\cos^2\theta(\sec^2\theta-1)^2+b^2\sin^2\theta}$$

$$=\sqrt{a^2\cos^2\theta\left(\frac{a+b}{a}-1\right)^2+b^2\sin^2\theta}$$

$$=\sqrt{a^2\cos^2\theta\frac{b^2}{a^2}+b^2\sin^2\theta}=b$$

Similarly, distance between $(0, b\operatorname{cosec}\theta)=a$

77. Let (x_1, y_1) be a point of contact of tangents from the origin $(0, 0)$ to the curve $y=\sin x$.

Here, $y=\sin x$

$\therefore \quad \frac{dy}{dx}=\cos x$

$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(x_1, y_1)}=\cos x_1$

Now, equation of tangent at (x_1, y_1) is

$$y-y_1=\left(\frac{dy}{dx}\right)_{(x_1, y_1)}(x-x_1)$$

$\Rightarrow \quad y-y_1=(\cos x_1)(x-x_1)$

$\because$ It passes through $(0, 0)$.

$\therefore \quad -y_1=(\cos x_1)(-x_1) \qquad ...(i)$

Also, (x_1, y_1) lies on the curve.

So, $y_1=\sin x_1 \qquad ...(ii)$

Squaring and adding Eqs. (i) and (ii), we get

$$\left(\frac{y_1}{x_1}\right)^2+y_1^2=\cos^2 x_1+\sin^2 x_1=1$$

or $y_1^2+x_1^2y_1^2=x_1^2$

i.e. $(x_1^2+1)y_1^2=x_1^2$

$\therefore$ The point of contact (x_1, y_1) lies on the curve $y^2=\frac{x^2}{x^2+1}$.

78. We must show that for a given $m\in R$ these exists $x\in R$ such that,

$$m^2x^2+\int_0^x f(t)\,dt=2$$

Let $f(x)=\int_0^x[2m^2t+f(t)]\,dt-2, \ x\in R$

Since, $f(x)$ is continuous and $2m^2t^2$ is continuous, therefore

$$\int_0^x[2m^2t+f(t)]\,dt \text{ continuous on } R,$$

$\therefore \quad f$ is continuous on R, also

$$f(0)=\int_0^0[2m^2t+f(t)]\,dt-2=0-2=-2$$

and $f(x)=\int_0^x[2m^2t+f(t)]\,dt-2$

where, $f(x)=m^2x^2+\int_0^x f(t)\,dt-2\to\infty$

$$\left[\because \int_0^x f(t)\,dt\to\infty\right]$$

As, $|x|\to\infty$

Thus, these exists some $a\in R$ such that;

$$f(x)>1, \ \text{for}\,|x|>a$$

Note that f is a continuous on $[0, a+1]$ and $f(0)\,f(a+1)<0$. By the intermediate value theorem of continuous functions, we have that there exists some $b\in(0, a+1)$ such that $f(b)=0$, i.e. there exists a real β which satisfies the equation

$$m^2x^2+\int_0^x f(t)\,dt=2$$

79. Tangent at any point $P(t_1)$, i.e. $(4t_1^2+3, 8t_1^3-1)$ be normal to the curve at $Q(t_2)$, i.e. $(4t_2^2+3, 8t_2^3-1)$.

The equation of the tangent at t_1 is

$$y-(8t_1^3-1)=\left(\frac{dy}{dx}\right)_{t_1}\cdot\{x-(4t_1^2+3)\}$$

or $$y-(8t_1^3-1)=\left(\frac{dy/dt}{dx/dt}\right)_{t_1}\cdot\{x-(4t_1^2+3)\}$$

or $$y-(8t_1^3-1)=\frac{24t_1^2}{8t_1}\cdot\{x-(4t_1^2+3)\}$$

or $$y-(8t_1^3-1)=3t_1\{x-(4t_1^2+3)\} \quad ...(i)$$

Clearly, slope of tangent at t_1 = slope of tangent at t_2.

$$\therefore \quad \left(\frac{dy}{dx}\right)_{t_1}=\frac{-1}{\left(\frac{dy}{dx}\right)_{t_2}} \; i.e.\; 3t_1=\frac{-1}{3t_2} \quad ...(ii)$$

$\Rightarrow$ Equation of normal at t_2 is $y-(8t_2^3-1)=3t_1\{x-(4t_2^3+3)\}$ ...(iii)

On subtracting Eq. (iii) from Eq. (i), we get

$$(8t_2^3-1)-(8t_1^3-1)=3t_1\{(4t_2^2+3)-(4t_1^2+3)\}$$

$$\Rightarrow \quad 2t_2^2=t_1t_2+t_1^2$$

$$\Rightarrow \quad 2\cdot\left(\frac{-1}{9t_1}\right)^2=-\frac{1}{9}+t_1^2 \quad \text{[using Eq. (ii)]}$$

$$\Rightarrow \quad 2=-9t_1^2+81t_1^4$$

$$\therefore \quad 81t_1^4-9t_1^2-2=0$$

$$\Rightarrow \quad t_1=\pm\frac{\sqrt{2}}{3}$$

Putting in Eq. (i), the equation is

$$27(y+1)\mp16\sqrt{2}=\pm\sqrt{2}(27x-105)$$

80. Equation of tangent at (x, y) is

$$Y-y=\frac{dx}{dy}(X-x)$$

$$\therefore \quad Q=\left(x-y\frac{dx}{dy},\,0\right)$$

Equation of normal at (x, y) is

$$Y-y=-\frac{dx}{dy}(X-x)$$

$$\therefore \quad R=\left(x+y\frac{dy}{dx},\,0\right)$$

Given, $QR=2$

$$\Rightarrow \quad y\frac{dy}{dx}+y\frac{dx}{dy}=2$$

$$\Rightarrow \quad y\left(\frac{dy}{dx}\right)^2-2\left(\frac{dy}{dx}\right)+y=0$$

$$\Rightarrow \quad \frac{dy}{dx}=\frac{2\pm\sqrt{4-4y^2}}{2y}=\frac{1\pm\sqrt{1-y^2}}{y}$$

$$\Rightarrow \quad \frac{y\,dy}{1\pm\sqrt{1-y^2}}=dx \text{ or } \frac{1\mp\sqrt{1-y^2}}{y}dy=dx$$

On integrating both the sides, we get

$$\Rightarrow \quad \log y\mp\left(\log\left|\frac{1-\sqrt{1-y^2}}{y}\right|+\sqrt{1-y^2}\right)=x+c$$

The curve passes through (1,1), so $c=-1$

Hence, the possible curves

$$\log y-x=\pm\left(\log\left|\frac{1-\sqrt{1-y^2}}{y}\right|+\sqrt{1-y^2}\right)-1$$

81. Let the point $P(x, y)$ be on the curve,

$$\log(x^2+y^2)=c\tan^{-1}\left(\frac{y}{x}\right)$$

Differentiating both the sides w.r.t. 'x', we get

$$\frac{2x+2yy'}{(x^2+y^2)}=\frac{c(xy'-y)}{(x^2+y^2)}$$

$$\Rightarrow \quad y'=\frac{2x+cy}{cx-2y}=m_1 \text{ (say)}$$

Slope of $OP=\frac{y}{x}=m_2$ (say)

Let the angle between the tangent at P and OP be θ.

Then, $$\tan\theta=\left|\frac{m_1-m_2}{1+m_1m_2}\right|=\left|\frac{\frac{2x+cy}{cx-2y}-\frac{y}{x}}{1+\frac{2xy+cy^2}{x(cx-2y)}}\right|=\frac{2}{c}$$

$$\therefore \quad \theta=\tan^{-1}\left(\frac{2}{c}\right)=\text{constant.}$$

Hence, the angle between the tangent at any point P and the line joining P to the origin O is the same.

82. (i) The given curves are

$$y^2=4ax \quad ...(i)$$

and $$x^2=4ay \quad ...(ii)$$

Point of intersection of Eqs. (i) and (ii) are $(0, 0)$ and $(4a, 4a)$.

From Eq. (i), $$\frac{dy}{dx}=\frac{2a}{y}=m_1 \text{ (say)}$$

From Eq. (ii), $$\frac{dy}{dx}=\frac{x}{2a}=m_2 \text{ (say)}$$

Let the angle of intersection of two curves is θ, then

$$\tan\theta=\left|\frac{m_1-m_2}{1+m_1m_2}\right|=\left|\frac{\frac{2a}{y}-\frac{x}{2a}}{1+\frac{x}{y}}\right|=\left|\frac{4a^2-xy}{2a(x+y)}\right|$$

$$\therefore \quad (\tan\theta)_{(0,0)}=\infty \quad \text{or} \quad \theta=90^\circ$$

$$\text{and } (\tan\theta)_{(4a,\,4a)}=\left|\frac{\frac{1}{2}-2}{1+1}\right|=\left|-\frac{3}{4}\right|=\frac{3}{4}$$

Hence, $$\theta=\tan^{-1}\left(\frac{3}{4}\right)$$

(ii) The given curves are $y^2 = 4ax$ ...(i)

and $x^2 = 4ay$ ...(ii)

Tangents of Eq. (i) in terms of slope m is

$$y = mx + \frac{a}{m} \quad ...(iii)$$

Now, Eq. (iii) is also tangent of Eq. (ii).

Eliminating y from Eqs. (ii) and (iii), we have

$$x^2 = 4a\left(mx + \frac{a}{m}\right)$$

$$\Rightarrow \quad x^2 - 4amx - \frac{4a^2}{m} = 0 \quad ...(iv)$$

$$\Rightarrow \quad B^2 - 4AC = 0$$

$$\Rightarrow \quad 16a^2m^2 - 4\left(-\frac{4a^2}{m}\right) = 0$$

$$\Rightarrow \quad m^3 = -1 \text{ or } m = -1$$

From Eq. (iii) common tangent is

$$y = -x - a \text{ or } y + x + a = 0$$

Hence, the common tangent is $x + y + a = 0$.

83. Let the coordinate system be chosen such that the given straight line is $x = p$ and the equations of the circles are $x^2 + y^2 = a^2$, $x^2 + y^2 = b^2$, $x^2 + y^2 = c^2$.

The line $x = p$ cuts these circles at A, B and C, respectively.

The coordinates of these points are $A(p, \sqrt{a^2 - p^2})$, $B(p, \sqrt{b^2 - p^2})$ and $C(p, \sqrt{c^2 - p^2})$.

Equations of the tangents at these points are

$$px + \sqrt{a^2 - p^2}\,y = a^2,\ px + \sqrt{b^2 - p^2}\,y = b^2$$

and $px + \sqrt{c^2 - p^2}\,y = c^2$.

These tangents intersect at

$$\left[\frac{p^2 - \sqrt{a^2 - p^2}\sqrt{b^2 - p^2}}{p}, \sqrt{a^2 - p^2} + \sqrt{b^2 - p^2}\right],$$

$$\left[\frac{p^2 - \sqrt{b^2 - p^2}\sqrt{c^2 - p^2}}{p}, \sqrt{b^2 - p^2} + \sqrt{c^2 - p^2}\right],$$

$$\left[\frac{p^2 - \sqrt{c^2 - p^2}\sqrt{c^2 - p^2}}{p}, \sqrt{c^2 - p^2} + \sqrt{a^2 - p^2}\right].$$

Area of Δ formed by the tangents at A, B, C is

$$\Delta = \frac{1}{2}\begin{vmatrix} \frac{p^2 - \sqrt{a^2 - p^2}\sqrt{b^2 - p^2}}{p} & \sqrt{a^2 - p^2} + \sqrt{b^2 - p^2} & 1 \\ \frac{p^2 - \sqrt{b^2 - p^2}\sqrt{c^2 - p^2}}{p} & \sqrt{b^2 - p^2} + \sqrt{c^2 - p^2} & 1 \\ \frac{p^2 - \sqrt{c^2 - p^2}\sqrt{c^2 - p^2}}{p} & \sqrt{c^2 - p^2} + \sqrt{a^2 - p^2} & 1 \end{vmatrix}$$

$$= \frac{(\sqrt{a^2 - p^2} - \sqrt{c^2 - p^2})(\sqrt{c^2 - p^2} - \sqrt{b^2 - p^2})(\sqrt{b^2 - p^2} - \sqrt{a^2 - p^2})}{2p}$$

$$= \frac{CA \cdot BC \cdot AB}{2p}$$

84. Let the curve be $y = f(x)$ and tangent drawn at $P(x, y)$ meets the X-axis at T.

We have, $OT = x^2$

Equation of tangent at $P(x, y)$;

$$Y - y = f'(x)(X - x)$$

$$\Rightarrow \quad T \equiv \left(\left|x - \frac{y}{f'(x)}\right|, 0\right)$$

$$\Rightarrow \quad \left|x - \frac{y}{f'(x)}\right| = x^2$$

$$\Rightarrow \quad x - \frac{f(x)}{f'(x)} = \pm x^2$$

$$\Rightarrow \quad \frac{xf'(x) - f(x)}{x^2} = \pm f'(x)$$

$$\Rightarrow \quad \frac{d}{dx}\left(\frac{f(x)}{x}\right) = \pm f'(x)$$

On integrating both the sides, we get $\frac{f(x)}{x} = \pm f(x) + c$

Since, the curve passes through (2, 1).

$$\therefore \quad \frac{1}{2} = \pm 1 + c$$

$$\Rightarrow \quad c = -\frac{1}{2}, \frac{3}{2}$$

$$\Rightarrow \quad f(x) = \frac{x}{2(x - 1)} \text{ or } f(x) = \frac{3x}{2(1 + x)}$$

Hence, possible curves are $y = \frac{x}{2(x - 1)}$ and $y = \frac{3x}{2(1 + x)}$.

85. For $y = x - x^3$, $\frac{dy}{dx} = 1 - 3x^2$

Therefore, the equation of the tangent at the point $P(x_1, y_1)$ is

$$y - y_1 = (1 - 3x_1^2)(x - x_1)$$

It meets the curve again at $Q(x_2, y_2)$.

Hence, $x_2 - x_2^3 - (x_1 - x_1^3) = (1 - 3x_1^2)(x_2 - x_1)$

$$\Rightarrow \quad (x_2 - x_1)[1 - (x_2^2 + x_1x_2 + x_1^2)] = (x_2 - x_1)(1 - 3x_1^2)$$

$$\Rightarrow \quad 1 - x_2^2 - x_1x_2 - x_1^2 = 1 - 3x_1^2$$

$$\Rightarrow \quad x_2^2 + x_1x_2 - 2x_1^2 = 0$$

$$\Rightarrow \quad \left(x_2 + \frac{x_1}{2}\right)^2 = \frac{9x_1^2}{4} \Rightarrow x_2 + \frac{x_1}{2} = \pm\frac{3x_1}{2}$$

Since, $x_1 \neq x_2$, we have $x_2 = -2x_1$

$\Rightarrow$ Q is $(-2x_1, -2x_1 + 8x_1^3)$.

If $L_1(\alpha, \beta)$ is the point of trisection of PQ, then $\alpha = \frac{2x_1 - 2x_1}{3} = 0$. Hence, L_1 lies on the Y-axis. If $L_2(h, k)$ is the other point of trisection, then $h = \frac{x_1 - 4x_1}{3} = -x_1$ and

$$k = \frac{y_1 - 4x_1 + 16x_1^3}{3}$$

i.e. $$k = \frac{x_1 - x_1^3 - 4x_1 + 16x_1^3}{3} = -x_1 + 5x_1^3$$

$$\Rightarrow \quad k = h - 5h^3$$

$\therefore$ Locus of (h, k) is $y = x - 5x^3$.

86. Let the curve be $y = f(x)$

The equation of the tangent at any point (x, y) is

$$Y - y = \frac{dy}{dx}(X - x)$$

Its intercept on the y-axis is given by $(X = 0)$

$$Y = y - x\frac{dy}{dx} = k\sqrt{x^2 + y^2}$$

So, $x\frac{dy}{dx} - y + k\sqrt{x^2 + y^2} = 0$ is the differential equation governing the curve. This can be written as

$$\frac{dy}{dx} = \frac{y - k\sqrt{x^2 + y^2}}{x}$$

Let $y = vx$, so that $\frac{dy}{dx} = v + x\frac{dv}{dx}$

The differential equation becomes

$$v + x\frac{dv}{dx} = v - k\sqrt{1 + v^2}$$

$$\Rightarrow \quad \frac{dv}{\sqrt{1 + v^2}} + k\frac{dx}{x} = 0$$

$$\Rightarrow \quad \log|v + \sqrt{1 + v^2}| + k\log|x| = c \quad \text{(on integrating)}$$

$$\Rightarrow \quad \log\left|\frac{y}{x} + \sqrt{1 + \frac{y^2}{x^2}}\right| + k\log|x| = c$$

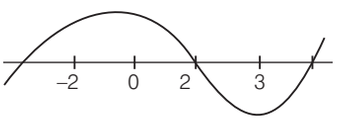
$$\Rightarrow \quad \log|y + \sqrt{x^2 + y^2}| + (k-1)\log|x| = c$$

$$\Rightarrow \quad (y + \sqrt{x^2 + y^2})\, x^{k-1} = c_1$$

87. We have, $2t^3 - 9t^2 + 30 - a = 0$

Any real root t_0 of this equation gives two real and distinct values of x if $|t_0| > 2$.

Thus, we need to find the condition for the equation in t to have three real and distinct roots none of which lies in $[-2,2]$.



Let $f(t) = 2t^3 - 9t^2 + 30 - a$

$$\Rightarrow \quad f'(t) = 6t^2 - 8t = 0 \quad \Rightarrow \quad t = 0, 3$$

So, the equation $f(t) = 0$ has three real and distinct roots, if $f(0) \cdot f(3) < 0$

$$\Rightarrow \quad (30 - a)(54 - 81 + 30 - a) < 0$$

$$\Rightarrow \quad (30 - a)(3 - a) < 0$$

$$\Rightarrow \quad (a - 3)(a - 30) < 0, \text{ using number line rule i.e.,}$$

$$\Rightarrow \quad a \in (3, 30) \qquad \ldots(i)$$

Also, none of the roots lie in $[-2,2]$

if $f(-2) > 0$ and $f(2) > 0$

$$\Rightarrow \quad (-16 - 36 + 30 - a) > 0 \quad \text{and} \quad (16 - 36 + 30 - a) > 0$$

$$\Rightarrow \quad a + 22 < 0 \quad \text{and} \quad a - 10 < 0$$

$$\Rightarrow \quad a < -22 \text{ and } a < 10$$

$$\Rightarrow \quad a < -22 \qquad \ldots(ii)$$

From Eqs. (i) and (ii) no real value of a exists.

88. Slope of tangent at the point (x_1, y_1) is given by $\left(\frac{dy}{dx}\right)_{(x_1, y_1)}$.

Given curve, $(y - x^5)^2 = x(1 + x^2)^2$

$$\Rightarrow \quad 2(y - x^5)\left(\frac{dy}{dx} - 5x^4\right) = (1 + x^2)^2 + 2x(1 + x^2)\cdot 2x$$

Put $x = 1$ and $y = 3$, then

$$dy/dx = 8$$

89. Given, $f(x) = 2 + \cos x, \forall x \in R$

Statement I There exists a point $\in [t, t + \pi]$, where $f'(c) = 0$

Hence, Statement I is true.

Statement II $f(t) = f(t + 2\pi)$ is true. But Statement II is not correct explanation for Statement I.

90. As, $|f(x_1) - f(x_2)| \le (x_1 - x_2)^2, \forall x_1, x_2 \in R$

$$\Rightarrow \quad |f(x_1) - f(x_2)| \le |x_1 - x_2|^2 \qquad [\text{as } x^2 = |x|^2]$$

$$\therefore \quad \left|\frac{f(x_1) - f(x_2)}{x_1 - x_2}\right| \le |x_1 - x_2|$$

$$\Rightarrow \quad \lim_{x_1 \to x_2}\left|\frac{f(x_1) - f(x_2)}{x_1 - x_2}\right| \le \lim_{x_1 \to x_2}|x_1 - x_2|$$

$$\Rightarrow \quad |f'(x_1)| \le 0, \forall x_1 \in R$$

$\therefore \quad |f'(x)| \le 0$, which shows $|f'(x)| = 0$

[as modulus is non-negative or $|f'(x)| \ge 0$]

$\therefore \quad f'(x) = 0$ or $f(x)$ is constant function.

$\Rightarrow$ Equation of tangent at (1, 2) is

$$\frac{y - 2}{x - 1} = f'(x)$$

or $\qquad y - 2 = 0 \qquad [\because f'(x) = 0]$

$\therefore \quad y - 2 = 0$ is required equation of tangent.

91. Given, $\qquad y^3 + 3x^2 = 12y \qquad \ldots(i)$

On differentiating w.r.t. x, we get

$$3y^2\frac{dy}{dx} + 6x = 12\frac{dy}{dx}$$

$$\Rightarrow \quad \frac{dy}{dx} = \frac{6x}{12 - 3y^2}$$

$$\Rightarrow \quad \frac{dx}{dy} = \frac{12 - 3y^2}{6x}$$

For vertical tangent,

$$\frac{dx}{dy} = 0$$

$$\Rightarrow \quad 12 - 3y^2 = 0$$

$$\Rightarrow \quad y = \pm 2$$

On putting, $y = 2$ in Eq. (i), we get $x = \pm\frac{4}{\sqrt{3}}$ and again putting $y = -2$ in Eq. (i), we get $3x^2 = -16$, no real solution.

So, the required point is $\left(\pm\frac{4}{\sqrt{3}}, 2\right)$.

92. Slope of tangent to the curve, $y = f(x)$ is

$$\left.\frac{dy}{dx}\right|_{(3,\,4)} = f'(x)_{(3,\,4)}$$

Therefore, slope of normal $= -\dfrac{1}{f'(x)_{(3,4)}} = -\dfrac{1}{f'(3)}$

But $\quad -\dfrac{1}{f'(3)} = \tan\left(\dfrac{3\pi}{4}\right)$ [given]

$\Rightarrow \quad \dfrac{-1}{f'(3)} = \tan\left(\dfrac{\pi}{2} + \dfrac{\pi}{4}\right) = -1$

$f'(3) = 1$

93. We have, $y = \dfrac{x+6}{(x-2)(x-3)}$

Point of intersection with Y-axis $(0, 1)$

$$y' = \frac{(x^2 - 5x + 6)(1) - (x+6)(2x-5)}{(x^2 - 5x + 6)^2}$$

$\Rightarrow y' = 1$ at point $(0, 1)$.

$\therefore$ Slope of normal is -1.

Hence, equation of normal is $x + y = 1$.

$\therefore \left(\dfrac{1}{2}, \dfrac{1}{2}\right)$ satisfy it.

94. Given equation of curve is

$$x^2 + 2xy - 3y^2 = 0 \quad \ldots(i)$$

On differentiating w.r.t. x, we get

$$2x + 2xy' + 2y - 6yy' = 0 \Rightarrow y' = \frac{x+y}{3y-x}$$

At $\quad x = 1, y = 1, y' = 1$ i.e. $\left(\dfrac{dy}{dx}\right)_{(1,1)} = 1$

Equation of normal at $(1, 1)$ is

$$y - 1 = -\frac{1}{1}(x-1) \Rightarrow y - 1 = -(x-1)$$

$$\Rightarrow \quad x + y = 2 \quad \ldots(ii)$$

On solving Eqs. (i) and (ii) simultaneously, we get

$$\Rightarrow \quad x^2 + 2x(2-x) - 3(2-x)^2 = 0$$

$$\Rightarrow \quad x^2 + 4x - 2x^2 - 3(4 + x^2 - 4x) = 0$$

$$\Rightarrow \quad -x^2 + 4x - 12 - 3x^2 + 12x = 0$$

$$\Rightarrow \quad -4x^2 + 16x - 12 = 0$$

$$\Rightarrow \quad 4x^2 - 16x + 12 = 0$$

$$\Rightarrow \quad x^2 - 4x + 3 = 0$$

$$\Rightarrow \quad (x-1)(x-3) = 0$$

$$\therefore \quad x = 1, 3$$

Now, when $x = 1$, then $y = 1$

and when $x = 3$, then $y = -1$.

$\therefore \quad P = (1, 1)$ and $Q = (3, -1)$

Hence, normal meets the curve again at $(3, -1)$ in fourth quadrant.

Aliter

Given, $\quad x^2 + 2xy - 3y^2 = 0$

$$\Rightarrow \quad (x-y)(x+3y) = 0$$

$$\Rightarrow \quad x - y = 0 \text{ or } x + 3y = 0$$

Equation of normal at $(1, 1)$ is

$$y - 1 = -1(x-1)$$

$$\Rightarrow \quad x + y - 2 = 0$$

It intersects $x + 3y = 0$ at $(3, -1)$ and hence normal meets the curve again in fourth quadrant.

Session 1

Monotonicity

Monotonicity

A function is said to be monotonic if it is either increasing or decreasing in its domain.

Strictly Increasing

Consider a function represented by the following graph.

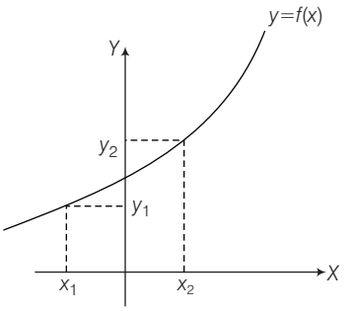

Figure 8.1

i.e. $x_1 < x_2$

implies $f(x_1) < f(x_2)$

Such a function is called a strictly increasing function or a monotonically increasing function.

For two different input arguments x_1 and x_2, where $x_1 < x_2$, $y_1 = f(x_1)$ will always be less than $y_2 = f(x_2)$.

The word 'monotonically' apparently has its origin in the word monotonous.

e.g. A monotonous routine is one in which one follows the same routine repeatedly or continuously.

Similarly, a monotonically increasing function is one that increases continuously.

e.g. consider $f(x) = [x]$.

For this function $x_1 < x_2$ does not always imply $f(x_1) < f(x_2)$.

However, $x_1 < x_2$ does imply $f(x_1) \le f(x_2)$.

In other words, $f(x) = [x]$ is not strictly (or monotonically) increases. It will nevertheless be termed **increasing**.

Strictly Decreasing

Now, we consider a function represented by the following graph.

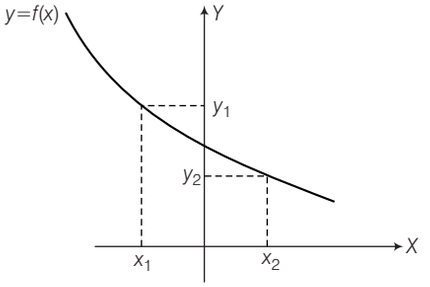

Figure 8.2

For two different input arguments x_1 and x_2, where $x_1 < x_2$, $y_1 = f(x_1)$ will always be greater than $y_2 = f(x_2)$.

i.e. $x_1 < x_2 \Rightarrow f(x_1) > f(x_2)$

Such a function is called a strictly decreasing function or a monotonically decreasing function. e.g. consider $f(x) = -[x]$.

For this function $x_1 < x_2$ does not imply $f(x_1) > f(x_2)$.

However, $x_1 < x_2 \Rightarrow f(x_1) \ge f(x_2)$

In other words, $f(x) = -[x]$ is not strictly decreasing. It would only be termed **decreasing**. The following table list down a few Examples of functions and their behaviour in different intervals.

Function	Behaviour
$f(x) = x$	Strictly increasing on R
$f(x) = x^2$	Strictly decreasing on $(-\infty, 0]$ Strictly increasing on $[0, \infty)$
$f(x) = \sqrt{x}$	Strictly increasing on $[0, \infty)$
$f(x) = x^3$	Strictly increasing on R
$f(x) = \lvert x \rvert$	Strictly decreasing on $(-\infty, 0]$
	Strictly increasing on $[0, \infty)$
$f(x) = \frac{1}{x}$	Neither decreasing nor increasing on R. Strictly decreasing on $(-\infty, 0)$, Strictly decreasing on $(0, \infty)$
$f(x) = [x]$	Increasing on R
$f(x) = \{x\}$	Neither increasing nor decreasing on R. However, strictly increasing on $[n, n+1)$, where $n \in Z$
$f(x) = \sin x$	Neither increasing nor decreasing on R. Strictly increasing on $\left[\left(2n - \frac{1}{2}\right)\pi, \left(2n + \frac{1}{2}\right)\pi\right]; n \in Z$ Strictly decreasing on $\left[\left(2n + \frac{1}{2}\right)\pi, \left(2n + \frac{3}{2}\right)\pi\right]; n \in Z$

Function	Behaviour
$f(x) = \cos x$	Neither increasing nor decreasing on R. Strictly increasing on $[(2n-1)\pi, 2n\pi]; n \in Z$ Strictly decreasing on $[2n\pi, (2n+1)\pi]; n \in Z$
$f(x) = \tan x$	Neither increasing nor decreasing on R. Strictly increasing on $\left[\left(n-\frac{1}{2}\right)\pi, \left(n+\frac{1}{2}\right)\pi\right]; n \in Z$
$f(x) = e^x$	Strictly increasing on R
$f(x) = e^{-x}$	Strictly decreasing on R
$f(x) = \ln x$	Strictly increasing on $(0, \infty)$

Monotonicity with the Help of Derivative

Let us now deduce the condition(s) on the derivative of a function $f(x)$ which determines whether $f(x)$ is increasing/decreasing on a given interval. We are assuming that $f(x)$ is everywhere differentiable.

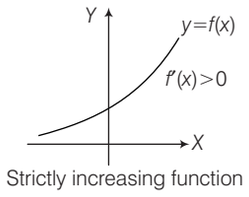

Figure 8.3

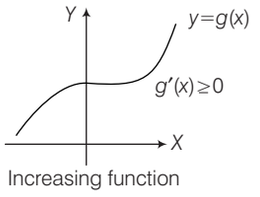

Figure 8.4

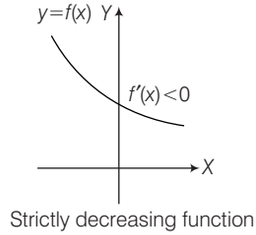
In figure 8.3, the function $y = f(x)$ is a strictly increasing function. Notice that the slope of the tangent drawn at any point on this curve is always positive.

Hence, a sufficient condition for $f(x)$ to be **strictly increasing** on a given domain D is $\boldsymbol{f'(x) > 0\ \forall\ x \in D}$ (Later on, we will see that this is not a necessary condition for a function to be strictly increasing).

In figure 8.4, the function $y = g(x)$ is not strictly increasing though it is increasing. Notice that $g'(x) > 0$ or $g'(x) = 0, \forall x$. $g'(x)$ is never negative.

Hence, a sufficient condition for $g(x)$ to be **increasing** on a given domain D is $\boldsymbol{g'(x) \geq 0,\ \forall\ x \in D}$. Now, consider $f(x)$ and $g(x)$ in given figure.



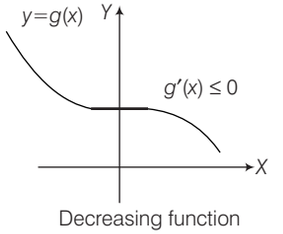


Figure 8.5

Extending as above, we get the conditions for a **strictly decreasing and decreasing** functions

Strictly decreasing : $f'(x) < 0 \quad \forall\ x \in D$

Decreasing : $g'(x) \leq 0 \quad \forall\ x \in D$

Note

(i) Above conditions on the derivatives to be applied, the function must be differentiable in the given domain. However, these conditions will hold good even if the function is non differentiable, at a finite number (or infinitely countable number) of points. e.g. $f(x) = [x] + \sqrt{\{x\}}$ is strictly increasing on R. However, $f(x)$ is non-differentiable at all integers (a countable set).

(ii) A function must be continuous for above conditions to be applied. Consider $y = \{x\}$. This is non-differentiable (due to discontinuities) at all integers. At all other points, $y' = 1 > 0$. However, we know that $y = \{x\}$ is not strictly increasing.

Similarly, $y = \frac{1}{x}$ is non-differentiable (and non-continuous) at $x = 0$. At all other points, $y' = \frac{-1}{x^2} < 0$, so y should be strictly decreasing on $R \setminus \{0\}$. However, it is not strictly decreasing on $R \setminus \{0\}$ although it is strictly decreasing in the separate intervals $(-\infty, 0)$ and $(0, \infty)$.

Therefore, we see that discontinuous functions cannot be subjected to the derivative condition. Even though they may be discontinuous only at finite (on infinitely countable) number of points.

Properties

(i) If $f(x)$ is strictly increasing, then $f^{-1}(x)$ is also strictly increasing. Similarly, if $f(x)$ is strictly decreasing, then $f^{-1}(x)$ is also strictly decreasing.

(ii) If $f(x)$ and $g(x)$ have the same monotonicity (both increasing or decreasing) on $[a, b]$, then $f(g(x))$ and $g(f(x))$ are monotonically increasing on $[a, b]$.

(iii) If $f(x)$ and $g(x)$ have opposite monotonicity on $[a, b]$, then $f(g(x))$ and $g(f(x))$ are strictly decreasing on $[a, b]$.

(iv) The inverse of a continuous function is continuous

(v) If $f'(x) > 0, \forall\ x \in (a, b)$ except for a finite (or an infinitely countable) number of points, where $f'(x) = 0$, $f(x)$ is still strictly increasing on (a, b). That is why, we said earlier that $f'(x) > 0, \forall\ x \in D$ is not necessary condition for strict increase. e.g. In a later Example, we will consider the graph of the function $f(x) = x + \cos x$. We will see that $f'(x) = 1 - \sin x$ is not always positive $\left(\text{at } x = 2n\pi + \frac{\pi}{2}, n \in Z, f'(x) = 0\right)$; even then, $f(x)$ increases strictly because the points at which $f'(x) = 0$ are countable.

(vi) Similarly if $f'(x) < 0, \forall\ x \in (a, b)$ except for a finite (or an infinitely countable) number of points, where $f'(x) = 0$, $f(x)$ is still strictly decreasing on (a, b).

Classification of Strictly Increasing Functions

Increasing functions can be classified as

(i) **Concave up** When $f'(x) > 0$ and $f''(x) > 0$, $\forall x \in$ domain.

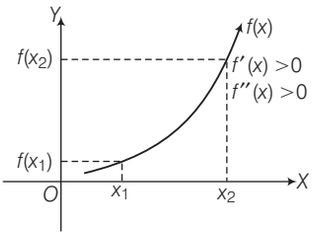

Figure 8.6

From the figure 8.6, it is clear that the graph of $f(x)$ is concave up and increasing as x increases.

(ii) **Concave down** When $f'(x) > 0$ and $f''(x) < 0$, $\forall x \in$ domain.

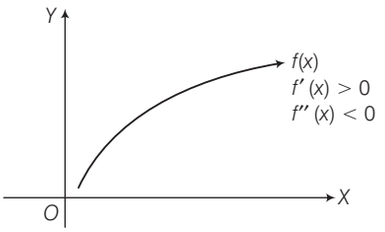

Figure 8.7

From the figure 8.7 it is clear that the graph of $f(x)$ is concave down and increasing as x increases.

(iii) When $f'(x) > 0$ and $f''(x) = 0$, $\forall x \in$ domain.

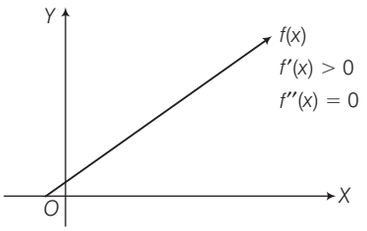

Figure 8.8

From the figure 8.8, it is clear that the graph of $f(x)$ is neither concave up nor concave down but still increasing as x increases.

Classification of Strictly Decreasing Functions

Decreasing functions can be classified as follows :

(i) **Concave up** When $f'(x) < 0$ and $f''(x) > 0$, $\forall x \in$ domain.

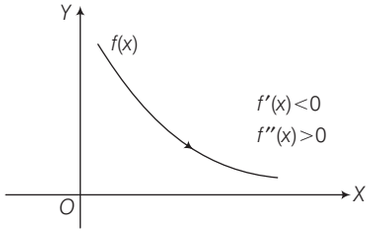

Figure 8.9

From the figure 8.9, it is clear that the graph of the function $f(x)$ is concave up and decreasing as x increases.

(ii) **Concave down** When $f'(x) < 0$ and $f''(x) < 0$, $\forall x \in$ domain.

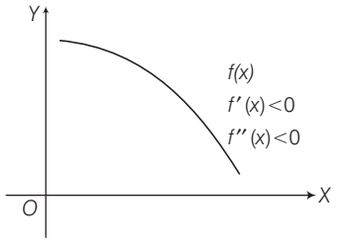

Figure 8.10

From the figure 8.10, it is clear that the graph of $f(x)$ is concave down and $f(x)$ is decreasing as x increases.

(iii) When $f'(x) < 0$ and $f''(x) = 0$, $\forall x \in$ domain.

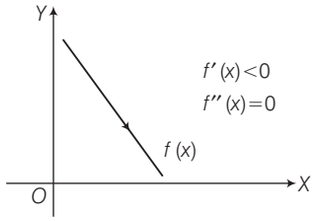

Figure 8.11

From the figure 8.11, it is clear that the graph of $f(x)$ is neither concave up nor concave down but $f(x)$ is decreasing as x increases.

Example 1 Find the interval in which $f(x) = 2x^3 + 3x^2 - 12x + 1$ is increasing.

Sol. Given, $f(x) = 2x^3 + 3x^2 - 12x + 1$

Differentiating both the sides, we have

$$f'(x) = 6x^2 + 6x - 12$$

$$\Rightarrow \quad f'(x) = 6(x^2 + x - 2)$$

$$\Rightarrow \quad f'(x) = 6(x+2)(x-1)$$

Using number line rule, we have

Hence, $f'(x) \geq 0$

when $x \in (-\infty, -2] \cup [1, \infty)$

$\Rightarrow f(x)$ is increasing when $x \in (-\infty, -2] \cup [1, \infty)$

Example 2 Find the interval in which $f(x) = x^3 - 3x^2 - 9x + 20$ is strictly increasing or strictly decreasing.

Sol. Given, $f(x) = x^3 - 3x^2 - 9x + 20$

$$f'(x) = 3x^2 - 6x - 9$$

$$\Rightarrow \quad f'(x) = 3(x^2 - 2x - 3)$$

$$\Rightarrow \quad f'(x) = 3(x-3)(x+1)$$

Using number line method as shown in figure,

$f'(x) > 0$

For $x \in (-\infty, -1) \cup (3, \infty)$ and $f'(x) < 0$,

For $x \in (-1, 3)$

Thus, $f(x)$ is strictly increasing for $x \in (-\infty, -1) \cup (3, \infty)$ and strictly decreasing for $x \in (-1, 3)$.

Example 3 Show that the function $f(x) = x^2$ is a strictly increasing function on $(0, \infty)$.

Sol. Given, $f(x) = x^2 \quad \Rightarrow \quad f'(x) = 2x$

$\Rightarrow \quad f'(x) > 0$ for $x \in (0, \infty) \qquad [\because \ x \in (0, \infty) \Rightarrow 2x > 0]$

Thus, $f(x)$ is strictly increasing for $x \in (0, \infty)$.

Example 4 ***Find the interval of increasing or decreasing of the*** $f(x) = \int_{-1}^{x} (t^2 + 2t)(t^2 - 1)\, dt$.

Sol. Given, $f(x) = \int_{-1}^{x} (t^2 + 2t)(t^2 - 1)\, dt$

On differentiating both the sides, we have

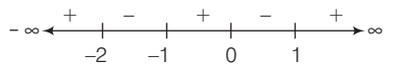
$$f'(x) = (x^2 + 2x)(x^2 - 1)\left\{\frac{d}{dx}(x)\right\} - (1-2)(1-1)\left\{\frac{d}{dx}(-1)\right\}$$

[using Leibnitz rule]

$$\Rightarrow \quad f'(x) = (x^2 + 2x)(x^2 - 1)$$

$$\Rightarrow \quad f'(x) = x(x+2)(x+1)(x-1)$$

Using number line rule as shown in figure,



Clearly, $f'(x) \geq 0$ when $x \in (-\infty, -2] \cup [-1, 0] \cup [1, \infty)$

and $f'(x) \leq 0$ when $x \in [-2, -1] \cup [0, 1]$.

Hence, $f(x)$ is increasing, when $x \in (-\infty, -2] \cup [-1, 0] \cup [1, \infty)$ and $f(x)$ is decreasing, when $x \in [-2, -1] \cup [0, 1]$.

Remark

In above example, Leibnitz rule is used which is stated as

$$\frac{d}{dx}\left[\int_{\phi(x)}^{\psi(x)} f(t)\, dt\right] = f(\psi(x))\left\{\frac{d}{dx}\psi(x)\right\} - f(\phi(x))\left\{\frac{d}{dx}\phi(x)\right\}.$$

Example 5 ***The function*** $f(x) = \sin^4 x + \cos^4 x$ ***increasing, if***

(a) $0 < x < \pi/8$ (b) $\pi/4 < x < 3\pi/8$

(c) $3\pi/8 < x < 5\pi/8$ (d) $5\pi/8 < x < 3\pi/4$

[IIT JEE 1999]

Sol. Here, $f(x) = \sin^4 x + \cos^4 x$

$$\Rightarrow \quad f'(x) = 4\sin^3 x \cdot \cos x + 4\cos^3 x\,(-\sin x)$$

$$f'(x) = 4\sin x \cos x\,(\sin^2 x - \cos^2 x)$$

$$f'(x) = 2(\sin 2x)(-\cos 2x) \Rightarrow f'(x) = -\sin 4x$$

Now, $f'(x) \geq 0$, if $\sin 4x \leq 0 \quad \Rightarrow \pi \leq 4x \leq 2\pi$

$\Rightarrow \quad \pi/4 \leq x \leq \pi/2$

Here, $\left(\frac{\pi}{4}, \frac{3\pi}{8}\right)$ is only subset of $\left[\frac{\pi}{4}, \frac{\pi}{2}\right]$.

Hence, (b) is the correct answer.

Example 6 ***Let*** $f(x) = \int_0^x e^t (t-1)(t-2)\, dt$. ***Then, f decreases in the interval*** ***[IIT JEE 2000]***

(a) $(-\infty, -2)$ (b) $(-2, -1)$

(c) $[1, 2]$ (d) $(2, \infty)$

Sol. Here, $f(x) = \int_0^x e^t (t-1)(t-2)\, dt$

$f'(x) = e^x (x-1)(x-2)$, [using Leibnitz rule]

Using number line rule for $f'(x)$, we get

$f'(x) \leq 0$ when $1 \leq x \leq 2$, as e^x is always positive.

$\therefore$ f decreases when $1 \leq x \leq 2$

Hence, (c) is the correct answer.

Example 7 If $f(x) = x \cdot e^{x(1-x)}$, then $f(x)$ is ***[IIT JEE 2000]***

(a) increasing on $\left[-\frac{1}{2}, 1\right]$ (b) decreasing on R

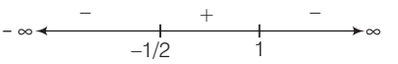
(c) increasing on R (d) decreasing on $\left[-\frac{1}{2}, 1\right]$

Sol. Here, $f'(x) = x \cdot e^{x(1-x)} \cdot (1-2x) + 1 \cdot e^{x(1-x)}$

$$f'(x) = e^{x(1-x)}[x - 2x^2 + 1]$$

$$f'(x) = -e^{x(1-x)}(x-1)(2x+1)$$

Using number line rule for $f'(x)$ we get, $f'(x) \geq 0$, when $x \in \left[-\frac{1}{2}, 1\right]$ as shown in figure.



Hence, (a) is the correct answer.

Example 8 Find the interval for which $f(x) = x - \sin x$ is increasing or decreasing.

Sol. Given, $f(x) = x - \sin x$,

Differentiating both the sides w.r.t. x, we have

$$f'(x) = 1 - \cos x$$

We know, $-1 \le \cos x \le 1$

or $\cos x \le 1$

$\Rightarrow$ $1 - \cos x \ge 0$

Therefore, $f'(x) \ge 0, \forall\, x \in R$

Which shows $f(x)$ is increasing for the entire number scale.

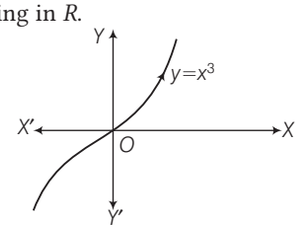
i.e. all real numbers.

Example 9 ***Discuss the nature of following functions graphically.***

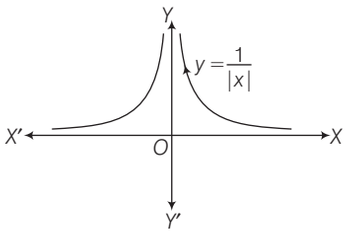
(i) $f(x) = x^3$ (ii) $f(x) = \dfrac{1}{|x|}$

(iii) $f(x) = e^x$ (iv) $f(x) = [x]$

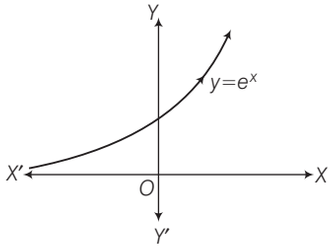
Sol. (i) $f(x) = x^3$ can be graphically plotted as shown in the following figure, which shows $f(x) = x^3$ is strictly increasing in R.



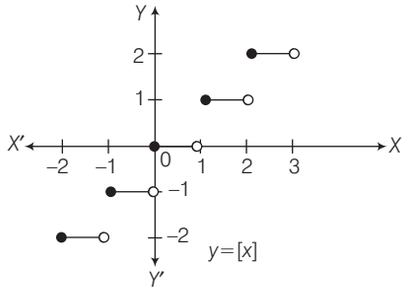
(ii) $f(x) = \dfrac{1}{|x|}$ can be graphically plotted as shown in the following figure, which shows $f(x) = \dfrac{1}{|x|}$ is strictly increasing in $]-\infty, 0[$ and strictly decreasing in $]0, \infty[$.



(iii) $f(x) = e^x$ can be graphically plotted as shown in the following figure, which shows $f(x) = e^x$ is strictly increasing in R.



(iv) $f(x) = [x]$ can be graphically plotted as shown in the following figure, which shows $f(x) = [x]$ is increasing but not strictly increasing i.e. non-decreasing in R.



Example 10 If $H(x_0) = 0$ for some $x = x_0$ and $\dfrac{d}{dx} H(x) > 2cx\, H(x)$ for all $x \ge x_0$, where $c > 0$, then prove that $H(x)$ cannot be zero for any $x > x_0$.

Sol. Given that, $\dfrac{d}{dx} H(x) > 2cx\, H(x)$

$\Rightarrow$ $\dfrac{d}{dx} H(x) - 2cx\, H(x) > 0$

$\Rightarrow$ $\dfrac{d}{dx}\{H(x)\}e^{-cx^2} - 2cxe^{-cx^2} \cdot H(x) > 0$

$\Rightarrow$ $\left\{\dfrac{d}{dx} H(x)\right\} e^{-cx^2} + H(x)\left\{\dfrac{d}{dx} e^{-cx^2}\right\} > 0$

$\Rightarrow$ $\left\{\dfrac{d}{dx} H(x) \cdot e^{-cx^2}\right\} > 0$

$\therefore$ $H(x)\, e^{-cx^2}$ is an strictly increasing function.

But $H(x_0) = 0$ and e^{-cx^2} is always positive.

$\Rightarrow$ $H(x_0) > 0$ for all $x > x_0$

$\Rightarrow$ $H(x)$ cannot be zero for any $x > x_0$.

Example 11 If $f(x)$ is a decreasing function and attain positive values, then the set of value of 'k', for which the major axis of the ellipse $\dfrac{x^2}{f(k^2 + 2k + 5)} + \dfrac{y^2}{f(k + 11)} = 1$, is the X-axis, is $(-a, b)$, then $(a + b)$ is

Sol. Here, $f(x)$ is decreasing function and major axis is X-axis

$\Rightarrow$ $f(k^2 + 2k + 5) > f(k + 11)$

[$\because$ for the ellipse $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$ major axis lies along X-axis, then $a^2 > b^2$]

As, $f(x)$ is decreasing, therefore

$$k^2 + 2k + 5 < k + 11$$

$\Rightarrow$ $k^2 + k - 6 < 0$

$\Rightarrow$ $(k + 3)(k - 2) < 0$

$\Rightarrow$ $k \in (-3, 2) = (-a, b)$

$\therefore$ $a + b = 5$

Example 12 Let $f(x)=3x+5$, then show that $f(x)$ is strictly increasing and $f^{-1}(x)$ exists and is strictly increasing for $x\in R$.

Sol. Here, $f(x)=3x+5$

$f'(x)=3>0$, which is strictly increasing for $x\in R$.

Now, finding $f^{-1}(x)$, let $f(x)=y$, $y=3x+5$

or $$x=\frac{y-5}{3}$$

or $$f^{-1}(y)=\frac{y-5}{3} \quad [\text{as } f(x)=y\Rightarrow x=f^{-1}(y)]$$

$$f^{-1}(x)=\frac{x-5}{3}$$

Which shows $f^{-1}(x)=\frac{x-5}{3}$ exists for all $x\in R$ and is strictly increasing as $\frac{d}{dx}(f^{-1}(x))=\frac{1}{3}>0$ for all $x\in R$.

Example 13 Let $\phi(x)=\sin(\cos x)$, then check whether it is increasing or decreasing in $[0,\pi/2]$.

Sol. I. Given, $\phi(x)=\sin(\cos x)$

$$\Rightarrow \quad \phi'(x)=\cos(\cos x)\cdot(-\sin x)$$

$$\Rightarrow \quad \phi'(x)=-\cos(\cos x)\cdot\sin x$$

$$\left[\because \cos(\cos x)>0 \text{ and } \sin x>0, \forall x\in\left(0,\frac{\pi}{2}\right)\right]$$

Therefore, it is clearly decreasing for $x\in[0,\pi/2]$ as $\phi'(x)\le 0$.

Aliter

Here, $f(x)=\sin x$ and $g(x)=\cos x$ are increasing and decreasing in $[0,\pi/2]$.

$\Rightarrow (fog)(x)=\phi(x)=\sin(\cos x)$ is decreasing.

Example 14 Let $\phi(x)=\cos(\cos x)$, then check whether it is increasing or decreasing in $[0,\pi/2]$.

Sol. Given, $\phi(x)=\cos(\cos x)$

$$\Rightarrow \quad \phi'(x)=-\sin(\cos x)\cdot(-\sin x)$$

$$\Rightarrow \quad \phi'(x)=\sin x\sin(\cos x)$$

$$\left[\because \sin(\cos x)>0 \text{ and } \sin x>0, \forall x\in\left(0,\frac{\pi}{2}\right)\right]$$

Therefore, it is clearly increasing for $x\in[0,\pi/2]$ as $\phi'(x)\ge 0$.

Aliter

Here, $f(x)=\cos x$ and $g(x)=\cos x$ are decreasing in $[0,\pi/2]$.

$\Rightarrow (fog)(x)=\cos(\cos x)=\phi(x)$ is increasing.

Example 15 ***Let*** $f(x)=\begin{cases} xe^{ax}; & x\le 0 \\ x+ax^2-x^3; & x>0 \end{cases}$ ***where a is positive constant. Find the interval in which*** $f'(x)$ ***is increasing.*** ***[IIT JEE 1996]***

Sol. Given, $f(x)=\begin{cases} xe^{ax}; & x\le 0 \\ x+ax^2-x^3; & x>0 \end{cases}$

Differentiating both the sides, we have

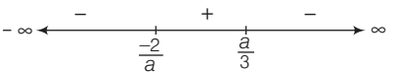
$$f'(x)=\begin{cases} axe^{ax}+e^{ax}; & x\le 0 \\ 1+2ax-3x^2; & x>0 \end{cases}$$

Again, differentiating both sides, we have

$$f''(x)=\begin{cases} 2ae^{ax}+a^2xe^{ax}; & x\le 0 \\ 2a-6x; & x>0 \end{cases}$$

Now, $f''(x)=0$, then in the interval $x\le 0$ the root is $x=-\frac{2}{a}$ and in interval $x>0$ root is $x=\frac{a}{3}$

Using sign scheme or number line rule as shown in figure, we get



$f'(x)$ decreases on $\left(-\infty,-\frac{2}{a}\right]\cup\left[\frac{a}{3},\infty\right)$ and increases on $\left[-\frac{2}{a},\frac{a}{3}\right]$.

Example 16 If $a<0$ and $f(x)=e^{ax}+e^{-ax}$ is monotonically decreasing. Find the interval to which x belongs.

Sol. Given, $a<0$ and $f(x)=e^{ax}+e^{-ax}$ is monotonically decreasing. ...(i)

$$\Rightarrow \quad f'(x)<0$$

$$\Rightarrow \quad ae^{ax}-ae^{-ax}<0$$

$$\Rightarrow \quad a\left(\frac{e^{2ax}-1}{e^{ax}}\right)<0 \qquad \text{...(ii)}$$

As from Eq. (i), $a<0$

$$\Rightarrow \quad (e^{2ax}-1)>0$$

$$\Rightarrow \quad e^{2ax}>1$$

$$\Rightarrow \quad 2ax>0$$

$$\Rightarrow \quad ax>0$$

$$\Rightarrow \quad x<0 \qquad [\text{as } a<0]$$

Thus, $f(x)$ is monotonically decreasing, if $x\in(-\infty,0)$.

Example 17 If $0<\alpha<\frac{\pi}{6}$, then the value of $(\alpha\ \text{cosec}\ \alpha)$ is

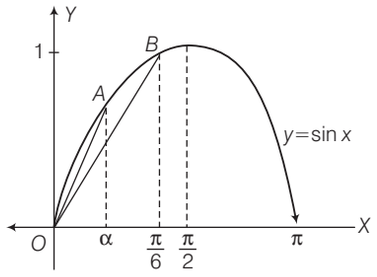
(a) less than $\frac{\pi}{3}$ (b) more than $\frac{\pi}{3}$

(c) less than $\frac{\pi}{6}$ (d) more than $\frac{\pi}{6}$

Sol. From the figure, we can say

Slope of $OA >$ Slope of OB

where $A = (\alpha, \sin\alpha)$ and $B\left(\frac{\pi}{6}, \sin\frac{\pi}{6}\right)$.



$$\Rightarrow \quad \frac{\sin\alpha - 0}{\alpha - 0} > \frac{\sin\frac{\pi}{6} - 0}{\frac{\pi}{6} - 0}$$

$$\Rightarrow \quad \frac{\sin\alpha}{\alpha} > \frac{3}{\pi} \quad \text{or} \quad \frac{\alpha}{\sin\alpha} < \frac{\pi}{3} \Rightarrow \alpha \operatorname{cosec}\alpha < \frac{\pi}{3}$$

Hence, (a) is the correct answer.

Example 18 If $f(x) = ax^3 + bx^2 + cx + d$, where a, b, c and d are real numbers and $3b^2 < c^2$, is an increasing cubic function and $g(x) = af'(x) + bf''(x) + c^2$, then

(a) $\int_a^x g(t)\,dt$ is a decreasing function

(b) $\int_a^x g(t)\,dt$ is an increasing function

(c) $\int_a^x g(t)\,dt$ is a neither increasing nor a decreasing function

(d) None of the above

Sol. $f'(x) = 3ax^2 + 2bx + c > 0$ [since, $f(x)$ is increasing]

$$\Rightarrow \quad a > 0 \text{ and } b^2 - 3ac < 0 \Rightarrow a > 0 \text{ and } b^2 < 3ac$$

Also, $g(x) = af'(x) + bf''(x) + c^2$

$$g(x) = 3a^2x^2 + 2abx + ac + 6abx + 2b^2 + c^2$$

$$g(x) = 3a^2x^2 + 8abx + (2b^2 + c^2 + ac)$$

where $D = 64a^2b^2 - 4 \cdot 3a^2 \cdot (2b^2 + c^2 + ac)$

$$= 4a^2(16b^2 - 6b^2 - 3c^2 - 3ac)$$

$$= 4a^2(10b^2 - 3c^2 - 3ac) < 4a^2(10b^2 - 3c^2 - b^2)$$

$$[\text{as } 3ac > b^2 \Rightarrow -3ac < -b^2]$$

$$= 4a^2(9b^2 - 3c^2) = 12a^2(3b^2 - c^2) \,[\text{given } 3b^2 < c^2]$$

$\therefore \quad D < 0 \Rightarrow g(x) > 0, \forall\ x \in R$

$\therefore \int_a^x g(t)\,dt$ is an increasing function.

$$\left[\because \frac{d}{dx}\left(\int_a^x g(t)dt\right) = g(x) > 0\right]$$

Hence, (b) is the correct answer.

Example 19 If $f : R \to R$, $f(x)$ is a differentiable bijective function, then which of the following is true?

(a) $(f(x) - x)\, f''(x) < 0, \forall\ x \in R$

(b) $(f(x) - x)\, f''(x) > 0, \forall\ x \in R$

(c) If $(f(x) - x)\, f''(x) > 0$, then $f(x) = f^{-1}(x)$ has no solution

(d) If $(f(x) - x)\, f''(x) > 0$, then $f(x) = f^{-1}(x)$ has at least one real solution

Sol. As, $(f(x) - x)\, f''(x) < 0, \forall\ x \in R$

$$\Rightarrow \quad (f(x) - x) > 0 \text{ and } f''(x) < 0)$$

or $\quad (f(x) - x) < 0 \text{ and } f''(x) > 0)$

Can't be true as $f(x) - x > 0$ and $f'(x)$ are decreasing. Then, $f(x)$ has to intersect the line $y = x$.

Similarly, $f(x) - x < 0$ and $f'(x)$ is increasing, is not possible.

Also, $\quad f(x) - x \neq 0$

$$\Rightarrow \quad f(x) = f^{-1}(x) \text{ has no solution.}$$

Hence, (c) is the correct answer.

Example 20 ***If*** $f(x)$ ***and*** $g(x)$ ***are two positive and increasing functions, then***

(a) $(f(x))^{g(x)}$ is always increasing

(b) if $(f(x))^{g(x)}$ is decreasing, then $f(x) < 1$

(c) if $(f(x))^{g(x)}$ is increasing, then $f(x) > 1$

(d) if $f(x) > 1$, then $(f(x))^{g(x)}$ is increasing

Sol. Let $h(x) = (f(x))^{g(x)}$

$$\Rightarrow \quad \log(h(x)) = g(x)\{\log f(x)\}$$

$$\Rightarrow \quad \frac{1}{h(x)} \cdot h'(x) = \frac{g(x)}{f(x)} \cdot f'(x) + \{\log f(x)\}\, g'(x)$$

and $h(x)$ is increasing, if $\log(f(x)) > 0 \Rightarrow f(x) > 1$

Hence, (d) is the correct answer.

Example 21 ***If the function*** $y = \sin(f(x))$ ***is monotonic for all values of x [where*** $f(x)$ ***is continuous], then the maximum value of the difference between the maximum and the minimum value of*** $f(x)$***, is***

(a) π (b) 2π (c) $\frac{\pi}{2}$ (d) None of these

Sol. As, $y = \sin(f(x))$ is monotonic for

$$f(x) \in \left[2n\pi - \frac{\pi}{2}, 2n\pi + \frac{\pi}{2}\right]$$

or $\quad \left[2n\pi + \frac{\pi}{2}, 2n\pi + \frac{3\pi}{2}\right]$

$\therefore$ The maximum value of difference is π.

Hence, (a) is the correct answer.

Example 22 ***If*** $f''(x) > 0$ ***and*** $f'(1) = 0$ ***such that*** $g(x) = f(\cot^2 x + 2\cot x + 2)$, ***where*** $0 < x < \pi$, ***then the interval in which*** $g(x)$ ***is decreasing is***

(a) $(0, \pi)$ (b) $\left(\frac{\pi}{2}, \pi\right)$

(c) $\left(\frac{3\pi}{4}, \pi\right)$ (d) $\left(0, \frac{3\pi}{4}\right)$

Sol. Here, $g(x) = f(\cot^2 x + 2\cot x + 2)$

$$\Rightarrow \quad g'(x) = f'(\cot^2 x + 2\cot x + 2) \cdot \{-2\cot x \ \text{cosec}^2 x - 2\ \text{cosec}^2\ x\}$$

for $g(x)$ to be decreasing, $g'(x) < 0$

$$\Rightarrow \quad f'\{(\cot x + 1)^2 + 1\} \cdot (-2\ \text{cosec}^2\ x)(\cot x + 1) < 0$$

$$\Rightarrow \quad f'\{(\cot x + 1)^2 + 1\} \cdot (\cot x + 1) > 0 \quad \ldots(\text{i})$$

As $f''(x) > 0 \Rightarrow f'(x)$ is increasing, then

$$f'\{(\cot x + 1)^2 + 1\} > f'(1) = 0, \ \forall \ \ x \in \left(0, \frac{3\pi}{4}\right) \cup \left(\frac{3\pi}{4}, \pi\right)$$

Thus, Eq. (i) holds, if $\cot x + 1 > 0$

$$\Rightarrow \quad \cot x > -1, \forall \ x \in \left(0, \frac{3\pi}{4}\right)$$

Hence, (d) is the correct answer.

Exercise for Session 1

1. The curve $y = f(x)$ which satisfies the condition $f'(x) > 0$ and $f''(x) < 0$ for all real x, is

(a) 
(b) 
(c) 
(d) 
2. The interval in which $f(x) = \cot^{-1} x + x$ increases, is

(a) R (b) $(0, \infty)$ (c) $R - \{n\pi\}$ (d) None of these

3. The interval in which $f(x) = 3\cos^4 x + 10\cos^3 x + 6\cos^2 x - 3$ increase or decrease in $(0, \pi)$

(a) decreases on $\left(\frac{\pi}{2}, \frac{2\pi}{3}\right)$ and increases on $\left(0, \frac{\pi}{2}\right) \cup \left(\frac{2\pi}{3}, \pi\right)$ (b) decreases on $\left(\frac{\pi}{2}, \pi\right)$ and increases on $\left(0, \frac{\pi}{2}\right)$

(c) decreases on $\left(0, \frac{\pi}{2}\right) \cup \left(\frac{2\pi}{3}, \pi\right)$ and increases on $\left(\frac{\pi}{2}, \frac{2\pi}{3}\right)$ (d) decreases on $\left(0, \frac{\pi}{2}\right)$ and increases on $\left(\frac{\pi}{2}, \pi\right)$

4. The interval in which $f(x) = \int_0^x \{(t+1)(e^t - 1)(t-2)(t+4)\}\, dt$ increases and decreases

(a) increases on $(-\infty, -4) \cup (-1, 0) \cup (2, \infty)$ and decreases on $(-4, -1) \cup (0, 2)$
(b) increases on $(-\infty, -4) \cup (-1, 2)$ and decreases on $(-4, -1) \cup (2, \infty)$
(c) increases on $(-\infty, -4) \cup (2, \infty)$ and decreases on $(-4, 2)$
(d) increases on $(-4, -1) \cup (0, 2)$ and decreases on $(-\infty, -4) \cup (-1, 0) \cup (2, \infty)$

5. The interval of monotonicity of the function $f(x) = \frac{x}{\log_e x}$, is

(a) increases when $x \in (e, \infty)$ and decreases when $x \in (0, e)$
(b) increases when $x \in (e, \infty)$ and decreases when $x \in (0, e) - \{1\}$
(c) increases when $x \in (0, e)$ and decreases when $x \in (e, \infty)$
(d) increases when $x \in (0, e) - \{1\}$ and decreases when $x \in (e, \infty)$

6. Let $f(x) = x^3 + ax^2 + bx + 5\ \sin^2 x$ be an increasing function on the set R. Then,

(a) $a^2 - 3b + 15 > 0$ (b) $a^2 - 3b + 5 < 0$ (c) $a^2 - 3b + 15 < 0$ (d) $a^2 - 3b + 5 > 0$

7. Let $g(x) = f(x) + f(1-x)$ and $f''(x) > 0, \forall\ x \in (0, 1)$. Then, $g(x)$ is

(a) increasing on $\left(0, \frac{1}{2}\right)$ and decreasing on $\left(\frac{1}{2}, 1\right)$ (b) increasing on $\left(\frac{1}{2}, 1\right)$ and decreasing on $\left(0, \frac{1}{2}\right)$

(c) increasing on $(0, 1)$ (d) decreasing on $(0, 1)$

Session 2

Critical Points

Critical Points

It is a collection of points for which,

(i) $f(x)$ does not exist (ii) $f'(x)$ does not exist

(iii) $f'(x)=0$.

All the values of x obtained from above conditions are said to be the critical points.

It should be noted that critical points are the interior points of an interval.

Example 23 Find the critical points for $f(x)=(x-2)^{2/3}(2x+1)$.

Sol. Given, $f(x)=(x-2)^{2/3}(2x+1)$

$$\Rightarrow \quad f'(x)=\frac{2}{3}(x-2)^{-1/3}(2x+1)+(x-2)^{2/3}\cdot 2$$

$$\text{or} \quad f'(x)=2\left[\frac{(2x+1)}{3(x-2)^{1/3}}+\frac{(x-2)^{2/3}}{1}\right]$$

Clearly, $f'(x)$ is not defined at $x=2$, so $x=2$ is a critical point.

Another critical point is given by

$$f'(x)=0$$

$$\text{i.e.} \quad 2\left[\frac{(2x+1)+3(x-2)}{(x-2)^{1/3}}\right]=0$$

$$\Rightarrow \quad 5x-5=0 \Rightarrow \quad x=1$$

Hence, $x=1$ and $x=2$ are two critical points of $f(x)$.

Example 24 Find all the values of a for which the function $f(x)=(a^2-3a+2)\cos\left(\frac{x}{2}\right)+(a-1)x$, possess critical points.

Sol. Given, $f(x)=(a^2-3a+2)\cos\left(\frac{x}{2}\right)+(a-1)x$

$$\Rightarrow \quad f'(x)=-\frac{1}{2}(a-1)(a-2)\sin\left(\frac{x}{2}\right)+(a-1)$$

$$\Rightarrow \quad f'(x)=(a-1)\left[1-\frac{1}{2}(a-2)\sin\left(\frac{x}{2}\right)\right]$$

If $f(x)$ possess critical points, then

$$f'(x)=0$$

$$\Rightarrow \quad (a-1)\left[1-\left(\frac{a-2}{2}\right)\sin\frac{x}{2}\right]=0$$

$$\Rightarrow \quad a=1 \text{ and } 1-\left(\frac{a-2}{2}\right)\sin\frac{x}{2}=0,$$

but at $a=1 \Rightarrow f(x)=0$

Thus, $\sin\left(\frac{x}{2}\right)=\frac{2}{a-2}$

$$\Rightarrow \quad \left|\frac{2}{a-2}\right|\le 1$$

$$\Rightarrow \quad |a-2|\ge 2 \Rightarrow a-2\ge 2$$

or $a-2\le -2$

$a\ge 4$ or $a\le 0$

Therefore, $a\in(-\infty,0]\cup[4,\infty)$

Example 25 The set of all values of 'b' for which the function $f(x)=(b^2-3b+2)(\cos^2 x-\sin^2 x)+(b-1)x+\sin 2$ does not possess stationary points is

(a) $[1,\infty)$ (b) $(0,1)\cup(1,4)$

(c) $\left(\frac{3}{2},\frac{5}{2}\right)$ (d) None of these

Sol. Here, $f(x)=(b^2-3b+2)(\cos^2 x-\sin^2 x)+(b-1)x+\sin 2$

$$=(b^2-3b+2)\cos 2x+(b-1)x+\sin 2$$

$$\Rightarrow \quad f'(x)=(b^2-3b+2)\cdot(-2\sin 2x)+(b-1).$$

As, $f(x)$ does not possess stationary points.

$$\Rightarrow \quad f'(x)\ne 0$$

$$\Rightarrow \quad (b-1)(b-2)(-2\sin 2x)+(b-1)\ne 0,$$

for any $x\in R$

$$\Rightarrow \quad (b-1)\{1-2(b-2)\sin 2x\}\ne 0$$

$$\Rightarrow \quad \left|\frac{1}{2(b-2)}\right|>1 \text{ and } b\ne 1$$

$$\Rightarrow \quad -\frac{1}{2}<b-2<\frac{1}{2} \text{ and } b\ne 1$$

$$\Rightarrow \quad \frac{3}{2}<b<\frac{5}{2} \Rightarrow b\in\left(\frac{3}{2},\frac{5}{2}\right)$$

Hence, (c) is the correct answer.

Example 26 ***Find the set of critical points of the function***

$$f(x) = x - \log x + \int_2^x \left(\frac{1}{z} - 2 - 2\cos 4z\right) dz.$$

Sol. Here, $f(x) = x - \log x + \int_2^x \left(\frac{1}{z} - 2 - 2\cos 4z\right) dz$

$\Rightarrow \quad f'(x) = 1 - \frac{1}{x} + \left(\frac{1}{x} - 2 - 2\cos 4x\right)(1) - 0$

$= -1 - 2\cos 4x$ [using Leibnitz rule]

Put $f'(x) = 0$,

$\Rightarrow \quad \cos 4x = -\frac{1}{2}$ or $\cos 4x = \cos\left(\pi - \frac{\pi}{3}\right)$

or $4x = 2n\pi + \frac{2\pi}{3}, n \in \text{Integer}$

$\Rightarrow \quad x = \frac{n\pi}{2} \pm \frac{\pi}{6}, n \in I$

But $\log x$ is defined for $x > 0$

$\therefore$ For $n = 0$, $x = \pm\frac{\pi}{6}$

$\Rightarrow \quad x = \frac{\pi}{6}$ [neglecting $x = -\pi/6$]

$\therefore$ Set of critical points $= \left\{\frac{\pi}{6}, \frac{n\pi}{2} \pm \frac{\pi}{6}\right\}$, where $n \in N$.

Exercise for Session 2

1. Determine all the critical points for the function $f(x) = 6x^5 + 33x^4 - 30x^3 + 100$.
2. Find the critical points of $f(x) = x^{2/3}(2x - 1)$.
3. Determine all the critical points for the function $f(x) = xe^{x^2}$.
4. The number of critical points of $f(x) = \max\{\sin x, \cos x\}, \forall\ x \in (-2\pi, 2\pi)$ is

   (a) 5 (b) 6

   (c) 7 (d) 8

Session 3

Comparison of Functions Using Calculus

Comparison of Functions Using Calculus

If we want to compare $\phi(x)$ and $g(x)$ then we consider a function $f(x)=\phi(x)-g(x)$ or $f(x)=g(x)-\phi(x)$ and check whether $f(x)$ is increasing or decreasing in given domain of $\phi(x)$ and $g(x)$. The procedure is illustrated by following examples :

Example 27 Using calculus, find the order relation between x and $\tan^{-1}x$ when $x\in[0,\infty)$.

Sol. Let $f(x)=x-\tan^{-1}(x)$

$$\Rightarrow \quad f'(x)=1-\frac{1}{1+x^2}$$

$$\Rightarrow \quad f'(x)=\frac{x^2}{1+x^2}\geq 0,\ \forall x\in[0,\infty)$$

Thus, $f(x)$ is an increasing function.

As, we know $x_1\leq x_2\Rightarrow f(x_1)\leq f(x_2)$ for increasing function

$$\therefore \quad x\geq 0,\ \forall x\in[0,\infty)$$

$$\Rightarrow \quad f(x)\geq f(0),\ \forall x\in[0,\infty)$$

$$\Rightarrow \quad x-\tan^{-1}x\geq 0-\tan^{-1}(0),\ \forall x\in[0,\infty)$$

$$\Rightarrow \quad x\geq\tan^{-1}x,\forall x\in[0,\infty)$$

Thus, the above relation is the order relation between x and $\tan^{-1}x$.

Example 28 ***Using calculus, find the order relation between x and*** $\tan^{-1}x$ ***when*** $x\in(-\infty,0]$.

Sol. Let $f(x)=(x)-\tan^{-1}(x)$

$$\Rightarrow \quad f'(x)=1-\frac{1}{1+x^2}$$

$$\Rightarrow \quad f'(x)=\frac{x^2}{1+x^2}\geq 0,\ \forall x\in(-\infty,0]$$

Thus, $f(x)$ is increasing function.

As, we know $x_1\leq x_2\Rightarrow f(x_1)\leq f(x_2)$ for increasing function.

$$\therefore \quad x\leq 0,\ \forall x\in(-\infty,0]$$

$$\Rightarrow \quad f(x)\leq f(0),\ \forall x\in(-\infty,0]$$

$$\Rightarrow \quad x-\tan^{-1}x\leq 0,\ \forall x\in(-\infty,0]$$

$$\Rightarrow \quad x\leq\tan^{-1}x,\ \forall x\in(-\infty,0]$$

Thus, the above relation is the order relation between x and $\tan^{-1}x$.

Example 29 For all $x\in(0,1)$ ***[IIT JEE 2000]***

(a) $e^x<1+x$ (b) $\log_e(1+x)<x$

(c) $\sin x>x$ (d) $\log_e x>x$

Sol. (a) Let $f(x)=e^x-1-x$

$$\Rightarrow\ f'(x)=e^x-1>0,\ \forall x\in(0,1)$$

So, $f(x)$ is increasing, when $0<x<1$

$$\Rightarrow \quad f(x)>f(0) \text{ or } e^x-1-x>0$$

$$\Rightarrow \quad e^x>1+x$$

Hence, (a) is false.

(b) Let $g(x)=\log(1+x)-x$

$$\Rightarrow\ g'(x)=\frac{1}{1+x}-1=\frac{-x}{1+x}<0,\ \forall x\in(0,1)$$

So, $g(x)$ is decreasing, when $0<x<1$

$$\Rightarrow \quad g(0)>g(x)\ \Rightarrow\ \log(1+x)<x$$

Hence, (b) is true.

(c) Let $h(x)=\sin x-x\ \Rightarrow\ h'(x)=\cos x-1<0,\ \forall x\in(0,1)$

So, $h(x)$ is decreasing, when $0<x<1\ \Rightarrow\ h(x)<h(0)$

$$\Rightarrow \quad \sin x<x$$

Hence, (c) is false.

(d) Let $g(x)=\log x-x\ \Rightarrow\ g'(x)=\frac{1}{x}-1$

$$\therefore\ g'(x)>0,\forall x\in(0,1) \text{ or } g(x)<g(1)$$

$$\Rightarrow \quad \log x-x<-1$$

$$\Rightarrow\ x-1>\log x \text{ or } x>\log x$$

Hence, (d) is false.

Thus, (b) is the correct answer.

Example 30 Prove that $\left(\tan^{-1}\frac{1}{e}\right)^2+\frac{2e}{\sqrt{e^2+1}}<(\tan^{-1}e)^2+\frac{2}{\sqrt{e^2+1}}$.

Sol. Let us consider a function $f(x)$,

i.e. $f(x)=(\tan^{-1}x)^2+\frac{2}{\sqrt{x^2+1}}$ for all $x\in R$

$$\therefore \quad f'(x)=\frac{2\tan^{-1}x}{1+x^2}-\frac{2x}{(x^2+1)^{3/2}}$$

$$=\frac{2}{1+x^2}\left[\tan^{-1}x-\frac{x}{\sqrt{x^2+1}}\right]$$

$\Rightarrow \quad f'(x) = \dfrac{2}{1+x^2}\, g(x),$

where $g(x) = \tan^{-1} x - \dfrac{x}{\sqrt{x^2+1}}$ ...(i)

$\therefore \quad g'(x) = \dfrac{1}{1+x^2} - \dfrac{1}{\sqrt{x^2+1}} + \dfrac{x^2}{(x^2+1)^{3/2}}$

$= \dfrac{1}{1+x^2} - \dfrac{1}{(x^2+1)^{3/2}}$

$= \dfrac{1}{1+x^2}\left(1 - \dfrac{1}{\sqrt{(x^2+1)}}\right) > 0$ for all $x \in R$

$\Rightarrow$ $g(x)$ is increasing for $x \in R$

$\Rightarrow$ $g(x) > g(0)$ for all $x \in R$

$\Rightarrow \quad \tan^{-1} x - \dfrac{x}{\sqrt{x^2+1}} > 0$ ...(ii)

$\therefore$ From Eqs. (i) and (ii), $f'(x) > 0$ for all $x > 0$

$\therefore$ $f(x)$ is increasing for all $x > 0$

$\Rightarrow \quad f(1/e) < f(e)$

$\Rightarrow \quad \left(\tan^{-1}\dfrac{1}{e}\right)^2 + \dfrac{2e}{\sqrt{e^2+1}} < (\tan^{-1} e)^2 + \dfrac{2}{\sqrt{e^2+1}}$

Exercise for Session 3

1. Show that $\sin x < x < \tan x$ for $0 < x < \pi/2$.

2. Show that $\dfrac{x}{(1+x)} < \log(1+x) < x$ for $x > 0$.

3. Show that $x - \dfrac{x^3}{6} < \sin x$ for $0 < x < \dfrac{\pi}{2}$.

4. If $ax^2 + \dfrac{b}{x} \geq c$ for all positive x, where $a, b > 0$, then

(a) $27ab^2 \geq 4c^3$ (b) $27ab^2 < 4c^3$

(c) $4ab^2 \geq 27c^3$ (d) None of these

5. If $ax + \dfrac{b}{x} \geq c$ for all positive x, where $a, b > 0$, then

(a) $ab < \dfrac{c^2}{4}$ (b) $ab \geq \dfrac{c^2}{4}$

(c) $ab \geq \dfrac{c}{4}$ (d) None of these

Session 4

Introduction to Maxima and Minima, Methods of Finding Extrema of Continuous Functions, Convexity/Concavity & Point of Inflection, Concept of Global Maximum/Minimum

Introduction to Maxima and Minima

By the maximum/minimum value of function $f(x)$ we mean local or regional maximum/minimum value and not the greatest/least value attainable by the function. It is also possible in a function that local maximum at one point is smaller than local minimum at another point. Sometimes, we use the word extrema for maxima and minima.

Definition A function $f(x)$ is said to have a maximum at $x = a$, if $f(a)$ is greatest of all values in the suitably small neighbourhood of a, where $x = a$ is an interior point in the domain of $f(x)$.

Analytically, this means $\boldsymbol{f(a) \geq f(a+h)}$ and $\boldsymbol{f(a) \geq f(a-h)}$, where $h \geq 0$ (very small quantity).

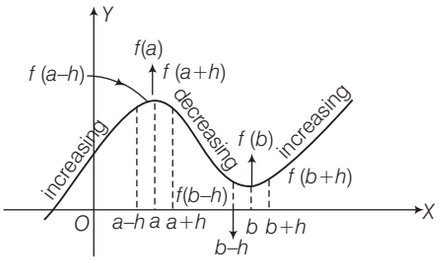


Figure 8.12

Similarly, a function $y = f(x)$ is said to have a minimum at $x = b$, if $f(b)$ is smallest of all values in the suitably small neighbourhood of b, where $x = b$ is an interior point in the domain of $f(x)$.

Analytically, $\boldsymbol{f(b) \leq f(b+h)}$ and $\boldsymbol{f(b) \leq f(b-h)}$, where $h \geq 0$ (very small quantity).

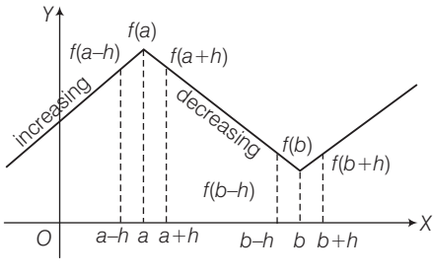

Figure 8.13

Methods of Finding Extrema of Continuous Functions

The following tests apply to a continuous function in order to get the extrema

First Derivative Test

As we know the function attains maximum, when it has assumed its maximum value and attains minimum, when it has assumed its minimum value which could be shown as

(i) At a critical point $x = a$

(a) **When $\boldsymbol{f(x)}$ attains maximum at $\boldsymbol{(x = a)}$**

Consider the following graph

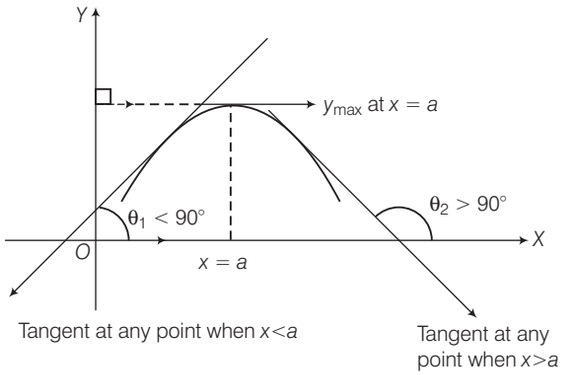

Figure 8.14

From above graph, we see that

$$\begin{cases} \text{for } x < a, \theta_1 < 90° \Rightarrow \tan\theta_1 > 0 \text{ or increasing for } x < a \\ \text{for } x = a, \tan\theta = 0 \Rightarrow \text{neither increasing nor decreasing for } x = a \\ \text{for } x > a, \theta_2 > 90° \Rightarrow \tan\theta_2 < 0 \text{ or decreasing for } x > a \end{cases}$$

Thus, we can say,

$f(x)$ is maximum at some point $(x = a)$.

$$\Rightarrow \quad \begin{cases} f(x) \text{ is increasing for } x < a \\ f(x) \text{ is decreasing for } x > a \end{cases}$$

(b) **When $f(x)$ attains minimum at $(x = a)$**
Consider the following graph

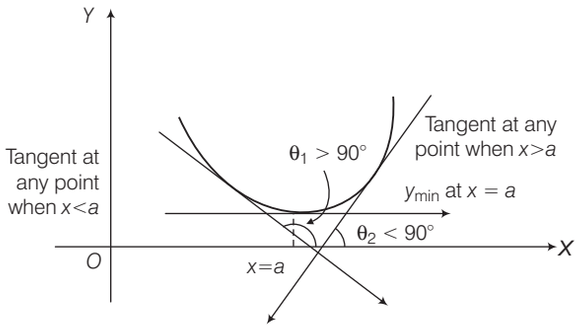

Figure 8.15

From the above graph, we see that

$$\begin{cases} \text{for } x < a, \theta_1 > 90^\circ \Rightarrow \tan\theta_1 < 0 \text{ or decreasing when } x < a \\ \text{for } x = a, \tan\theta = 0 \Rightarrow \text{neither increasing nor} \\ \text{decreasing for } x = a \\ \text{for } x > a, \theta_2 < 90^\circ \Rightarrow \tan\theta_2 > 0 \text{ or increasing when } x > a \end{cases}$$

Thus, we can say,

$f(x)$ is minimum at some points '$x = a$',

$$\Rightarrow \quad \begin{cases} f(x) \text{ is decreasing for } x < a \\ f(x) \text{ is increasing for } x > a \end{cases}$$

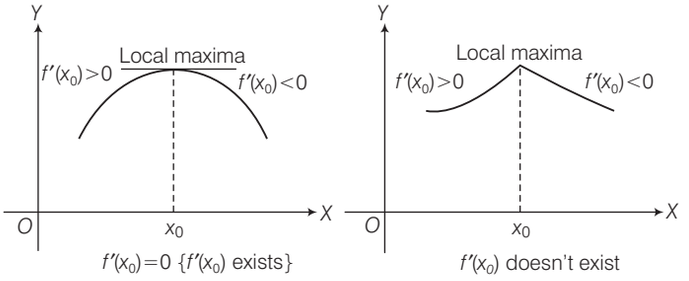
Here, some of the examples are given to make it more clear.

Remark *(Ex. Nos. 31-33)*

Statement of example Number 31, 32, 33 can be used directly as result.

Example 31 If $f'(x)$ changes from positive to negative at x_0 while moving from left to right,
i.e. $f'(x) > 0, \quad x < x_0$
$f'(x) < 0, \quad x > x_0$, *then $f(x)$ has local maximum value at $x = x_0$.*

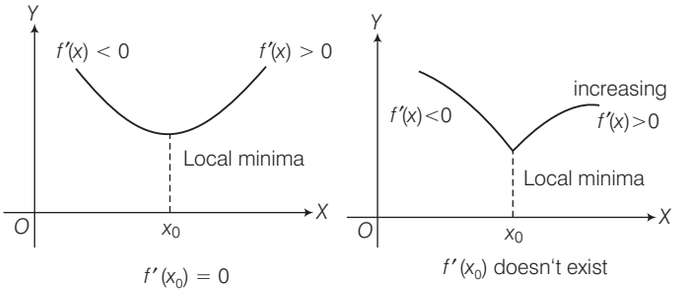
Sol. Consider the following graph



In both the graph we see that $f'(x)$ changes its sign from positive to negative when we move through x_0 and the function has local maxima at $x = x_0$.

Example 32 If $f'(x)$ changes from negative to positive at x_0 while moving from left to right,
i.e. $f'(x) < 0, \; x < x_0$
$f'(x) > 0, \; x > x_0$,
then $f(x)$ has local minimum value at $x = x_0$

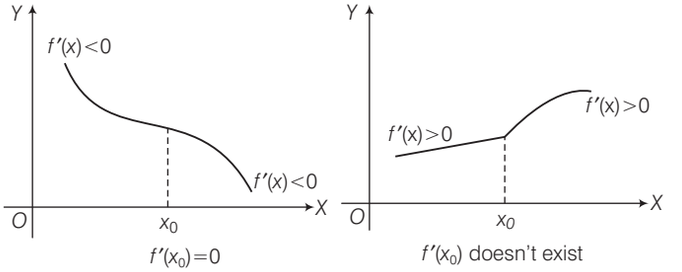
Sol. Consider the following graph



In both the graph we see that $f'(x)$ changes its sign from negative to positive when we move through x_0 and the curve has local minima at $x = x_0$.

Example 33 If sign of $f'(x)$ doesn't change at x_0, while moving from left to right, then $f(x)$ has neither a maximum nor a minimum at x_0.

Sol. Consider the following graph



In both the graph we see that $f'(x)$ has same sign when we move through x_0, therefore $f(x)$ has neither maxima nor minima at $x = x_0$.

Example 34 Let $f(x) = x^3 - 3x^2 + 6$ find the point at which $f(x)$ assumes local maximum and local minimum.

Sol. Given, $\quad f(x) = x^3 - 3x^2 + 6$

$$\Rightarrow \quad f'(x) = 3x^2 - 6x = 3x(x - 2)$$

Using number line rule,

$f'(x)$ changes sign from +ve to –ve at $x = 0$ and $f'(x)$ changes sign from –ve to +ve at $x = 2$.

Therefore, at $x = 0$, we have local maxima and at $x = 2$, we have local minima.

Example 35 Let $f(x) = x^3$ find the point at which $f(x)$ assumes local maximum and local minimum.

Sol. Given, $f(x) = x^3$

$\Rightarrow$ $f'(x) = 3x^2$

Here, $f'(x) \geq 0$ for all x, it does not change sign from negative to positive or positive to negative.

Thus, $f(x)$, we has neither maximum nor minimum.

Example 36 ***Let*** $f(x) = x + \frac{1}{x}$, $x \neq 0$***. Discuss the maximum and minimum value of*** $f(x)$***.***

Sol. Here, $f(x) = x + \frac{1}{x}$

$\Rightarrow$ $f'(x) = 1 - \frac{1}{x^2}$

$$f'(x) = \frac{x^2 - 1}{x^2} = \frac{(x-1)(x+1)}{x^2}$$

Using number line rule, we have maximum at $x = -1$ and minimum at $x = 1$

$\therefore$ At $x = -1$, we have local maximum $\Rightarrow f(x)_{\max} = -2$

and at $x = 1$, we have local minimum $\Rightarrow f(x)_{\min} = 2$

Example 37 The function $f(x) = \int_{-1}^{x} t(e^t - 1)(t-1)(t-2)^3(t-3)^5 dt$ has a local maximum at x equals ***[IIT JEE 1999]***

(a) 0 (b) 1

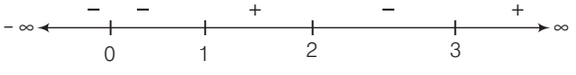
(c) 2 (d) 3

Sol. Given, $f(x) = \int_{-1}^{x} t(e^t - 1)(t-1)(t-2)^3(t-3)^5 dt$

$$f'(x) = x(e^x - 1)(x-1)(x-2)^3(x-3)^5$$

[using Leibnitz rule]

Using number line rule for $f'(x)$, we get the following figure which shows local maxima at $x = 2$ as $f'(x)$ changes from (+ve) to (−ve) and local minima at $x = 1$ and $x = 3$ as $f'(x)$ changes from (−ve) to (+ve).



$\therefore$ Local minima at $x = 1,3$ and local maxima at $x = 2$.

Hence, (c) is the correct answer.

(ii) At left end point a and right end point b in $[a, b]$

Let $f(x)$ be defined on $[a, b]$ and if $f'(x) < 0$ for $x > a$, then $f(x)$ has local maximum at $x = a$ and local minimum at $x = b$.

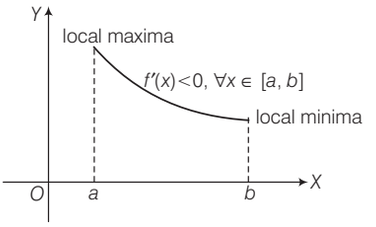


Figure 8.16

Again, if $f'(x) > 0$ for $x > a$, then $f(x)$ has local minimum at $x = a$ and local maximum at $x = b$.

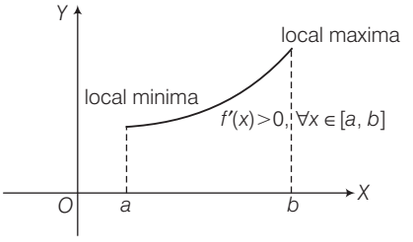

Figure 8.17

We can summarise above result as

(a) If a function is strictly increasing in $[a, b]$, then
$\begin{cases} f(a) \text{ is local minimum} \\ f(b) \text{ is local maximum} \end{cases}$

(b) If a function is strictly decreasing in $[a, b]$, then
$\begin{cases} f(a) \text{ is local maximum} \\ f(b) \text{ is local minimum} \end{cases}$

Example 38 Find the local maximum and local minimum of $f(x) = x^3 + 3x$ in $[-2, 4]$.

Sol. Given, $f(x) = x^3 + 3x$

$\Rightarrow$ $f'(x) = 3x^2 + 3$ which is strictly increasing for all $x \in R$ and thus, increasing for $[-2, 4]$.

Hence, local minimum is $f(-2) = (-2)^3 + 3(-2) = -14$

and local maximum is $f(4) = (4)^3 + 3(4) = 76$

Example 39 ***If*** $f(x) = \begin{cases} 3x^2 + 12x - 1, & -1 \leq x \leq 2 \\ 37 - x, & 2 < x \leq 3, \end{cases}$

then

(a) $f(x)$ is increasing on $[-1, 2]$ ***[IIT JEE 1993]***

(b) $f(x)$ is continuous on $[-1, 3]$

(c) $f'(x)$ does not exist at $x = 2$

(d) $f(x)$ has the maximum value at $x = 2$

Sol. Given, $f(x) = \begin{cases} 3x^2 + 12x - 1, & -1 \leq x \leq 2 \\ 37 - x, & 2 < x \leq 3 \end{cases}$

$\Rightarrow$ $f'(x) = \begin{cases} 6x + 12, & -1 \leq x < 2 \\ -1, & 2 < x \leq 3 \end{cases}$

(a) Which shows $f'(x) > 0$ for $x \in [-1, 2]$

So, $f(x)$ is increasing on $[-1, 2]$. Hence, (a) is correct.

(b) For continuity of $f(x)$. [check at $x = 2$]

$\because \quad f(x) = 3x^2 + 12x - 1, -1 \le x \le 2$

It is a polynomial, therefore continuous in $[-1, 2]$.

Also, for (2,3], $f(x) = 37 - x$ which is again a polynomial, therefore continuous in (2,3].

Now, we have to check continuity of $f(x)$ at $x = 2$

$$\text{LHL} = \lim_{h\to 0} f(2-h) = \lim_{h\to 0} 3(2-h)^2 + 12(2-h) - 1 = 35$$

$$\text{RHL} = \lim_{h\to 0} f(2+h) = \lim_{h\to 0} 37 - (2+h) = 35$$

RHL = 35 , LHL = 35 and $f(2) = 35$

So, (b) is correct.

(c) As discussed in previous chapter,

$$Rf'(2) = \lim_{h\to 0} \frac{37-(2+h)-35}{h} = -1$$

and $$Lf'(2) = \lim_{h\to 0} \frac{3(2-h)^2 + 12(2-h) - 1 - 35}{-h} = 24$$

So, not differentiable at $x = 2$

Hence, (c) is correct.

(d) We know $f(x)$ is increasing on $[-1, 2]$ and decreasing on (2, 3]. Thus, maximum at $x = 2$

Hence, (d) is correct.

$\therefore$ Hence, (a), (b), (c) and (d) all are correct answers.

Example 40 ***Let*** $f(x) = \sin x - x$ ***on*** $[0, \pi/2]$ ***, find local maximum and local minimum.***

Sol. Given, $f(x) = \sin x - x$

$$f'(x) = \cos x - 1, \ \forall x \in [0, \pi/2]$$

$$(\cos x - 1) \le 0, \forall x \in [0, \pi/2], \text{ as } \cos x \le 1$$

$\therefore \quad f'(x) \le 0, \forall x \in [0, \pi/2]$

$\therefore$ $f(x)$ is decreasing for $x \in [0, \pi/2]$.

Hence, maximum value of $f(x)$ is at $x = 0$

i.e. $f_{\max}(0) = \sin 0 - 0 = 0$

and minimum value of $f(x)$ is at $x = \pi/2$

i.e. $$f_{\min}\left(\frac{\pi}{2}\right) = \sin\frac{\pi}{2} - \frac{\pi}{2} = 1 - \frac{\pi}{2}$$

"n^{th} Derivative Test"

First we find the root of $f'(x) = 0$. Suppose $x = a$ is one of the roots of $f'(x) = 0$.

Now, find $f''(x)$ at $x = a$

(i) If $f''(a) =$ negative, then $f(x)$ is maximum at $x = a$

(ii) If $f''(a) =$ positive, then $f(x)$ is minimum at $x = a$

(iii) If $f''(a) =$ zero

Then, we find $f'''(x)$ at $x = a$

If $f'''(a) \ne 0$, then $f(x)$ has neither maximum nor minimum (inflexion point), at $x = a$.

But, if $f'''(a) = 0$, then find $f^{iv}(a)$

If $f^{iv}(a) =$ positive, then $f(x)$ is minimum at $x = a$.

If $f^{iv}(a) =$ negative, then $f(x)$ is maximum at $x = a$.

and so on, process is repeated till point is discussed.

Convexity/Concavity and Point of Inflection

Observe the two graphs sketched in the figure below. What is the difference between them? Although they are both increasing, the first graph's rate of increase in itself increasing whereas the rate of increase is decreasing in case of the second graph.

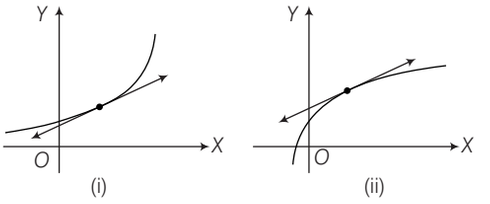

Figure 8.18

On graph (i), if you draw a tangent any where, the entire curve will lie above this tangent. Such a curve is called a **concave upwards curve.**

For graph (ii), the entire curve will lie below any tangent drawn to itself. Such a curve is called a **concave downwards curve.**

The concavity's nature can of course be restricted to particular intervals. e.g. A graph might be concave upwards in some interval while concave downwards in another shown in fig. 8.19.

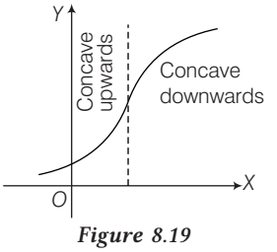

Figure 8.19

Relation of Concavity with the Derivative

Let us again consider a graph in figure. This is a concave upwards curve. We see that the rate of increase of the graph itself increases with increasing x, i.e. rate of increase of slope is positive.

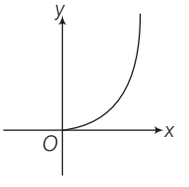

Figure 8.20

$$\frac{d}{dx}\left(\frac{dy}{dx}\right) > 0 \Rightarrow \frac{d^2y}{dx^2} > 0$$

Similarly, for **a concave downwards curve,** $\frac{d^2y}{dx^2} < 0$

The nature of concavity is simply related to the sign of the second derivative.

We now finally come to what we mean by point of inflection.

Consider $f(x) = x^3$ again $f'(0) = f''(0) = 0$

$f''(x) < 0$ for $x < 0$

and > 0 for $x > 0$

$\Rightarrow f''(x)$ changes sign as x crosses 0.

$\Rightarrow f(x)$ changes the nature of its concavity as x crosses 0.

Such a point is called a **point of inflection**, a point at which the concavity of the graph changes.

Notice that $f''(a) = 0$ alone is not sufficient to guarantee a point of inflection at $x = a$. $f''(x)$ must also change sign as x crosses a.

e.g. In $f(x) = x^4$, $f''(0) = 0$, but $x = 0$ is not a point of inflection since $f''(x)$ does not change its sign as x crosses 0. From the higher order derivative test, we know that $x = 0$ is a local minimum for $f(x) = x^4$.

A summary of results for maxima, minima and point of Inflection

	First order derivative test	Second order derivative test	Higher order derivative test
Max.	$f'(a) = 0$ $f'(x)$ changes sign from +ve to –ve as x crosses a	$f'(a) = 0$ $f''(a) < 0$	$f'(a) = 0$ $f''(a) = 0$ $\vdots$ $f^{n-1}(a) = 0$ $f^n(a) < 0$ where n is even (If n is odd, $x = a$ is not an extremum point; it is a point of inflextion)
Min.	$f'(a) = 0$ $f'(x)$ changes sign from –ve to +ve as x crosses a	$f'(a) = 0$ $f''(a) > 0$	$f'(a) = 0$ $f''(a) = 0$ $\vdots$ $f^{n-1}(a) = 0$ $f^n(a) > 0$ where n is even (If n is odd, $x = a$ is not an extremum point; it is a point of inflextion)
Point of inflection			$f''(x)$ change sign at $x = a$

Example 41 Let $f(x) = x(x-1)^2$, find the point at which $f(x)$ assumes maximum and minimum.

Sol. Given, $f(x) = x(x-1)^2$

$$f'(x) = 2x(x-1) + (x-1)^2$$

$$f'(x) = (x-1)[2x + x - 1]$$

$$f'(x) = (x-1)(3x-1)$$

Using number line rule for $f'(x)$, we have the following figure which shows $f'(x)$ changes sign from + ve to – ve at $x = 1/3$. Hence, at $x = 1/3$, we have maximum and $f'(x)$ changes sign from – ve to + ve at $x = 1$.

Hence, $f(x)$ is minimum at $x = 1$.

Aliter

We have, $f'(x) = (x-1)(3x-1)$ and $f''(x) = 6x - 4$

Let $f'(x) = 0 \Rightarrow x = 1, 1/3$ [critical points]

$\therefore$ $f''(1) = 2 > 0$, i.e. minimum at $x = 1$

and $f''(1/3) = -2 < 0$, i.e. maximum at $x = 1/3$

Example 42 ***Let*** $f(x) = (x-1)^4$ ***discuss the point at which*** $f(x)$ ***assumes maximum or minimum value.***

Sol. Given, $f(x) = (x-1)^4$

$$f'(x) = 4(x-1)^3$$

Using number line rule.

Shows $f'(x)$ changes sign from –ve to + ve.

Therefore, $f(x)$ assumes minimum at $x = 1$.

Aliter

Given, $f(x) = (x-1)^4 \Rightarrow f'(x) = 4(x-1)^3$

Let $f'(x) = 0 \Rightarrow x = 1$

Now, $f''(x) = 12(x-1)^2$ which is zero at $x = 1$

i.e. $f''(1) = 0$

Thus, finding $f'''(x) = 24(x-1)$ which is again zero at $x = 1$

i.e. $f'''(1) = 0$

Again, finding $f^{iv}(x) = 24$ which is positive at $x = 1$,

i.e. $f^{iv}(1) > 0$

Therefore, minimum at $x = 1$.

Example 43 Discuss the function $f(x) = x^6 - 3x^4 + 3x^2 - 5$, and plot the graph.

Sol. The domain is obviously R.

$f(x)$ is an even function.

Since $f(x)$ is a polynomial function, it is continuous and differentiable on R.

$f'(x) = 6x^5 - 12x^3 + 6x = 6x(x^4 - 2x^2 + 1) = 6x(x^2 - 1)^2$

$f'(x) = 0 \Rightarrow 0, \pm 1$

$f''(x) = 6(x^2 - 1)^2 + 24x^2(x^2 - 1)$

$= (x^2 - 1)\{6(x^2 - 1) + 24x^2\}$

$= (x^2 - 1)(30x^2 - 6)$ ...(i)

$= 6(5x^4 - 6x^2 + 1)$

$f''(0) = 6,\ f''(\pm 1) = 0$

$\Rightarrow x = 0$ is a point of local minimum and $x = \pm 1$ are points of inflection

(verify that $f''(x)$ does not change sign as x crosses ± 1).

Now, $f'(x) > 0$ if $x > 0$ and $f'(x) < 0$ if $x < 0$.

Therefore, $f(x)$ decreases on $(-\infty, 0)$ and increases on $(0, -\infty)$.

There is one more important fact we must take into account. $f''(x)$ has roots ± 1 and additionally, $\pm \frac{1}{\sqrt{5}}$.

[from Eq. (i)]

Therefore, at these four points the convexity of the graph changes

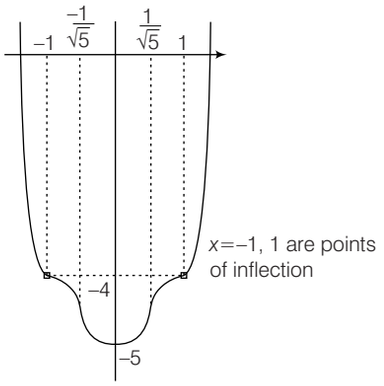
$\Rightarrow f''(x) > 0 \forall\ x \in (-\infty, -1) \cup \left(\frac{-1}{\sqrt{5}}, \frac{1}{\sqrt{5}}\right) \cup (1, \infty)$ so that $f(x)$ is concave upwards in these intervals.

$\Rightarrow f''(x) < 0 \forall\ x \in \left(-1, \frac{-1}{\sqrt{5}}\right) \cup \left(\frac{1}{\sqrt{5}}, 1\right)$ so that $f(x)$ is concave downwards in these intervals.

$f(0) = -5,\ f(\pm 1) = -4,\ f(\pm 2) = 23$

Therefore one root each of $f(x)$ lies in $(-2, -1)$ and $(1, 2)$.

This information is sufficient to accurately draw the graph of the given function.



Example 44 Discuss the function $f(x) = \frac{1}{2}\sin 2x + \cos x$., and plot its graph.

Sol. The domain of $f(x)$ is R.

$f(x)$ is periodic with period 2π and therefore we need to analyse it only in $[0, 2\pi]$.

$f(x)$ is continuous and differentiable on R.

$f'(x) = \cos 2x - \sin x$

$= 1 - 2\sin^2 x - \sin x$

$= (1 + \sin x)(1 - 2\sin x)$

This is 0 in $[0, 2\pi]$ when $x = \frac{\pi}{6}, \frac{5\pi}{6}, \frac{3\pi}{2}$

$f''(x) = -2\sin 2x - \cos x$

Now, $f''\left(\frac{\pi}{6}\right) < 0,\ f''\left(\frac{5\pi}{6}\right) > 0$ and $f''\left(\frac{3\pi}{2}\right) = 0$

$\Rightarrow x = \frac{\pi}{6}$ is a local maximum for $f(x)$; $f\left(\frac{\pi}{6}\right) = \frac{3\sqrt{3}}{4}$

$x = \frac{5\pi}{6}$ is a local minimum for $f(x)$; $f\left(\frac{5\pi}{6}\right) = \frac{-3\sqrt{3}}{4}$

$x = \frac{3\pi}{2}$ is a point of inflection; $f\left(\frac{3\pi}{2}\right) = 0$

We now need to analyse the sign of $f''(x)$.

$f''(x) = -2\sin 2x - \cos x$

$= -4\sin x \cos x - \cos x$

$= -\cos x(1 + 4\sin x)$

This is 0 in $[0, 2\pi]$ when

$x = \frac{\pi}{2}, \pi + \sin^{-1}\frac{1}{4}, \frac{3\pi}{2}, 2\pi - \sin^{-1}\frac{1}{4}$

We see that $f(x)$ will change its convexity at four different points.

$\Rightarrow f''(x) > 0 \forall\ x \in \left(\frac{\pi}{2}, \pi + \sin^{-1}\frac{1}{4}\right) \cup \left(\frac{3\pi}{2}, 2\pi - \sin^{-1}\frac{1}{4}\right)$

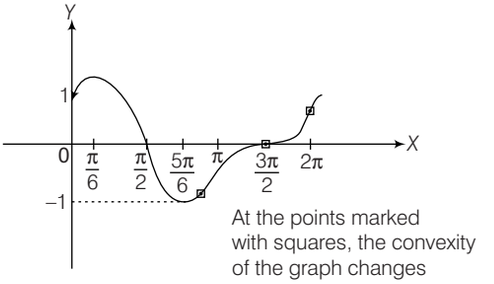
So that $f(x)$ is concave upwards in these intervals

$\Rightarrow \quad f''(x) < 0\ \forall\ x \in \left(0, \frac{\pi}{2}\right) \cup \left(\pi + \sin^{-1}\frac{1}{4}, \frac{3\pi}{2}\right) \cup \left(2\pi - \sin^{-1}\frac{1}{4}, 2\pi\right)$

So that, $f(x)$ is concave downwards in these intervals.

$f(0) = 1,\ f\left(\frac{\pi}{2}\right) = 0,\ f(2\pi) = 1$

The graph has been plotted below for $[0, 2\pi]$



Example 45 Discuss the function $y = x + \ln(x^2 - 1)$ and plot its graph.

Sol. The domain is given by $x^2 - 1 > 0$

$\Rightarrow$ $D = R \setminus [-1, 1]$

$f(x)$ is continuous and differentiable on D.

$\therefore$ $\lim\limits_{x \to 1^+} y = -\infty$; $\lim\limits_{x \to 1^-} y = -\infty$

$\Rightarrow x = \pm 1$ are vertical asymptotes to the curve.

Verify that the graph has no other asymptotes.

$$y' = 1 + \frac{2x}{x^2 - 1}$$

$\Rightarrow$ $y' = 0$ when $x^2 + 2x - 1 = 0$

$\Rightarrow$ $x = -1 \pm \sqrt{2}$

$x = -1 + \sqrt{2}$ does not belong to D.

$x = -1 - \sqrt{2}$ is an extremum point.

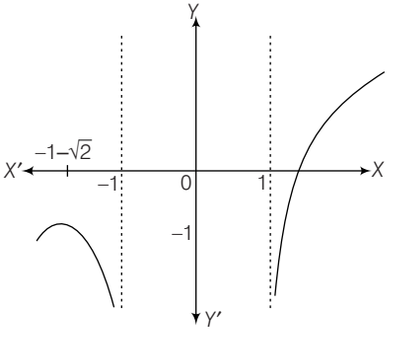
$\Rightarrow$ $$y'' = -\frac{2(x^2 + 1)}{(x^2 - 1)^2} < 0, \forall\ x$$

$\Rightarrow$ The curve is always concave downwards so that $x = -1 - \sqrt{2}$ is a point of local maximum.

$$\lim_{x \to +\infty} y = \infty$$

$$\lim_{x \to -\infty} y = -\infty$$

$\therefore$ Based on this data, the graph can be plotted as shown below.



Concept of Global Maximum/Minimum

Let $y = f(x)$ be a given function with domain D.

Let $[a, b] \subseteq D$, then global maximum/minimum of $f(x)$ in $[a, b]$ is basically the greatest/least value of $f(x)$ in $[a, b]$.

Global maxima/minima in $[a, b]$ would always occur at critical points of $f(x)$ within $[a, b]$ or at the end points of the interval.

Global Maximum/Minimum in $[a, b]$

In order to find the global maximum and minimum of $f(x)$ in $[a, b]$, find out all critical points of $f(x)$ in $[a, b]$ (i.e. all points at which $f'(x) = 0$).

Let $c_1, c_2, c_3, \ldots, c_n$ be the points at which $f'(x) = 0$

and let $f(c_1), f(c_2), \ldots, f(c_n)$ be the values of the function at these points,

$$\max\{f(a), f(c_1), f(c_2), \ldots, f(c_n), f(b)\} = M_1 \quad \text{(say)}$$

$$\min\{f(a), f(c_1), f(c_2), \ldots, f(c_n), f(b)\} = M_2 \quad \text{(say)}$$

Then, M_1 is the greatest value or global maxima in $[a, b]$ and M_2 is the least value or global minima in $[a, b]$.

Example 46 Let $f(x) = 2x^3 - 9x^2 + 12x + 6$. Discuss the global maxima and minima of $f(x)$ in $[0, 2]$.

Sol. Given, $f(x) = 2x^3 - 9x^2 + 12x + 6$

$\Rightarrow$ $f'(x) = 6x^2 - 18x + 12$

$\Rightarrow$ $f'(x) = 6(x^2 - 3x + 2)$

$\Rightarrow$ $f'(x) = 6(x - 1)(x - 2)$

Put $f'(x) = 0$

$\therefore$ $x = 1, 2$ [say c_1 and c_2]

Then, for global maximum or global minimum.

We have, $f(0) = 6,\ f(1) = 11,\ f(2) = 10,$

$\therefore$ Global maximum $\Rightarrow$ $M_1 = \max\{6, 10, 11\} = 11$

and global minimum $\Rightarrow$ $M_2 = \min\{6, 10, 11\} = 6$

$\therefore$ $f(1) = 11$ global maximum and $f(0) = 6$ global minimum.

Global Maximum/Minimum in (a, b)

Method for obtaining the greatest and least values of $f(x)$ in (a, b) is almost the same as the method used for obtaining the greatest and least values in $[a, b]$.

However a caution may be exercised

let $M_1 = \max\{f(c_1), f(c_2), \ldots, f(c_n)\}$

and $M_2 = \min\{f(c_1), f(c_2), \ldots, f(c_n)\}$

Now, M_1 and M_2 are global maximum and global minimum, respectively.

But, if $\lim\limits_{x \to a^+} f(x) > M_1$

or $\lim\limits_{x \to b^-} f(x) < M_2$

$\Rightarrow f(x)$ would not possess global maximum or global minimum in (a, b).

This means that if **limiting values at the end points are greater than M_1 or less than M_2, then global maximum or global minimum does not exist in (a, b).**

Example 47 ***Let*** $f(x)=2x^3-9x^2+12x+6$. ***Discuss the global maxima and global minima of*** $f(x)$ ***in (1, 3).***

Sol. Given, $f(x)=2x^3-9x^2+12x+6$

$\Rightarrow \quad f'(x)=6x^2-18x+12 \quad \Rightarrow \quad f'(x)=6(x-1)(x-2)$

Put $f'(x)=0 \Rightarrow x=1,2$

$\therefore \quad f(1)=11 \quad$ and $\quad f(2)=10 \quad$ ...(i)

Let us consider the open interval (1, 3).

Clearly, $x=2$ is the only point in (1, 3).

And $\quad f(2)=10 \quad$ [from Eq. (i)]

Now, $\lim\limits_{x\to 1^+} f(x)=\lim\limits_{h\to 0} f(1+h)=\lim\limits_{h\to 0} 2(1+h)^3-9(1+h)^2$
$+12(1+h)+6=11$

and $\lim\limits_{x\to 3^-} f(x)=\lim\limits_{h\to 0} f(3-h)=\lim\limits_{h\to 0} 2(3-h)^3-9(3-h)^2$
$+12(3-h)+6=15$

Thus, $x=2$ is the point of global minima in (1, 3) and global maxima does not exist in (1, 3).

Remark

Based on the above discussion, we can summarize things in a single graph as given below.

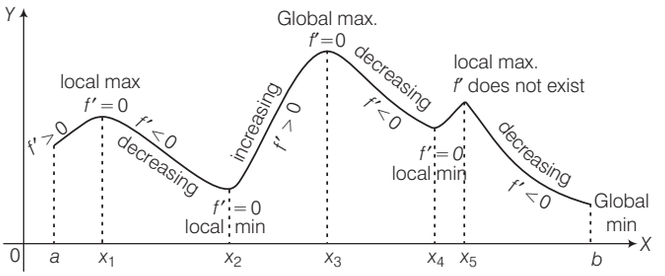


Figure 8.21

Exercise for Session 4

1. The minimum value of x^x is attained when x is equal to

(a) e (b) e^{-1} (c) 1 (d) e^2

2. The function f is defined by $f(x)=x^p(1-x)^q$ for all $x\in R$, where p,q are positive integers, has a maximum value, for x is equal to

(a) $\dfrac{pq}{p+q}$ (b) 1 (c) 0 (d) $\dfrac{p}{p+q}$

3. The least area of the circle circumscribing any right triangle of area S is

(a) πS (b) $2\pi S$ (c) $\sqrt{2}\pi S$ (d) $4\pi S$

4. The coordinates of the point on the curve $x^2=4y$, which is atleast distance from the line $y=x-4$ is

(a) (2, 1) (b) (– 2, 1)

(c) (– 2, –1) (d) none of these

5. The largest area of a rectangle which has one side on the x-axis and the two vertices on the curve $y=e^{-x^2}$ is

(a) $\sqrt{2}\,e^{-1/2}$ (b) $2\,e^{-1/2}$

(c) $e^{-1/2}$ (d) none of these

6. Let $f(x)=\ln(2x-x^2)+\sin\dfrac{\pi x}{2}$. Then,

(a) graph of f is symmetrical about the line $x=1$ (b) graph of f is symmetrical about the line $x=2$

(c) maximum value of f is 1 (d) minimum value of f does not exist

7. The sum of the legs of a right triangle is 9 cm. When the triangle rotates about one of the the legs, a cone results which has the maximum volume. Then,

(a) slant height of such a cone is $3\sqrt{5}$ (b) maximum volume of the cone is $32\,\pi$

(c) curved surface of the cone is $18\sqrt{5}\,\pi$ (d) semi vertical angle of cone is $\tan^{-1}\sqrt{2}$

8. Least value of the function $f(x)=2^{x^2}-1+\dfrac{2}{2^{x^2}+1}$ is

(a) 0 (b) $\dfrac{3}{2}$ (c) $\dfrac{2}{3}$ (d) 1

9. The greatest and the least value of the function, $f(x) = \sqrt{1-2x+x^2} - \sqrt{1+2x+x^2},\ x \in (-\infty, \infty)$ are

(a) 2, – 2 (b) 2, – 1

(c) 2, 0 (d) none

10. The minimum value of the polynomial $x(x+1)(x+2)(x+3)$ is

(a) 0 (b) $\frac{9}{16}$

(c) – 1 (d) $-\frac{3}{2}$

11. The difference between the greatest and least values of the functions, $f(x) = \cos x + \frac{1}{2}\cos 2x - \frac{1}{3}\cos 3x$ is

(a) $\frac{4}{3}$ (b) 1

(c) $\frac{9}{4}$ (d) $\frac{1}{6}$

12. The point at which the slope of the tangent of the function, $f(x) = e^x \cdot \cos x$ attains minima, when $x \in [0, 2\pi]$ is

(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$

(c) $\frac{3\pi}{4}$ (d) π

13. If λ, μ are real numbers such that, $x^3 - \lambda x^2 + \mu x - 6 = 0$ has its real roots and positive, then the minimum value of μ is

(a) $3(6)^{1/3}$ (b) $3(6)^{2/3}$

(c) $(6)^{1/3}$ (d) $(6)^{2/3}$

14. The points for which the function $f(x) = \int_1^x \{2(t-1)(t-2)^3 + 3(t-1)^2(t-2)^2\}\, dt$ attains maxima and minima, is

(a) maximum when $x = \frac{7}{5}$ and minimum when $x = 1$ (b) maximum when $x = 1$and minimum when $x = 0$

(c) maximum when $x = 1$and minimum when $x = 2$ (d) maximum when $x = 1$and minimum when $x = \frac{7}{5}$

15. The set of values of 'a' for which the function $f(x) = \frac{ax^3}{3} + (a+2)x^2 + (a-1)x + 2$ possess a negative point of inflection.

(a) $(-\infty, -2) \cup (0, \infty)$ (b) $\{-4/5\}$

(c) $(-2, 0)$ (d) empty set

Session 5

Maxima and Minima of Discontinuous Functions

Maxima and Minima of Discontinuous Functions

In discontinuous functions we don't apply any of the methods discussed earlier but we observe certain conditions and their graphs which would give you more clear picture.

Minimum of Discontinuous Functions

Let $f(x)$ be a function discontinuous or not differentiable at $x = a$, then the following four cases arise for minimum at $x = a$

Case (i) From figure 8.22

$$f(a) < f(a+h) \qquad f(a) < f(a-h)$$

Case (ii) From figure 8.23

$$f(a) < f(a+h) \qquad f(a) < f(a-h)$$

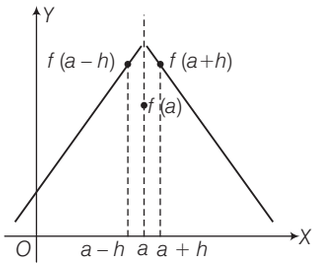

Figure 8.22

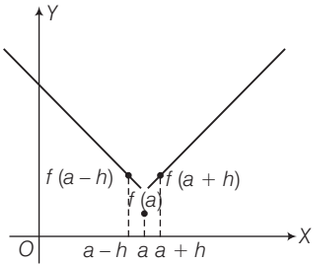

Figure 8.23

Case (iii) From figure 8.24

$$f(a) < f(a+h) \qquad f(a) \le f(a-h)$$

Case (iv) From figure 8.25

$$f(a) \le f(a+h) \qquad f(a) < f(a-h)$$

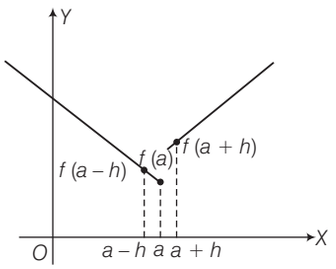

Figure 8.24

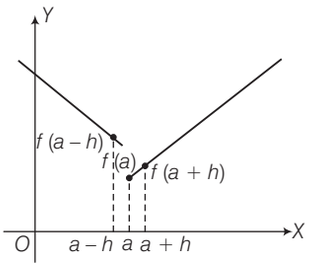

Figure 8.25

from all the four above mentioned cases for minimum of discontinuous functions, we have

$$f(a) \le f(a+h) \text{ and } f(a) \le f(a-h)$$

Example 48 Discuss the minima of $f(x) = \{x\}$, (where $\{.\}$ denotes the fractional part of x) for $x = 6$.

Sol. As we have discussed for discontinuous functions, minimum at $x = a$ is attained when,

$f(a) \le f(a+h)$ and $f(a) \le f(a-h) \Rightarrow f(x)$ is minimum at $x = a$

Here, $f(x) = \{x\}$ is discontinuous function at $x = 6$

where, $f(6) = 0$

$f(6+h) > 0$ and $f(6-h) > 0$

So, $f(6) < f(6+h)$ and $f(6) < f(6-h)$

$\Rightarrow$ $f(x)$ is minimum at $x = 6$.

$\therefore$ $f(x)$ attains local minima for $x = 6$.

Example 49 Let $f(x) = \begin{cases} |x-2| + a^2 - 9a - 9, & \text{if } x < 2 \\ 2x - 3, & \text{if } x \ge 2 \end{cases}$.

Then, find the value of 'a' for which $f(x)$ has local minimum at $x = 2$.

Sol. We have, $f(x) = \begin{cases} |x-2| + a^2 - 9a - 9, & \text{if } x < 2 \\ 2x - 3, & \text{if } x \ge 2 \end{cases}$

$f(x)$ has local minima at $x = 2$.

Since, $f(x) = 2x - 3$ for $x \ge 2$ [is strictly increasing]

$\therefore$ $\lim\limits_{x \to 2^-} f(x) \ge f(2)$ or $\lim\limits_{h \to 0} f(2-h) \ge f(2)$

$\Rightarrow \lim\limits_{h \to 0} \{|2-h-2| + a^2 - 9a - 9\} \ge 1 \quad [\because f(2) = 2 \times 2 - 3 = 1]$

$\Rightarrow$ $a^2 - 9a - 10 \ge 0$

$\Rightarrow$ $(a+1)(a-10) \ge 0$

$\Rightarrow$ $a \le -1$ or $a \ge 10$

Maximum of Discontinuous Functions

Let $f(x)$ be a function discontinuous or not differentiable at $x = a$, then the following four cases arise for maximum at $x = a$.

(i) From figure 8.26

$$f(a) > f(a+h) \qquad f(a) > f(a-h)$$

(ii) From figure 8.27

$$f(a) > f(a+h) \qquad f(a) > f(a-h)$$

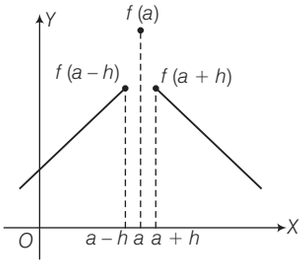

Figure 8.26

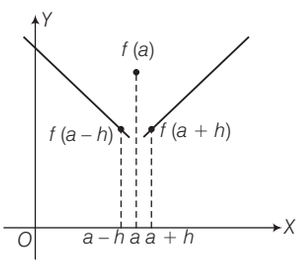

Figure 8.27

(iii) From figure 8.28

$f(a) > f(a+h)$

$f(a) \geq f(a-h)$

(iv) From figure 8.29

$f(a) \geq f(a+h)$

$f(a) > f(a-h)$

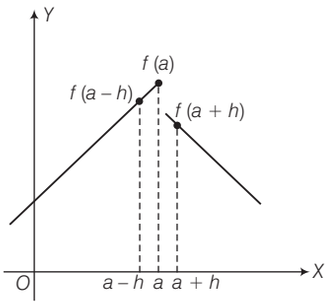

Figure 8.28

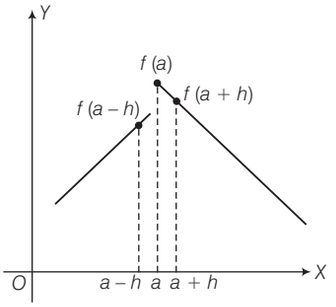

Figure 8.29

From all the above four mentioned cases for maximum of discontinuous functions, we have

$$f(a) \geq f(a+h),\ f(a) \geq f(a-h)$$

Neither Maximum Nor Minimum for Discontinuous Functions

Let $f(x)$ be a function discontinuous or not differentiable at $x = a$, then the following cases arise for neither maximum nor minimum at $x = a$

(i) $f(a) < f(a-h)$

$f(a) \geq f(a+h)$

(ii) $f(a) \leq f(a+h)$

$f(a) > f(a-h)$

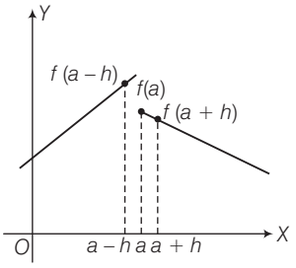

Figure 8.30

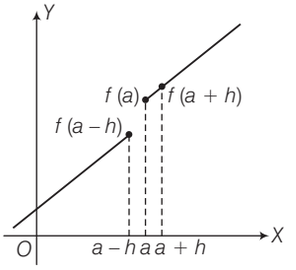

Figure 8.31

(iii) $f(a) < f(a+h)$

$f(a) \geq f(a-h)$

(iv) $f(a) \leq f(a-h)$

$f(a) > f(a+h)$

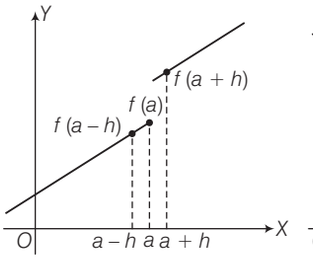

Figure 8.32

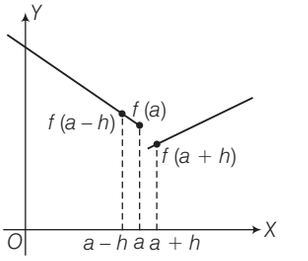

Figure 8.33

(v) $f(a) < f(a-h)$

$f(a) > f(a+h)$

(vi) $f(a) < f(a-h)$

$f(a) \geq f(a+h)$

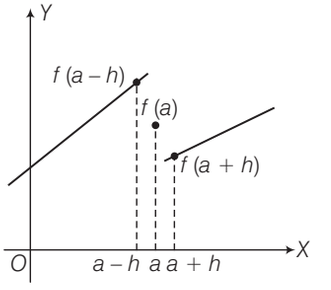

Figure 8.34

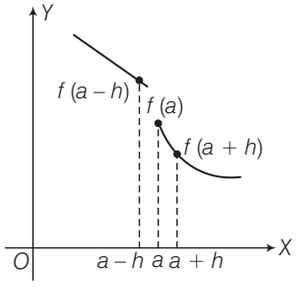

Figure 8.35

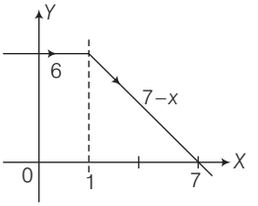
In all above cases no extremum exist.

Example 50 Let $f(x) = \begin{cases} 6, & x \leq 1 \\ 7-x, & x > 1 \end{cases}$, then for $f(x)$ at $x = 1$ discuss maxima and minima.

Sol. Here, $f(x) = \begin{cases} 6, & x \leq 1 \\ 7-x, & x > 1 \end{cases}$



Clearly, $f(x)$ is not differentiable at $x = 1$

$\Rightarrow \quad f(1) = 6 \ \Rightarrow \ f(1-h) = 6$

and $\quad f(1+h) = 7-(1+h) = 6-h < 6$

Thus, $x = 1$ is a point of maxima.

Example 51 Find the values of 'a' for which,

$$f(x) = \begin{cases} 4x - x^3 + \log(a^2 - 3a + 3), & 0 \leq x < 3 \\ x - 18, & x \geq 3 \end{cases}$$

has a local maxima at $x = 3$.

Sol. Given, $f(x) = \begin{cases} 4x - x^3 + \log(a^2 - 3a + 3), & 0 \leq x < 3 \\ x - 18, & x \geq 3 \end{cases}$

Since, function attains maxima at $x = 3$

$\Rightarrow \quad f(3) \geq f(3-0)$

$\Rightarrow \quad -15 \geq 12 - 27 + \log(a^2 - 3a + 3)$

$\Rightarrow \quad \log(a^2 - 3a + 3) \le 0$

Where for 'log' to exists,

$a^2 - 3a + 3 > 0$ and $\log(a^2 - 3a + 3) \le 0$

$\Rightarrow \quad 0 < a^2 - 3a + 3 \le 1$

i.e. $(a-2)(a-1) \le 0$

Using number line rule, we have

i.e. $1 \le a \le 2$

$\therefore$ $f(x)$ attains local maxima at $x = 3$, when $a \in [1, 2]$.

Nature of Roots of Cubic Polynomials

Let $f(x) = ax^3 + bx^2 + cx + d$ be the given cubic polynomial and $f(x) = 0$ be the corresponding cubic equations, where $a, b, c, d \in R$ and $a > 0$.

Now, $f'(x) = 3ax^2 + 2bx + c$

Let $D = 4b^2 - 12ac = 4(b^2 - 3ac)$ be the discriminant of the equations $f'(x) = 0$.

Now, we have the following three cases.

***Case* I** If $D < 0 \Rightarrow f'(x) > 0, \forall x \in R$, i.e. $f(x)$ would be an increasing function of x. Also, $\lim\limits_{x \to \infty} f(x) = \infty$ and $\lim\limits_{x \to -\infty} f(x) = -\infty$.

Since, $f(x)$ is an increasing function, so it will intersect the X-axis at only once.

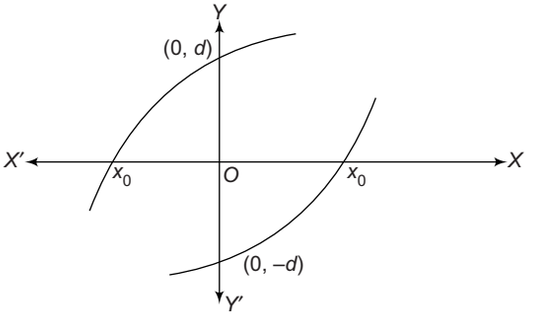


Figure 8.36

Clearly, $x_0 > 0$ if $d < 0$ and $x_0 < 0$, if $d > 0$

***Case* II** If $D > 0, f'(x) = 0$ would have two real roots (say) α and β (where $\alpha < \beta$)

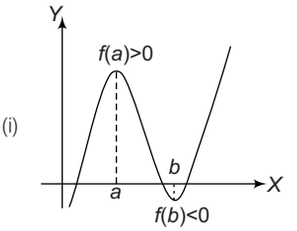
$\Rightarrow \quad f'(x) = 3a(x - \alpha)(x - \beta)$

$$\Rightarrow \quad \begin{cases} f'(x) < 0, x \in (\alpha, \beta) \\ f'(x) > 0, x \in (-\infty, \alpha) \cup (\beta, \infty) \\ f'(x) = 0, x \in \{\alpha, \beta\} \end{cases}$$

Here, $x = \alpha$, will be point of local maxima and $x = \beta$ will be point of local minima.

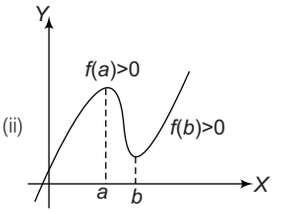
***Case* III** If $D = 0$, $f'(x) = 3a(x - \alpha)^2$, where α is a root of $f'(x) = 0$, then $f(x) = a(x - \alpha)^3 + K$. If $K = 0$, then $f(x) = 0$ has three equal real roots. if $K \neq 0$, then $f(x) = 0$ has one real root.

Graphical Representation of Roots of Cubic Polynomials



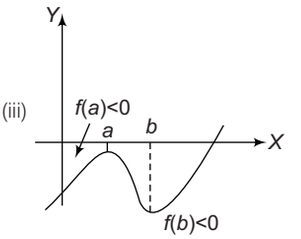
$f(x)$ has three distinct roots

Figure 8.37



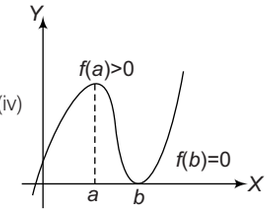
$f(x)$ has one real root

Figure 8.38



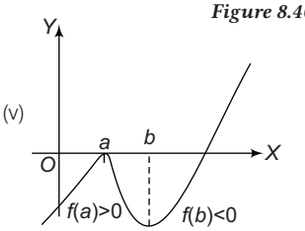
$f(x)$ has one real root

Figure 8.39



$f(x)$ has three real roots
(b being repeated)

Figure 8.40



$f(x)$ has three real roots
(a being repeated)

Figure 8.41

Conclusions

(i) If $f(a) \cdot f(b) < 0$, then $f(x)$ has three distinct roots (see figure 8.37).

(ii) If $f(a) \cdot f(b) > 0$, then $f(x)$ has one real and two imaginary roots (see figure 8.38 and 8.39).

(iii) If $f(a) \cdot f(b) = 0$, then $f(x)$ has three roots but two roots are identical (see figure 8.40 and 8.41).

Example 52 If $4x^3 - 3x - p = 0$, where $-1 \le p \le 1$ has unique root in $\left[\frac{1}{2}, 1\right]$, then the root is *[IIT JEE 2005]*

(a) $\frac{\cos^{-1} p}{3}$ (b) $\cos\left(\frac{1}{3}\cos^{-1} p\right)$

(c) $\cos(\cos^{-1} p)$ (d) None of these

Sol. Given that, $-1 \le p \le 1$

Let $f(x) = 4x^3 - 3x - p$

Now, $f\left(\frac{1}{2}\right) = \frac{1}{2} - \frac{3}{2} - p = -1 - p \le 0 \quad [\because p \ge -1]$

and $f(1) = 4 - 3 - p = 1 - p \ge 0 \quad [\because p \le 1]$

$\therefore$ $f(x)$ has atleast one real root between $\left[\frac{1}{2}, 1\right]$.

To find a root we observe $f(x)$ contains $4x^3 - 3x$, which is multiple angle formula for $\cos 3\theta$.

$\therefore$ We put $x = \cos\theta$, then

$$4\cos^3\theta - 3\cos\theta - p = 0$$

$$\Rightarrow \quad p = \cos 3\theta$$

$$\Rightarrow \quad \theta = \frac{1}{3}\cos^{-1}(p)$$

$\therefore$ Root is $\cos\left(\frac{1}{3}\cos^{-1} p\right)$

Hence, (b) is the correct answer.

Example 53 The number of distinct real roots of $x^4 - 4x^3 + 12x^2 + x - 1 = 0$ *[IIT JEE 2011]*

Sol. Given, $f(x) = x^4 - 4x^3 + 12x^2 + x - 1$

$$\Rightarrow \quad f'(x) = 4x^3 - 12x^2 + 24x + 1$$

$$\Rightarrow \quad f''(x) = 12x^2 - 24x + 24$$

$$\Rightarrow \quad f''(x) = 12(x^2 - 2x + 2)$$

$$\Rightarrow \quad f''(x) = 12((x-1)^2 + 1) \Rightarrow f''(x) > 0$$

$\Rightarrow$ $f'(x)$ is an increasing cubic function.

$\Rightarrow$ $f'(x)$ has only one real root and two imaginary root.

$\therefore$ $f(x)$ cannot have all distinct roots, atmost two real roots.

Now, $f(-1) = 15, f(0) = -1, f(1) = 9$

$\therefore$ $f(x)$ must have one root in $(-1, 0)$ and other in $(0,1)$.

Hence, there are 2 real roots.

Exercise for Session 5

1. Let $f(x) = \begin{cases} x^3 - x^2 + 10x - 5, & x \le 1 \\ -2x + \log_2(b^2 - 2), & x > 1 \end{cases}$ the set of values of b for which $f(x)$ have greatest value at $x = 1$ is given by

(a) $1 < b \le 2$ (b) $b = \{1,2\}$ (c) $b \in (-\infty, -1)$ (d) $[-\sqrt{130}, -\sqrt{2}) \cup (\sqrt{2}, \sqrt{130}]$

2. Number of solution(s) satisfying the equations, $3x^2 - 2x^3 = \log_2(x^2 + 1) - \log_2 x$ is

(a) 1 (b) 2 (c) 3 (d) None of these

3. Let $f(x) = \cos 2\pi x + x - [x]$([.] denotes the greatest integer function). Then, number of points in [0, 10] at which $f(x)$ assumes its local maximum value, is

(a) 0 (b) 10 (c) 9 (d) infinite

4. If $f(x) = |x| + |x - 1| + |x - 2|$, then

(a) $f(x)$ has minima at $x = 1$ (b) $f(x)$ has maxima at $x = 0$

(c) $f(x)$ has neither maxima nor minima at $x = 3$ (d) None of these

5. The function $f(x) = 1 + [\cos x]x$, in $0 < x \le \frac{\pi}{2}$

(a) has a minimum value 0 (b) has a maximum value 2

(c) is continuous in $\left[0, \frac{\pi}{2}\right]$ (d) is not differentiable at $x = \frac{\pi}{2}$

6. If $\lim_{x \to a} f(x) = \lim_{x \to a} [f(x)]$([.] denotes the greater integer function) and $f(x)$ is non-constant continuous function, then

(a) $\lim_{x \to a} f(x)$ is irrational (b) $\lim_{x \to a} f(x)$ is non-integer

(c) $f(x)$ has local maxima at $x = a$ (d) $f(x)$ has local minima at $x = a$

7. Find the value of a if $x^3 - 3x + a = 0$ has three distinct real roots.

8. Prove that there exist exactly three non- similar isosceles ΔABC such that $\tan A + \tan B + \tan C = 100$.

JEE Type Solved Examples :
Single Option Correct Type Questions

● ***Ex. 1*** *The values of 'K' for which the point of minimum of the function* $f(x)=1+K^2x-x^3$ *satisfy the inequality* $\frac{(x^2+x+2)}{(x^2+5x+6)}<0$, *belongs*

(a) $(-3\sqrt{3},\infty)$

(b) $(-3\sqrt{3},-2\sqrt{3})\cup(0,\infty)$

(c) $(-3\sqrt{3},-2\sqrt{3})\cup(2\sqrt{3},3\sqrt{3})$

(d) $(0,\infty)$

Sol. Here, $\frac{x^2+x+2}{x^2+5x+6}<0 \Rightarrow \frac{\left(x+\frac{1}{2}\right)^2+\frac{7}{4}}{(x+2)(x+3)}<0$

$+ \quad - \quad +$

$-3 \qquad -2$

where $\left(x+\frac{1}{2}\right)^2+\frac{7}{4}$ is always positive.

$\therefore$ Using number line rule for $(x+2)(x+3)$ as shown above, we get

$$\frac{x^2+x+2}{x^2+5x+6}<0 \quad \Rightarrow \quad -3<x<-2 \qquad ...(i)$$

Now, consider $f(x)=1+K^2x-x^3$

$$f'(x)=K^2-3x^2, \quad f''(x)=-6x$$

For maximum/minimum let $f'(x)=0$,

$$\Rightarrow \qquad x=\pm\frac{|K|}{\sqrt{3}}$$

Let $\qquad x_1=\frac{|K|}{\sqrt{3}}$ and $x_2=-\frac{|K|}{\sqrt{3}}$

$\therefore \qquad f''(x_1)<0$ and $f''(x_2)>0$

$\Rightarrow$ $f(x)$ is maximum at $x=x_1$ and $f(x)$ is minimum at $x=x_2$.

$\therefore \qquad -3<x_2<-2$

$$\Rightarrow \qquad -3<\frac{-|K|}{\sqrt{3}}<-2 \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow \qquad 3\sqrt{3}>|K|>2\sqrt{3}$$

$$\Rightarrow \qquad K\in(-3\sqrt{3},-2\sqrt{3})\cup(2\sqrt{3},3\sqrt{3})$$

Hence, (c) is the correct answer.

● ***Ex. 2*** *The values of a and b for which all the extrema of the function,* $f(x)=a^2x^3-0.5ax^2-2x-b$, *is positive and the minimum is at the point* $x_0=\frac{1}{3}$, *are*

(a) when $a=-2\Rightarrow b<-\frac{11}{27}$ and when $a=3\Rightarrow b<-\frac{1}{2}$

(b) when $a=3\Rightarrow b<-\frac{11}{27}$ and when $a=2\Rightarrow b<-\frac{1}{2}$

(c) when $a=-2\Rightarrow b<-\frac{1}{2}$ and when $a=3\Rightarrow b<-\frac{11}{27}$

(d) None of the above

Sol. Given, $\qquad f(x)=a^2x^3-0.5ax^2-2x-b$

$$\Rightarrow \qquad f'(x)=3a^2x^2-ax-2$$

For extrema, $f'(x)=0$

$$\Rightarrow \quad 3a^2x^2-ax-2=0 \text{ at } x=\frac{1}{3}$$

$$\left[\text{as at } x=\frac{1}{3} \text{ function is minimum}\right]$$

$$\therefore \qquad 3a^2\left(\frac{1}{3}\right)^2-a\left(\frac{1}{3}\right)-2=0 \quad \Rightarrow \quad \frac{a^2}{3}-\frac{a}{3}-2=0$$

$$\Rightarrow \qquad a^2-a-6=0 \quad \text{or} \quad a=-2,3$$

So, their arise two cases as

***Case* I** At $a=3$, if function attains minimum and is positive.

Then, $\qquad 9\left(\frac{1}{3}\right)^3-(0.5)(3)\left(\frac{1}{3}\right)^2-2\left(\frac{1}{3}\right)-b>0$

$$\left[\because \text{minimum at } x=\frac{1}{3} \text{and} \, a=3\Rightarrow f\left(\frac{1}{3}\right)>0 \text{ when} \, a=3\right]$$

$$\Rightarrow \qquad b<\frac{1}{3}-\frac{1.5}{9}-\frac{2}{3} \quad \Rightarrow \quad b<-\frac{1}{2}$$

***Case* II** At $a=-2$, if function attains minimum and is positive.

Then, $\qquad (-2)^2\left(\frac{1}{3}\right)^3-(0.5)(-2)\left(\frac{1}{3}\right)^2-2\left(\frac{1}{3}\right)-b>0$

$$\left[\begin{array}{l}\text{since minimum at } x=\frac{1}{3}, \text{ when } a=-2\\ \Rightarrow f\left(\frac{1}{3}\right)>0, \text{ when } a=-2\end{array}\right]$$

$$\Rightarrow \qquad b<\frac{4}{27}+\frac{1}{9}-\frac{2}{3} \quad \text{or} \quad b<-\frac{11}{27}$$

$\therefore$ When $a=3\Rightarrow b<-\frac{1}{2}$ and when $a=-2\Rightarrow b<-\frac{11}{27}$

Hence, (a) is the correct answer.

● ***Ex. 3*** *If* $f''(x)+f'(x)+f^2(x)=x^2$ *is the differential equation of a curve and let P be the point of maxima, then number of tangents which can be drawn from P to* $x^2-y^2=a^2$ *is/are*

(a) 2 (b) 1

(c) 0 (d) either 1 or 2

Sol. At point of maxima $f'(x) = 0$ and $f''(x) < 0$

$\Rightarrow$ $f''(x) = x^2 - f^2(x) \le 0$

(Since, the curve is $x^2 - y^2 = a^2$ and $x^2 - f^2(x) \le 0$

$\therefore x_1^2 - y_1^2 < a^2 \Rightarrow$ point lies outside the hyperbola)

$\Rightarrow$ Point $P(x, f(x))$ lies outside $x^2 - y^2 = a^2$

$\therefore$ Two tangents can be drawn.

Hence, (a) is the correct answer.

● ***Ex. 4*** *Let* $f(x) = \int_0^x \cos\left(\frac{t^2 + 2t + 1}{5}\right) dt, 0 < x < 2$, *then* $f(x)$

(a) increases monotonically

(b) decreasing monotonically

(c) has one point of local maximum

(d) has one point of local minima

Sol. We have, $f'(x) = \cos\left(\frac{x^2 + 2x + 1}{5}\right) \times 1 = \cos\left(\frac{(x+1)^2}{5}\right)$

Since, $0 < x < 2 \Rightarrow 1/5 < \frac{(x+1)^2}{5} > 9/5$

Now, $\cos\left(\frac{(x+1)^2}{5}\right) = 0$

$\Rightarrow$ $\frac{(x+1)^2}{5} = \frac{\pi}{2}$

$f'(x) > 0$, if $0 < x < (\sqrt{5\pi/2} - 1)$

and $f'(x) < 0$, if $(\sqrt{5\pi/2} - 1) < x < 2$

$\therefore$ $x = (\sqrt{5\pi/2} - 1)$ is a point of local maxima

Hence, (c) is the correct answer.

● ***Ex. 5*** *As 'x' ranges over the interval* $(0, \infty)$, *the function* $f(x) = \sqrt{9x^2 + 173x + 900} - \sqrt{9x^2 + 77x + 900}$, *ranges over*

(a) (0, 4) (b) (0, 8)

(c) (0, 12) (d) (0, 16)

Sol. $\because \sqrt{9x^2 + 173x + 900} > \sqrt{9x^2 + 77x + 900}, \forall\ x \in (0, \infty)$

$\Rightarrow$ $f(x) > 0, \forall\ x \in (0, \infty)$

Now, $f(x) = \frac{96x}{\sqrt{9x^2 + 173x + 900} + \sqrt{9x^2 + 77x + 900}}$

[rationalise]

$\therefore$ $\lim_{x \to \infty} f(x) = \lim_{x \to \infty} \frac{96}{\sqrt{9 + \frac{173}{x} + \frac{900}{x^2}} + \sqrt{9 + \frac{77}{x} + \frac{900}{x^2}}}$

$= \frac{96}{6} = 16$

$\therefore$ Range of $f(x) \in (0, 16)$

Hence, (d) is the correct answer.

● ***Ex. 6*** *Let* $g:[1, 6] \to [0, \infty)$ *be a real valued differentiable function satisfying* $g'(x) = \frac{2}{x + g(x)}$ *and* $g(1) = 0$, *then the maximum value of g cannot exceed*

(a) $\log 2$ (b) $\log 6$ (c) $6 \log 2$ (d) $2 \log 6$

Sol. Here, $g'(x) = \frac{2}{x + g(x)} > 0$, for all $x \in [1, 6]$

$\Rightarrow$ $g(x)$ is increasing function on $[1, 6]$

$\therefore$ $\int_1^6 g'(x)\, dx \le \int_1^6 \frac{2}{x} dx$

$\Rightarrow$ $(g(x))_1^6 \le 2 (\log_e x)_1^6$

$\Rightarrow$ $g(6) - g(1) \le 2 \log 6$

$\therefore$ $g(6) \le 2 \log 6$, as $g(1) = 0$

$\Rightarrow$ g cannot exceed $2 \log 6$.

Hence, (d) is the correct answer.

● ***Ex. 7*** *The minimum value of the function,* $f(x) = x^{3/2} + x^{-3/2} - 4\left(x + \frac{1}{x}\right)$. *for all permissible real values of x, is*

(a) -10 (b) -6 (c) -7 (d) -8

Sol. Here, $f(x) = x^{3/2} + x^{-3/2} - 4\left(x + \frac{1}{x}\right)$

$f(x) = \left(\sqrt{x} + \frac{1}{\sqrt{x}}\right)^3 - 3\left(\sqrt{x} + \frac{1}{\sqrt{x}}\right) - 4\left(\left(\sqrt{x} + \frac{1}{\sqrt{x}}\right)^2 - 2\right)$

Let $\sqrt{x} + \frac{1}{\sqrt{x}} = t$, $[x > 0]$

$\therefore$ $g(t) = t^3 - 3t - 4(t^2 - 2)$

Now, $g(t) = t^3 - 4t^2 - 3t + 8$, where $t \in [2, \infty)$

$g'(t) = 3t^2 - 8t - 3 = (t - 3)(3t + 1)$

$g'(t) = 0 \Rightarrow t = 3 (t \ne -1/3)$

$g''(t) = 6t - 8$

$\Rightarrow$ $g''(3) = 10 > 0$

$\therefore$ Minimum value is

$g(3) = 27 - 36 - 9 + 8 = -10$

Hence, (a) is the correct answer.

● ***Ex. 8*** *The tangent to the curve* $y = 1 - x^2$ *at* $x = \alpha$, *where* $0 < \alpha < 1$, *meets the axes at P and Q. If* α *varies and the minimum value of the area of the* ΔOPQ *is k times the area bounded by the axis and the part of the curve for* $0 < x < 1$, *then k is equal to*

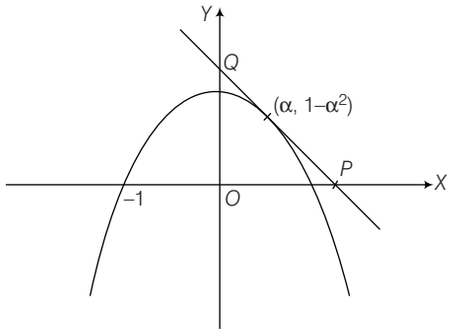
(a) $2/\sqrt{3}$ (b) $75/16$ (c) $25/18$ (d) $2/3$

Sol. Here, equation of tangent

$y + 2\alpha x = \alpha^2 + 1$ ...(i)

From Eq. (i) intersect the axes at

$$P\left(\frac{\alpha^2+1}{2\alpha}, 0\right) \text{ and } Q(0, \alpha^2+1)$$



$$\therefore \text{ Area of } \Delta OPQ = \frac{1}{2}\cdot\frac{(\alpha^2+1)^2}{2\alpha} = \frac{(\alpha^2+1)^2}{4\alpha}$$

$$f(\alpha) = \frac{1}{4}(\alpha^3 + 2\alpha + 1/\alpha)$$

$$f'(\alpha) = \frac{1}{4}(3\alpha^2 + 2 - 1/\alpha^2) = \frac{1}{4}\frac{(3\alpha^4 + 2\alpha^2 - 1)}{\alpha^2}$$

$$= \frac{1}{4}\cdot\frac{(\alpha^2+1)(3\alpha^2-1)}{\alpha^2}$$

$$= \frac{1}{4}\frac{(\alpha^2+1)(\sqrt{3}\alpha-1)(\sqrt{3}\alpha+1)}{\alpha^2}$$

Using number line rule, we have

$\therefore$ Minimum when $\alpha = 1/\sqrt{3}$

Thus, minimum area of triangle $= 4/3\sqrt{3}$

Given, $\frac{4}{3\sqrt{3}} = k\int_0^1 (1-x^2)\,dx = k\left(x - \frac{x^3}{3}\right)_0^1 = \frac{2k}{3}$

$$\Rightarrow \qquad k = 2/\sqrt{3}$$

● ***Ex. 9*** *Least natural number a for which* $x + ax^{-2} > 2, \forall\ x \in [0, \infty)$ *is*

(a) 1 (b) 2 (c) 5 (d) None of these

Sol. Here, $x + ax^{-2} > 2$

$$\Rightarrow \qquad x^3 - 2x^2 + a > 0$$

Let $f(x) = x^3 - 2x^2 + a$

Since, $f(x) > 0, \forall\ x \in [0, \infty), f(0) > 0$

and $\min f(x) > 0$

$\Rightarrow$ $a > 0$ and for minimum $f(x)$

$$f'(x) = 3x^2 - 4x = 0$$

$$\Rightarrow \qquad x = 0, \frac{4}{3}$$

$\therefore$ $f(x)$ is minimum at $x = \frac{4}{3}$

$$f\left(\frac{4}{3}\right) > 0 \Rightarrow a > \frac{32}{27}$$

Hence, (b) is the correct answer.

● ***Ex. 10*** *If* $k\sin^2 x + \frac{1}{k}\operatorname{cosec}^2 x = 2, x \in \left(0, \frac{\pi}{2}\right)$, *then* $\cos^2 x + 5\sin x\cos x + 6\sin^2 x$ *is equal to*

(a) $\frac{k^2+5k+6}{k^2}$ (b) $\frac{k^2-5k+6}{k^2}$

(c) 6 (d) None of these

Sol. Given, $k\sin^2 x + \frac{1}{k\sin^2 x} = 2$

$$\Rightarrow \qquad \left(\sqrt{k}\sin x - \frac{1}{\sqrt{k}\sin x}\right)^2 = 0$$

$$\Rightarrow \qquad \sin^2 x = \frac{1}{k}$$

So, $\cos^2 x + 5\sin x\cos x + 6\sin^2 x$

$$= \frac{k-1}{k} + \frac{5\sqrt{k-1}}{k} + \frac{6}{k}$$

$$= \frac{k+5+5\sqrt{k-1}}{k}$$

Hence, (d) is the correct answer.

● ***Ex. 11*** *The least value of the expression* $x^2 + 4y^2 + 3z^2 - 2x - 12y - 6z + 14$ *is*

(a) 0

(b) 1

(c) no least value

(d) None of the above

Sol. Let $f(x, y, z) = x^2 + 4y^2 + 3z^2 - 2x - 12y - 6z + 14$

$$= (x-1)^2 + (2y-3)^2 + 3(z-1)^2 + 1$$

For least value of $f(x, y, z)$

$$x - 1 = 0, 2y - 3 = 0 \text{ and } z - 1 = 0$$

$$\therefore \qquad x = 1, \ y = \frac{3}{2}, \ z = 1$$

Hence, least value of $f(x, y, z)$ is $f\left(1, \frac{3}{2}, 1\right) = 1$

Hence, (b) is the correct answer.

● **Ex. 12** *On the interval* $\left[\frac{5\pi}{4}, \frac{4\pi}{3}\right]$, *the least value of the function* $f(x) = \int_{5\pi/4}^{x} (3\sin t + 4\cos t)\, dt$ *is*

(a) $\frac{3}{2} + \frac{1}{\sqrt{2}} - 2\sqrt{3}$ (b) $\frac{3}{2} - \frac{1}{\sqrt{2}} + 2\sqrt{3}$

(c) $\frac{3}{2} - \frac{1}{\sqrt{2}} - 2\sqrt{3}$ (d) None of these

Sol. Given, $f(x) = \int_{5\pi/4}^{x} (3\sin t + 4\cos t)\, dt,\ x \in \left[\frac{5\pi}{4}, \frac{4\pi}{3}\right]$.

$$f'(x) = 3\sin x + 4\cos x$$

$f'(x) < 0$ as $\sin x, \cos x$ are negative for $x \in \left[\frac{5\pi}{4}, \frac{4\pi}{3}\right]$.

$$\Rightarrow \quad f(x)|_{\min} = f\left(\frac{4\pi}{3}\right) = \int_{5\pi/4}^{4\pi/3} (3\sin t + 4\cos t)\, dt$$

$$= \frac{3}{2} + \frac{1}{\sqrt{2}} - 2\sqrt{3}$$

Hence, (a) is the correct answer.

● **Ex. 13** *For any real* θ, *the maximum value of* $\cos^2(\cos\theta) + \sin^2(\sin\theta)$ *is*

(a) 1 (b) $1 + \sin^2 1$ (c) $1 + \cos^2 1$ (d) does not exist

Sol. The maximum value of $\cos^2(\cos\theta)$ is 1 and that of $\sin^2(\sin\theta)$ is $\sin^2 1$, both exists for $\theta = \frac{\pi}{2}$.

So, maximum value is $1 + \sin^2 1$.

Hence, (b) is the correct answer.

● **Ex. 14** *If* $\sin\theta + \cos\theta = 1$, *then the minimum value of* $(1 + \text{cosec}\,\theta)(1 + \sec\theta)$ *is*

(a) 3 (b) 4 (c) 6 (d) 9

Sol. We know that, AM $\geq$ GM

$$\frac{\sin\theta + \cos\theta}{2} \geq \sqrt{\sin\theta\cos\theta} \quad \Rightarrow \quad \sin\theta\cos\theta \leq \frac{1}{4}$$

Now, let $\sin\theta = x, \cos\theta = y$

and $(1 + \text{cosec}\,\theta)(1 + \sec\theta) \geq p$

$$\Rightarrow \quad \left(1 + \frac{1}{x}\right)\left(1 + \frac{1}{y}\right) \geq p$$

$$\Rightarrow \quad \left(\frac{1+x}{x}\right)\left(\frac{1+y}{y}\right) \geq p$$

$$\Rightarrow \quad xy + x + y + 1 \geq pxy$$

$$\Rightarrow \quad x + y + 1 \geq (p-1)\,xy$$

$$\Rightarrow \quad 2 \geq (p-1)\,xy \qquad [\text{since, } x + y = 1]$$

$$\Rightarrow \quad xy \leq \frac{2}{p-1}$$

$$\Rightarrow \frac{2}{p-1} = \frac{1}{4} \Rightarrow p - 1 = 8 \ \Rightarrow \ p = 9$$

Hence, (d) is the correct answer.

● **Ex. 15** *The coordinates of the point on the curve* $x^3 = y(x-a)^2, a > 0$, *where the ordinate is minimum*

(a) $(2a, 8a)$ (b) $\left(-2a, \frac{-8a}{9}\right)$

(c) $\left(3a, \frac{27a}{4}\right)$ (d) $\left(-3a, \frac{-27a}{16}\right)$

Sol. The ordinates of any point on the curve is given by

$$y = \frac{x^3}{(x-a)^2}$$

$$\frac{dy}{dx} = \frac{x^2(x-3a)}{(x-a)^3}$$

Now, $\frac{dy}{dx} = 0$

$$\Rightarrow \quad x = 0 \text{ or } x = 3a$$

$$\left[\frac{d^2y}{dx^2}\right]_{x=0} = 0 \quad \text{and} \quad \left[\frac{d^2y}{dx^2}\right]_{x=3a} = \frac{72a^5}{(2a)^6} > 0$$

So, y is minimum at $x = 3a$ and is equal to $\frac{27a}{4}$.

Hence, (c) is the correct answer.

● **Ex. 16** *If* $x^2 + y^2 + z^2 = 1$ *for* $x, y, z \in R$, *then the maximum value of* $x^3 + y^3 + z^3 - 3xyz$ *is*

(a) $\frac{1}{2}$ (b) 1 (c) 2 (d) 3

Sol. Let $t = xy + yz + zx$, so $-\frac{1}{2} \leq t \leq 1$

$$\therefore \quad x^3 + y^3 + z^3 - 3xyz$$

$$= (x + y + z)(x^2 + y^2 + z^2 - xy - yz - zx)$$

$$= \sqrt{(1+2t)}\,(1-t)$$

Let $f(t) = (1+2t)(1-t)^2$

$$f'(t) = 6t(t-1) = 0$$

Clearly, $t_{\max} = f(0) = 1$

Hence, (b) is the correct answer.

● **Ex. 17** *If* $a, b \in R$ *distinct numbers satisfying* $|a-1| + |b-1| = |a| + |b| = |a+1| + |b+1|$, *then the minimum value of* $|a-b|$ *is*

(a) 3 (b) 0

(c) 1 (d) 2

Sol. Let $a < b$ and $f(x) = |x - a| + |x - b|, \forall\ x \in R$

So, $f(x)$ is decreasing in $(-\infty, a]$ constant in $[a, b]$ and increasing in $[b, \infty)$, we have

$$f(0) = f(1) = f(-1)$$

$\Rightarrow$ $\{-1, 0, 1\} \in [a, b]$

$\therefore$ $|a - b|_{\min} = 2$

Hence, (d) is the correct answer.

● **Ex. 18** *Let $f(x) = x^4 + ax^3 + 3x^2 + bx + 1, a, b \in R$. If $f(x) \geq 0, \forall\ x \in R$, then the maximum value of $a^2 + b^2$ is equal to*

(a) 10 (b) 12

(c) 16 (d) None of these

Sol. Given, $f(x) = x^4 + ax^3 + 3x^2 + bx + 1$ and $f(x) \geq 0$

$$\Rightarrow \left(x^2 + \frac{a}{2}x\right)^2 + \left(3 - \frac{a^2 + b^2}{4}\right)x^2 + \left(\frac{b}{2}x + 1\right)^2 \geq 0$$

which holds only when $3 - \frac{a^2 + b^2}{4} \geq 0$

$$\Rightarrow a^2 + b^2 \leq 12$$

Hence, (b) is the correct answer.

● **Ex. 19** *The maximum value of $(\sqrt{-3 + 4x - x^2} + 4)^2 + (x - 5)^2$ (where $1 \leq x \leq 3$) is*

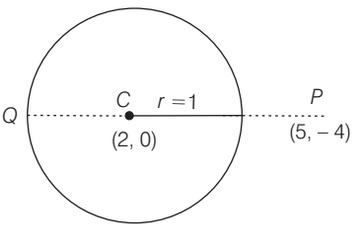
(a) 34 (b) 36

(c) 32 (d) 20

Sol. Here, $(\sqrt{-3 + 4x - x^2} + 4)^2 + (x - 5)^2$, represents the square of the distance between circle $y = \sqrt{-3 + 4x - x^2}$ and point $(5, -4)$.

Clearly, the centre and radius of the circle respectively are $(2, 0)$ and 1.

i.e. Maximum distance between $x^2 + y^2 - 4x + 3 = 0$ and $(5, -4)$,



$$\Rightarrow PQ^2 = (PC + \text{radius})^2$$

$$= (\sqrt{(5-2)^2 + (4-0)^2} + 1)^2$$

$$= 6^2 = 36$$

Hence, (b) is the correct answer.

● **Ex. 20** *If $a > b > 0$ and $f(\theta) = \frac{(a^2 - b^2)\cos\theta}{a - b\sin\theta}$, then the maximum value of $f(\theta)$, is*

(a) $2\sqrt{a^2 + b^2}$ (b) $\sqrt{a^2 + b^2}$

(c) $\sqrt{a^2 - b^2}$ (d) $\sqrt{b^2 - a^2}$

Sol. Here, $f(\theta) = \frac{(a^2 - b^2)\cos\theta}{a - b\sin\theta} = \frac{(a^2 - b^2)}{a\sec\theta - b\tan\theta}$

or $f(\theta) = \frac{a^2 - b^2}{h(\theta)}$, where $h(\theta) = a\sec\theta - b\tan\theta$

$\therefore$ $f(\theta)$ is maximum and minimum as $h(\theta)$ is minimum and maximum respectively.

$\Rightarrow$ $h(\theta) = a\sec\theta - b\tan\theta$

$\Rightarrow$ $h'(\theta) = \sec\theta\,(a\tan\theta - b\sec\theta)$

For maximum and minimum put $h'(\theta) = 0$

$\Rightarrow$ $\sin\theta = \frac{b}{a}$ $[\sec\theta \neq 0]$ ...(i)

Also, $h''(\theta) = a\sec^3\theta + a\sec\theta \cdot \tan^2\theta - 2b\sec^2\theta\tan\theta$

or $h''(\theta) = \frac{a + a\sin^2\theta - 2b\sin\theta}{\cos^3\theta}$

When $\sin\theta = \frac{b}{a}$

$$(h''(\theta)) = \frac{a + a\cdot\frac{b^2}{a^2} - 2b\cdot\frac{b}{a}}{\left(1 - \frac{b^2}{a^2}\right)^{3/2}} = \frac{a^2 - b^2}{a\left(\frac{a^2 - b^2}{a^2}\right)^{3/2}} > 0$$

[as $a > b$]

$\Rightarrow h(\theta)$ is minimum, when $\sin\theta = \frac{b}{a}$

$\therefore$ $f(\theta)$ is maximum, when

$$\sin\theta = \frac{b}{a} \Rightarrow f_{\max}(\theta) = \sqrt{a^2 - b^2}$$

Hence, (c) is the correct answer.

● **Ex. 21** *A solid cylinder of height H has a conical portion of same height and radius 1/3rd of height removed from it. Rain water is accumulating in it, at the rate equal to π times the instantaneous radius of the water surface inside the hole, the time after which hole will filled with water is*

(a) $\frac{H^2}{3}$ (b) H^2 (c) $\frac{H^2}{6}$ (d) $\frac{H^2}{4}$

Sol. Here radius, $r = \frac{H}{3}, \frac{x}{r} = \frac{y}{H} \Rightarrow 3x = y \Rightarrow \frac{dv}{dt} = \pi x$

$$\Rightarrow \frac{d}{dt}\left(\frac{1}{3}\pi x^2 y\right) = \pi x \Rightarrow 3\int_0^r x\,dx = \int_0^t dt$$

$$\Rightarrow 3\frac{r^2}{2} = t \Rightarrow \frac{3}{2}\cdot\frac{H^2}{9} = t \Rightarrow t = \frac{H^2}{6}$$

Hence, (c) is the correct answer.

● **Ex. 22** *If composite function* $f_1(f_2(f_3(....(f_n(x)))))$ *n times, is an increasing function and if r of* f_i*'s are decreasing function while rest are increasing, then maximum value of function is*

(a) $\frac{n^2-1}{4}$ when n is an even number

(b) $\frac{n^2}{4}$ when n is an odd number

(c) $\frac{n^2-1}{4}$ when n is an odd number

(d) None of the above

Sol. r must be an even integer because two decreasing are required to make it increasing function.

Let $y = r(n-r)$,

When n is odd

$$r = \frac{n-1}{2} \text{ or } \frac{n+1}{2} \text{ for maximum value of } y$$

When n is even

$$r = \frac{n}{2} \text{ for maximum value of } y$$

$\therefore$ Maximum $(y) = \frac{n^2-1}{4}$, when n is odd and $\frac{n^2}{4}$

When n is even.

Hence, (c) is the correct answer.

JEE Type Solved Examples :
More than One Correct Option Type Questions

● **Ex. 23** *Let* $f(x) = \sin x + ax + b$*. Then,* $f(x) = 0$ *has*

(a) only one real root which is positive, if $a > 1, b < 0$

(b) only one real root which is negative, if $a > 1, b > 0$

(c) only one real root which is negative, if $a < -1, b < 0$

(d) None of the above

Sol. Given, $f(x) = \sin x + ax + b$

$\Rightarrow f'(x) = -\cos x + a$, if $a > 1$, then $f(x)$ is entirely increasing. So, $f(x) = 0$ has only one real root, which is positive, if $f(x) < 0$ and negative, if $f(0) > 0$. Similarly, when $a < -1$ then, $f(x)$ entirely decreasing. Therefore, $f(x)$ has only one real root which is positive, if $f(0) < 0$ and negative, if $f(0) > 0$.

Hence, (a), (b) and (c) are the correct answers.

● **Ex. 24** *If* $a > 0, b > 0, c > 0$ *and* $a + b + c = abc$*, then atleast one of the numbers* a, b, c *exceeds*

(a) $\frac{3}{2}$ (b) $\frac{17}{10}$

(c) 2 (d) $\frac{13}{10}$

Sol. We may suppose $a \geq b \geq c$

$$abc = a + b + c \geq 3c$$

So, $$ab \geq 3, a \geq b \text{ and } a \geq \sqrt{3} > \frac{17}{10}$$

Aliter $(a+b+c)^3 \geq 27\ abc \geq 27\ (a+b+c)$

$\therefore \quad a + b + c \geq 3\sqrt{3}$

$\Rightarrow$ Atleast one of them $\geq \sqrt{3}$

Hence, (a), (b) and (d) are the correct answers.

● **Ex. 25** *Let* $f(x, y) = x^2 + 2xy + 3y^2 - 6x - 2y$*, where* $x, y \in R$*, then*

(a) $f(x, y) \geq -11$ (b) $f(x, y) \geq -10$

(c) $f(x, y) > -11$ (d) $f(x, y) > -12$

Sol. Let $z = x^2 + 2xy + 3y^2 - 6x - 2y$

$\Rightarrow \quad x^2 + 2xy + 3y^2 - 6x - 2y - z = 0$ as $x \in R$

$\therefore \quad D \geq 0$

$\Rightarrow \quad 4(y-3)^2 - 4(3y^2 - 2y - z) \geq 0$

$\Rightarrow \quad y^2 + 9 - 6y - 3y^2 + 2y + z \geq 0$

$\Rightarrow \quad -2y^2 - 4y + 9 + z \geq 0$

$\Rightarrow \quad z \geq 2(y^2 + 2y + 1) - 11 = 2(y+1)^2 - 11$

$\Rightarrow \quad z \geq -11$

Hence, (a), (c) and (d) are the correct answers.

● **Ex. 26** *Let* $g(x) = f(\tan x) + f(\cot x), \forall\ x \in \left(\frac{\pi}{2}, \pi\right)$*. If* $f''(x) < 0, \forall\ x \in \left(\frac{\pi}{2}, \pi\right)$*, then*

(a) $g(x)$ is increasing in $\left(\frac{\pi}{2}, \frac{3\pi}{4}\right)$

(b) $g(x)$ has local minimum at $x = \frac{3\pi}{4}$

(c) $g(x)$ is decreasing in $\left(\frac{3\pi}{4}, \pi\right)$

(d) $g(x)$ has local maximum at $x = \frac{3\pi}{4}$

Sol. Given, $g(x) = f(\tan x) + f(\cot x)$

$$g'(x) = f'(\tan x)\sec^2 x - f'(\cot x)\operatorname{cosec}^2 x$$

For increasing $g'(x) > 0$

$$f'(\tan x) > f'(\cot x)$$

$$[\because f''(x) < 0 \text{ and } \tan x < \cot x, \forall\ x \left(\frac{\pi}{4}, \frac{\pi}{2}\right)]$$

Also, $\sec^2 x > \text{cosec}^2 x,\ x \in \left(\frac{\pi}{2}, \frac{3\pi}{4}\right)$

$$g'(x) > 0 \Rightarrow g(x) \text{ is increasing in } \left(\frac{\pi}{2}, \frac{3\pi}{4}\right)$$

Similarly, $g(x)$ is decreasing in $\left(\frac{3\pi}{4}, \pi\right)$

Also, $g(x)$ has local maximum at $x = \frac{3\pi}{4}$. Hence, (a), (c) and (d) are the correct answers.

● ***Ex. 27*** *The function* $f(x) = \int_0^x \sqrt{1-t^4}\ dt$ *is such that*

(a) it is defined on the interval $[-1, 1]$
(b) it is an increasing function
(c) it is an odd function
(d) the point $(0, 0)$ is the point of inflection

Sol. $f'(x) = \sqrt{1-x^4} > 0$ in $(-1, 1) \Rightarrow f$ is increasing

Now, $f(x) + f(-x) = \int_0^x \sqrt{1-t^4}\ dt + \int_0^{-x} \sqrt{1-t^4}\ dt$

$$\Rightarrow \quad \int_0^x \sqrt{1-t^4}\ dt + \left(-\int_0^x \sqrt{1-y^4}\ dy\right)(t = -y) = 0$$

$\Rightarrow f(x)$ is odd

Again, $f''(x) = \frac{-4x^3}{2\sqrt{1-x^4}}$ which vanished at $x = 0$

and changes sign $\Rightarrow (0, 0)$ is point of inflection since, f is well defined in $[-1, 1]$.

Hence, (a), (b), (c) and (d) are the correct answers.

● ***Ex. 28*** *The function* $\frac{\sin(x+a)}{\sin(x+b)}$ *has no maxima or minima, if*

(a) $b - a = n\pi, n \in I$ (b) $b - a = (2n+1)\pi, n \in I$
(c) $b - a = 2n\pi, n \in I$ (d) None of these

Sol. Given, $f(x) = \frac{\sin(x+a)}{\sin(x+b)}$

$$f'(x) = \frac{\sin(x+b) \times \cos(x+a) - \sin(x+a)\cos(x+b)}{\sin^2(x+b)}$$

$$= \frac{\sin(b-a)}{\sin^2(x+b)}$$

If $\sin(b-a) = 0$, then $f'(x) = 0$

$\Rightarrow f(x)$ will be constant.

i.e. $b - a = n\pi$ or $b - a = (2n+1)\pi$

or $b - a = 2n\pi$,

then $f(x)$ has no minima.

Hence, (a), (b) and (c) are the correct answers.

● ***Ex. 29*** *Let* $F(x) = 1 + f(x) + (f(x))^2 + (f(x))^3$, *where* $f(x)$ *is an increasing differentiable function and* $F(x) = 0$ *has a positive root, then*

(a) $F(x)$ is an increasing function (b) $F(0) \le 0$
(c) $f(0) \le -1$ (d) $F'(0) > 0$

Sol. Given, $F(x) = 1 + f(x) + (f(x))^2 + (f(x))^3$

$F'(x) = (1 + 2f(x) + 3(f(x))^2)\ f'(x) > 0$, so $F(x)$ is increasing.

So, $F(0) < 0 \Rightarrow (1 + f(0))(1 + f(0))^2) < 0 \Rightarrow f(0) < -1$

Hence, (a), (b), (c) and (d) are the correct answers.

● ***Ex. 30*** *The extremum values of the function* $f(x) = \frac{1}{\sin x + 4} - \frac{1}{\cos x - 4}$, *where* $x \in R$ *is*

(a) $\frac{4}{8-\sqrt{2}}$ (b) $\frac{2\sqrt{2}}{8-\sqrt{2}}$ (c) $\frac{2\sqrt{2}}{4\sqrt{2}+1}$ (d) $\frac{4\sqrt{2}}{8+\sqrt{2}}$

Sol. Given, $f(x) = \frac{1}{\sin x + 4} - \frac{1}{\cos x - 4}$

$$\Rightarrow \quad f'(x) = \frac{-\cos x}{(\sin x + 4)^2} + \frac{\sin x}{(\cos x - 4)^2}$$

$$\Rightarrow \quad f'(x) = 0 \ \Rightarrow\ (\sin x + \cos x)\ (\text{non-zero quantity})$$

$$= 0 \ \Rightarrow\ \tan x = -1$$

$$\Rightarrow \quad x = \frac{3\pi}{4} \quad \text{or} \quad \frac{7\pi}{4}$$

Global minimum $= x = 2n\pi + \left(\frac{3\pi}{4}\right)$

Global maximum $= x = 2n\pi + \left(\frac{7\pi}{4}\right)$

$$M = \frac{4}{8-\sqrt{2}},\ m = \frac{4}{8+\sqrt{2}} = \frac{2\sqrt{2}}{4\sqrt{2}+1}$$

Hence, (a) and (c) are the correct answers.

● ***Ex. 31*** *The function* $f(x) = x^{1/3}(x-1)$

(a) has 2 inflection points

(b) is strictly increasing for $x > \frac{1}{4}$ and strictly decreasing for $x < \frac{1}{4}$

(c) is concave down in $\left(-\frac{1}{2}, 0\right)$

(d) area enclosed by the curve lying in the fourth quadrant is $\frac{9}{28}$

Sol. $y = x^{1/3}(x-1)$

$$\frac{dy}{dx} = \frac{4}{3}x^{1/3} - \frac{1}{3} \cdot \frac{1}{x^{2/3}} = \frac{1}{3x^{2/3}}[4x - 1]$$

$x^{2/3}$ is always positive and $x = \frac{1}{4}$ has a local minima.

Hence, f is increasing for $x > \frac{1}{4}$

and f is decreasing for $x < \frac{1}{4}$

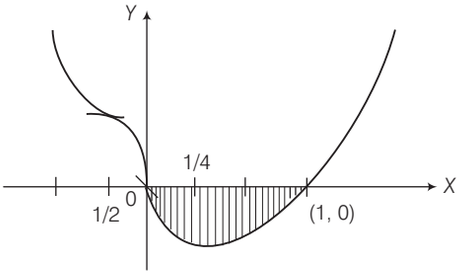
Now, $f'(x) = \frac{4}{3}x^{1/3} - \frac{1}{3}\cdot x^{-2/3}$

[non-existence at $x = 0$, vertical tangent]

$$f''(x) = \frac{4}{9}\cdot\frac{1}{x^{2/3}} + \frac{1}{3}\cdot\frac{2}{3}\cdot\frac{1}{x^{5/3}} = \frac{2}{9x^{2/3}}\left[2 + \frac{1}{x}\right]$$

$$= \frac{2}{9x^{2/3}}\left[\frac{2x+1}{x}\right]$$

$\therefore$ $f''(x) = 0$ at $x = -\frac{1}{2}$ [inflection point]



Graph of $f(x)$ is as $A = \int_0^1 (x^{4/3} - x^{1/3})\,dx$

$$= \left[\frac{3}{7}x^{3/7} - \frac{3}{4}x^{4/3}\right]_0^1 = \left|\frac{3}{7} - \frac{3}{4}\right| = 3\left|\frac{4-7}{28}\right| = \frac{9}{28}$$

Hence, (a), (b), (c) and (d) are the correct answers.

● ***Ex. 32*** *Assume that inverse of the function f is denoted by g, then which of the following statement hold good?*

(a) If f is increasing, then g is also increasing
(b) If f is decreasing, then g is increasing
(c) The function f is injective
(d) The function g is onto

Sol. If f and g are inverse, then $(fog)(x) = x$

$$f'[g(x)]g'(x) = 1$$

If f is increasing $\Rightarrow f' > 0 \Rightarrow$ Sign of g' is also positive.

Therefore, option (a) is correct.

If f is decreasing $\Rightarrow f' < 0 \Rightarrow$ Sign of g' is negative.

Therefore, option (b) is false.

Since, f has an inverse.

$\Rightarrow$ f is bijective $\Rightarrow$ f is injective

Therefore, option (c) is correct.

Inverse of a bijective mapping is bijective.

$\Rightarrow$ g is also bijective $\Rightarrow$ g is onto

Therefore, option (d) is correct.

Hence, (a), (c) and (d) are the correct answers

JEE Type Solved Examples :
Statements I and II Type Questions

■ **Directions** (Ex. Nos. 33 to 39) *For the following questions, choose the correct answers from the codes (a), (b), (c) and (d) defined as follows*

(a) Statement I is true, Statement II is also true, Statement II is the correct explanation of Statement I.
(b) Statement I is true, Statement II is also true, Statement II is not the correct explanation of Statement I
(c) Statement I is true, Statement II is false
(d) Statement I is false, Statement II is true

● ***Ex. 33*** **Statement I** *Among all the rectangles of the given perimeter, the square has the largest area. Also, among all the rectangles of given area, the square has the least perimeter.*

Statement II *For $x > 0, y > 0$, if $x + y$ = constant, then xy will be maximum for $y = x$ and if xy = constant, then $x + y$ will be minimum for $y = x$.*

Sol. Statement II $x + y = k$

then $xy = x(k - x) = f(x)$, $f'(x) = k - 2x = 0$

$\Rightarrow$ $x = \frac{k}{2}, y = \frac{k}{2}$

$\Rightarrow$ $y = x$

$$x + y = x + \frac{k}{x} = f(x),\ f'(x) = 1 - \frac{k}{x^2} = 0$$

$\Rightarrow$ $x = \sqrt{k}, y = \sqrt{k}$

So, Statement II is true and it explains Statement I.

Hence, (a) is the correct answer.

● ***Ex. 34*** **Statement I** *The function $f(x) = (x^3 + 3x - 4)(x^2 + 4x - 5)$ has local extremum at $x = 1$.*

Statement II *$f(x)$ is continuous and differentiable and $f'(1) = 0$.*

Sol. Statement I is correct because $f(1)^- > f(1) < f(1)^+$.

Statement II is correct as $f(x)$ has a repeated root at $x = 1$.

Statement II is not the correct explanation of Statement I as $f'(c) = 0$ doesn't imply that f has an extrema at $x = c$.

Hence, (b) is the correct answer.

● ***Ex. 35*** **Statement I** *If $f(x)$ is increasing function with upward concavity, then concavity of $f^{-1}(x)$ is also upwards.*

Statement II *If $f(x)$ is decreasing function with upwards concavity, then concavity of $f^{-1}(x)$ is also upwards.*

Sol. Let $g(x)$ be the inverse function of $f(x)$.

Then, $f(g(x)) = x$

$\therefore$ $f'(g(x)) \cdot g'(x) = 1$

i.e. $g'(x) = \dfrac{1}{f'(g(x))}$

$\therefore$ $g'' = -\dfrac{1}{(f'(g(x)))^2} \cdot f''(g(x)) \cdot g'(x)$

In Statement I $f''(g(x)) > 0$

and $g'(x) > 0$

$\Rightarrow$ $g''(x) < 0$

$\Rightarrow$ Concavity of $f^{-1}(x)$ is downwards.

$\therefore$ Statement I is false.

In Statement II $f''(g(x)) > 0$

and $g'(x) < 0$

$\Rightarrow$ $g''(x) > 0$

$\Rightarrow$ Concavity of $f^{-1}(x)$ is upwards.

$\therefore$ Statement II is true.

Hence, (d) is the correct answer.

● ***Ex. 36*** **Statement I** *The minimum distance of the fixed point $(0, y_0)$, where $0 \le y_0 \le \dfrac{1}{2}$, from the curve $y = x^2$ is y_0.*

Statement II *Maxima and minima of a function is always a root of the equation $f'(x) = 0$.*

Sol. Let the point on the parabola be (t, t^2).

Let d be the distance between (t, t^2) and $(0, y_0)$,

then $d^2 = t^2 + (t^2 - y_0)^2 = t^4 + (1 - 2y_0)\, t^2 + y_0^2$

$= z^2 + (1 - 2y_0)\, z + y_0^2, z \ge 0$

Its vertex is at $x = y_0 - \dfrac{1}{2} < 0$

$\therefore$ The minimum value of d^2 is at $z = 0$, i.e. $t^2 = 0$

$\therefore$ $d = y_0$

Statement I is true. Statement II is false because extremum can occur at a point where $f'(x)$ does not exist.

Hence, (c) is the correct answer.

● ***Ex. 37*** *Let $f : R \to R$ is differentiable and strictly increasing function throughout its domain.*

Statement I *If $|f(x)|$ is also strictly increasing function, then $f(x) = 0$ has no real roots.*

Statement II *At ∞ or $-\infty$, $f(x)$ may approach to 0, but cannot be equal to zero.*

Sol. Suppose $f(x) = 0$ has a real root say $x = a$, then $f(x) < 0$ for $x < a$. Thus, $|f(x)|$ becomes strictly decreasing on $(-\infty, a)$, which is a contradiction.

Hence, (a) is the correct answer.

● ***Ex. 38*** **Statement I** *$f(x) = x + \cos x$ is strictly increasing.*

Statement II *If $f(x)$ is strictly increasing, then $f'(x)$ may tend to zero at some finite number of points.*

Sol. Given, $f(x) = x + \cos x$

$\therefore$ $f'(x) = 1 - \sin x > 0, \ \forall \ x \in R,$

except at $x = 2n\pi + \dfrac{\pi}{2}$

and $f'(x) = 0$ at $x = 2n\pi + \dfrac{\pi}{2}$

$\therefore$ $f(x)$ is strictly increasing.

Statement II is true but does not explain Statement I.

Statement II gives $f'(x)$ may tend to zero at finite number of points but in Statement I $f'(x)$ tend to zero at infinite number of points.

Hence, (b) is the correct answer.

● ***Ex. 39*** **Statement I** *The largest term in the sequence*

$$a_n = \frac{n^2}{n^3 + 200}, n \in N \text{ is } \frac{(400)^{2/3}}{600}$$

Statement II $f(x) = \dfrac{x^2}{x^3 + 200}, x > 0$, *then at* $x = (400)^{1/3}$, *$f(x)$ is maximum.*

Sol. **Statement II** Given, $f(x) = \dfrac{x^2}{x^3 + 200}$

$$f'(x) = \frac{(x^3 + 200)\, 2x - 3x^2 x^2}{(x^3 + 200)^2} = \frac{-x^4 + 400x}{(x^3 + 200)^2}$$

$x \to 0^+ \ f(x) = 0^+ \ \Rightarrow \ x = 400^{1/3} \ f(x) = \dfrac{400^{2/3}}{600}$

$x \to \infty \ f(x) \to 0$

So, Statement II is true. But Statement I is false as $x \in N$.

Hence, (d) is the correct answer.

JEE Type Solved Examples : Passage Based Questions

Passage I

(Ex. Nos. 40 to 42)

Let x_1, x_2, x_3, x_4 be the roots (real or complex) of the equation $x^4 + ax^3 + bx^2 + cx + d = 0$. If $x_1 + x_2 = x_3 + x_4$ and $a, b, c, d \in R$, then

● **Ex. 40** *If $a = 2$, then the value of $b - c$ is*

(a) -1 (b) 1 (c) -2 (d) 2

● **Ex. 41** *If $b < 0$, then how many different values of a, we may have*

(a) 3 (b) 2 (c) 1 (d) 0

● **Ex. 42** *If $b + c = 1$ and $a \neq -2$, then for real values of $a, c \in$*

(a) $\left(-\infty, \frac{1}{4}\right)$ (b) $(-\infty, 3)$

(c) $(-\infty, 1)$ (d) $(-\infty, 4)$

■ **Sol.** (Ex. Nos. 40 to 42)

Let $x^4 + ax^3 + bx^2 + cx + d = (x - x_1)(x - x_2)(x - x_3)(x - x_4)$

Let $(x - x_1)(x - x_2) = x^2 + px + q$

and $(x - x_3)(x - x_4) = x^2 + px + r$

$\therefore \quad q = x_1x_2$ and $r = x_3x_4$

$x^4 + ax^3 + bx^2 + cx + d$

$= x^4 + 2px^3 + (p^2 + q + r)x^2 + p(q + r)x + qr$

$\therefore \quad a = 2p, b = p^2 + q + r, c = p(q + r), d = qr$

Clearly, $a^3 - 4ab + 8c = 0$ ...(i)

40. If $a = 2 \Rightarrow b - c = 1$

Hence, (b) is the correct answer.

41. Investigating the nature of the cubic equation of a.

Let $f(a) = a^3 - 4ab + 8c$

$f'(a) = 3a^2 - 4b$

If $b < 0 \Rightarrow f'(a) > 0$

$\therefore$ The equation $a^3 - 4ab + 8c = 0$, has only one real root.

Hence, (c) is the correct answer.

42. Substituting $c = 1 - b$ in Eq. (i), we have

$(a + 2)[(a - 1)^2 + 3 - 4b] = 0$

$\Rightarrow \quad 4b - 3 > 0$

$\Rightarrow \quad b > \frac{3}{4} \quad \Rightarrow \quad c < \frac{1}{4}.$

Hence, (a) is the correct answer.

Passage II

(Ex. Nos. 43 to 45)

Consider a ΔOAB formed by the point $O(0, 0), A(2, 0), B(1, \sqrt{3})$. $P(x, y)$ is an arbitrary interior point of triangle moving in such a way that $d(P, OA) + d(P, AB) + d(P, OB) = \sqrt{3}$, where $d(P, OA), d(P, AB), d(P, OB)$ represent the distance of P from the sides OA, AB and OB , respectively.

● **Ex. 43** *Area of region representing all possible position of point P is equal to*

(a) $2\sqrt{3}$ (b) $\sqrt{6}$ (c) $\sqrt{3}$ (d) None of these

● **Ex. 44** *If the point P moves in such a way that $d(P, OA) \leq \min(d(P, OB), d(P, AB))$, then area of region representing all possible position of point P is equal to*

(a) $\sqrt{3}$ (b) $\sqrt{6}$ (c) $\frac{1}{\sqrt{3}}$ (d) $\frac{1}{\sqrt{6}}$

● **Ex. 45** *If the point P moves in such a way that $d(P, OA) \geq \min(d(P, OB), d(P, AB))$, then area of region representing all possible position of point P is equal to*

(a) $\sqrt{3}$ (b) $\sqrt{6}$ (c) $1/\sqrt{3}$ (d) $\frac{1}{\sqrt{6}}$

■ **Sol.** (Ex. Nos. 43 to 45)

43. ΔOAB is clearly equilateral

$\Delta\, OAB = \Delta\, OPA + \Delta\, APB + \Delta\, OPB = \frac{\sqrt{3}}{4} \times 4 = \frac{1}{2} \cdot 2$

$(d(P, OA) + (P, AB) + (P, OB))$

$d(P, OA) + d(P, AB) + d(P, OB) = \frac{4}{\sqrt{3}}$

Hence, (c) is the correct answer.

44. We must have, $d(P, OA) \leq d(P, OB)$ as well as $d(P, OA) \leq d(P, AB)$, then P lies either on or below the angle bisector of $\angle BOA$ and $\angle BAO$ area

$= \frac{1}{3}\Delta\, OAB = \frac{1}{\sqrt{3}}.$

Hence, (c) is the correct asnwer.

45. We must have $d(P, OA) \geq d(P, OB)$ as well as $d(P, OA) \geq d(P, AB)$, then P must be above bisector of $\angle BOA$ and $\angle BAO$.

Area of triangle $= \frac{1}{3}\Delta\, OAB = \frac{1}{\sqrt{3}}$

Hence, (c) is the correct answer.

Passage III

(Ex. Nos. 46 to 48)

Let $f(x) = ax^2 + bx + c, a, b, c \in R$. *It is given* $|f(x)| \le 1, |x| \le 1$

● ***Ex. 46*** *The possible value of* $|a + c|$, *if* $\frac{8}{3}a^2 + 2b^2$ *is maximum, is given by*

(a) 1 (b) 0 (c) 2 (d) 3

● ***Ex. 47*** *The possible value of* $|a + b|$, *if* $\frac{8}{3}a^2 + 2b^2$ *is maximum, is given by*

(a) 1 (b) 0 (c) 2 (d) 3

● ***Ex. 48*** *The possible maximum value of* $\frac{8}{3}a^2 + 2b^2$ *is given by*

(a) 32 (b) $\frac{32}{3}$

(c) $\frac{2}{3}$ (d) $\frac{16}{3}$

■ ***Sol.*** (Ex. Nos. 46 to 48)

We know that for $|u| \le 1; |v| \le 1$, then $|u - v| \le 2$

Now, $|f(1) - f(0)| \le 2 \Rightarrow |a + b| \le 2$

$\Rightarrow (a + b)^2 \le 4$ ...(i)

Also, $|f(-1) - f(0)| \le 2 \Rightarrow |a - b| \le 2$

$\Rightarrow (a - b)^2 \le 4$ ...(ii)

Now, $4a^2 + 3b^2 = 2(a + b)^2 + 2(a - b)^2 - b^2 \le 16$

$\Rightarrow (4a^2 + 3b^2)_{\max} = 16$ when $b = 0$

$\Rightarrow |a + b| = |a - b| = |a| = 2$

Also, $|f(1) - f(0)| = |(a + c) - c| = |a| = 2$

$\Rightarrow |a + c| = |c| = 1$

The possible ordered triplet (a, b, c) are $(2, 0, -1)$ or $(-2, 0, 1)$.

Also, $\frac{8}{3}a^2 + 2b^2 = \frac{2}{3}(4a^2 + 3b^2) \le \frac{2}{3} + 16$

Ans. 46. (a) **47.** (c) **48.** (b)

Passage IV

(Ex. Nos. 49 to 53)

The absolute maximum and minimum values of functions can be found by their monotonic and asymptotic behaviour provided they exist. We may agree that finite limiting values may be regarded as absolute maximum or minimum. For instance the absolute maximum value of $\frac{1}{1 + x^2}$ *is unity. It is attained at* $x = 0$ *while absolute minimum value of the same function is zero which is a limiting value of* $(x \to \infty$ *or* $x \to -\infty)$

● ***Ex. 49*** *The function* $x^4 - 4x + 1$ *will have*

(a) absolute maximum value
(b) absolute minimum value
(c) both absolute maximum and minimum values
(d) None of the above

● ***Ex. 50*** *The absolute minimum value of the function* $\frac{x - 2}{\sqrt{x^2 + 1}}$ *is*

(a) -1 (b) $\frac{1}{2}$ (c) $-\sqrt{5}$ (d) None of these

● ***Ex. 51*** *The absolute minimum and maximum values of the function* $\frac{x^2 - x + 1}{x^2 + x + 1}$ *is*

(a) 1 and 3 (b) $\frac{1}{2}$ and 3

(c) $\frac{1}{3}$ and 3 (d) None of these

● ***Ex. 52*** *The function* $f(x) = \frac{4}{x - 1} - \frac{9}{x + 1}$ *will*

(a) have absolute maximum value $-\frac{1}{2}$
(b) have absolute minimum value $-\frac{25}{2}$
(c) not lie between $-\frac{25}{2}$ and $-\frac{1}{2}$
(d) always be negative

● ***Ex. 53*** *Which of the following functions will have absolute minimum value?*

(a) $\cot(\sin x)$ (b) $\tan(\log x)$

(c) $x^{2005} - x^{1947} + 1$ (d) $x^{2006} + x^{1947} + 1$

■ ***Sol.*** (Ex. Nos. 49 to 53)

49. Since, $f'(x) = 4x^3 - 4 = 0 \Rightarrow x = 1$

$\Rightarrow$ There is only one extrema which is minima.

$\Rightarrow$ 1 is a point of absolute minima.

Hence, (b) is the correct answer.

50. Since, $f'(x) = \frac{1 + 2x}{(x^2 + 1)^{3/2}}$

$\Rightarrow f(x)$ is increasing in $\left(-\frac{1}{2}, \infty\right)$ and decreasing in $\left(-\infty, -\frac{1}{2}\right)$

$\Rightarrow$ Absolute minimum occurs at $x = -\frac{1}{2}$, we have $= -\sqrt{5}$

Hence, (c) is the correct answer.

51. $yx^2 + yx + y = x^2 - x + 1$

$x^2(1-y) - x(1+y) + (1-y) = 0 \ \because D \geq 0$

$\Rightarrow (1+y)^2 - 4(1-y)^2 \geq 0 \Rightarrow -(3y-1)(y-3) \geq 0$

$\Rightarrow \quad \frac{1}{3} \leq y \leq 3$

Hence, (c) is the correct answer.

52. Should be the correct choice (we can prove by using monotonically that f cannot lie between $-\frac{25}{2}$ and $-\frac{1}{2}$. This is an Ex. of a function whose maximum (local) value is smaller than minimum value).

Hence, (c) is the correct answer.

53. As even degree polynomial will have absolute minimum essentially.

Hence, (d) is the correct answer.

Passage V

(Ex. Nos. 54 to 56)

We are given the curves $y = \int_{-\infty}^{x} f(t)\,dt$ *through the point* $\left(0, \frac{1}{2}\right)$ *and* $y = f(x)$, *where* $f(x) > 0$ *and* $f(x)$ *is differentiable,* $\forall\ x \in R$ *through* $(0,1)$. *If tangents drawn to both the curves at the points with equal abscissae intersect on the same point on the X-axis, then*

● ***Ex. 54*** *Number of solutions* $f(x) = 2ex$ *is equal to*

(a) 0 (b) 1
(c) 2 (d) None of these

● ***Ex. 55*** $\lim_{x \to \infty} (f(x))^{f(-x)}$ *is*

(a) 3 (b) 6
(c) 1 (d) None of these

● ***Ex. 56*** *The function* $f(x)$ *is*

(a) increasing for all x (b) non-monotonic
(c) decreasing for all x (d) None of these

■ ***Sol.*** (Ex. Nos. 54 to 56)

We have, the equations of the tangents to the curves $y = \int_{-\infty}^{x} f(t)\,dt$ and $y = f(x)$ at arbitrary points on them are

$$Y - \int_{-\infty}^{x} f(t)\,dt = f(x)(X - x) \qquad \ldots(i)$$

and $$Y - f(x) = f'(x)(X - X) \qquad \ldots(ii)$$

As Eqs. (i) and (ii), intersect at the same point on X-axis.

On putting $Y = 0$ and equating x-coordinates, we have

$$x - \frac{f(x)}{f'(x)} = x - \frac{\int_{-\infty}^{x} f(t)\,dt}{f(x)} \Rightarrow \frac{f(x)}{\int_{-\infty}^{x} f(t)\,dt} = \frac{f'(x)}{f(x)}$$

$$\Rightarrow \quad \int_{-\infty}^{x} f(t) = cf(x) \qquad \ldots(iii)$$

As, $f(0) = 1 \Rightarrow \int_{-\infty}^{0} f(t)\,dt = \frac{1}{2} = c \times 1 \Rightarrow c = \frac{1}{2}$

$\Rightarrow \int_{-\infty}^{x} f(t)\,dt = \frac{1}{2} f(x)$, differentiating both the sides and on integrating and using boundary condition, we get $f(x) = e^{2x}$, $y = 2ex$ is tangent to $y = e^{2x}$

$\Rightarrow$ Number of solutions = 1

Clearly, $f(x)$ is increasing for all x.

$$\lim_{x \to \infty} (e^{2x})^{e^{-2x}} = 1 \qquad [\infty^0 \text{ form}]$$

Ans. 54. (b) **55.** (c) **56.** (a)

Passage VI

(Ex. Nos. 57 to 59)

Let $f(x) = \left(1 + \frac{1}{x}\right)^x \ (x > 0)$ *and*

$$g(x) = \begin{cases} x \ln(1 + (1/x)), & \text{if } 0 < x \leq 1 \\ 0, & \text{if } x = 0 \end{cases}$$

● ***Ex. 57*** $\lim_{x \to 0^+} g(x)$

(a) is equal to 0 (b) is equal to 1
(c) is equal to e (d) is non-existent

● ***Ex. 58*** *The function* f

(a) has a maxima but not minima
(b) has a minima but not maxima
(c) has both of maxima and minima
(d) is a monotonic

● ***Ex. 59*** $\lim_{n \to \infty} \left\{ f\left(\frac{1}{n}\right) \cdot f\left(\frac{2}{n}\right) \cdot f\left(\frac{3}{n}\right) \ldots f\left(\frac{n}{n}\right) \right\}^{1/n}$ *equals*

(a) $\sqrt{2}e$ (b) $\sqrt{2e}$
(c) $2\sqrt{e}$ (d) $\sqrt{e}$

■ ***Sol.*** (Ex. Nos. 57 to 59)

57. $\lim_{x \to 0^+} x \ln\left(1 + \frac{1}{x}\right) = \lim_{x \to 0^+} \frac{\ln\left(\frac{x+1}{x}\right)}{\frac{1}{x}} \qquad \left[\frac{\infty}{\infty} \text{form}\right]$

Using L'Hospital's rule,

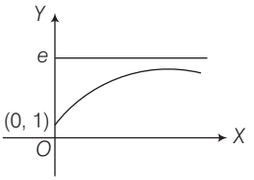
$$l = \lim_{x \to 0} -\left(\frac{1}{x+1} - \frac{1}{x}\right) x^2 = \lim_{x \to 0} \left(\frac{1}{x} - \frac{1}{x+1}\right) \cdot x^2$$

$$= \lim_{x \to 0} \frac{1}{x(x+1)} \cdot x^2 = \lim_{x \to 0} \frac{x}{(x+1)} = 0$$

Hence, (a) is the correct answer.

58. $\lim\limits_{x \to 0} f(x) = 1$ (can be verified)

$\lim\limits_{x \to \infty} f(x) = e$



Also, f is increasing for all

$x > 0$

$\Rightarrow$ (d) (can be verified)

Hence, (d) is the correct answer.

59. Given, $\lim\limits_{n \to \infty}\left(f\left(\frac{1}{n}\right) f\left(\frac{2}{n}\right) \ldots f\left(\frac{n}{n}\right)\right)^{1/n}$

$$l = \left(\prod_{k=1}^{n} \left(1 + \frac{n}{k}\right)^{k/n} \right)^{1/n}$$

$$[\text{given } f(x) = (1 + 1/x)^x \text{ and } f(k/n) = \left(1 + \frac{n}{k}\right)^{k/n}]$$

Taking log,

$$\ln l = \lim_{n \to \infty} \frac{1}{n} \cdot \sum_{k=1}^{n} \ln \left(1 + \frac{n}{k}\right)^{k/n}$$

$$= \lim_{n \to \infty} \frac{1}{n} \cdot \sum_{k=1}^{n} \frac{k}{n} \ln \left(1 + \frac{1}{k/n}\right)$$

$$= \int_0^1 \underbrace{x}_{\text{II}} \underbrace{\ln \left(1 + \frac{1}{x}\right)}_{\text{I}} dx = \left[\ln \left(1 + \frac{1}{x}\right) \cdot \frac{x^2}{2} \right]_0^1 + \int_0^1 \left(\frac{1}{x} - \frac{1}{x+1} \right) \cdot \frac{x^2}{2} dx$$

$$= \left(\frac{1}{2} \ln 2 - 0 \right) + \frac{1}{2} \int_0^1 \frac{x + 1 - 1}{x + 1} dx$$

$$= \frac{1}{2} \ln 2 + \frac{1}{2} [x - \ln (x + 1)]_0^1$$

$$= \frac{1}{2} \ln 2 + \frac{1}{2} [(1 - \ln 2) - 0] = \frac{1}{2}; \quad l = \sqrt{e}$$

Hence, (d) is the correct answer.

Passage VII

(Ex. Nos. 60 to 62)

Consider the cubic $f(x) = 8x^3 + 4ax^2 + 2bx + a$, where $a, b \in R$.

● ***Ex. 60*** *For $a = 1$, if $y = f(x)$ is strictly increasing, $\forall\ x \in R$, then maximum range of the values of b is*

(a) $\left(-\infty, \frac{1}{3}\right]$ (b) $\left(\frac{1}{3}, \infty\right)$

(c) $\left[\frac{1}{3}, \infty\right)$ (d) $(-\infty, \infty)$

● ***Ex. 61*** *For $b = 1$, if $y = f(x)$ is non-monotonic, then the sum of the integral values of $a \in [1, 100]$, is*

(a) 4950 (b) 5049

(c) 5050 (d) 5047

● ***Ex. 62*** *If the sum of the base 2 logarithms of the roots of the cubic $f(x) = 0$ is 5, then the value of a is*

(a) -64 (b) -8 (c) -128 (d) -256

■ ***Sol.*** (Ex. Nos. 60 to 62)

60. $a = 1$

$$f(x) = 8x^3 + 4x^2 + 2bx + 1$$

$$f'(x) = 24x^2 + 8x + 2b = 2(12x^2 + 4x + b)$$

For increasing function $f'(x) \geq 0, \forall\ x \in R$

$\therefore \quad D \leq 0$

$\Rightarrow \quad 16 - 48b \leq 0 \quad \Rightarrow \quad b \geq \frac{1}{3}$

Hence, (c) is the correct answer.

61. If $b = 1$

$$f(x) = 8x^3 + 4ax^2 + 2x + a$$

$$f'(x) = 24x^2 + 8ax + 2 \quad \text{or} \quad 2(12x^2 + 4ax + 1)$$

For non-monotonic $f'(x) = 0$ must have distinct roots hence,

$$D > 0, \quad \text{i.e.} \quad 16a^2 - 48 > 0$$

$\Rightarrow \quad a^2 > 3$

$\therefore \quad a > \sqrt{3}$ or $a < -\sqrt{3}$

$\therefore \quad a \in 2, 3, 4, \ldots,$

Sum $= 5050 - 1 = 5049$

Hence, (b) is the correct answer.

62. If x_1, x_2 and x_3 are the roots, then

$$\log_2 x_1 + \log_2 x_2 + \log_2 x_3 = 5$$

$$\log_2 (x_1 x_2 x_3) = 5$$

$$x_1 x_2 x_3 = 32$$

$$-\frac{a}{8} = 32 \Rightarrow a = -256$$

Hence, (d) is the correct answer.

Passage VIII

(Ex. Nos. 63 to 65)

Let $f(x) = \begin{cases} \max & \{t^3 - t^2 + t + 1, 0 \leq t \leq x\}, 0 \leq x \leq 1 \\ \min & \{3 - t, 1 < t \leq x\}, 1 < x \leq 2 \end{cases}$ *and*

$g(x) = \begin{cases} \max & \{3/8\, t^4 + 1/2\, t^3 - 3/2\, t^2 + 1, 0 \leq t \leq x\}, 0 \leq x \leq 1 \\ \min & \{3/8\, t + 1/32 \sin^2 \pi t + 5/8, 1 \leq t \leq x\}, 1 \leq x \leq 2 \end{cases}$

Define $f(x)$ and $g(x)$ expilicitly and then answer the following questions.

● ***Ex. 63*** *The function $f(x), \forall\ x \in [0, 2]$ is*

(a) continuous and differentiable

(b) continuous but not differentiable

(c) discontinuous and not differentiable

(d) None of the above

● ***Ex. 64*** *Which of the following is true.*

(a) $\lim_{x\to 1^-}(fog)(x) > \lim_{x\to 1^+}(gof)(x)$

(b) $\lim_{x\to 1^-}(fog)(x) < \lim_{x\to 1^+}(gof)(x)$

(c) $\lim_{x\to 1^-}(fog)(x) = \lim_{x\to 1^+}(gof)(x)$

(d) None of the above

● ***Ex. 65*** *Let* $z(x)=\dfrac{d}{dx}f(x)^{g(x)}$ *and* $y(x)=\dfrac{d}{dx}g(x)^{f(x)}$, *then* $z(x)$ *and* $y(x)$ *vanish simultaneously at*

(a) $x=-1/3$ (b) $x=0$

(c) $x=1$ (d) No real value of x

■ ***Sol.*** (Ex. Nos. 63 to 65)

Consider $f(x)$ in $[0,1]$

$$f'(t)=3t^2-2t+1>0,\ \forall\ t\in(0,1)$$

$\Rightarrow$ $f(t)$ is increasing on $(0,1)$

Maximum occurs at $t=x$

and $$f(x)=\begin{cases}x^3-x^2+x+1, & 0\le x\le 1\\ 3-x, & 1<x\le 2\end{cases}$$

Again, consider $g(x)$ in $(0,1)$

$$g(t)=3/8t^4+1/2t^3-3/2t^2+1$$

$$g'(t)=3/2t^3+3/2t^2-3t=3/2t(t^2+t-2)$$

$$=3/2t(t-1)(t+2)$$

$g(t)$ decreases in $[0,1)\Rightarrow$ maximum occurs when $t=0$ and $g(0)=1$, again consider $g(x)$ function in $[1,2]$.

$$g(t)=3/8t+1/32\sin^2\pi t+5/8$$

$$g'(t)=3/8+\pi/32\sin(2\pi t)>0,\ \forall\ t\in R$$

$\therefore$ $g(t)$ is an increasing function in $[1,2]$.

$\Rightarrow$ Minimum occurs when $t=1$ and $g(1)=1$

Hence, $$g(x)=\begin{cases}1, & 0\le x\le 1\\ 1, & 1<x\le 2\end{cases}=1$$

$\Rightarrow$ $$g(x)=1,\ \forall\ x\in[0,2]$$

63. $f(x)$ is continuous but not differentiable at $x=1$

64. $\lim_{x\to 1^-} fog(x)=f(1)$ and $\lim_{x\to 1^+} gof(x)=1$, also $f(1)>1$

65. $z(x)=\dfrac{d}{dx}f(x)^{g(x)}=\dfrac{d}{dx}(f(x))^1,\ \forall\ x\in[0,1)\cup(1,2]$

$=f'(x),\ \forall\ x\in[0,1)\cup(1,2]$

and $$y(x)=\frac{d}{dx}(g(x))^{f(x)}$$

$$=\frac{d}{dx}(1)^{f(x)}=0,$$

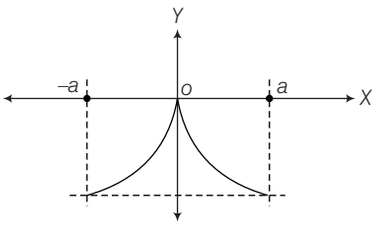
$$\forall\ x\in[0,1)\cup(1,2]$$

Hence, the functions $y(x)$ and $z(x)$ can vanish simultaneously at $f'(x)=0$, which is not possible for any real x.

Passage IX

(Ex. Nos. 66 to 69)

The graph of derivative of a function $f(x)$ *is given* (i.e. $y=f'(x)$). *Analyse the graph in the given domain and answer the following questions, if it is given that* $f(0)=0$



● ***Ex. 66*** *The function* $f'(x)$ *is*

(a) even function (b) odd function

(c) neither even nor odd (d) indefinite

● ***Ex. 67*** *The function* $f(x)$ *is*

(a) even function (b) odd function

(c) neither even nor odd (d) indefinite

● ***Ex. 68*** *The graph of* $y=f(x)$ *has*

(a) no inflexion point (b) one point of inflexion

(c) one extreme point (d) two extreme points

● ***Ex. 69*** *The function* $f(x)$ *for* $-a\le x\le a$, *is*

(a) always decreasing

(b) always increasing

(c) increasing for $(-a,0)$ and decreasing for $(0,a)$

(d) increasing for $(0,a)$ and decreasing for $(-a,0)$

■ ***Sol.*** (Ex. Nos 66 to 69)

66. The graph of $y=f'(x)$ is symmetrical about Y-axis, so $f(x)$ is an even function.

67. $f(0)=0$, so $f(x)$ is an odd function (i.e. derivative of an odd function is an even function)

68. Here, $f''(x)>0$, as $x<0$ and $f''(x)<0$, as $x>0$

$\therefore$ $x=0$, is the point of inflexion

69. $f'(x)\le 0,\ \forall\ x$

So, $f(x)$ is always decreasing.

Passage X

(Ex. Nos. 70 to 72)

If a function (continuous and twice differentiable) is always concave upward in an interval, then its graph lies always below the segment joining extremities of the graph in that interval and vice-versa.

● ***Ex. 70*** *If* $\sin x+x\ge|k|x^2,\ \forall\ x\in[0,\pi/2]$, *then the greatest value of k, is*

(a) $\dfrac{-2(2+\pi)}{\pi^2}$ (b) $\dfrac{2(2+\pi)}{\pi^2}$

(c) can't be determined finitely

(d) zero

● ***Ex. 71*** *Let $f(x)$, $f'(x)$ and $f''(x)$ are all positive, $\forall\, x \in [0,7]$. If $f^{-1}(x)$ exists, then $3f^{-1}(4) - f^{-1}(2) - 2f^{-1}(5)$, is*

(a) always positive (b) always negative
(c) non-negative (d) non-positive

● ***Ex. 72*** *Let $f: R^+ \to R^+$ is such that $f''(x) \geq 0$, $\forall\, x \in [a,b]$, then value of $\int_a^b f(x)dx$, cannot exceed*

(a) $\dfrac{(f(a)+f(b))(b-a)}{3}$ (b) $\dfrac{(f(b)-f(a))(b-a)}{2}$

(c) $\dfrac{(f(b)+f(a))(b-a)}{2}$ (d) None of these

■ ***Sol.*** (Ex. Nos. 70 to 72)

70. $f(x) = \sin x + x \Rightarrow f'(x) = \cos x + 1$

$\Rightarrow f''(x) = -\sin x$

f is concave downward for $x \in [0, \pi/2]$

Irrespective of k, $g(x) = |k|x^2$ is concave upward

So, if $g(\pi/2) \leq f(\pi/2)$, then $f(x) \geq g(x)$

$\Rightarrow \quad 1 + \pi/2 \geq |k|\dfrac{\pi^2}{4} \;\Rightarrow\; k \in \left[\dfrac{(-2\pi+4)}{\pi^2}, \dfrac{(2\pi+4)}{\pi^2}\right]$

71. $f''(x) > 0$

$\Rightarrow$ f is concave upwards $\Rightarrow f^{-1}$ is concave downwards

Consider point dividing the join of this segment in ratio 2:1 is given as $\left(4, \dfrac{2f^{-1}(5) + f^{-1}(2)}{3}\right)$ when upon a point $(4,\ f^{-1}(4))$ on graph of $f^{-1}(x)$ is always above it.

$\Rightarrow \qquad 3f^{-1}(4) - f^{-1}(2) - 2f^{-1}(5) > 0$

72. $\int_a^b f(x)dx$, is area bounded by curve in first quadrant.

$\dfrac{(f(a)+f(b))(b-a)}{2}$ is area of trapezium $ABCD$, which is always more than or equal to $\int_a^b f(x)dx$.

Passage XI

(Ex. Nos. 73 to 74)

Consider a twice differentiable function $f(x)$ of degree four symmetrical to line $x = 1$, defined as $f: R \to R$ and $f''(2) = 0$, then

● ***Ex. 73*** *The sum of roots of the cubic, $f'(x) = 0$, is*

(a) 0 (b) 1 (c) 2 (d) 9/5

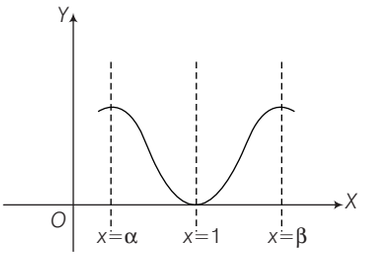
● ***Ex. 74*** *If $f(1) = 0$, $f(2) = 1$, then the value of $f(3)$, is*

(a) 6/7 (b) 7/5 (c) 8/5 (d) 9/5

■ ***Sol.*** (Ex. Nos. 73 to 74)

Since, $f(x)$ is symmetric about $x = 1$ and it is twice differentiable.

So, $f'(x)$ must have one root $x = 1$



$\therefore \qquad f'(x) = a(x-1)(x-\alpha)(x-\beta)$

$= a(x-1)[x^2 - (\alpha+\beta)x + \alpha\beta]$

$= a(x-1)[x^2 - 2x + \alpha\beta]$, as $\dfrac{\alpha+\beta}{2} = 1$

$\therefore \qquad f'(x) = a(x^3 - 2x^2 + \alpha\beta x - x^2 + 2x - \alpha\beta)$

$f''(x) = a(3x^2 - 6x + \alpha\beta + 2)$

$f''(2) = a(12 - 12 + \alpha\beta + 2) = a(\alpha\beta + 2) = 0$

$\therefore \qquad \alpha\beta = -2$ and $\alpha + \beta = 2$

$\Rightarrow \qquad \alpha - \dfrac{2}{\alpha} = 2 \;\Rightarrow\; \alpha^2 - 2\alpha - 2 = 0$

$\therefore \qquad \alpha = 1 - \sqrt{3}, \beta = 1 + \sqrt{3}$

So, sum $= 1 + \alpha + \beta = 3$

$f'(x) = a(x-1)(x^2 - 2x - 2) = a(x-1)[(x-1)^2 - 3]$

On integrating, we get

$f(x) = a\left[\dfrac{(x-1)^4}{4} - \dfrac{3(x-1)^2}{2}\right] + C$

$\{\because f(1) = 0$, so $C = 0$ and $f(2) = 1$, so $a = -4/5\}$

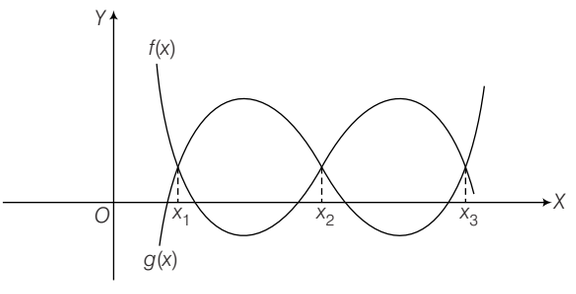
$\Rightarrow \qquad f(x) = -4/5\left[\dfrac{(x-1)^4}{4} - \dfrac{3(x-1)^2}{2}\right]$

$f(3) = -\dfrac{4}{5}\left[\dfrac{16}{4} - \dfrac{3}{2}(2)^2\right] = 8/5$

Passage XII

(Ex. Nos. 75 to 76)

Let $y = f(x)$ and $y = g(x)$ be the two functions, then the number of solutions of these two functions means the number of values of x for which these two function gives same of y as it is shown below.



● ***Ex. 75*** *Let* $\max\{|x+y|, |x-y|\} = 1$ *and* $y = x - [x]$ *be two equations which x and y satisfy, then the number of ordered pairs* (x, y) *is*

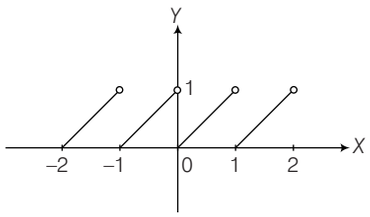
(a) 6 (b) 8 (c) 0 (d) ∞

● ***Ex. 76*** *If* $f(x) = \left\{\frac{1}{x}\right\}$ *and* $g(x) = \{x^2\}$, *then the number of positive roots satisfying the equations* $f(x) = g(x)$ *such that* $2 < x^2 < 3$

(a) 1 (b) 0 (c) 3 (d) 2

■ ***Sol.*** (Ex. Nos. 75 to 76)

75. Here, $y = x - [x] = \{x\}$ and we know graph of fractional part of x.



Also, we have $\max\{|x+y|, |x-y|\} = 1$

If $|x+y| \geq |x-y|$, then $|x+y| = 1$

On squaring above inequality, we get

$$x^2 + y^2 + 2xy \geq x^2 + y^2 - 2xy$$

$\Rightarrow 4xy \geq 0$, then $|x+y| = 1$, i.e. if function lies in I or III quadrant,

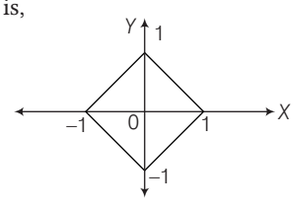
$$|x+y| = 1 \Rightarrow x + y = \pm 1 \quad \text{...(i)}$$

and of $|x+y| \leq |x-y|$, then $|x-y| = 1$

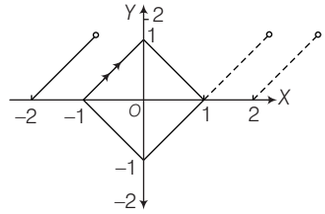
On squaring both sides $4xy \leq 0$ means x and y lies in II or IV quadrant. So, if curves lies in II or IV quadrant, then

$$|x-y| = 1 \Rightarrow x - y = \pm 1 \quad \text{...(ii)}$$

So, graph is,



Combining both graph,
when $-1 \leq x < 0$, then both graph coincide.



So, number of solutions is infinite.

76. If $2 < x^2 < 3 \Rightarrow \sqrt{2} < x < \sqrt{3}$ [as $x > 0$]

So, if $\sqrt{2} < x < \sqrt{3}$, then $\frac{1}{\sqrt{3}} < \frac{1}{x} < \frac{1}{\sqrt{2}}$

$$\Rightarrow \quad \left\{\frac{1}{x}\right\} = \frac{1}{x} \quad \text{...(i)}$$

and $$\{x^2\} = x^2 - 2 \quad \text{...(ii)}$$

So, from Eqs. (i) and (ii), we get

$$\left\{\frac{1}{x}\right\} = \{x^2\}$$

$$\therefore \quad \frac{1}{x} = x^2 - 2 \Rightarrow x^3 - 2x - 1 = 0$$

$$\Rightarrow (x+1)(x^2 - x - 1) = 0$$

So, $$x = -1, \frac{1 \pm \sqrt{5}}{2}, \text{ but as } x > 0$$

$$\therefore \quad x = \frac{1+\sqrt{5}}{2} \qquad \left(\frac{1-\sqrt{5}}{2} \text{ and } -1 \text{ are neglected}\right)$$

JEE Type Solved Examples :
Matching Type Questions

● ***Ex. 77*** *Match the statements of Column I with values of Column II.*

	Column I		Column II
(A)	Number of the values of x lying in $\left(0, \frac{\pi}{2}\right)$ at which $f(x) = \ln(\sin x)$ is not monotonic, is	(p)	0
(B)	If the greatest interval of decrease of the function $f(x) = x^3 - 3x + 2$ is $[a, b]$, then $a + b$ equals	(q)	2
(C)	Let $f(x) = \frac{x^2+2}{[x]}$, $1 \leq x \leq 3$, where [.] greatest integer function, then least value of $f(x)$ is	(r)	-3
(D)	Set of all possible values of a such that $f(x) = e^{2x} - (a+1)e^x + 2x$ is monotonically increasing for all $x \in R$ is $(-\infty, a]$, then a equals	(s)	3

Sol. (A) → (p), (B) → (p), (C) → (s), (D) → (s)

(A) $f(x) = \ln(\sin x) \Rightarrow f'(x) = \dfrac{\cos x}{\sin x} > 0$

$\therefore$ Required number of values of x is 0.

(B) $f'(x) = 3x^2 - 3 \le 0$, if $-1 \le x \le 1$

$\therefore \quad a = -1, b = 1 \quad \therefore \quad a + b = 0$

(C) $f(x) = \begin{cases} x^2 + 2, & 1 \le x < 2 \\ \dfrac{x^2+2}{2}, & 2 \le x < 3 \\ \dfrac{x^2+2}{3}, & x = 3 \end{cases} \Rightarrow f'(x) = \begin{cases} 2x, & 1 < x < 2 \\ x, & 2 < x < 3 \end{cases}$

$\therefore$ Least value of $f(x)$ in $[1, 2]$ is 3.

Least value of $f(x)$ in $[2, 3)$ is 3.

$$f(3) = \frac{11}{3}$$

$\therefore$ Least value of $f(x)$ is 3.

(D) $f(x) = e^{2x} - (a+1)e^x + 2x$

$f'(x) = 2e^{2x} - (a+1)e^x + 2$

Now, $2e^{2x} - (a+1)e^x + 2 \ge 0$, for all $x \in R$

$\Rightarrow \quad 2\left(e^x + \dfrac{1}{e^x}\right) - (a+1) \ge 0$, for all $x \in R$

$\Rightarrow \quad 4 - (a+1) \ge 0 \Rightarrow a \le 3 \quad \therefore \quad a = 3$

● ***Ex. 78*** *Match the statements of Column I with values of Column II.*

	Column I	Column II	
(A)	The dimensions of the rectangle of perimeter 36 cm, which sweeps out the largest volume when revolved about one of its sides, are	(p)	6
(B)	Let $A(-1, 2)$ and $B(2, 3)$ be two fixed points, A point P lying on $y = x$ such that perimeter of ΔPAB is minimum, then sum of the abscissa and ordinate of point P, is	(q)	12
(C)	If x_1 and x_2 are abscissae of two points on the curve $f(x) = x - x^2$ in the interval $[0, 1]$, then maximum value of expression $(x_1 + x_2) - (x_1^2 + x_2^2)$ is	(r)	4
(D)	The number of non-zero integral values of a for which the function $f(x) = x^4 + ax^3 + \dfrac{3x^2}{2} + 1$ is concave upward along the entire real line is	(s)	$\dfrac{1}{2}$

Sol. (A) → (p, q), (B) → (r), (C) → (s), (D) → (r)

(A) Perimeter of the rectangle is 36 cm.

If one side is x, then the other side $= 18 - x$

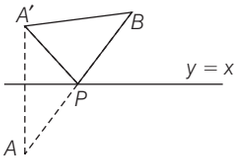
If the rectangle is revolved around the side x, then volume swept out $V = \pi x(18 - x)^2$

$$\frac{dV}{dx} = \pi[(18-x)^2 - 2x(18-x)]$$

$$= \pi(18-x)(18-x-2x)$$

$\therefore \quad x = 6$ and $y = 12$

(B) $A(-1, 2)$, $B(2, 3)$ and P in a point on $y = x$. Perimeter of ΔPAB is minimum when $PA + PB$ is minimum image of $A(-1, 2)$ in the line $y = x$ is $A'(2, -1)$. Equation of $A'B$ is $x = 2$, hence P is $(2, 2)$.



(C) Let (x_1, y_1) and (x_2, y_2) are two points.

$\therefore \quad y_1 + y_2 = (x_1 + x_2) - (x_1^2 + x_2^2)$

Now, $\quad y = x - x^2 = -\left(x - \dfrac{1}{2}\right)^2 + \dfrac{1}{4}$

$\therefore \quad (y_1 + y_2)_{\max} = 2 \times \dfrac{1}{4} = \dfrac{1}{2}$

(D) $f''(x) = 12x^2 + 6ax + 3 \ge 0, \forall\ x \in R \Rightarrow a \in [-2, 2]$

$\Rightarrow$ Number of non-zero integer values of a is 4.

JEE Type Solved Examples :
Single Integer Answer Type Questions

● ***Ex. 79*** *The function* $S(x) = \int_0^x \sin\left(\dfrac{\pi t^2}{2}\right) dt$ *has two critical points in the interval* $[1, 2.4]$*. One of the critical points is a local minimum and the other is a local maximum. The local minimum occurs at x equals ..... .*

Sol. Given, $S(x) = \int_0^x \sin\left(\dfrac{\pi t^2}{2}\right) dt$, $S'(x) = \sin\left(\dfrac{\pi x^2}{2}\right) = 0$

$\Rightarrow \quad \dfrac{\pi x^2}{2} = n\pi \quad \Rightarrow \quad x^2 = 2n \quad [1 \le x^2 \le 5.76$ as is given$]$

Hence, $\quad n = 1$ or 2

$$x = \sqrt{2} \text{ or } x = 2, S''(x) = \cos\left(\frac{\pi x^2}{2}\right) \cdot \pi x$$

$S''(\sqrt{2}) < 0$ and $S''(2) > 0$

$\Rightarrow \quad$ minimum at $x = 2$

● ***Ex. 80*** *The radius of a right circular cylinder increases at a constant rate. Its altitude is a linear function of the radius and increases three times as fast as radius. When the radius is* 1 *cm the altitude is* 6 *cm. When the radius is* 6 *cm, the volume is increasing at the rate of* 1 *cu cm/s. When the radius is* 36 *cm, the volume is increasing at a rate of n cu cm/s. The value of n/*11 *is equal to ..... .*

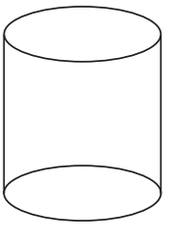
Sol. Here, $\frac{dr}{dt} = c$ and $h = ar + b$

Also, $\frac{dh}{dt} = 3\frac{dr}{dt}$ [given]

$\therefore \quad a\frac{dr}{dt} = 3\frac{dr}{dt} \Rightarrow a = 3$

Hence, $h = 3r + b$

when $r = 1, h = 6 \Rightarrow 6 = 3 + b \Rightarrow b = 3$



$\therefore \quad h = 3(r + 1)$

$V = \pi r^2 h = 3\pi r^2 (r + 1) = 3\pi (r^3 + r^2)$

$\frac{dV}{dt} = 3\pi (3r^2 + 2r)\frac{dr}{dt}$

where $r = 6, \frac{dV}{dt} = 1$ cc/s

$\therefore \quad 1 = 3\pi (108 + 12)\frac{dr}{dt} \Rightarrow 360\,\pi\frac{dr}{dt} = 1$

Again when $r = 23, \frac{dV}{dt} = n$

$n = 3\pi ((3.36)^2 + 2.36)\frac{dr}{dt}$

$n = 3\pi \cdot 36(110)\cdot\frac{1}{360\pi} \Rightarrow n = 33$

$\Rightarrow \quad \frac{n}{11} = \frac{33}{11} = 3$

● ***Ex. 81*** *The set of all points where* $f(x)$ *is increasing is* $(a, b) \cup (c, \infty)$*, then find* $[a + b + c]$ *{where* $[.]$ *denotes GIF}. Given that*

$$f(x) = 2f\left(\frac{x^2}{2}\right) + f(6 - x^2), \forall\, x \in R$$

and $f''(x) > 0, \forall\, x \in R.$

Sol. Here, $f(x) = 2f\left(\frac{x^2}{2}\right) + f(6 - x^2)$

$f'(x) = 2f'\left(\frac{x^2}{2}\right)\cdot x - 2x\,f'(6 - x^2)$

$f'(x) = 2x\left(f'\left(\frac{x^2}{2}\right) - f'(6 - x^2)\right)$

$f'\left(\frac{x^2}{2}\right) > f'(6 - x)^2$, if $\frac{x^2}{2} > 6 - x^2$

[$\because f'(x)$ is increasing]

$\frac{x^2}{2} > 6 - x^2 \Rightarrow x^2 > 4$

$\Rightarrow \quad f'\left(\frac{x^2}{2}\right) - f'(6 - x^2) > 0$

when $x < -2$ or $x > 2 \Rightarrow f'(x) > 0$

when $x \ (-2, 0) \cup (2, \infty)$

$\therefore \quad a + b + c = 0$

$\Rightarrow \quad [a + b + c] = 0$

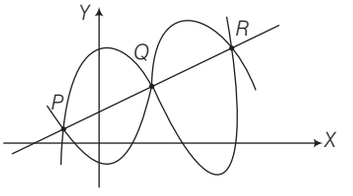
● ***Ex. 82*** *The graphs* $y = 2x^3 - 4x + 2$ *and* $y = x^3 + 2x - 1$ *intersect at exactly* 3 *distinct points. The slope of the line passing through two of these points is equal* to..... .

Sol. Let (x_1, y_1) and (x_2, y_2) be two of these points. Given, $y = x^3 + 2x - 1$ and $y = 2x^3 - 4x + 2$

$\therefore \quad y_1 = 2x_1^3 - 4x_1 + 2$ ...(i)

and $2y_1 = 2x_1^3 + 4x_1 - 2$ ...(ii)

Subtracting Eq. (i) from Eq. (ii), we get



$y_1 = 8x_1 - 4$ ...(iii)

Similarly, $y_2 = 8x_2 - 4$ ...(iv)

$y_2 - y_1 = 8(x_2 - x_1)$

$\frac{y_2 - y_1}{x_2 - x_1} = 8$

● ***Ex. 83*** *The length of the shortest path that begins at the point* (2, 5)*, touches the X-axis and then ends at a point on the circle* $x^2 + y^2 + 12x - 20y + 120 = 0$*, is..... .*

Sol. Circles with centre $(-6, 10)$ and radius

$= \sqrt{36 + 100 - 120} = 4$

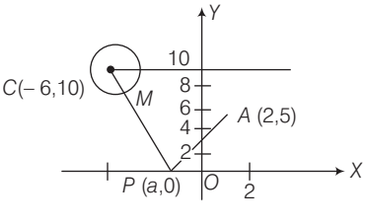
Now, let $(a, 0)$ be a point on the X-axis. If y is the distance from A to P and P to M

$y = \sqrt{(a - 2)^2 + 25} + \sqrt{(a + 6)^2 + 100} - 4$

$\frac{dy}{dx} = \frac{2(a - 2)}{2\sqrt{(a - 2)^2 + 25}} + \frac{2(a + 6)}{2\sqrt{(a + 6)^2 + 100}}$

$\frac{dy}{da}$ can be zero only if $a - 2 > 0$ and $a + 6 < 0$ not possible or $a - 2 < 0$ and $a + 6 > 0$, hence $a \in (-6, 2)$

Solving $\frac{dy}{da}=0$, gives $a=10$ (rejected) or $a=-\frac{2}{3}$



Hence, $y_{\min}=\sqrt{\frac{64}{9}+25}+\sqrt{\frac{256}{9}+100}-4$

$=\frac{17}{3}+\frac{\sqrt{1156}}{3}-4=\frac{17}{3}+\frac{34}{3}-4=17-4=13$

● ***Ex. 84*** *If $f:[1,\infty)\to R: f(x)$ is monotonic and differentiable function and $f(1)=1$, then number of solutions of the equation $f(f(x))=\frac{1}{x^2-2x+2}$ is/are ....*

Sol. Let $g(x)=f(f(x))$, given $f(x)$ is monotonic and differentiable

$\therefore \quad g'(x)=f'(f(x))\cdot f'(x)$, since $f(x)$ is monotonic

$\Rightarrow \quad f'(x)\cdot f'(f(x))>0$ for all $x\geq 1$

Here, $g(1)=f(f(1))$

$\therefore \quad g(1)=f(1)=1$ [given, $f(1)=1$] ...(i)

Since, $g(x)$ is increasing for $x\geq 1$.

$\therefore \quad g(x)\geq g(1)\Rightarrow \frac{1}{x^2-2x+2}\geq 1$

$\Rightarrow \quad \frac{1}{(x-1)^2+1}\geq 1$, i.e. only possible when $x=1$.

$\therefore$ Number of solutions of $f(f(x))$ is 1.

● ***Ex. 85*** *The set of values of 'a' for which the equation $x^4+4x^3+ax^2+4x+1=0$ has all its roots real is given by $(a_1,a_2]\cup\{a_3\}$. Then, $|a_3+a_2|$ is*

Sol. Here, $x^4+4x^3+ax^2+4x+1=0$

dividing by x^2 $\quad \left(x^2+\frac{1}{x^2}\right)+4\left(x+\frac{1}{x}\right)+a=0$

$\Rightarrow \quad \left(x+\frac{1}{x}\right)^2+4\left(x+\frac{1}{x}\right)+(a-2)=0$

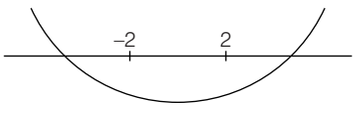
Put $x+\frac{1}{x}=y$, $(y\geq 2$ or $y\leq -2)$

$\therefore \quad y^2+4y+(a-2)=0$

For y to be real $D\geq 0$.

$16-4(a-2)\geq 0 \Rightarrow a\leq 6$ ...(i)

Also, if $f(y)=y^2+4y+(a-2) \Rightarrow f(-2)\cdot f(2)\geq 0$



$\Rightarrow \quad (4+8+a-2)(4-8+a-2)\geq 0$

$\Rightarrow \quad (a+10)(a-6)\geq 0$ ...(ii)

From Eqs. (i) and (ii), we get $a\in(-\infty,-10]\cup\{6\}$

when $a=6$, $y^2+4y+4=0 \Rightarrow y=-2$

$\therefore \quad a\in(-\infty,-10]\cup\{6\}$

$a_2=-10, a_3=6 \Rightarrow |a_2+a_3|=4$

● ***Ex. 86*** *Let $f(x)$ be a cubic polynomial defined by $f(x)=\frac{x^3}{3}+(a-3)x^2+x-13$. Then, the sum of all possible value (s) of 'a' for which $f(x)$ has negative point of local minimum in the interval $[1,5]$, is*

Sol. We have, $f(x)=\frac{x^3}{3}+(a-3)x^2+x-13$

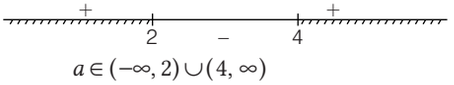
$\therefore$ For $f(x)$ have negative point of local minimum, the equation $f'(x)=0$ must have two distinct negative roots.

Now, $f'(x)=x^2+2(a-3)x+1$

$\therefore$ Following condition(s) must be satisfied simultaneously

(i) $D>0$ (ii) $\alpha+\beta<0$ (iii) $\alpha\beta>0$

Now, $D>0 \Rightarrow 4(a-3)^2-4>0 \Rightarrow (a-2)(a-4)>0$



$\therefore \quad a\in(-\infty,2)\cup(4,\infty)$ ...(i)

Also, $-2(a-3)<0 \Rightarrow a-3>0 \Rightarrow a>3$ ...(ii)

and product of root(s) $=1>0, \forall\, a\in R$

$\therefore$ (i) $\cap$ (ii) $\cap$ (iii) $\Rightarrow a\in(4,\infty)$ ...(iii)

$\therefore \quad a=5$, as $a\in[1,5]$

Thus, sum of all possible values is 5

● ***Ex. 87*** *Consider a polynomial $P(x)$ of the least degree that has a maximum equal to 6 at $x=1$ and a minimum equal to 2 at $x=3$. Then, the value of $P(2)+P'(0)-7$, is*

Sol. The polynomial is an everywhere differentiable function. Therefore, the points of extremum can only be roots of derivative. Further more, the derivative of a polynomial is a polynomial.

The polynomial of the least degree with roots $x_1=1$ and $x_2=3$ has the form $a(x-1)(x-3)$.

Hence, $P'(x)=a(x-1)(x-3)=a(x^2-4x+3)$

Since, at $x=1$, there must be $P(1)=6$, we have

$P(x)=\int_1^x P'(x)dx+6=a\int_1^x(x^2-4x+3)dx+6$

$=a\left(\frac{x^3}{3}-2x^2+3x-\frac{4}{3}\right)+6$

Also, $P(3)=2 \Rightarrow a=3$

Hence, $P(x)=x^3-6x^2+9x+2$

Now, $P(2)=8-24+18+2=4$, also

$P'(x)=3(x^2-4x+3) \Rightarrow P'(0)=9$

$\therefore \quad P(2)+P'(0)-7=6$

Subjective Type Questions

● **Ex. 88** *Let $g'(x) > 0$ and $f'(x) < 0, \forall\, x \in R$, then show*

(i) $g(f(x+1)) < g(f(x-1))$ (ii) $f(g(x+1)) < f(g(x-1))$

Sol. Here, $g'(x) > 0$ and $f'(x) < 0, \forall\, x \in R$

i.e. $g(x)$ is increasing [or if $x_1 > x_2 \Rightarrow g(x_1) > g(x_2)$]

and $f(x)$ is decreasing

[or if $x_1 > x_2 \Rightarrow f(x_1) < f(x_2), \forall\, x \in R$]

$\therefore$ $f(x+1) < f(x-1)$ ...(i)

and $g(x+1) > g(x-1)$

[as $(x+1) > (x-1)$] ...(ii)

***Case* I** As, $g(x)$ is increasing (so greater input gives greater output)

$\Rightarrow$ $g(f(x-1)) > g(f(x+1))$ [using Eq. (i)]

or $g(f(x+1)) < g(f(x-1))$

***Case* II** $f(x)$ is decreasing (so greater input gives smaller output)

$\Rightarrow$ $f(g(x+1)) < f(g(x-1))$ [using Eq. (ii)]

● **Ex. 89** *Let $f'(\sin x) < 0$ and $f''(\sin x) > 0, \forall\, x \in \left(0, \frac{\pi}{2}\right)$ and $g(x) = f(\sin x) + f(\cos x)$, then find the interval in which $g(x)$ is increasing and decreasing.*

Sol. Here, $f'(\sin x) < 0$ and $f''(\sin x) > 0, \forall\, x \in \left(0, \frac{\pi}{2}\right)$ ...(i)

and $g(x) = f(\sin x) + f(\cos x)$

$\Rightarrow$ $g'(x) = f'(\sin x) \cdot \cos x + f'(\cos x)(-\sin x)$

$\Rightarrow$ $g''(x) = \{-f'(\sin x) \cdot \sin x + f''(\sin x) \cdot \cos^2 x\}$

$- \{f'(\cos x) \cdot \cos x - f''(\cos x) \cdot \sin^2 x\}$ ...(ii)

As, $f'(\sin x) < 0$, $f''(\sin x) > 0$,

$\sin x > 0, \cos x > 0, \forall\, x \in \left(0, \frac{\pi}{2}\right)$ ...(iii)

$\therefore$ From Eqs. (ii) and (iii), we can say

$$g''(x) = \underbrace{\{-f'(\sin x) \cdot \cos x\}}_{+\text{ve}} + \underbrace{\{f''(\sin x) \cdot \cos^2 x\}}_{+\text{ve}} + \underbrace{\{f''(\cos x) \cdot \sin^2 x\}}_{+\text{ve}} + \underbrace{\{-f'(\cos x) \cdot \cos x\}}_{+\text{ve}}$$

$\Rightarrow$ $g''(x) > 0, \forall\, x \in \left(0, \frac{\pi}{2}\right)$ ...(iv)

$\Rightarrow$ $g'(x)$ is increasing in $\left(0, \frac{\pi}{2}\right)$ ...(v)

Now, putting $g'(x) = 0$,

$g'(x) = f'(\sin x) \cdot \cos x - f'(\cos x) \cdot \sin x = 0$

$\Rightarrow$ $x = \frac{\pi}{4}$

and $g'(x) > 0$, when $x \in \left(\frac{\pi}{4}, \frac{\pi}{2}\right)$

$g'(x) < 0$, when $x \in \left(0, \frac{\pi}{4}\right)$

$\therefore$ $g(x)$ is increasing, when $x \in \left(\frac{\pi}{4}, \frac{\pi}{2}\right)$

$g(x)$ is decreasing, when $x \in \left(0, \frac{\pi}{4}\right)$.

● **Ex. 90** *If $f(x) = \frac{x}{\sin x}$ and $g(x) = \frac{x}{\tan x}$, where $0 < x \leq 1$, then in this interval find that $f(x)$ and $g(x)$ are increasing or decreasing.*

Sol. Here, $f(x) = \frac{x}{\sin x}$

$\Rightarrow$ $f'(x) = \frac{\sin x \cdot 1 - x \cdot \cos x}{\sin^2 x}$ ...(i)

where $\sin^2 x$ is always positive when $0 < x \leq 1$.

But to check numerator we again let, $h(x) = \sin x - x \cos x$

$\Rightarrow$ $h'(x) = \cos x - 1 \cdot \cos x + x \sin x = x \sin x$, which is +ve for $0 < x \leq 1$

$\therefore$ $h'(x) > 0$

$\Rightarrow h(x)$ is increasing, when $0 < x \leq 1$

$\Rightarrow$ $h(0) < h(x)$

$\Rightarrow$ $0 < \sin x - x \cos x$

$\therefore$ In Eq. (i), $(\sin x - x \cos x) > 0$,

$\Rightarrow$ $f'(x) > 0$, when $0 < x \leq 1$

Hence, $f(x)$ is increasing, when $0 < x \leq 1$

Again, $g(x) = \frac{x}{\tan x}$ [given]

$\Rightarrow$ $g'(x) = \frac{\tan x \cdot 1 - x \cdot \sec^2 x}{\tan^2 x}$ ...(ii)

where $\tan^2 x > 0$

we let $\phi(x) = \tan x - x \sec^2 x$

$\Rightarrow$ $\phi'(x) = \sec^2 x - \sec^2 x - x\,(2 \sec x) \cdot (\sec x \tan x)$

$\phi'(x) = -2x \sec^2 x \tan x$

As $\phi'(x) < 0, \forall 0 < x \leq 1$

[$\because$ $x \in (0,1], \sec^2 x > 0, \tan x > 0$]

$\therefore$ $\phi(x)$ is decreasing, when $0 < x \leq 1$.

$\Rightarrow$ $\phi(0) > \phi(x)$ or $0 > \tan x - x \sec^2 x$

$\therefore$ In Eq. (ii), $(\tan x - x \sec^2 x) < 0$

$\Rightarrow$ $g'(x) < 0$, when $0 < x \leq 1$

$\therefore$ $g(x)$ is decreasing, when $0 < x \leq 1$.

● ***Ex. 91*** *Let $f:[0,\infty)\to[0,\infty)$ and $g:[0,\infty)\to[0,\infty)$ be non-increasing and non-decreasing function and $h(x)=g(f(x))$ and if f and g are differentiable for all points in their respective domains and $h(0)=0$. Then, show $h(x)$ is always identically zero.*

Sol. Here, $h(x)=g(f(x))$, since, $g(x)\in[0,\infty)$

$h(x)\geq 0, \forall\ x\in$ domain

Also, $h'(x)=g'(f(x))\cdot f'(x)\leq 0$, as $g'(x)\geq 0$

and $h(x)\leq 0, \forall\ x\in$ domain as $h(0)=0$

Hence, $h(x)=0, \forall\ x\in$ domain

● ***Ex. 92*** *A cubic function $f(x)$ tends to zero at $x=-2$ and has relative maximum/ minimum at $x=-1$ and $x=\frac{1}{3}$. If $\int_{-1}^{1} f(x)\,dx=\frac{14}{3}$. Find the cubic function $f(x)$.* ***[IIT JEE 1992]***

Sol. $f(x)$ is a cubic polynomial. Therefore, $f'(x)$ is a quadratic polynomial and $f(x)$ has relative maximum and minimum at $x=\frac{1}{3}$ and $x=-1$, respectively.

$\therefore$ -1 and $\frac{1}{3}$ are roots of $f'(x)=0$

$$\Rightarrow \quad f'(x)=a(x+1)\left(x-\frac{1}{3}\right)=a\left(x^2+\frac{2}{3}x-\frac{1}{3}\right)$$

Now, integrating w.r.t. x, we get

$$f(x)=a\left[\frac{x^3}{3}+\frac{x^2}{3}-\frac{x}{3}\right]+c,\ c \text{ is constant of integration.}$$

Again, $f(-2)=0$ [given]

$$\therefore \quad f(-2)=a\left(\frac{-8}{3}+\frac{4}{3}+\frac{2}{3}\right)+c=0$$

$$\Rightarrow \quad \frac{-2a}{3}+c=0 \quad \text{or} \quad c=\frac{2a}{3}$$

$$\Rightarrow \quad f(x)=a\left(\frac{x^3}{3}+\frac{x^2}{3}-\frac{x}{3}\right)+\frac{2a}{3}$$

$$\Rightarrow \quad f(x)=a\left(\frac{x^3}{3}+\frac{x^2}{3}-\frac{x}{3}+\frac{2}{3}\right)$$

Again, $\int_{-1}^{1} f(x)\,dx=\frac{14}{3}$ [given]

$$\Rightarrow \quad \frac{a}{3}\int_{-1}^{1}(x^3+x^2-x+2)\,dx=\frac{14}{3}$$

Because, $y=x^3$ and $y=-x$ are odd functions.

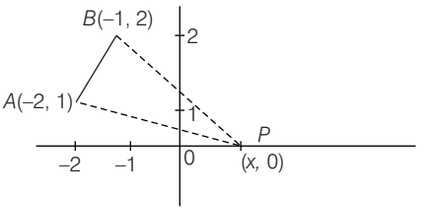
So, $\int_{-1}^{1} x^3dx=\int_{-1}^{1} x\,dx=0$

$$\therefore \quad \frac{a}{3}\left[\frac{2x^3}{3}+4x\right]_0^1=\frac{14}{3} \quad \Rightarrow \quad a=3$$

$$\therefore \quad f(x)=x^3+x^2-x+2$$

● ***Ex. 93*** *Given that, $S=|\sqrt{x^2+4x+5}-\sqrt{x^2+2x+5}|$ for all real x, then find the maximum value of S^4.*

Sol. Here, $S=\left|\sqrt{(x+2)^2+1}-\sqrt{(x+1)^2+4}\right|$



$$\therefore \quad S=\left|\sqrt{(x-(-2))^2+(1-0)^2}-\sqrt{(x-(-1))^2+(2-0)^2}\right|$$

$$=|PA-PB| \qquad \ldots(i)$$

Since, $|PA-PB|\leq AB$, using triangle law.

$$\therefore \quad |PA-PB|_{\max}=\sqrt{1+1}=\sqrt{2}$$

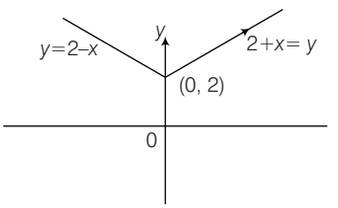
$$[\because AB=\sqrt{-1+2^2+(2-1)^2}=\sqrt{2}] \ldots(ii)$$

$$\therefore \quad S_{\max}=\sqrt{2}$$

$$\Rightarrow \quad S^4=4$$

● ***Ex. 94*** *If $f(x)=\max|2\sin y-x|$, (where $y\in R$), then find the minimum value of $f(x)$.*

Sol. Here, $f(x)=\max|2\sin y-x|=\begin{cases}2-x, & x\leq 0\\ 2+x, & x>0\end{cases}$



$\therefore$ Minimum value of $f(x)=2$

● ***Ex. 95*** *Find the maximum and minimum value of*

$$f(x)=\frac{40}{3x^4+8x^3-18x^2+60}.$$

Sol. Given, $f(x)=\frac{40}{3x^4+8x^3-18x^2+60}$ is maximum or minimum according by $3x^4+8x^3-18x^2+60$ is minimum or maximum.

Then, $f_{\max}$, if $3x^4+8x^3-18x^2+60$ is minimum.

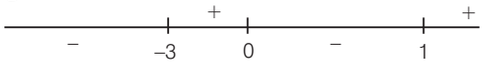
$f_{\min}$, if $3x^4+8x^3-18x^2+60$ is maximum.

Let $g(x)=3x^4+8x^3-18x^2+60$

$\Rightarrow \quad g'(x) = 12x(x^2 + 2x - 3)$

$\Rightarrow \quad g'(x) = 12x(x+3)(x-1)$

Using number line rule,



which indicates $g'(x)$ changes sign from −ve to +ve at $x = -3, 1$.

$\therefore$ Local minimum at $x = -3, 1$

and local maximum at $x = 0$ [as changes from +ve to −ve]

$\Rightarrow \quad g(x)$ is maximum at $x = 0$

i.e. $g_{\max}(0) = 60$

and for $g(x)$ to be minimum,

$g_{\min}(-3) = 243 - 216 - 162 + 60 = -75$

$g_{\min}(1) = 3 + 8 - 18 + 60 = 53$

Substituting these values in Eq. (i), we get

$f_{\max}(x)$ when $g_{\min}$, i.e. $f(x) = \dfrac{40}{-75}$ and $\dfrac{40}{53}$

Maximum value $= \dfrac{40}{53}, \dfrac{-8}{15}$

$f_{\min}(x)$ when $g_{\max}$ i.e. $f(x) = \dfrac{40}{60} = \dfrac{2}{3}$

Minimum value $= \dfrac{2}{3}$

● ***Ex. 96*** *Use the function $f(x) = x^{1/x}$, $x > 0$ and determine the bigger of the two numbers e^{π} and π^e.*

Sol. Given, $f(x) = x^{1/x}$, $x > 0$

Let $y = f(x) = x^{1/x}$

Taking log on both sides, we have $\log y = \dfrac{1}{x}\log x$

Differentiating both the sides, we have

$$\frac{1}{y}\cdot\frac{dy}{dx} = \frac{1}{x^2} + \log x\left(-\frac{1}{x^2}\right)$$

or $$\frac{dy}{dx} = y\left[\frac{1 - \log x}{x^2}\right]$$

$\therefore \quad f'(x) = \dfrac{x^{1/x}}{x^2}[1 - \log x]$

Let $f'(x) = 0$,

$\Rightarrow \quad \log x = 1 \quad$ or $\quad x = e$

Again, $f''(x) = \dfrac{x^{1/x}}{x^2}\left[0 - \dfrac{1}{x}\right] + (1 - \log x)\dfrac{d}{dx}\left(\dfrac{x^{1/x}}{x^2}\right)$

$\therefore \quad f''(e) = \dfrac{e^{1/e}}{e^2}\left(-\dfrac{1}{e}\right) + 0$

$\Rightarrow \quad f''(e) < 0$

$\therefore$ 'f' has a maximum at $x = e$

But $x = e$ is the only extreme value.

$\therefore \quad f$ has the greatest value at $x = e$

$\Rightarrow \quad f(e) > f(\pi), \quad$ for all $x > 0$

$\Rightarrow \quad (e)^{\frac{1}{e}} > (\pi)^{\frac{1}{\pi}}$

$\Rightarrow \quad e^{\pi} > \pi^e$

● ***Ex. 97*** *Using the relation $2(1 - \cos x) < x^2$, $x \neq 0$ or otherwise prove that $\sin(\tan x) \geq x$ for all $x \in \left[0, \dfrac{\pi}{4}\right]$.* ***[IIT JEE 2003]***

Sol. Let $f(x) = \sin(\tan x) - x$

Then, $f'(x) = \cos(\tan x)\cdot\sec^2 x - 1$

$\Rightarrow \quad f'(x) = \cos(\tan x)\{1 + \tan^2 x\} - 1$

$\Rightarrow \quad f'(x) = \tan^2 x \cos(\tan x) - \{1 - \cos(\tan x)\}$

[using $2(1 - \cos x) < x^2$]

$$f'(x) > \tan^2 x \cos(\tan x) - \frac{1}{2}\tan^2 x$$

$\Rightarrow \quad f'(x) > \dfrac{1}{2}\tan^2 x\{2\cos(\tan x) - 1\}$

[again, using $2(1 - \cos x) < x^2$]

$$f'(x) > \frac{1}{2}\tan^2 x(1 - \tan^2 x)$$

$\Rightarrow \quad f'(x) \geq 0, \forall \quad x \in \left[0, \dfrac{\pi}{4}\right]$

$\Rightarrow \quad f(x)$ is increasing function for all $x \in \left[0, \dfrac{\pi}{4}\right]$.

$\therefore \quad f(x) \geq f(0),$ for all $x \in \left[0, \dfrac{\pi}{4}\right]$

$\Rightarrow \quad \sin(\tan x) - x > \sin(\tan 0) - 0$

$\Rightarrow \quad \sin(\tan x) \geq x,$ for all $x \in \left[0, \dfrac{\pi}{4}\right]$

● ***Ex. 98*** *If $P(1) = 0$ and $\dfrac{d}{dx}\{P(x)\} > P(x)$ for all $x \geq 1$, then prove that $P(x) > 0$ for all $x > 1$.* ***[IIT JEE 2003]***

Sol. Here, $\dfrac{d}{dx}\{P(x)\} > P(x)$, for all $x \geq 1$

or $\dfrac{d}{dx}\{P(x)\}e^{-x} > P(x)e^{-x}$, for all $x \geq 1$

$\Rightarrow \quad \dfrac{d}{dx}\{P(x)\}e^{-x} - P(x)e^{-x} > 0,$ for all $x \geq 1$

$\Rightarrow \quad \dfrac{d}{dx}\{e^{-x}P(x)\} > 0,$ for all $x \geq 1$

$\Rightarrow \quad P(x)e^{-x}$ is an increasing function for all $x \geq 1$

$\Rightarrow \quad P(x)\,e^{-x} > P(1)\,e^{-1}$, for all $x > 1$

$\Rightarrow \quad P(x)\,e^{-x} > 0$, for all $x > 1$ [as $P(1) = 0$, given]

Thus, $P(x) > 0$, for all $x > 1$ [as $e^{-x} > 0$, for all x]

● ***Ex. 99*** *In the graph of the function* $y = \frac{3}{\sqrt{2}}\,x \log x$, *where* $x \in [e^{-1.5}, \infty[$; *find the point* $P(x, y)$ *such that the segment of the tangent to the graph of the function at the point, intercepted between the point P and Y-axis, is shortest.*

Sol. Given, $y = \frac{3}{\sqrt{2}}\,x \log x$

Differentiating w.r.t. x, the given function, we have

$$\frac{dy}{dx} = \frac{3}{\sqrt{2}}\left(x \cdot \frac{1}{x} + \log_e x\right) = \frac{3}{\sqrt{2}}(1 + \log_e x)$$

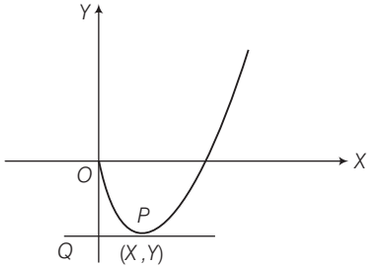
Let the point $P(x, y) \Rightarrow P\left(x, \frac{3}{\sqrt{2}}\,x \log_e x\right)$

Hence, the equation of tangent to the curve at the point $P\left(x, \frac{3}{\sqrt{2}}\,x \log_e x\right)$ is

$$Y - \frac{3}{\sqrt{2}}\,x \log_e x = \frac{3}{\sqrt{2}}(1 + \log_e x)(X - x)$$

When it cuts Y-axis, $X = 0$

Thus, $y = \frac{3}{\sqrt{2}}\,x \log_e x - \frac{3}{\sqrt{2}}(1 + \log_e x)\,x$



So, $y = -\frac{3}{\sqrt{2}}\,x$

Hence, the given tangent intersects axis at

$$Q\left(0, -\frac{3}{\sqrt{2}}\,x\right)$$

Now, $PQ^2 = x^2 + \left(y + \frac{3}{\sqrt{2}}\,x\right)^2$

$$= x^2 + \left(\frac{3}{\sqrt{2}}\,x\,(1 + \log_e x)\right)^2$$

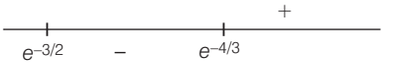
$$PQ^2 = x^2\left[1 + \frac{9}{2}(1 + \log_e x)^2\right]$$

Differentiating w.r.t. x, we have

$$\frac{d(PQ^2)}{dx} = x^2\left[\frac{9}{2} \cdot 2(1 + \log_e x) \cdot \frac{1}{x}\right] + \left[1 + \frac{9}{2}(1 + \log_e x)^2\right]2x$$

$$= x\,[9(1 + \log_e x) + 2 + 9(1 + \log_e x)^2]$$

For extremum $\frac{d(PQ^2)}{dx} = 0$



Since, $x \neq 0$, $9(1 + \log x)^2 + 9(1 + \log x) + 2 = 0$

$\Rightarrow \quad (1 + \log x) = -1/3, -2/3$

$\Rightarrow \quad \log x = -4/3, -5/3$

$\Rightarrow \quad x = e^{-4/3}, e^{-5/3}$

$x = e^{-5/3}$ lie outside the interval $(e^{-1.5}, \infty)$.

The sign scheme for $\frac{d(PQ^2)}{dx}$ is shown in figure, which shows that PQ^2 is minimum.

Therefore, PQ is minimum when $x = e^{-4/3}$.

● ***Ex. 100*** *John has x children from his first wife. Mary has* $(x + 1)$ *children from her first husband. They marry and have children of their own. The whole family has* 24 *children. Assuming that the two children of same parents do not fight, then find the maximum possible number of fights that can take place.*

Sol. Since, the whole family has 24 children, those of John and Mary are

$$24 - x - (x + 1)$$

i.e. $(23 - 2x)$

Now, F = Total number of fights.

= (number of fights when a John's child fights a Mary's child) + (number of fights when a John child fights a John-Mary's child) + (number of fights when a Mary's child fights a John-Mary's child)

$= x(x + 1) + x(23 - 2x) + (x + 1)(23 - 2x)$

$= 23 + 45x - 3x^2$

For maximum, $\frac{dF}{dx} = 0$

$\Rightarrow \quad 45 - 6x = 0$ or $x = 7.5$

$\Rightarrow \quad \frac{d^2F}{dx^2} = 45 > 0$

$\therefore f(x)$ is minimum when $x = 7.5$

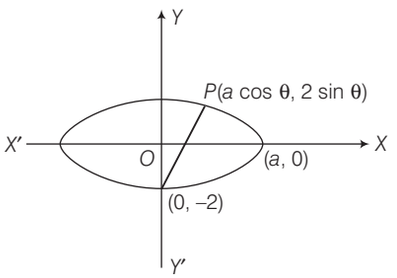
But in this case fractional value is not possible. The nearest integral values are $x = 7$ and $x = 8$.

In either case the total number of fights $= 23 + 45 \times 7 - 3(7)^2$
$= 191$

● **Ex. 101** *Find the point on the curve* $4x^2 + a^2y^2 = 4a^2$; $4 < a^2 < 8$ *that is farthest from the point* $(0, -2)$.

Sol. The equation of given curve can be expressed as shown in the figure

$\frac{x^2}{a^2} + \frac{y^2}{4} = 1$, where $4 < a^2 < 8$ which is equation of ellipse.



Hence, let us consider a point $P(a\cos\theta, 2\sin\theta)$ on the ellipse.

Let the distance of $P(a\cos\theta, 2\sin\theta)$ from $(0, -2)$ be L.

Then, $L^2 = (a\cos\theta - 0)^2 + (2\sin\theta + 2)^2$

Differentiating w.r.t. θ, we have

$$\frac{d(L^2)}{d\theta} = a^2 \cdot 2\cos\theta(-\sin\theta) + 4 \cdot 2(\sin\theta + 1)\cdot\cos\theta$$

$$= \cos\theta\,[-2a^2\sin\theta + 8\sin\theta + 8] = 0$$

$\Rightarrow$ Either $\cos\theta = 0$ or $(8 - 2a^2)\sin\theta + 8 = 0$

i.e. $\theta = \pi/2$ or $\sin\theta = \frac{4}{a^2 - 4}$

Since, $a^2 < 8$

$\Rightarrow$ $a^2 - 4 < 4$

$\Rightarrow$ $\frac{4}{a^2 - 4} > 1 \Rightarrow \sin\theta > 1$, which is not possible.

Further, $\frac{d^2(L^2)}{d\theta^2} = \cos\theta\,[-2a^2\cos\theta + 8\cos\theta]$

$+ (-\sin\theta)[-2a^2\sin\theta + 8\sin\theta + 8]$

At $\theta = \pi/2$, $\frac{d^2(L^2)}{d\theta^2} = 0 - [16 - 2a^2] = 2(a^2 - 8) < 0$ [as $a^2 < 8$]

Hence, L is maximum at $\theta = \pi/2$ and the farthest point is $(0, 2)$.

● **Ex. 102** *Let* $f(x) = \sin^{-1}\left(\frac{2\phi(x)}{1 + \phi^2(x)}\right)$, *then find the interval in which* $f(x)$ *is increasing or decreasing.*

Sol. Here, $f(x) = \sin^{-1}\left(\frac{2\phi(x)}{1 + \phi^2(x)}\right)$

***Case* I** $|\phi(x)| < 1$

Let $\phi(x) = \tan\theta$

$\therefore$ $f(x) = \sin^{-1}\left(\frac{2\tan\theta}{1 + \tan^2\theta}\right) = \sin^{-1}(\sin 2\theta) = 2\theta$

$\Rightarrow$ $f(x) = 2\tan^{-1}\{\phi(x)\}$

$\Rightarrow$ $f'(x) = \frac{2}{1 + \{\phi(x)^2\}} \cdot \phi'(x)$

where $\phi'(x) > 0 \Rightarrow f'(x) > 0 \Rightarrow f(x)$ is increasing
[since $\phi(x) = \tan\theta$, which is increasing]

***Case* II** When $|\phi(x)| > 1$ or $\left|\frac{1}{\phi(x)}\right| < 1$

Now, put $\frac{1}{\phi(x)} = \tan\theta$

$\therefore$ $f(x) = \sin^{-1}\left(\frac{2\cdot\frac{1}{\phi(x)}}{1 + \left(\frac{1}{\phi(x)}\right)^2}\right)$

$\Rightarrow$ $f(x) = \sin^{-1}\left(\frac{2\tan\theta}{1 + \tan^2\theta}\right)$

$f(x) = \sin^{-1}(\sin 2\theta) = 2\theta = 2\tan^{-1}\left(\frac{1}{\phi(x)}\right)$

$= 2\cot^{-1}(\phi(x))$

$\Rightarrow$ $f'(x) = -2 \cdot \frac{1}{1 + (\phi(x))^2} \cdot \phi'(x)$

where $\phi'(x) > 0$

$\Rightarrow$ $f'(x) < 0$ for all $|\phi(x)| > 1$

Hence, $f(x)$ is increasing, when $|\phi(x)| < 1$ and $f(x)$ is decreasing, when $|\phi(x)| > 1$.

● **Ex. 103** *Find the minimum value of*

$$f(x) = \big||x + 2| - 2|x - 2|\big| + |x|.$$

Sol. Here, $f(x) = \big||x + 2| - 2|x - 2|\big| + |x|$, which gives rise to four cases as

***Case* I** $x < -2$

$f(x) = |-(x + 2) + 2(x - 2)| - x$

$= |-x - 2 + 2x - 4| - x$

$= |x - 6| - x = -(x - 6) - x$

$\Rightarrow$ $f(x) = -2x + 6$ ...(i)

***Case* II** $-2 \le x < 0$

$f(x) = |(x + 2) + 2(x - 2)| - x$

$= |3x - 2| - x = -(3x - 2) - x$

$\Rightarrow$ $f(x) = -4x + 2$ ...(ii)

***Case* III** $0 \le x < 2$

$$f(x) = |x + 2 + 2(x-2)| + x$$
$$= |3x - 2| + x$$
$$= \begin{cases} -(3x-2) + x, \text{ for } 0 \le x < \frac{2}{3} \\ (3x-2) + x, \quad \text{for } \frac{2}{3} \le x < 2 \end{cases}$$

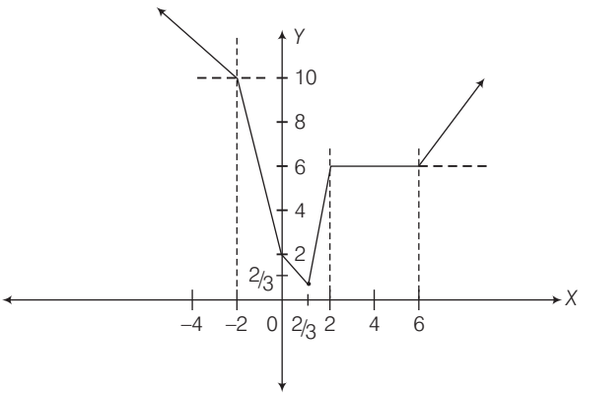
$$\Rightarrow \quad f(x) = \begin{cases} -2x + 2, 0 \le x < 2/3 \\ 4x - 2, 2/3 \le x < 2 \end{cases} \quad \text{...(iii)}$$

***Case* IV** $x \ge 2$

$$f(x) = |x + 2 - 2(x-2)| + x = |-x + 6| + x = |x - 6| + x$$
$$= \begin{cases} -(x-6) + x, 2 \le x < 6 \\ (x-6) + x, \ x \ge 6 \end{cases}$$

$$f(x) = \begin{cases} 6, & 2 \le x < 6 \\ 2x - 6, & x \ge 6 \end{cases} \quad \text{...(iv)}$$

From Eqs. (i), (ii), (iii) and (iv), we have the following figure.



From the graph, minimum value of $f(x) = \frac{2}{3}$.

● ***Ex. 104*** *Which normal to the curve $y = x^2$ forms the shortest chord?* ***[IIT JEE 1992]***

Sol. Let (t, t^2) be any point on the parabola $y = x^2$

Now, $\frac{dy}{dx} = 2x \Rightarrow \left(\frac{dy}{dx}\right)_{(t, t^2)} = 2t$, which is the slope of tangent.

So, the slope of the normal to $y = x^2$ at (t, t^2) is $\left(-\frac{1}{2t}\right)$.

$\therefore$ The equation of the normal to $y = x^2$ at (t, t^2) is

$$y - t^2 = \left(-\frac{1}{2t}\right)(x - t) \quad \text{...(i)}$$

Suppose Eq. (i) meets the curve again at $B(t_1, t_1^2)$, then

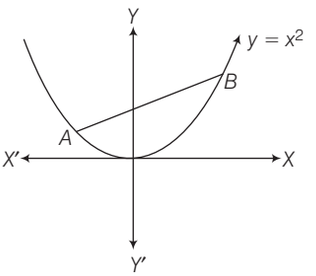
$$t_1^2 - t^2 = -\frac{1}{2t}(t_1 - t) \Rightarrow t_1 + t = -\frac{1}{2t}$$

$$\Rightarrow \quad t_1 = -t - \frac{1}{2t} \quad \text{...(ii)}$$

Let L be the length of the chord AB (as normal)

$$L = AB^2 = (t - t_1)^2 + (t^2 - t_1^2)^2$$
$$= (t - t_1)^2 [1 + (t + t_1)^2]$$
$$= \left(t + t + \frac{1}{2t}\right)^2 \left[1 + \left(t - t - \frac{1}{2t}\right)^2\right] \quad \text{[using Eq. (ii)]}$$
$$= \left(2t + \frac{1}{2t}\right)^2 \left(1 + \frac{1}{4t^2}\right)$$

$$L = 4t^2 \left(1 + \frac{1}{4t^2}\right)^3$$



$$\Rightarrow \quad \frac{dL}{dt} = 8t\left(1 + \frac{1}{4t^2}\right)^3 + 12t^2\left(1 + \frac{1}{4t^2}\right)^2 \cdot \left(-\frac{2}{4t^3}\right)$$

$$\Rightarrow \quad \frac{dL}{dt} = 2\left(1 + \frac{1}{4t^2}\right)^2 \left[4t\left(1 + \frac{1}{4t^2}\right) - \frac{3}{t}\right]$$

$$\Rightarrow \quad \frac{dL}{dt} = 2\left(1 + \frac{1}{4t^2}\right)^2 \left(4t - \frac{2}{t}\right) = 4\left(1 + \frac{1}{4t^2}\right)^2 \left(2t - \frac{1}{t}\right)$$

For extremum, let $\frac{dL}{dt} = 0$

$$\Rightarrow \quad t = \pm\frac{1}{\sqrt{2}}$$

Again,

$$\frac{d^2L}{dt^2} = 8\left(1 + \frac{1}{4t^2}\right)\left(-\frac{1}{2t^2}\right)\left(2t - \frac{1}{t}\right) + 4\left(1 + \frac{1}{4t^2}\right)^2 \left(2 + \frac{1}{t^2}\right)$$

$$\Rightarrow \quad \left(\frac{d^2L}{dt^2}\right)_{t = \pm\frac{1}{\sqrt{2}}} > 0$$

$\therefore$ Minimum when $t = \pm\frac{1}{\sqrt{2}}$

Thus, points are $A\left(\pm\frac{1}{\sqrt{2}}, \frac{1}{2}\right)$ and $B(\mp\sqrt{2}, 2)$.

$\Rightarrow$ Equation of normal AB is $\sqrt{2}x + 2y - 2 = 0$ and $\sqrt{2}x - 2y + 2 = 0$.

● ***Ex. 105*** *Let $f(x) = \sin^3 x + \lambda \sin^2 x$ where $-\pi/2 < x < \pi/2$. Find the intervals in which λ should lie in order that $f(x)$ has exactly one minimum.*

Sol. Given, $f(x) = \sin^3 x + \lambda \sin^2 x$

$\therefore \quad f'(x) = 3\sin^2 x (\cos x) + \lambda \cdot 2 \sin x (\cos x)$

$= \sin x \cos x (3 \sin x + 2\lambda)$

For extremum, let $f'(x) = 0$

$\therefore \quad \sin x = 0, \quad \cos x = 0,$

$\sin x = -2\lambda/3$

Since, $-\pi/2 < x < \pi/2$

$\therefore \quad \cos x \neq 0$

$\Rightarrow \quad \sin x = 0 \quad \Rightarrow \quad x = 0$

and $\sin x = \frac{-2\lambda}{3} \Rightarrow x = \sin^{-1}\left(\frac{-2\lambda}{3}\right)$ ...(i)

One of these from Eq. (i) will give maximum and one minimum, provided

$$-1 < \sin x = \frac{-2\lambda}{3} < 1$$

i.e. $$-1 < \frac{-2\lambda}{3} < 1$$

$\Rightarrow \quad -3 < -2\lambda < 3 \Rightarrow -3 < 2\lambda < 3$

i.e. $-3/2 < \lambda < 3/2$

But, if $\lambda = 0$, then $\sin x = 0$ has only one solution.

$\therefore \quad \lambda \in (-3/2, 3/2) - \{0\}$

$\Rightarrow \quad \lambda \in (-3/2, 0) \cup (0, 3/2)$

For this value of λ there are two distinct solutions.

Since, $f(x)$ is continuous, these solutions give one maximum and one minimum because for a continuous function, between two maxima there must lie one minima and *vice-versa*.

● ***Ex. 106*** *Determine the points of maxima and minima of the function, $f(x) = \frac{1}{8}\log x - bx + x^2, x > 0$ when $b \geq 0$ is a constant.* ***[IIT JEE 1996]***

Sol. Here, $f(x) = \frac{1}{8}\log x - bx + x^2$ is defined and continuous for all $x > 0$.

Then, $f'(x) = \frac{1}{8x} - b + 2x$

or $f'(x) = \frac{16x^2 - 8bx + 1}{8x}$

For extrema let $f'(x) = 0$

$\Rightarrow \quad 16x^2 - 8bx + 1 = 0$

So, $x = \frac{8b \pm \sqrt{64(b^2 - 1)}}{2 \times 16}$

or $x = \frac{b \pm \sqrt{b^2 - 1}}{4}$

Obviously the roots are real, if $b^2 - 1 \geq 0$

$\Rightarrow \quad b > 1 \quad [\text{as } b > 0]$

Hence, when $b > 1$, then using number line rule for $f'(x)$ as shown in given figure.

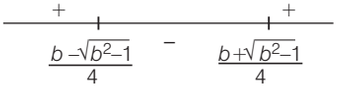
We know $f'(x)$ changes sign from +ve to −ve at

$$x = \frac{b - \sqrt{b^2 - 1}}{4}$$

$\therefore \quad f(x)_{\max}$ at $x = \frac{b - \sqrt{b^2 - 1}}{4}$

and $f'(x)$ changes sign from −ve to +ve at

$$x = \frac{b + \sqrt{b^2 - 1}}{4}$$



$\therefore \quad f(x)_{\min}$ at $x = \frac{b + \sqrt{b^2 - 1}}{4}$

Also, if $b = 1$ $f'(x) = \frac{16x^2 - 8x + 1}{8x} = \frac{(4x - 1)^2}{8x}$ no change in sign.

$\therefore$ Neither maximum nor minimum, if $b = 1$

Thus,

$$f(x) = \begin{cases} f(x)_{0_{\max}} \text{ when } x = \frac{b - \sqrt{b^2 - 1}}{4} \text{ and } b > 1 \\ f(x)_{\min} \text{ when } x = \frac{b + \sqrt{b^2 - 1}}{4} \text{ and } b > 1 \\ f(x) \text{ neither maximum nor minimum when } b = 1 \end{cases}$$

● ***Ex. 107*** *Find the points on the curve $ax^2 + 2bxy + ay^2 = c$, $0 < a < b < c$, whose distance from the origin is minimum.*

Sol. Let $P(x, y)$ be a point on the curve $ax^2 + 2bxy + ay^2 = c$, whose distance from the origin is r.

$\therefore \quad x = r \cos\theta \quad \text{and} \quad y = r \sin\theta$

As, $r\cos\theta$ and $r\sin\theta$ lies on $ax^2 + 2bxy + ay^2 = c$

$\Rightarrow \quad ar^2 \cos^2\theta + 2br^2 \sin\theta \cos\theta + ar^2 \sin^2\theta = c$

$\Rightarrow \quad (a + b\sin 2\theta) r^2 = c$

$\Rightarrow \quad r^2 = \frac{c}{a + b\sin 2\theta}$ ...(i)

From Eq. (i) r is minimum when $(a + b \sin 2\theta)$ is maximum, i.e. $\sin 2\theta$ is maximum.

i.e. $$2\theta = \frac{\pi}{2} \text{ or } \frac{5\pi}{2} \Rightarrow \theta = \frac{\pi}{4}, \frac{5\pi}{4}$$

For θ, maximum value of $(a + b \sin 2\theta) = a + b$

$$\therefore \quad r_{\min} = \sqrt{\frac{c}{a+b}}$$

Also, when $\theta = \frac{\pi}{4}$, $P\left(\frac{r}{\sqrt{2}}, \frac{r}{\sqrt{2}}\right) = \left(\sqrt{\frac{c}{2(a+b)}}, \sqrt{\frac{c}{2(a+b)}}\right)$

Again, when $\theta = \frac{5\pi}{4}$,

$$P\left(\frac{-r}{\sqrt{2}}, \frac{-r}{\sqrt{2}}\right) = \left(-\sqrt{\frac{c}{2(a+b)}}, -\sqrt{\frac{c}{2(a+b)}}\right)$$

Thus, the required points are $\pm\left(\sqrt{\frac{c}{2(a+b)}}, \sqrt{\frac{c}{2(a+b)}}\right)$.

● ***Ex. 108*** *Find the value of n, for which* $f(x) = (x^2 - 4)^n (x^2 - x + 1)$, $n \in N$ *assumes a local minima at* $x = 2$.

Sol. Here, $f(x) = (x^2 - 4)^n (x^2 - x + 1)$ assumes local minima at $x = 2$

$\Rightarrow$ $f(2) < f(2 - h)$ and $f(2) < f(2 + h)$, where $h > 0$

where $f(2) = 0$

$\Rightarrow$ $f(2 - h) > 0$ and $f(2 + h) > 0, \forall\ h > 0$

$\Rightarrow$ $(-h)^n (4 - h)^n \cdot \{h^2 - 3h + 1\} > 0$

and $h^n (4 + h)^n (h^2 + 5h + 1) > 0$

i.e. $(-h)^n > 0$

$[\because (4 - h) > 0, h^2 - 3h + 1 > 0, 4 + h > 0, h^2 + 5h + 1 > 0, \forall\ h > 0]$

$\Rightarrow n \in$ even number.

● ***Ex. 109*** *The interval to which b may belong so that the function,*

$$f(x) = \left(1 - \frac{\sqrt{21 - 4b - b^2}}{b+1}\right) x^3 + 5x + \sqrt{16},$$

increases for all x.

Sol. If $f(x) = \left(1 - \frac{\sqrt{21 - 4b - b^2}}{b+1}\right) x^3 + 5x + \sqrt{16}$, increases we must have $f'(x) > 0, \forall\ x \in$ real number.

Then, $f'(x) = \left(1 - \frac{\sqrt{21 - 4b - b^2}}{b+1}\right) 3x^2 + 5 > 0, \forall\ x \in R$

[as we know $ax^2 + bx + c > 0, \forall\ x \in R$, we must have $a > 0$ and $D < 0$]

$$\therefore \quad 1 - \frac{\sqrt{21 - 4b - b^2}}{b+1} > 0$$

and $(0)^2 - 4 \times 3\left(1 - \frac{\sqrt{21 - 4b - b^2}}{b+1}\right) 5 < 0$

$$\Rightarrow \quad 1 - \frac{\sqrt{21 - 4b - b^2}}{b+1} > 0$$

The above inequality holds, when, (i) $b + 1 < 0$ and (ii)

$$21 - 4b - b^2 > 0$$

$\therefore$ $b < -1$ and $b^2 + 4b - 21 < 0$

$\Rightarrow$ $b < -1$ and $(b + 7)(b - 3) < 0$

$\Rightarrow$ $b < -1$ and $-7 < b < 3$ [using number line rule]

$\therefore$ $b \in (-7, -1)$ ...(i)

Again, when $b + 1 > 0$, $f(x)$ will be increasing for all x, if

$$21 - 4b - b^2 > 0 \quad \text{and} \quad 1 > \frac{\sqrt{21 - 4b - b^2}}{b+1}$$

$\Rightarrow$ $b^2 + 4b - 21 < 0$

and $(b + 1)^2 > (21 - 4b - b^2)$ [as $b + 1 > 0$]

$\Rightarrow$ $(b + 7)(b - 3) < 0$ and $b^2 + 3b - 10 > 0$

$\Rightarrow$ $(-7 < b < 3)$ and $(b < -5 \text{ or } b > 2)$

$\Rightarrow$ $2 < b < 3$ ...(ii)

From Eqs. (i) and (ii), we have concluded that.

$$b \in (-7, -1) \cup (2, 3)$$

● ***Ex. 110*** *Find the set of all values of 'a' for which* $f(x) = \left(\frac{\sqrt{a+4}}{1-a} - 1\right) x^5 - 3x + \log 5$ *monotonically decreases for all x.*

Sol. Given, $f(x) = \left(\frac{\sqrt{a+4}}{1-a} - 1\right) x^5 - 3x + \log 5$ decreases for all x.

Then, $f'(x) = \left(\frac{\sqrt{a+4}}{1-a} - 1\right) 5x^4 - 3 < 0, \forall\ x \in R$

i.e. $5\left(\frac{\sqrt{a+4}}{1-a} - 1\right) x^4 - 3 < 0, \forall\ x \in R$

$\Rightarrow$ $\left(\frac{\sqrt{a+4}}{1-a} - 1\right) < 0, \forall\ x \in R$

[as $ax^2 + bx + c < 0 \Rightarrow a < 0$ and $D < 0$] ...(i)

Now, two cases arise

Case **I** If $1 - a < 0 \Rightarrow a > 1$,

then $\sqrt{a+4} > (1 - a)$ and $a + 4 > 0$

Which is always true as LHS > 0 and RHS < 0

$\therefore$ Above inequality is true for all $a > 1$ ...(ii)

***Case* II** If $1-a>0 \Rightarrow a<1$

$\Rightarrow \sqrt{a+4}<1-a$ and $a>-4$

$\Rightarrow a^2-3a-3>0$ and $a>-4$

$\Rightarrow a<\frac{3-\sqrt{21}}{2}$

or $a>\frac{3+\sqrt{21}}{2}$ and $a>-4$

$\Rightarrow -4<a<\frac{3-\sqrt{21}}{2}$ ...(iii)

From Eqs. (ii) and (iii), we conclude

$$a\in\left(-4,\frac{3-\sqrt{21}}{2}\right)\cup(1,\infty)$$

● ***Ex. 111*** *Let $a+b=4$, where $a<2$ and let $g(x)$ be a differentiable function. If $\frac{dg}{dx}>0, \forall\ x$ prove that $\int_0^b g(x)\,dx+\int_0^a g(x)\,dx$ increases as $(b-a)$ increases.*

[IIT JEE 1997]

Sol. Let $(b-a)=t$ and since $a+b=4$, we have $a=\frac{4-t}{2}$

and $b=\frac{t+4}{2}$ ...(i)

where $t>0$ (as $a<2$ and $b>2$)

Let $\int_0^a g(x)\,dx+\int_0^b g(x)\,dx=\phi(t)$

$\Rightarrow \phi(t)=\int_0^{\frac{4-t}{2}} g(x)\,dx+\int_0^{\frac{4+t}{2}} g(x)\,dx$

$\therefore \phi'(t)=g\left(\frac{4-t}{2}\right).\left(\frac{-1}{2}\right)+g\left(\frac{4+t}{2}\right)\left(\frac{1}{2}\right)$

[using Leibnitz rule]

$\Rightarrow \phi'(t)=\frac{1}{2}\left[g\left(\frac{4+t}{2}\right)-g\left(\frac{4-t}{2}\right)\right]$ ...(ii)

Since, $g(x)$ is increasing and we know

$x_1>x_2$

$\Rightarrow g(x_1)>g(x_2)\quad\left[\because \frac{dg}{dx}>0\right]$

Here, $\frac{4+t}{2}>\frac{4-t}{2}$ and $g(x)$ is increasing.

$\therefore g\left(\frac{4+t}{2}\right)>g\left(\frac{4-t}{2}\right)$ ...(iii)

Then, $\phi'(t)=\frac{1}{2}\left[g\left(\frac{4+t}{2}\right)-g\left(\frac{4-t}{2}\right)\right]>0$ [using Eq. (iii)]

$\Rightarrow \phi'(t)>0$

Hence, $\phi(t)$ increases as t increases.

or $\int_0^a g(x)\,dx+\int_0^b g(x)\,dx$ is increasing as $(b-a)$ increases.

● ***Ex. 112*** *Let $g(x)=2f\left(\frac{x}{2}\right)+f(2-x)$ and $f''(x)<0$, $\forall\ x\in(0,2)$. Find the intervals of increase and decrease of $g(x)$.*

Sol. We have, $g(x)=2f\left(\frac{x}{2}\right)+f(2-x)$

$\Rightarrow g'(x)=2f'\left(\frac{x}{2}\right)\cdot\left(\frac{1}{2}\right)+f'(2-x)\cdot(-1)$

$\Rightarrow g'(x)=f'\left(\frac{x}{2}\right)-f'(2-x)$ ...(i)

We are given that $f''(x)<0, \forall\ x\in(0,2)$

It means that $f'(x)$ would be decreasing on $(0, 2)$.

Now, two cases arise

***Case* I** $\frac{x}{2}>(2-x)$ and $f'(x)$ is decreasing.

$\Rightarrow f'\left(\frac{x}{2}\right)<f'(2-x), \forall\ x>\frac{4}{3}$

$\left[\text{As } \frac{x}{2}>2-x\Rightarrow x>\frac{4}{3}\right]$

or $g'(x)=f'\left(\frac{x}{2}\right)-f'(2-x)<0, \forall\ \frac{4}{3}<x<2$

$\therefore$ $g(x)$ is decreasing in $\left(\frac{4}{3},2\right)$. ...(ii)

***Case* II** $\frac{x}{2}<(2-x)$ and $f'(x)$ is decreasing.

$\Rightarrow f\left(\frac{x}{2}\right)>f(2-x), \forall\ x<\frac{4}{3}\quad\left[\text{As } \frac{x}{2}<2-x\Rightarrow x<\frac{4}{3}\right]$

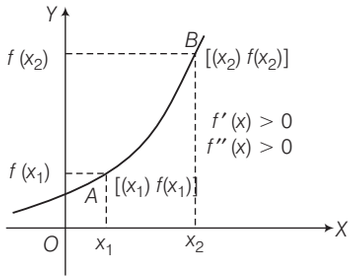
or $g'(x)=f\left(\frac{x}{2}\right)-f(2-x)>0, \forall\ 0<x<\frac{4}{3}$

$\therefore$ $g(x)$ is increasing in $\left(0,\frac{4}{3}\right)$. ...(iii)

From Eqs. (ii) and (iii), we conclude $g(x)$ is increasing in $\left(0,\frac{4}{3}\right)$ and decreasing in $\left(\frac{4}{3},2\right)$.

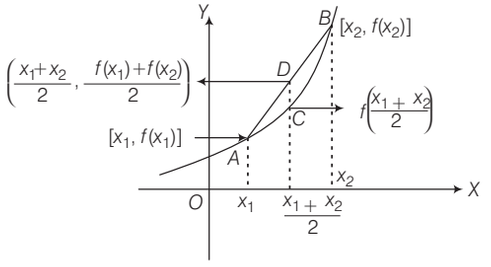
● ***Ex. 113*** *Let $f'(x) > 0$ and $f''(x) > 0$ where $x_1 < x_2$. Then, show $f\left(\frac{x_1 + x_2}{2}\right) < \frac{f(x_1) + f(x_2)}{2}$.*

Sol. As we have discussed in theory, if $f'(x) > 0$ and $f''(x) > 0$, then graphically it can be expressed as shown in the following figure



We know, $x_1 < \frac{x_1 + x_2}{2} < x_2$

and $\left(\frac{x_1 + x_2}{2}, \frac{f(x_1) + f(x_2)}{2}\right)$ is mid-point of the chord joining A and B.

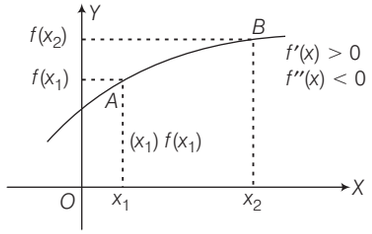


Thus, it can be expressed, from the figure as

$$f\left(\frac{x_1 + x_2}{2}\right) < \frac{f(x_1) + f(x_2)}{2}$$

● ***Ex. 114*** *Let $f'(x) > 0$ and $f''(x) < 0$ where $x_1 < x_2$. Then, show $f\left(\frac{x_1 + x_2}{2}\right) > \frac{f(x_1) + f(x_2)}{2}$.*

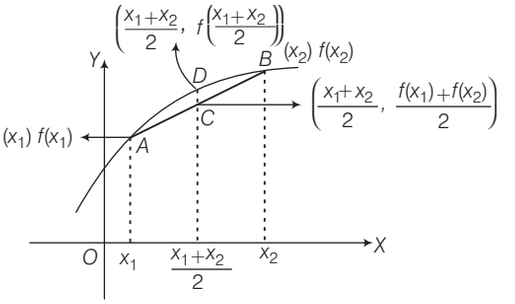
Sol. As we know, if $f'(x) > 0$ and $f''(x) < 0$. Then, it could be expressed graphically as shown in the following figure



We know, $x_1 < \frac{x_1 + x_2}{2} < x_2$

and $\left(\frac{x_1 + x_2}{2}, \frac{f(x_1) + f(x_2)}{2}\right)$ is the mid-point of chord joining A and B.

Thus, it can be expressed as shown in figure



From the adjacent figure, $f\left(\frac{x_1 + x_2}{2}\right) > \frac{f(x_1) + f(x_2)}{2}$.

● ***Ex. 115*** *If $f(x)$ is monotonically increasing function for all $x \in R$, such that $f''(x) > 0$ and $f^{-1}(x)$ exists, then prove that $\frac{f^{-1}(x_1) + f^{-1}(x_2) + f^{-1}(x_3)}{3} < f^{-1}\left(\frac{x_1 + x_2 + x_3}{3}\right)$*

Sol. Let $g(x) = f^{-1}(x)$

Since, g is the inverse of f.

$\Rightarrow \quad fog(x) = gof(x) = x \Rightarrow g'(x) = \frac{1}{f'(g(x))}$

$\Rightarrow \quad g'(x) > 0$ [as $f(x)$ is increasing] ...(i)

$\Rightarrow$ $g(x)$ is increasing for all $x \in R$.

$\Rightarrow$ $f^{-1}(x)$ is increasing for all $x \in R$.

Again, $g'(x) = \frac{1}{f'(g(x))}$

$\Rightarrow \quad g''(x) = -\frac{1}{(f'(g(x)))^2} f''(g(x))\, g'(x)$, for all $x \in R$

$\Rightarrow \quad g''(x) < 0$,

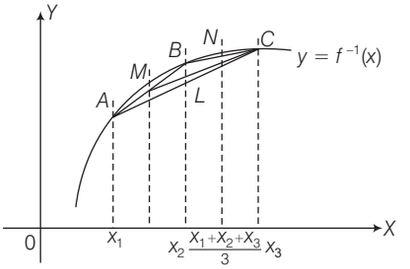
{as $g'(x) > 0$, from relation

(i) $f''(x) > 0$, given

$\Rightarrow$ $g'(x)$ is decreasing for all $x \in R$.

$\Rightarrow$ $f^{-1}(x)$ is increasing and $\frac{d}{dx}\{f^{-1}(x)\}$ is decreasing.

Thus, the graph for $f^{-1}(x)$ could be plotted as



In above figure, we have taken three points A, B, C as; $A\,(x_1, f^{-1}(x_1))$, $B\,(x_2, f^{-1}(x_2))$, $C\,(x_3, f^{-1}(x_3))$.

Also, M is the mid-point of AB as

$$\left(\frac{x_1+x_2}{2}, \frac{f^{-1}(x_1)+f^{-1}(x_2)}{2}\right)$$

and L as the centroid of ΔABC,

i.e. $$L=\left(\frac{x_1+x_2+x_3}{3}, \frac{f^{-1}(x_1)+f^{-1}(x_2)+f^{-1}(x_3)}{3}\right)$$

Correspondingly a point N lies on the curve;

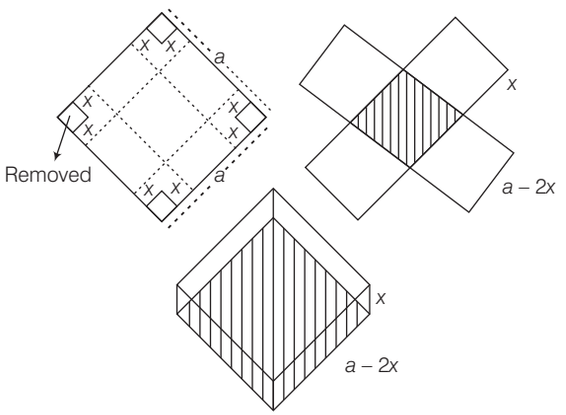
$$N=\left(\frac{x_1+x_2+x_3}{3}, f^{-1}\left(\frac{x_1+x_2+x_3}{3}\right)\right)$$

Also, from above figure it is clear that ordinate of $N >$ ordinate of L

$$\Rightarrow\quad f^{-1}\left(\frac{x_1+x_2+x_3}{3}\right) > \frac{f^{-1}(x_1)+f^{-1}(x_2)+f^{-1}(x_3)}{3}$$

● ***Ex. 116*** *A box of maximum volume with top open is to be made by cutting out four equal squares from four corners of a square tin sheet of side length a feet and then folding up the flaps. Find the side of the square cut-off.*

Sol. Volume of the box is, $V=(a-2x)^2\cdot x$ i.e. squares of side x are cut out, then we will get a box with a square base of side $(a-2x)$ and height x.



Volume of box $(V)=(2a-x)^2\cdot x$

$$\therefore\quad \frac{dV}{dx}=(a-2x)^2+x\cdot 2(a-2x)\cdot(-2)=(a-2x)(a-6x)$$

For V to be extremum, $\dfrac{dV}{dx}=0$

$$\Rightarrow\quad x=a/2, a/6$$

But when $x=a/2$; $V=0$ (minimum) and we know minimum and maximum occurs simultaneously in a continuous function.

Hence, V is maximum when $x=a/6$.

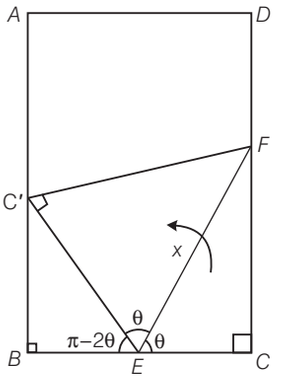
● ***Ex. 117*** *One corner of a long rectangular sheet of paper of width* 1 *unit is folded over so as to reach the opposite edge of the sheet. Find the minimum length of the crease.*

Sol. Let $ABCD$ be the rectangular sheet whose corner C is folded over along EF so as to reach the edge AB at C'.

Let $EF=x$

$$\angle FEC=\theta=\angle FEC'$$

$$\therefore\quad EC=x\cos\theta=EC'$$



From $\Delta BEC'$, we have $BE=C'E\cos(\pi-2\theta)$

$$\Rightarrow\quad BE=-x\cos\theta\cdot\cos 2\theta$$

$$\therefore\quad BC=BE+EC$$

$$1=-x\cos\theta\cos 2\theta+x\cos\theta$$

$$\Rightarrow\quad x=\frac{1}{\cos\theta(1-\cos 2\theta)} \qquad ...(i)$$

Let $Z=\cos\theta(1-\cos 2\theta)\,x$ to be minimum, Z has to be maximum.

$$Z=\cos\theta(1-\cos 2\theta) \qquad ...(ii)$$

Differentiating Eq. (ii) w.r.t. θ, we get

$$\frac{dZ}{d\theta}=\cos\theta(0+2\sin 2\theta)-\sin\theta(1-\cos 2\theta)$$

and $$\frac{d^2Z}{d\theta^2}=\cos\theta(4\cos 4\theta)-2\sin 2\theta\cdot\sin\theta$$

$$-\sin\theta(2\sin 2\theta)-\cos\theta(1-\cos 2\theta)$$

For maximum/minimum,

$$\frac{dZ}{d\theta}=0$$

$$\Rightarrow\quad 2\sin\theta(2-3\sin^2\theta)=0$$

$$\therefore\quad \sin\theta=+\sqrt{2/3} \qquad [\because \sin\theta\neq 0]$$

When $\sin\theta=\sqrt{\dfrac{2}{3}}$

$$\Rightarrow\quad \frac{d^2Z}{d\theta^2}=-\frac{5}{5\sqrt{3}}-\frac{16}{3\sqrt{3}}-\frac{1}{\sqrt{3}}=-\frac{8}{\sqrt{3}}<0$$

Hence, Z is maximum.

$\Rightarrow$ $x = \dfrac{1}{Z}$ is minimum [from Eq. (i)]

$\therefore$ x is minimum.

$\Rightarrow$ $x_{\min} \Rightarrow \dfrac{1}{Z} = \dfrac{1}{(1/\sqrt{3})\left(1+\dfrac{1}{3}\right)} = \dfrac{3\sqrt{3}}{4}$ unit

● ***Ex. 118*** *Find the volume of the greatest right circular cone that can be described by the revolution about a side of a right angled triangle of hypotenuse* 1 *ft.*

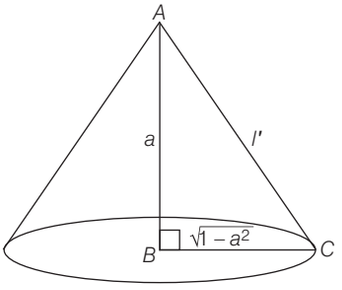
Sol. Let ABC be right angled triangle .

Let the cone be revolved about AB.

$AC = 1$ ft [given]

Let $AB = a$ = height of cone

$\therefore$ $BC = \sqrt{1-a^2}$ = radius of cone



Volume of cone $= \dfrac{1}{3}\pi(1-a^2)a$

$$V = \frac{1}{3}\pi(a - a^3)$$

$\Rightarrow$ $\dfrac{dV}{da} = \dfrac{1}{3}\pi(1-3a^2)$

and $\dfrac{d^2V}{da^2} = \dfrac{1}{3}\pi(-6a) < 0$

$\therefore$ Maximum volume when $\dfrac{dV}{da} = 0$

i.e. when $a = \dfrac{1}{\sqrt{3}}$

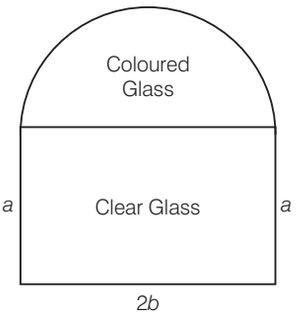
Putting $a = \dfrac{1}{\sqrt{3}}$, we get $V_{\max} = \dfrac{2\sqrt{3}}{27}\pi$ cu ft

● ***Ex. 119*** *A window of fixed perimeter (including the base of the arc) is in the form of a rectangle surmounted by a semi-circle. The semi-circular portion is fitted with coloured glass while the rectangular portion is fitted with clear glass. The clear glass transmits three times as much light per square metre as the coloured glass does. What is the ratio of the sides of the rectangle so that the window transmits the maximum light?* ***[IIT JEE 1991]***

Sol. Let $2b$ be the diameter of the circular portion and a be the lengths of the other side of the rectangle.

Total perimeter $= 2a + 4b + \pi b = K$ [say]...(i)

Now, let the light transmission rate (per square metre) of the coloured glass be L and Q be the total amount of transmitted light.



Then, $Q = 2ab\cdot(3L) + \dfrac{1}{2}\pi b^2\cdot(L)$

$$Q = \frac{L}{2}[\pi b^2 + 12ab]$$

$$Q = \frac{L}{2}[\pi b^2 + 6b(K - 4b - \pi b)]$$

$$Q = \frac{L}{2}[6Kb - 24b^2 - 5\pi b^2]$$

$\therefore$ $\dfrac{dQ}{db} = \dfrac{L}{2}[6K - 48b - 10\pi b] = 0$

$$b = \frac{6K}{48 + 10\pi} \quad \text{...(ii)}$$

and $\dfrac{d^2Q}{db^2} = \dfrac{L}{2}[-48 - 10\pi] < 0$

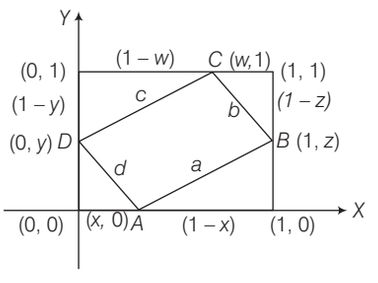
Thus, Q is maximum and from Eqs. (i) and (ii)

$$(48 + 10\pi)\, b = 6K = 6\{2a + 4b + \pi b\}$$

Thus, the ratio $= \dfrac{2b}{a} = \dfrac{6}{6+\pi}$

● ***Ex. 120*** *Let S be a square of unit area. Consider any quadrilateral which has one vertex on each side of S. If a, b, c and d denote the lengths of the sides of the quadrilateral, prove that* $2 \le a^2 + b^2 + c^2 + d^2 \le 4$ ***[IIT JEE 1997]***

Sol. Let S be the square of unit area and $ABCD$ be the quadrilateral of sides a, b, c and d.



Here, $a^2 = (1-x^2) + z^2,\ b^2 = w^2 + (1-z)^2$

$c^2 = (1-w^2) + (1-y)^2, d^2 = x^2 + y^2$

Adding all the above, $a^2 + b^2 + c^2 + d^2$

$= \{x^2 + (1-x)^2\} + \{y^2 + (1-y)^2\} + \{z^2 + (1-z)^2\}$

$+ \{w^2 + (1-w)^2\}$

where $0 \le x, y, z, w \le 1$

Let us consider a function,

$$f(x) = x^2 + (1-x)^2, 0 \le x \le 1$$

Then, $f'(x) = 2x - 2(1-x)$

Let $f'(x) = 0$ for maximum/minimum.

$\Rightarrow \quad 4x - 2 = 0 \Rightarrow x = 1/2$

Again, $f''(x) = 4 > 0$ when $x = 1/2$

$\therefore$ $f(x)$ is minimum at $x = 1/2$ and maximum at $x = 1$

$\Rightarrow \quad 2 \le a^2 + b^2 + c^2 + d^2 \le 4$

● ***Ex. 121*** *Show that a triangle of maximum area that can be inscribed in a circle of radius a is an equilateral triangle.*

Sol. Let BC be one of the sides of the triangle and the third vertex A should be in a position that the altitude AD is maximum (for area of the triangle to be maximum).

For that the ΔABC must be symmetric about AD.

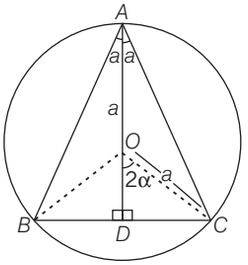
i.e. D should be the mid-point of BC.

Let $\angle A = 2\alpha$

$\therefore \quad \angle BOD = \angle COD = 2\alpha$

Thus, $AD = AO + OD = a + a\cos 2\alpha$

and $CD = a \sin 2\alpha$



Hence, area of $\Delta ABC = A = \frac{1}{2} \cdot AD \cdot BC$

Area, $A = \frac{1}{2} \cdot a(1 + \cos 2\alpha) \cdot a \sin 2\alpha$

$$A = \frac{a^2}{2}(\sin 2\alpha + \frac{1}{2}\sin 4\alpha)$$

Differentiating w.r.t. α, we get

$$\frac{dA}{d\alpha} = \frac{a^2}{2}[2\cos 2\alpha + 2\cos 4\alpha] = 0$$

$\therefore \quad 2a^2 \cos 3\alpha \cdot \cos \alpha = 0$

$\Rightarrow$ Either $\cos 3\alpha = 0$ or $\cos \alpha = 0$

$\Rightarrow \quad \alpha = \pi/6, \pi/2$

But $\alpha = \pi/2$ is not possible.

Now, $\frac{d^2A}{d\alpha^2} = 2a^2[-\sin 2\alpha - 4\sin 4\alpha] = -\text{ve at } \alpha = \pi/6$

$\therefore$ A is maximum when $\alpha = \pi/6$.

Also, $\angle A = \pi/3$ and triangle is isosceles.

Hence, ΔABC must be equilateral.

● ***Ex. 122*** *Show that the height of the cylinder of maximum volume that can be inscribed in a sphere of radius a is $2a/\sqrt{3}$.*

Sol. Let h be the height and r be the radius of the cylinder. Let O be the centre of the sphere.

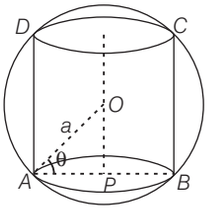
From the figure,

$$OA^2 = OP^2 + PA^2$$

i.e. $$a^2 = \frac{h^2}{4} + r^2 \qquad \text{...(i)}$$

Now, volume of the cylinder,

$$V = \pi r^2 h = \pi h\left(a^2 - \frac{h^2}{4}\right) \qquad \text{[using Eq. (i)]}$$



Differentiating w.r.t. h, we have

$$\frac{dV}{dh} = \pi\left[a^2 - \frac{3h^2}{4}\right] = 0 \text{ for extremum}$$

$\Rightarrow \quad h = \frac{2a}{\sqrt{3}}$

Also, $\frac{d^2V}{dh^2} = -\frac{3\pi}{2}h < 0$

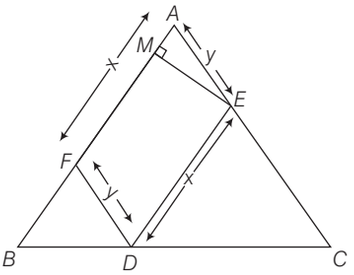
at $h = \frac{2a}{\sqrt{3}}$

Thus, volume is maximum when $h = \frac{2a}{\sqrt{3}}$.

● ***Ex. 123*** *Let $A(p^2, p), B(q^2, -q)$ and $C(r^2, -r)$ be the vertices of the ΔABC. A parallelogram AFDE is drawn with vertices D, E, F on the line segments BC, CA and AB, respectively. Show that maximum area of such a parallelogram is $\frac{1}{4}(p-q)(q-r)(r-p)$.*

Sol. Let $AF = x = DE$ and $AE = y = DF$

Since, $\Delta's$ CAB and CED are similar.



We have, $\frac{CE}{CA} = \frac{DE}{AB}$ [as shown in figure]

$\Rightarrow$ $\frac{b-y}{b} = \frac{x}{c}$

[here, $BC = a$, $AC = b$ and $AB = c$] ...(i)

Now, area of parallelogram,

$$S = AF \cdot EM = xy \sin A$$

$$S = x \cdot b\left(1 - \frac{x}{c}\right)\sin A \quad \text{[from Eq. (i)]} \ldots(ii)$$

Differentiating w.r.t. x, we have

$$\frac{dS}{dx} = \frac{b}{c}(c - 2x)\sin A \quad [\text{where } \sin A \text{ is constant}]$$

For extremum, $\frac{dS}{dx} = 0$

$\Rightarrow$ $x = \frac{c}{2}$

Also, $\frac{d^2S}{dx^2} = -\frac{2b}{c} < 0$

at $x = \frac{c}{2}$

Hence, S is maximum when $x = \frac{c}{2}$

Now, $S_{\max} = \frac{1}{4}bc \sin A$ [from Eq. (ii)]

$$S_{\max} = \frac{1}{2}\left(\frac{1}{2}bc \sin A\right)$$

$$S_{\max} = \frac{1}{2}(\text{area of } \Delta ABC)$$

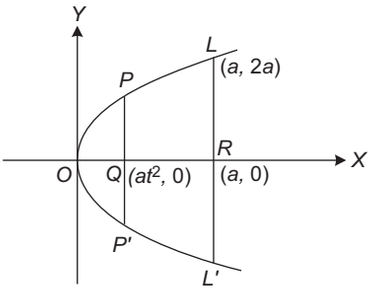
$$S_{\max} = \frac{1}{4}\begin{vmatrix} p^2 & -p & 1 \\ q^2 & -q & 1 \\ r^2 & -r & 1 \end{vmatrix}$$

$$S_{\max} = \frac{1}{4}(p-q)(q-r)(r-p)$$

● **Ex. 124** *LL' be latusrectum of the parabola $y^2 = 4ax$ and PP' is a double ordinate between the vertex and the latusrectum. Show that the area of trapezium $PP'L'L$ is maximum when the distance of PP' from the vertex is $\frac{a}{9}$.*

Sol. Let the double ordinate PP' be drawn at a distance $x = at^2$ from the origin. (vertex).

Thus, the coordinate of P is $(at^2, 2at)$ as shown in figure



Hence, the area of trapezium is,

$$A = \frac{1}{2}(PP' + LL') \cdot QR$$

$$= \frac{1}{2}(4at + 4a) \cdot (a - at^2)$$

$$A = 2a^2(t+1)(1-t^2)$$

$\therefore$ $\frac{dA}{dt} = 2a^2(t+1)(1-3t) = 0$ [for extremum]

$\Rightarrow$ $t = -1, 1/3$

Also, $\frac{d^2A}{dt^2} = 2a^2(-6t - 2)$

Thus, A is maximum when $t = 1/3$ as $\frac{d^2A}{dt^2} < 0$

Hence, $x = at^2 = \frac{a}{9}$ is the point at which area of trapezium is maximum.

● **Ex. 125** *The circle $x^2 + y^2 = 1$ intersects the X-axis at P and Q. Another circle with centre at Q and variable radius intersects the first circle at R, above the X-axis and the line segment PQ at S. Find the maximum area of the ΔQSR.*

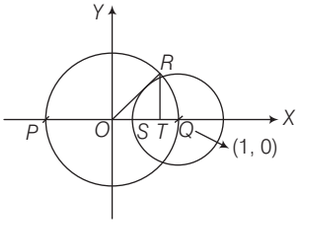
[IIT JEE 1994]

Sol. The centre of the circle

$$x^2 + y^2 = 1 \quad \ldots(i)$$

is (0, 0) and radius $OP = 1 = OQ$

So, coordinates of Q are (1,0).



Let the radius of the variable circle be r.

Hence, its equation is

$$(x-1)^2 + (y)^2 = r^2 \quad \ldots(ii)$$

Subtracting Eq. (ii) from Eq. (i), we get

$$2x - 1 = 1 - r^2$$

$$x = 1 - \frac{r^2}{2} = OT \quad \text{...(iii)}$$

Now, $RT = \sqrt{OR^2 - OT^2} = \sqrt{1 - \left(1 - \frac{r^2}{2}\right)^2} = \sqrt{r^2 - \frac{r^4}{4}}$ ...(iv)

Now, the area of ΔQSR is, $A = \frac{1}{2} \cdot QS \cdot RT$

$$\therefore \quad A^2 = \frac{1}{4}(QS^2) \cdot (RT^2)$$

$$\Rightarrow \quad A^2 = \frac{1}{4} r^2 \left(r^2 - \frac{r^4}{4}\right)$$

[using Eqs. (ii) and (iv)]

$$\Rightarrow \quad A^2 = \frac{1}{16}(4r^4 - r^6) = f(r) \quad \text{(say)}$$

Thus, $$\frac{df(r)}{dr} = \frac{1}{16}(16r^3 - 6r^5) = 0$$

[for extremum]

$$\Rightarrow \quad r = 2\sqrt{\frac{2}{3}}$$

Also, $$\frac{d^2 f(r)}{dr^2} = \frac{1}{16}(48r^2 - 30r^4) = -\frac{16}{3} < 0$$

where $$r = 2\sqrt{\frac{2}{3}}$$

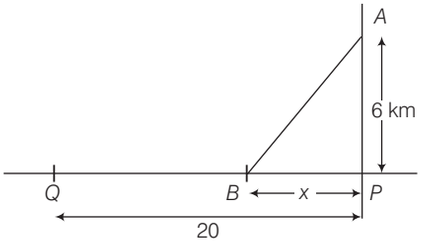
Hence, area is maximum at $r = 2\sqrt{\frac{2}{3}}$ and $A_{\max} = \frac{4}{3\sqrt{3}}$ sq unit.

● ***Ex. 126*** *A despatch rider is in open country at a distance of 6 km from the nearest point P of a straight road. He wishes to proceed as quickly as possible to a point Q on the road 20 km from P. If his maximum speed across country is 40 km/h, 50 km/h on road, then at what distance from P, he should touch the road.*

Sol. Let A be the initial position of rider.

Then, $PB = x \Rightarrow QB = 20 - x$

and $AB = \sqrt{AP^2 + BP^2} = \sqrt{6^2 + x^2}$ km



$\therefore$ Total time T,

$$T = \frac{\sqrt{x^2 + 36}}{40} + \frac{20 - x}{50}$$

$$\Rightarrow \quad \frac{dT}{dx} = \frac{1}{40} \cdot \frac{(2x)}{2\sqrt{x^2 + 36}} - \frac{1}{50}$$

For maximum and minimum value, we must have

$$\frac{dT}{dx} = 0$$

$$\Rightarrow \quad \frac{x}{40\sqrt{x^2 + 36}} = \frac{1}{50}$$

or $$\frac{5x}{4} = \sqrt{x^2 + 36}$$

or $$\frac{25x^2}{16} - x^2 = 36$$

$$\Rightarrow \quad x^2 = \frac{36 \times 16}{9}$$

$$\Rightarrow \quad x = \frac{6 \times 4}{3} = 8 \text{ km}$$

● ***Ex. 127*** *From point A located on a highway a boy has to get his bus to his school B located in the field at a distance l from the highway in the least possible time. At what distance from D should the bus leave the highway when the bus moves n times slower in the field than on the highway?*

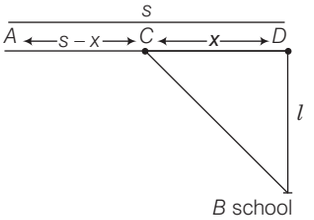
Sol. Let $AD = s$ and $CD = x$, where C is a point where the bus leaves the highway.

Also, let the speed of the bus is 'v' on the highway.

$\therefore$ Total time taken,

$$t = \frac{AC}{v} + \frac{BC}{(v/n)}$$

$$\Rightarrow \quad t = \frac{s - x}{v} + \frac{n\sqrt{l^2 + x^2}}{v}$$



Differentiating w.r.t. x, we have

$$\frac{dt}{dx} = \frac{1}{v}\left[-1 + \frac{n}{2\sqrt{l^2 + x^2}}(+2x)\right] = 0 \quad \text{[for extremum]}$$

$$\Rightarrow \quad n^2 x^2 = l^2 + x^2$$

$$\Rightarrow \quad x = \frac{l}{\sqrt{n^2 - 1}}$$

Thus, 't' is minimum when $x = \frac{l}{\sqrt{n^2 - 1}}$, as shown in figure.

● ***Ex. 128*** *Two men are walking on a path $x^3 + y^3 = a^3$ when the first man arrives at a point (x_1, y_1), he finds the second man in the direction of his own instantaneous motion. If the coordinates of the second man are (x_2, y_2), then show that*

$$\frac{x_2}{x_1} + \frac{y_2}{y_1} + 1 = 0.$$

Sol. Since, (x_1, y_1) and (x_2, y_2) lies on the curve.

$\therefore$ $x_1^3 + y_1^3 = a^3$ ...(i)

and $x_2^3 + y_2^3 = a^3$ ...(ii)

Subtracting Eqs. (i) from (ii), we get

$$(x_2^3 - x_1^3) + (y_2^3 - y_1^3) = 0$$

or $x_2^3 - x_1^3 = -(y_2^3 - y_1^3)$ ...(iii)

Now, differentiating both sides of $x^3 + y^3 = a^3$ w.r.t. x, we get

$$3x^2 + 3y^2 \frac{dy}{dx} = 0$$

Slope of tangent at $(x_1, y_1) = -\frac{x_1^2}{y_1^2}$

$\therefore$ The equation of tangent at (x_1, y_1)

$$y - y_1 = -\frac{x_1^2}{y_1^2}(x - x_1)$$

It passes through (x_2, y_2).

$\therefore$ $y_2 - y_1 = \frac{-x_1^2}{y_1^2}(x_2 - x_1)$

or $x_1^2(x_2 - x_1) = -y_1^2(y_2 - y_1)$ ...(iv)

Dividing Eq. (iii) by Eq. (iv), we get

$$\frac{x_2^3 - x_1^3}{x_1^2(x_2 - x_1)} = \frac{-(y_2^3 - y_1^3)}{-y_1^2(y_2 - y_1)}$$

$$\Rightarrow \quad \frac{x_2^2 + x_1^2 + x_1x_2}{x_1^2} = \frac{y_2^2 + y_1^2 + y_1y_2}{y_1^2}$$

$$\Rightarrow \quad \left(\frac{x_2}{x_1}\right)^2 + \left(\frac{x_2}{x_1}\right) + 1 = \left(\frac{y_2}{y_1}\right)^2 + \left(\frac{y_2}{y_1}\right) + 1$$

$$\Rightarrow \quad \left(\frac{x_2}{x_1}\right)^2 - \left(\frac{y_2}{y_1}\right)^2 = \left(\frac{y_2}{y_1}\right) - \left(\frac{x_2}{x_1}\right)$$

$$\Rightarrow \quad \left(\frac{x_2}{x_1} - \frac{y_2}{y_1}\right) \cdot \left(\frac{x_2}{x_1} + \frac{y_2}{y_1}\right) + \left(\frac{x_2}{x_1} - \frac{y_2}{y_1}\right) = 0$$

$$\Rightarrow \quad \left(\frac{x_2}{x_1} - \frac{y_2}{y_1}\right) \cdot \left(\frac{x_2}{x_1} + \frac{y_2}{y_1} + 1\right) = 0$$

i.e. either $\frac{x_2}{x_1} = \frac{y_2}{y_1}$

or $\frac{x_2}{x_1} + \frac{y_2}{y_1} + 1 = 0$

But, $\frac{x_2}{x_1} \neq \frac{y_2}{y_1}$

$\therefore$ $\frac{x_2}{x_1} + \frac{y_2}{y_1} + 1 = 0$

● ***Ex. 129*** *In still water a boat moves with a velocity which is K times less than velocity the river has current. At what angle to the stream direction must the boat move to minimize drifting.*

Sol. Let the flow velocity of river be u and the velocity of boat in still water be v.

Thus, $v = u/K$

Also, let the boat moves at an angle θ with direction of stream.

Now, the velocity of boat in the river is vector resultant of the velocity of boat and velocity of following water or water current, which can be written as,

$$\bar{v}_B = (u - v\cos\alpha)\hat{\mathbf{i}} + (u\sin\alpha)\hat{\mathbf{j}} = (u + v\cos\theta)\hat{\mathbf{i}} + (u\sin\theta)\hat{\mathbf{j}}$$

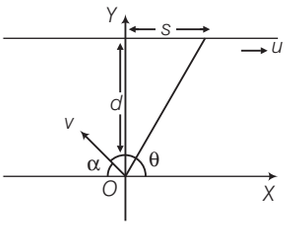
Hence, the time taken to cross the river

$$= \frac{d}{u\sin\theta} \qquad [\text{where, } d = \text{width of river}]$$

Thus, the drift $s = (u + v\cos\theta)\cdot d$

$$\Rightarrow \quad s = d\left(\operatorname{cosec}\theta + \frac{v}{u}\cot\theta\right)$$

$$\Rightarrow \quad \frac{ds}{d\theta} = d\left(-\operatorname{cosec}\theta\cot\theta - \frac{v}{u}\operatorname{cosec}^2\theta\right) = 0$$



$$\Rightarrow \quad -\frac{v}{u}\operatorname{cosec}^2\theta = \operatorname{cosec}\theta\cot\theta$$

$$\Rightarrow \quad \operatorname{cosec}\theta = -1/K$$

$$\Rightarrow \quad \theta = \cos^{-1}(-1/K)$$

● ***Ex. 130*** *Consider a square with vertices at* (1, 1) (−1, 1) (−1, −1) *and* (1, −1). *Let S be the region consisting of all points inside the square which are nearer to the origin than to any edge. Sketch the region S and find its area.* ***[IIT JEE 1995]***

Sol. Let the square $ABCD$ and the equations of the sides of the square are as follows

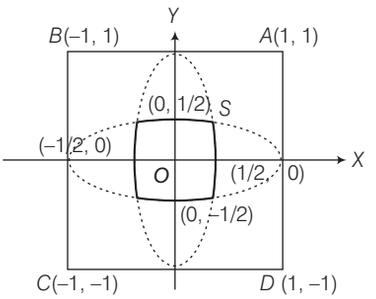
$AB : y = 1, \quad BC : x = -1, \quad CD : y = -1, \quad DA : x = 1$

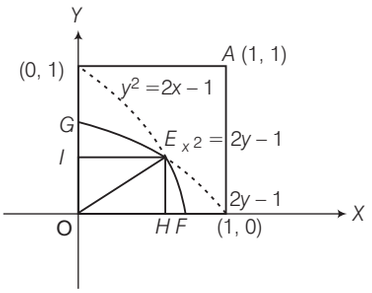
Let the region be S and (x, y) is any point inside it. Then, according to given conditions,

$$\sqrt{x^2+y^2} < |1-x|, |1+x|, |1-y|, |1+y|$$

$$\Rightarrow (x^2+y^2) < x^2-2x+1, x^2+2x+1, y^2-2y+1, y^2+2y+1$$

$$\Rightarrow y^2 < 1-2x, y^2 < 1+2x, x^2 < 1-2y \text{ and } x^2 < 2y+1$$





Now, in $y^2 = 1-2x$ and $y^2 = 2x+1$, the first equation represents a parabola with vertex $(1/2,0)$ and second equation represents a parabola with vertex $(-1/2, 0)$ and in $x^2 = 1-2y$ and $x^2 = 1+2y$, the first equation represents parabola with vertex at $(0, 1/2)$ and second equation represents a parabola with vertex at $(0,-1/2)$.

So, the region S is the region lying inside the four parabolas.

$$y^2 = 1-2x$$
$$y^2 = 1+2x$$
$$x^2 = 1-2y$$
$$x^2 = 1+2y$$

Now, S is symmetrical in all four quadrants.

$\therefore$ $S = 4 \times$ area lying in first quadrant.

Now, $y^2 = 1-2x$

and $x^2 = 1-2y$ intersect on $y = x$

The point of intersection is $E(\sqrt{2}-1, \sqrt{2}-1)$.

$\therefore$ Area of region $OEFO$ = Area of ΔOEH + Area of region $HEFH$

$$= \frac{1}{2}(\sqrt{2}-1)^2 + \int_{\sqrt{2}-1}^{1/2} \sqrt{1-2x}\, dx$$

$$= \frac{1}{2}(2+1-2\sqrt{2}) + \frac{2}{3}[(1-2x)^{3/2}]_{\sqrt{2}-1}^{1/2}$$

$$= \frac{1}{2}(3-2\sqrt{2}) + \frac{1}{3}(3-2\sqrt{2})^{3/2}$$

$$= \frac{1}{2}(3-2\sqrt{2}) + \frac{1}{3}(\sqrt{2}-1)^3$$

$$= \frac{1}{2}(3-2\sqrt{2}) + \frac{1}{3}(5\sqrt{2}-7) = \frac{1}{6}[4\sqrt{2}-5]$$

Similarly, area of region $OEGO = \frac{1}{6}(4\sqrt{2}-5)$

So, area of S lying in first quadrant $= \frac{2}{6}(4\sqrt{2}-5)$

Hence, $S = \frac{4}{3}(4\sqrt{2}-5)$

● ***Ex. 131*** *If x is increasing at the rate of 2 cm/s at the instant when $x = 3$ cm and $y = 1$ cm, at what rate y must be changing in order that the quantity $(2xy - 3x^2y)$ shall be neither increasing nor decreasing.*

If $S = \{(a, b) \in R \times R : x = a, y = b, 2xy - 3x^2y = \text{constant} \Rightarrow \frac{dy}{dx} > 0\}$

$S' = \{(x, y) \in A \times B : -1 \le A \le 1$ and $-1 \le B \le 1\}$, then find the area $S \cap S'$.

Sol. Here, $x = 3$ cm, $y = 1$ cm and $\frac{dx}{dt} = 2$ cm/s

Let $f = 2xy - 3x^2y$

$$\Rightarrow \frac{df}{dt} = 2y\frac{dx}{dt} + 2x\frac{dy}{dt} - 3x^2\frac{dy}{dt} - 6xy\frac{dx}{dt}$$

$$= (2x-3x^2)\frac{dy}{dx} + (2y-6xy)\frac{dx}{dt} \quad \ldots(i)$$

$\because f$ is neither increasing nor decreasing.

$$\therefore \left(\frac{df}{dt}\right)_{(3,1)} = 0$$

$$\Rightarrow (2\times 3 - 27)\frac{dy}{dt} + (2-18)2 = 0$$

$$\Rightarrow dy/dt = -32/21$$

Now, for S, f = constant

$$\Rightarrow 0 = (2x-3x^2)\frac{dy}{dt} + (2y-6xy)\frac{dx}{dt}$$

$$\Rightarrow \frac{dy}{dx} = \frac{6xy-2y}{2x-3x^2}$$

$$\Rightarrow \frac{dy}{dx} > 0 \Rightarrow \frac{6xy-2y}{2x-3x^2} > 0$$

$$\Rightarrow \frac{y(3x-1)}{x(3x-2)} < 0,$$

Thus, there arise two cases

***Case* I** $y(3x-1) > 0$ and $x(3x-2) < 0$

$\Rightarrow$ $(y > 0$ and $x > 1/3)$ or $(y < 0$ and $x < 1/3)$

and $\left(0 < x < \frac{2}{3}\right)$

$$\Rightarrow \left(y > 0 \text{ and } \frac{1}{3} < x < \frac{2}{3}\right) \text{ or } \left(y < 0 \text{ and } 0 < x < \frac{1}{3}\right)$$

***Case* II** $y(3x-1)<0$ and $x(3x-2)>0$

$\Rightarrow$ $(y>0$ and $x<1/3)$

or $(y<0$ and $x>1/3)$

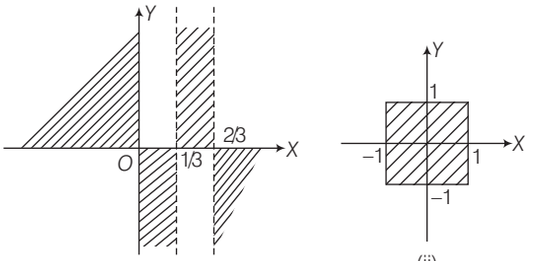
and $(x<0$ or $x>2/3)$

$\Rightarrow$ $(y>0$ and $x<0)$

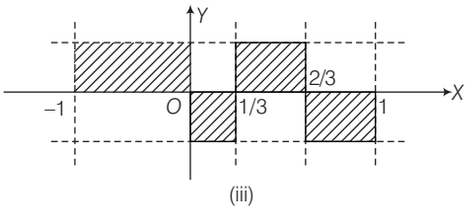
or $(y<0$ and $x>2/3)$

Thus, S is shaded portion shown in figure (i).

Also, S' represents the portion shown in figure (ii).



Thus, area for $S \cap S'$ is shown in figure (iii).



Thus, the area of $S \cap S' = 2$

● ***Ex. 132*** *In how many parts an integer $N \geq 5$ should be divide so that the product of the parts is maximized?*

Sol. Let $x_1 + x_2 + x_3 + ... + x_n = N$

$\therefore$ To maximize the value of $x_1x_2x_3 \ldots x_n$

Using AM > GM

$$\frac{x_1 + x_2 + \ldots + x_n}{n} > (x_1x_2 \ldots x_n)^{1/n}$$

$$\Rightarrow \quad x_1x_2 \ldots x_n \leq \left(\frac{x_1 + x_2 + \ldots + x_n}{n}\right)^n$$

which shows maximum value of $x_1x_2 \ldots x_n$ is obtained when $x_1 = x_2 = x_3 = \ldots = x_n$

Now, function to be maximized is $\left(\frac{x_1 + x_2 + \ldots + x_n}{n}\right)^n$ which is discrete function of n. In order to arrive at some possible neighbourhood first we make it continuous. Thus, by changing the variable n to x.

We write $f(x) = \left(\frac{N}{x}\right)^x$

For maxima $f'(x) = 0$

i.e. $\left(\frac{N}{x}\right)^x \left\{\log \frac{N}{x} - 1\right\} = 0 \Rightarrow \frac{N}{x} = e$

or $x = \frac{N}{e}$, now as $x \in$ integer

$\Rightarrow$ The nearest integer is $\left[\frac{N}{e}\right]$ or $\left[\frac{N}{e}\right] + 1$.

Monotonicity, Maxima and Minima Exercise 1 :
Single Option Correct Type Questions

1. If $f : [1, 10] \to [1, 10]$ is a non-decreasing function and $g : [1, 10] \to [1, 10]$ is a non-increasing function. Let $h(x) = f(g(x))$ with $h(1) = 1$. Then, $h(2)$
(a) lies in (1, 2) (b) is more than two
(c) is equal to one (d) is not defined

2. P is a variable point on the curve $y = f(x)$ and A is a fixed point in the plane not lying on the curve. If PA^2 is minimum, then the angle between PA and the tangent at P is
(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{3}$
(c) $\frac{\pi}{2}$ (d) None of these

3. Let $f(x) = \begin{cases} 1+\sin x, & x < 0 \\ x^2 - x + 1, & x \geq 0 \end{cases}$. Then,
(a) f has a local maximum at $x = 0$
(b) f has a local minimum at $x = 0$
(c) f is increasing everywhere
(d) f is decreasing everywhere

4. If m and n are positive integers and $f(x) = \int_1^x (t-a)^{2n}(t-b)^{2m+1}dt,\ a \neq b$, then
(a) $x = b$ is a point of local minimum
(b) $x = b$ is a point of local maximum
(c) $x = a$ is a point of local minimum
(d) $x = a$ is a point of local maximum

5. Let $f(x) = x^{n+1} + a \cdot x^n$, where a is a positive real number. Then, $x = 0$ is a point of
(a) local minimum for any integer n
(b) local maximum for any integer n
(c) local minimum if n is an even integer
(d) local minimum if n is an odd integer

6. If $f(x) = \begin{cases} 2x^2 + \frac{2}{x^2}, & 0 < |x| \leq 2 \\ 3, & x > 2 \end{cases}$, then
(a) $x = 1, -1$ are the points of global minima
(b) $x = 1, -1$ are the points of local minima
(c) $x = 0$ is the points of local minima
(d) None of the above

7. Given a function $y = x^x,\ x > 0$ and $0 < x < 1$. The values of x for which the function attain values exceeding the values of its inverse are
(a) $0 < x < 1$ (b) $1 < x < \infty$
(c) $0 < x < 2$ (d) None of these

8. $\sin x + \cos x = y^2 - y + a$ has no value of x for any y, if a belongs
(a) $(0, \sqrt{3})$ (b) $(-\sqrt{3}, 0)$
(c) $(-\infty, -\sqrt{3})$ (d) $(\sqrt{3}, \infty)$

9. If $f : R \to R$ is the function defined by $f(x) = \frac{e^{x^2} - e^{-x^2}}{e^{x^2} + e^{-x^2}}$, then
(a) $f(x)$ is an increasing function
(b) $f(x)$ is a decreasing function
(c) $f(x)$ is a onto
(d) None of the above

10. Let $f(x)$ be a quadratic expression positive for all real x. If $g(x) = f(x) - f'(x) + f''(x)$, then for any real x
(a) $g(x) > 0$ (b) $g(x) \leq 0$
(c) $g(x) \geq 0$ (d) $g(x) < 0$

11. $f(x) = \min\{1, \cos x, 1 - \sin x\},\ -\pi \leq x \leq \pi$, then
(a) $f(x)$ is differentiable at 0
(b) $f(x)$ is differentiable at $\frac{\pi}{2}$
(c) $f(x)$ has local maxima at 0
(d) None of the above

12. $f(x) = \begin{cases} 2 - |x^2 + 5x + 6|, & x \neq -2 \\ a^2 + 1, & x = -2 \end{cases}$, then the range of a, so that $f(x)$ has maxima at $x = -2$ is
(a) $|a| \geq 1$ (b) $|a| < 1$ (c) $a > 1$ (d) $a < 1$

13. Maximum number of real solution for the equation $ax^n + x^2 + bx + c = 0$, where $a,\ b,\ c \in R$ and n is an even positive number, is
(a) 2 (b) 3 (c) 4 (d) infinite

14. Maximum area of rectangle whose two sides are $x = x_0,\ x = \pi - x_0$ and which is inscribed in a region bounded by $y = \sin x$ and X-axis is obtained when $x_0 \in$
(a) $\left(\frac{\pi}{4}, \frac{\pi}{3}\right)$ (b) $\left(\frac{\pi}{6}, \frac{\pi}{4}\right)$
(c) $\left(0, \frac{\pi}{6}\right)$ (d) None of these

15. $f(x) = -1 + kx + k$ neither touches nor intersect the curve $f(x) = \ln x$, then minimum value of $k \in$
(a) $\left(\frac{1}{e}, \frac{1}{\sqrt{e}}\right)$ (b) (e, e^2)
(c) $\left(\frac{1}{\sqrt{e}}, e\right)$ (d) None of these

16. Let $f(x)$ be a polynomial with real coefficients satisfies $f(x)=f'(x)\times f'''(x)$. If $f(x)=0$ satisfies $x=1, 2, 3$ only, then the value of $f'(1)\times f'(2)\times f'(3)$ is equal to
(a) positive (b) negative
(c) 0 (d) inadequate data

17. A curve whose concavity is directly proportional to the logarithm of its x-coordinates at any of the curve, is given by
(a) $c_1\cdot x^2(2\log x-3)+c_2x+c_3$
(b) $c_1x^2(2\log x+3)+c_2x+c_3$
(c) $c_1x^2(2\log x)+c_2$
(d) None of the above

18. $f(x)=4\tan x-\tan^2 x+\tan^3 x, \forall\, x\neq n\pi+\dfrac{\pi}{2}, \forall\ n\in I$, then
(a) $f(x)$ is increasing for all $x\in R$
(b) $f(x)$ is decreasing for all $x\in R$
(c) $f(x)$ is increasing in its domain
(d) None of the above

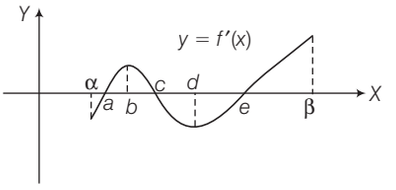
19. If $f(x)=\begin{cases}3+|x-k|, & \text{for } x\le k\\ a^2-2+\dfrac{\sin(x-k)}{x-k}, & \text{for } x>k\end{cases}$ has minimum at $x=k$, then
(a) $a\in R$ (b) $|a|<2$
(c) $|a|>2$ (d) $1<|a|<2$

20. Let f be a linear function with properties $f(1)\le f(2)$, $f(3)\ge f(4)$ and $f(5)=5$, then which of the following is true?
(a) $f(0)<0$ (b) $f(0)=0$
(c) $f(1)<f(0)<f(-1)$ (d) $f(0)=5$

21. If $P(x)$ is polynomial satisfying $P(x^2)=x^2\ P(x)$ and $P(0)=-2$, $P'(3/2)=0$ and $P(1)=0$.
The maximum value of $P(x)$ is
(a) $-\dfrac{1}{3}$ (b) $-\dfrac{1}{4}$
(c) $-\dfrac{1}{2}$ (d) None of these

22. If the curve $x^2=-4(y-a)$ does not intersect the curve $y=[x^2-x+1]$ (where [.] denotes the greatest integer function) in $\left[0, \dfrac{1+\sqrt{5}}{2}\right]$, then
(a) $\dfrac{1}{3}<a<1$ (b) $-1<a<1$
(c) $\dfrac{1}{4}<a<1$ (d) None of these

23. Analyze the following graph of $f'(x)$



which is incorrect about $f(x)$ for $\alpha<x<\beta$?
(a) only three extreme points
(b) two inflexion points
(c) $f'''(x)>0$ for $d<x<e$
(d) $x=e$ is the point of local maxima

24. Let $f(x)=x^2-2x$ and $g(x)=f(f(x)-1)+f(5-f(x))$, then
(a) $g(x)<0, \forall\ x\in R$
(b) $g(x)<0$, for some $x\in R$
(c) $g(x)\ge 0$, for some $x\in R$
(d) $g(x)\ge 0, \forall\ x\in R$

25. Let $f: N\to N$ be such that $f(n+1)>f(f(n))$ for all $n\in N$, then
(a) $f(x)=x^2-x+1$
(b) $f(x)=x-1$
(c) $f(x)=x^2+1$
(d) None of the above

26. The equation $|2ax-3|+|ax+1|+|5-ax|=\dfrac{1}{2}$ possesses
(a) infinite number of real solutions for some $a\in R$
(b) finitely many real solutions for some $a\in R$
(c) no real solutions for some $a\in R$
(d) no real solutions for all $a\in R$

27. If $\int_0^x 2x f^2(t)\,dt=\left(\int_0^x 2f(x-t)\,dt\right)^2$ for $f(1)=1$ and $f(x)$ is continuous function for $x>0$ and $\{a_n\}$ is a sequence such that $a_{n+1}=a_n+\sqrt{1+a_n^2}$ for $a=0$; if $f(x)$ is an increasing function, then $\lim\limits_{n\to\infty}\dfrac{a_k}{2^{n-1}}=$
(where $k=f(n^{\sqrt{2}-1})$) is
(a) $\pi/4$ (b) $4/\pi$ (c) π (d) $\pi/2$

28. A function f is defined by $f(x)=|x|^m|x-1|^n, \forall\ x\in R$. The maximum value of the function is $(m, n\in N)$
(a) 1 (b) $m^n\cdot n^m$
(c) $\dfrac{m^m\cdot n^n}{(m+n)^{m+n}}$ (d) $\dfrac{(mn)^{mn}}{(m+n)^{m+n}}$

Monotonicity, Maxima and Minima Exercise 2 : More than One Option Correct Type Questions

29. Which of the following is/are true?

(you may use $f(x)=\frac{\ln(\ln x)}{\ln x}$)

(a) $(\ln 2.1)^{\ln 2.2} > (\ln 2.2)^{\ln 2.1}$

(b) $(\ln 4)^{\ln 5} < (\ln 5)^{\ln 4}$

(c) $(\ln 30)^{\ln 31} > (\ln 31)^{\ln 30}$

(d) $(\ln 28)^{30} < (\ln 30)^{\ln 28}$

30. If $\lim_{x\to a} f(x) = \lim_{x\to a}[f(x)]$ (where $[\cdot]$ denotes the greatest integer function) and $f(x)$ is non-constant continuous function, then

(a) $\lim_{x\to a} f(x)$ is an integer

(b) $\lim_{x\to a} f(x)$ is non-integer

(c) $f(x)$ has local maximum at $x = a$

(d) $f(x)$ has local minimum at $x = a$

31. Let S be the set of real values of parameter λ for which the equation $f(x) = 2x^3 - 3(2+\lambda)x^2 + 12\lambda x$ has exactly one local maximum and exactly one local minimum. Then, S is a subset of

(a) $(-4, \infty)$ (b) $(-3, 3)$

(c) $(3, \infty)$ (d) $(-\infty, 0)$

32. $h(x) = 3f\left(\frac{x^2}{3}\right) + f(3-x^2),\ \forall\ x \in (-3,\ 4)$, where $f''(x) > 0,\ \forall\ x \in (-3,\ 4)$, then $h(x)$ is

(a) increasing in $\left(\frac{3}{2}, 4\right)$

(b) increasing in $\left(-\frac{3}{2}, 0\right)$

(c) decreasing in $\left(-3, -\frac{3}{2}\right)$

(d) decreasing in $\left(0, \frac{3}{2}\right)$

33. $f(x) = \tan^{-1}(\sin x + \cos x)$, then $f(x)$ is increasing in

(a) $\left(-\frac{\pi}{2}, \frac{\pi}{4}\right)$ (b) $\left(-\frac{\pi}{4}, \frac{\pi}{4}\right)$

(c) $\left(\frac{5\pi}{4}, \frac{3\pi}{2}\right)$ (d) $\left(-2\pi, -\frac{7\pi}{4}\right)$

34. If maximum and minimum values of the determinant

$$\begin{vmatrix} 1+\sin^2 x & \cos^2 x & \sin 2x \\ \sin^2 x & 1+\cos^2 x & \sin 2x \\ \sin^2 x & \cos^2 x & 1+\sin 2x \end{vmatrix}$$

are α and β, then

(a) $\alpha + \beta^{99} = 4$

(b) $\alpha^3 - \beta^{17} = 26$

(c) $(\alpha^{2n} - \beta^{2n})$ is always an even integer for $n \in N$

(d) a triangle can be drawn having it's sides as α, β and $\alpha - \beta$

35. Let $f(x) = \begin{cases} x^2 + 4x, & -3 \le x \le 0 \\ -\sin x, & 0 < x \le \frac{\pi}{2} \\ -\cos x - 1, & \frac{\pi}{2} < x \le \pi \end{cases}$. Then,

(a) $x = -2$ is the point of global minima

(b) $x = \pi$ is the point of global maxima

(c) $f(x)$ is non-differentiable at $x = \frac{\pi}{2}$

(d) $f(x)$ is discontinuous at $x = 0$

36. Let $f(x) = ab\sin x + b\sqrt{1-a^2}\cos x + c$, where $|a| < 1,\ b > 0$, then

(a) maximum value of $f(x)$ is b, if $c = 0$

(b) difference of maximum and minimum value of $f(x)$ is $2b$

(c) $f(x) = c$, if $x = -\cos^{-1} a$

(d) $f(x) = c$, if $x = \cos^{-1} a$

37. If $f(x) = \int_{x^m}^{x^n} \frac{dt}{\ln t},\ x > 0$ and $n > m$, then

(a) $f'(x) = \frac{x^{m-1}(x-1)}{\ln x}$

(b) $f(x)$ is decreasing for $x > 1$

(c) $f(x)$ is increasing in $(0, 1)$

(d) $f(x)$ is increasing for $x > 1$

38. $f(x) = \sqrt{x-1} + \sqrt{2-x}$ and $g(x) = x^2 + bx + c$ are two given functions such that $f(x)$ and $g(x)$ attain their maximum and minimum values respectively for same value of x, then

(a) $f(x)_{\max}$ at $x = \frac{1}{2}$ (b) $f(x)_{\max}$ at $x = \frac{3}{2}$

(c) $b = 3$ (d) $b = -3$

39. If $f(x) = a^{\{a^{|x|} \operatorname{sgn} x\}}$; $g(x) = a^{[a^{|x|} \operatorname{sgn} x]}$ for $a > 0, a \neq 1$ and $x \in R$, where {} and [·] denote the fractional part and integral part functions respectively, then which of the following statements can hold good for the function $h(x)$? where $(\ln a)\, h(x) = (\ln f(x) + \ln g(x))$

(a) h is even and increasing

(b) h is odd and decreasing

(c) h is even and decreasing

(d) h is odd and increasing

40. For the function $f(x) = \ln(1 - \ln x)$, which of the following do not hold good?

(a) increasing in (0, 1) and decreasing in $(1, e)$

(b) decreasing in (0, 1) and increasing in $(1, e)$

(c) $x = 1$ is the critical number for $f(x)$

(d) f has two asymptotes

41. The function $f(x) = \begin{cases} x + 2, & \text{if } x < -1 \\ x^2, & \text{if } -1 \le x < 1 \\ (x-2)^2, & \text{if } x \ge 1 \end{cases}$

(a) is continuous for all $x \in R$

(b) is continuous but not differentiable, $\forall\ x \in R$

(c) is such that $f'(x)$ change its sign exactly twice

(d) has two local maxima and two local minima

42. A function f is defined by $f(x) = \int_0^{\pi} \cos t \cos(x - t)\, dt$, $0 \le x \le 2\pi$, then which of the following hold(s) good?

(a) $f(x)$ is continuous but not differentiable in $(0, 2\pi)$

(b) Maximum value of f is π

(c) There exists atleast one $c \in (0, 2\pi)$ if $f'(c) = 0$

(d) Minimum value of f is $-\dfrac{\pi}{2}$

43. Let $f(x) = \dfrac{x-1}{x^2}$, then which of the following is correct?

(a) $f(x)$ has minima but no maxima

(b) $f(x)$ increases in the interval $(0, 2)$ and decreases in the interval $(-\infty, 0) \cup (2, \infty)$

(c) $f(x)$ can come down in $(-\infty, 0) \cup (2, 3)$

(d) $x = 3$ is the point of inflection

44. Let $f(x)$ be differentiable function on the interval $(-\infty, \infty)$ such that $f(1) = 5$ and $\lim\limits_{a \to x} \dfrac{af(x) - xf(a)}{a - x} = 2$, for all $x \in R$. Then, which of the following alternative(s) is/are correct?

(a) $f(x)$ has an inflection point

(b) $f'(x) = 3, \forall\ x \in R$

(c) $\int_0^2 f(x)\, dx = 10$

(d) Area bounded by $f(x)$ with coordinate axes is $(2/3)$

45. Let $f : (0, \infty) \to (0, \infty)$ be a derivable function and $F(x)$ is the primitive of $f(x)$ such that $2(F(x) - f(x)) = f^2(x)$ for any real positive x

(a) f is strictly increasing (b) $\lim\limits_{x \to \infty} \dfrac{f(x)}{x} = 1$

(c) f is strictly decreasing (d) f is non-monotonic

Monotonicity, Maxima and Minima Exercise 3 : Statements I and II Type Questions

Directions (Q. Nos. 46 to 54) *For the following questions, choose the correct answers from the codes (a), (b), (c) and (d) defined as follows.*

(a) Statement I is true, Statement II is also true, Statement II is the correct explanation of Statement I

(b) Statement I is true, Statement II is also true, Statement II is not the correct explanation of Statement I

(c) Statement I is true, Statement II is false

(d) Statement I is false, Statement II is true

46. **Statement I** The equation $3x^2 + 4ax + b = 0$ has atleast one root in (0, 1), if $3 + 4a = 0$.

Statement II $f(x) = 3x^2 + 4x + b$ is continuous and differentiable in (0, 1).

47. **Statement I** For the function $f(x) = \begin{cases} 15 - x, & x < 2 \\ 2x - 3, & x \ge 2 \end{cases}$ $x = 2$ has neither a maximum nor a minimum point.

Statement II $f'(x)$ does not exist at $x = 2$.

48. **Statement I** $\phi(x) = \int_0^x (3\sin t + 4\cos t)\, dt, x \in \left[\dfrac{\pi}{6}, \dfrac{\pi}{3}\right]$ $\phi(x)$ attains its maximum value at $x = \dfrac{\pi}{3}$.

Statement II $\phi(x) = \int_0^x (3\sin t + 4\cos t)\, dt, \phi(x)$ is increasing function in $\left[\dfrac{\pi}{6}, \dfrac{\pi}{3}\right]$.

49. Let $f(x)$ be a twice differentiable function in $[a, b]$, given that $f(x)$ and $f''(x)$ has same sign in $[a, b]$.

Statement I $f'(x) = 0$ has at the most one real root in $[a, b]$.

Statement II An increasing function can intersect the X-axis at the most once.

50. Let $u = \sqrt{c+1} - \sqrt{c}$ and $v = \sqrt{c} - \sqrt{c-1}$, $c > 1$ and let $f(x) = \ln(1+x)$, $\forall\ x \in (-1, \infty)$.

Statement I $f(u) > f(v)$, $\forall\ c > 1$ because

Statement II $f(x)$ is increasing function, hence for $u > v$, $f(u) > f(v)$.

51. Let $f(0) = 0$, $f\left(\frac{\pi}{2}\right) = 1$, $f\left(\frac{3\pi}{2}\right) = -1$ be a continuous and twice differentiable function.

Statement I $|f''(x)| \le 1$ for atleast one $x \in \left(0, \frac{3\pi}{2}\right)$ because

Statement II According to Rolle's theorem, if $y = g(x)$ is continuous and differentiable, $\forall x \in [a, b]$ and $g(a) = g(b)$, then there exists atleast one c such that $g'(c) = 0$.

52. **Statement I** For any ΔABC

$$\sin\left(\frac{A+B+C}{3}\right) \ge \frac{\sin A + \sin B + \sin C}{3}$$

Statement II $y = \sin x$ is concave downward for $x \in (0,\ \pi]$.

53. **Statement I** If $f(x) = [x](\sin x + \cos x - 1)$ (where $[\cdot]$ denotes the greatest integer function), then $f'(x) = [x](\cos x - \sin x)$ for any $x \in$ integer.

Statement II $f'(x)$ does not exist for any $x \in$ integer.

54. $f(x)$ is a polynomial of degree 3 passing through origin having local extrema at $x = \pm a$.

Statement I Ratio of areas in which $f(x)$ cuts the circle $x^2 + y^2 = 36$ is 1 : 1.

Statement II Both $y = f(x)$ and the circle are symmetric about origin.

Monotonicity, Maxima and Minima Exercise 4 : Passage Based Questions

Passage I

(Q. Nos. 55 to 57)

Let $f(x) = \frac{1}{1+x^2}$, let m be the slope, a be the x-intercept and b be the y-intercept of a tangent to $y = f(x)$.

55. Abscissa of the point of contact of the tangent for which m is greatest, is

(a) $\frac{1}{\sqrt{3}}$ (b) 1

(c) -1 (d) $-\frac{1}{\sqrt{3}}$

56. Value of b for the tangent drawn to the curve $y = f(x)$ whose slope is greatest, is

(a) $\frac{9}{8}$ (b) $\frac{3}{8}$

(c) $\frac{1}{8}$ (d) $\frac{5}{8}$

57. Value of a for the tangent drawn to the curve $y = f(x)$ whose slope is greatest, is

(a) $-\sqrt{3}$

(b) 1

(c) -1

(d) $\sqrt{3}$

Passage II

(Q. Nos. 58 to 60)

Consider the function $f(x) = \max\{x^2, (1-x)^2, 2x(1-x)\}$, $x \in [0, 1]$

58. The interval in which $f(x)$ is increasing, is

(a) $\left(\frac{1}{3}, \frac{2}{3}\right)$ (b) $\left(\frac{1}{3}, \frac{1}{2}\right)$

(c) $\left(\frac{1}{3}, \frac{1}{2}\right) \cup \left(\frac{1}{2}, \frac{2}{3}\right)$ (d) $\left(\frac{1}{3}, \frac{1}{2}\right) \cup \left(\frac{2}{3}, 1\right)$

59. Let RMVT is applicable for $f(x)$ on $(a,\ b)$, then $a+b+c$ is (where c is the point such that $f'(c) = 0$)

(a) $\frac{2}{3}$ (b) $\frac{1}{3}$

(c) $\frac{1}{2}$ (d) $\frac{3}{2}$

60. The interval in which $f(x)$ is decreasing, is

(a) $\left(\frac{1}{3}, \frac{2}{3}\right)$ (b) $\left(\frac{1}{3}, \frac{1}{2}\right)$

(c) $\left(0, \frac{1}{3}\right) \cup \left(\frac{1}{2}, \frac{2}{3}\right)$ (d) $\left(\frac{1}{3}, \frac{1}{2}\right) \cup \left(\frac{2}{3}, 1\right)$

Passage III

(Q. Nos. 61 to 63)

$f(x)$, $g(x)$, $h(x)$ all are continuous and differentiable functions in $[a, b]$ also $a < c < b$ and $f(a) = g(a) = h(a)$. Point of intersection of the tangent at $x = c$ with chord joining $x = a$ and $x = b$ is on the left of c in $y = f(x)$ and on the right in $y = h(x)$. And tangent at $x = c$ is parallel to the chord in case of $y = g(x)$.
Now, answer the following questions.

61. If $f'(x) > g'(x) > h'(x)$, then

(a) $f(b) < g(b) < h(b)$ (b) $f(b) > g(b) > h(b)$
(c) $f(b) \le g(b) \le h(b)$ (d) $f(b) \ge g(b) \ge h(b)$

62. If $f(b) = g(b) = h(b)$, then

(a) $f'(c) = g'(c) = h'(c)$ (b) $f'(c) > g'(c) > h'(c)$
(c) $f'(c) < g'(c) < h'(c)$ (d) None of these

63. If $c = \dfrac{a+b}{2}$ for each b, then

(a) $g(x) = Ax^2 + Bx + C$
(b) $g(x) = \log x$
(c) $g(x) = \sin x$
(d) $g(x) = e^x$

Passage IV

(Q. Nos. 64 to 66)

In the non-decreasing sequence of odd integers $(a_1, a_2, a_3, \ldots) = \{1, 3, 3, 3, 5, 5, 5, 5, 5, \ldots\}$ each positive odd integer k appears k times. It is a fact that there are integers b, c and d such that for all positive integer n, $a_n = b[\sqrt{n + c}] + d$ (where $[.]$ denotes greatest integer function).

64. The possible value of $b + c + d$ is

(a) 0 (b) 1 (c) 2 (d) 4

65. The possible value of $\dfrac{b-2d}{8}$ is

(a) 0 (b) 1
(c) 2 (d) 4

66. The possible value of $\dfrac{c+d}{2b}$ is

(a) 0 (b) 1
(c) 2 (d) 4

Passage V

(Q. Nos. 67 to 69)

Let $g(x) = a_0 + a_1x + a_2x^2 + a_3x^3$ and $f(x) = \sqrt{g(x)}$, $f(x)$ have its non-zero local minimum and maximum values at -3 and 3, respectively. If $a_3 \in$ the domain of the function

$$h(x) = \sin^{-1}\left(\frac{1 + x^2}{2x}\right)$$

67. The value of $a_1 + a_2$ is equal to

(a) 30 (b) -30
(c) 27 (d) -27

68. The value of a_0 is

(a) equal to 50
(b) greater than 54
(c) less than 54
(d) less than 50

69. $f(-10)$ is defined for

(a) $a_0 > 830$
(b) $a_0 < 830$
(c) $a_0 = 830$
(d) None of the above

Passage VI

(Q. Nos. 70 to 74)

If $f : D \to R$, $f(x) = \dfrac{x^2 + bx + c}{x^2 + b_1x + c_1}$, where α, β are the roots of the equation $x^2 + bx + c = 0$ and α_1, β_1 are the roots of $x^2 + b_1x + c_1 = 0$. Now, answer the following questions for $f(x)$. A combination of graphical and analytical approach may be helpful in solving these problems. (If α_1 and β_1 are real, then $f(x)$ has vertical asymptote at $x = \alpha_1, \beta_1$). Then,

70. If $\alpha_1 < \alpha < \beta_1 < \beta$, then

(a) $f(x)$ is increasing in (α_1, β_1)
(b) $f(x)$ is decreasing in (α, β)
(c) $f(x)$ is decreasing in (β_1, β)
(d) $f(x)$ is decreasing in $(-\infty, \alpha)$

71. If $\alpha_1 < \beta_1 < \alpha < \beta$, then

(a) $f(x)$ has a maxima in $[\alpha_1, \beta_1]$ and a minima is $[\alpha, \beta]$
(b) $f(x)$ has a minima in (α_1, β_1) and a maxima in (α, β)
(c) $f'(x) > 0$ where ever defined
(d) $f'(x) < 0$ where ever defined

72. If the equations $x^2 + bx + c = 0$ and $x^2 + b_1x + c_1 = 0$ do not have real roots, then

(a) $f'(x) = 0$ has real and distinct roots
(b) $f'(x) = 0$ has real and equal roots
(c) $f'(x) = 0$ has imaginary roots
(d) nothing can be said

73. In the above problem, $\lim\limits_{x \to \infty} [f(x)] \cdot \lim\limits_{x \to \infty} [f(x)]$ (where $[.]$ denotes the greatest integer function) is equal to

(a) 1
(b) 0
(c) -1
(d) does not exist

74. In the last problem, if $b > b_1$, then

(a) x-coordinate of point of minima is greater than the x-coordinate of point of maxima
(b) x-coordinate of point of minima is less than x-coordinate of point of maxima
(c) it also depends upon c and c_1
(d) nothing can be said

Passage VII

(Q. Nos. 75 to 77)

Consider the function $f(x) = \dfrac{x^2}{x^2 - 1}$

75. The interval in which f is increasing is

(a) $(-1, 1)$
(b) $(-\infty, -1) \cup (-1, 0)$
(c) $(-\infty, \infty) - \{-1, 1\}$
(d) $(0, 1) \cup (1, \infty)$

76. If f is defined from $R - \{-1, 1\} \to R$, then f is

(a) injective but not surjective
(b) surjective but not inective
(c) injective as well as surjective
(d) neither injective nor surjective

77. f has

(a) local maxima but not local minima
(b) local minima but not local maxima
(c) both local maxima and local minima
(d) neither local maxima nor local minima

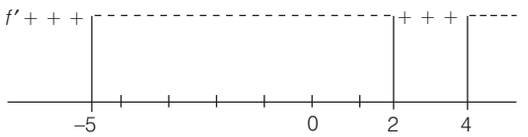
Passage VIII

(Q. Nos. 78 to 80)

Suppose you do not know the function $f(x)$*, however some information about* $f(x)$ *is listed below.*

Read the following carefully before attempting the questions

(i) $f(x)$ *is continuous and defined for all real numbers*
(ii) $f'(-5) = 0$, $f'(2)$ *is not defined and* $f'(4) = 0$
(iii) $(-5, 12)$ is a point which lies on the graph of $f(x)$
(iv) $f''(2)$ *is undefined, but* $f''(x)$ *is negative everywhere else*
(v) *The signs of* $f'(x)$ *is given below*



78. On the possible graph of $y = f(x)$, we have

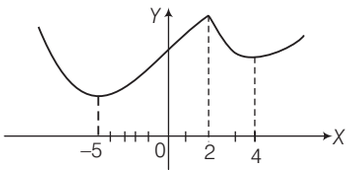
(a) $x = -5$ is a point of relative minima
(b) $x = 2$ is a point of relative maxima
(c) $x = 4$ is a point of relative minima
(d) graph of $y = f(x)$ must have a geometrically sharp corner

79. From the possible graph of $y = f(x)$, we can say that

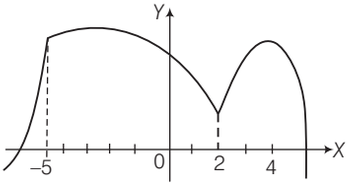
(a) there is exactly one point of inflection on the curve
(b) $f(x)$ increases on $-5 < x < 2$ and $x > 4$ and decreases on $-\infty < x < -5$ and $2 < x < 4$
(c) the curve is always concave down
(d) curve always concave up

80. Possible graph of $y = f(x)$ is

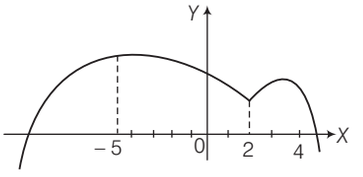
(a)



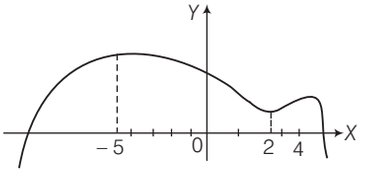
(b)



(c)



(d)



Passage IX

(Q. Nos. 81 to 83)

Let $f(x) = e^{(p+1)x} - e^x$ *for real number* $p > 0$*, then*

81. The value of $x = s_p$ for which $f(x)$ is minimum, is

(a) $\dfrac{-\log_e(p+1)}{p}$ (b) $-\log_e(p+1)$

(c) $-\log_e p$ (d) $\log_e\left(\dfrac{p+1}{p}\right)$

82. Let $g(t) = \int_t^{t+1} f(x)\, e^{t-x}\, dx$. The value of $t = t_p$, for which $g(t)$ is minimum, is

(a) $-\log_e \dfrac{(e^p - 1)}{p}$ (b) $-\dfrac{1}{p}\log_e\left(\dfrac{e^p - 1}{p}\right)$

(c) $-\dfrac{1}{p}\log_e\left(\dfrac{(p+1)(e^p - 1)}{p}\right)$ (d) $-\log_e((p+1)(e^p - 1))$

83. Use the fact that $1 + \dfrac{p}{2} \le \dfrac{e^p - 1}{p} \le 1 + \dfrac{p}{2} + p^2$ $(0 < p \le 1)$, the value of $\lim\limits_{p \to 0^+} (s_p - t_p)$ is

(a) 0 (b) $\dfrac{1}{2}$ (c) 1 (d) non-existent

Passage X

(Q. Nos. 84 to 86)

Consider f, g and h be three real valued function defined on R.

Let $f(x)=\sin 3x+\cos x$, $g(x)=\cos 3x+\sin x$ *and* $h(x)=f^2(x)+g^2(x)$.

84. The length of a longest interval in which the function $g=h(x)$ is increasing, is

(a) $\pi/8$ (b) $\pi/4$ (c) $\pi/6$ (d) $\pi/2$

85. The general solution of the equation $h(x)=4$, is

(a) $(4n+1)\pi/8$ (b) $(8n+1)\pi/8$
(c) $(2n+1)\pi/4$ (d) $(7n+1)\pi/4$

86. Number of point(s) where the graphs of the two function, $y=f(x)$ and $y=g(x)$ intersects in $[0,\pi]$, is

(a) 2 (b) 3
(c) 4 (d) 5

Passage XI

(Q. Nos. 87 to 89)

Consider f, g and h be three real valued functions defined on R.

Let $f(x)=\begin{cases}-1, & x<0\\ 0, & x=0\\ 1, & x>0\end{cases}$, $g(x)=x(1-x^2)$ *and* $h(x)$ *be such that* $h''(x)=6x-4$.

Also, $h(x)$ *has local minimum value* 5 *at* $x=1$.

87. The equation of tangent at $m(2,7)$ to the curve $y=h(x)$, is

(a) $5x+y=17$ (b) $x+5y=37$
(c) $x-5y+33=0$ (d) $5x-y=3$

88. The area bounded by $y=h(x)$, $y=g(f(x))$ between $x=0$ and $x=2$ equals

(a) 23/2 (b) 20/3 (c) 32/3 (d) 40/3

89. Range of function $\sin^{-1}\sqrt{(fog(x))}$ is

(a) $(0,\pi/2)$ (b) $\{0,\pi/2\}$
(c) $\{-\pi/2,0,\pi/2\}$ (d) $\{\pi/2\}$

Passage XII

(Q. Nos. 90 to 92)

Consider f, g and h be three real valued differentiable functions defined on R.

Let $g(x)=x^3+g''(1)x^2+(3g'(1)-g''(1)-1)x+3g'(1)$

$f(x)=x\,g(x)-12x+1$

and $f(x)=(h(x))^2$, *where* $h(0)=1$.

90. The function $y=f(x)$ has

(a) Exactly one local minima and no local maxima
(b) Exactly one local maxima and no local minima
(c) Exactly one local maxima and two local minima
(d) Exactly two local maxima and one local minima

91. Which of the following is/are true for the function $y=g(x)$?

(a) $g(x)$ monotonically decreases inEREDEDDD $\left(-\infty,2-\frac{1}{\sqrt{3}}\right)\cup\left(2+\frac{1}{\sqrt{3}},\infty\right)$

(b) $g(x)$ monotonically increases in $\left[2-\frac{1}{\sqrt{3}},2+\frac{1}{\sqrt{3}}\right)$

(c) There exists exactly one tangent to $y=g(x)$ which is parallel to the chord joining the points $(1,\ g(1))$ and $(3,\ g(3))$

(d) There exists exactly two distinct lagrange's mean value in $(0,\ 4)$ for the function $y=g(x)$

92. Which one of the following does not hold good for $y=h(x)$?

(a) Exactly one critical point
(b) No point of inflexion
(c) Exactly one real zero in $(0,3)$
(d) Exactly one tangent parallel to X-axis

Monotonicity, Maxima and Minima Exercise 5 : Matching Type Questions

93. Match the following :

	Column I	Column II
(A)	The maximum value attained by $y=10-\lvert x-10\rvert$, $-1\le x\le 3$ is	(p) 3
(B)	If $P(t^2,2t)$, $t\in[0,2]$ is an arbitrary point on parabola $y^2=4x$, Q is foot of perpendicular from focus S on the tangent at P, then maximum area of ΔPQS is	(q) $\frac{1}{3}$
(C)	If $a+b=1$, $a,b>0$, then maximum value of $\sqrt{\left(1+\frac{1}{a}\right)\left(1+\frac{1}{b}\right)}$ is	(r) 5
(D)	For real values of x, the greatest and least value of expression $\frac{x+2}{2x^2+3x+6}$ is	(s) $-\frac{1}{13}$

94. Match the entries of the following two columns.

	Column I	Column II
(A)	The least value of the function $f(x) = 2\cdot 3^{3x} - 3^{2x}\cdot 4 + 2\cdot 3^{x}$ in $[-1, 1]$ is	(p) 5
(B)	The minimum value of the polynomial $f(x) = (x-1)x(x+1)$ is	(q) -1
(C)	The value of the polynWmial $\int_{-1}^{3}(\|x-2\|-[x])dx$ (where $[\cdot]$ denotes the greatest integer function) is	(r) 3
(D)	If period of the function $f(x) = \sin 36x \tan 42x$ is p, then $\frac{18p}{\pi}$ equals	(s) 0

95. Match the following :

	Column I	Column II
(A)	$f(x) = \int_{0}^{2x^2}(t-2)(t+1)^3(t-3)^2\,dt$ is/has in $(-1, 1)$	(p) local maxima
(B)	$f(x)=\begin{cases}\sin\left(\frac{\pi x}{4}\right), x\le 2\\ 9-4x, \quad x>2\end{cases}$ is/has in $(0,2)$	(q) local minima
(C)	$f(x) = \{2x\}$ denotes fractional part of x is/has in $(0, 1)$	(r) continuous
(D)	$f(x)=\begin{cases}\|\|x-2\|-2\|, & x<2\\ [x], & x\ge 2\end{cases}$ (where $[\cdot]$ denotes the greatest integer function), then $f(x)$ is/has in $(-1, 4)$	(s) non-differentiable

96. Match the statements of Column I with the values of Column II.

	Column I	Column II
(A)	$f(x) = \cos\pi x + 10x + 3x^2 + x^3$, $-2 \le x \le 3$. The absolute minimum value of $f(x)$ is	(p) 3/4
(B)	If $x \in [-1, 1]$, then the minimum value of $f(x) = x^2 + x + 1$ is	(q) 2
(C)	Let $f(x) = \frac{4}{3}x^3 - 4x$, $0 \le x \le 2$. Then, the global minimum value of the function is	(r) -15
(D)	Let $f(x) = 6 - 12x + 9x^2 - 2x^3$, $1 \le x \le 4$. Then, the absolute maximum value of $f(x)$ in the interval is	(s) $-8/3$

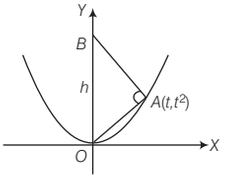
Monotonicity, Maxima and Minima Exercise 6 : Single Integer Answer Type Questions

97. A particular substance is being cooled by a streem of cold air (temperature of the air is constant and is 5°C) where rate of cooling is directly proportional to square of difference of temperature of the substance and the air. If the substance is cooled from 40°C to 30°C in 15 min and temperature after 1 hour is T°C, then find the value of $[T]/2$, where $[.]$ represents the greatest integer function.

98. The minimum value of $\dfrac{\tan\left(x+\frac{\pi}{6}\right)}{\tan x}$ is ..... .

99. The figure shows a right triangle with its hypotenuse OB along the Y-axis and its vertex A on the parabola $y = x^2$. Let h represents the length of the hypotenuse which depends on the x-coordinate of the point A.

The value of $\lim\limits_{x\to 0}(h)$ equals ..... .

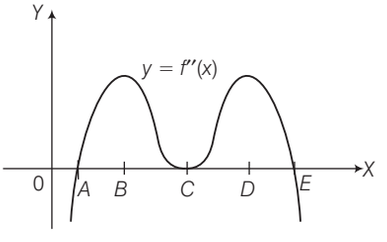


100. Number of positive integral values of a for which the curve $y = a^x$ intersects the line $y = x$ is ..... .

101. The least value of a for which the equation, $\dfrac{4}{\sin x} + \dfrac{1}{1-\sin x} = a$ has atleast one solution in the interval $(0, \pi/2)$ is ..... .

102. Let $f(x)=\begin{cases}x^{3/5} & \text{if } x\le 1\\ -(x-2)^3 & \text{if } x>1\end{cases}$, then the number of critical points on the graph of the function are ..... .

103. The graph of $y = f''(x)$ for a function f is shown. Number of points of inflection for $y = f(x)$ is ..... .



104. Number of critical points of the function, $f(x)=\frac{2}{3}\sqrt{x^3}-\frac{x}{2}+\int_1^x\left(\frac{1}{2}+\frac{1}{2}\cos 2t-\sqrt{t}\right)dt$ which lie in the interval $[-2\pi, 2\pi]$ is ..... .

105. Let $f(x)$ and $g(x)$ be two continuous functions defined from $R\to R$, such that $f(x_1)>f(x_2)$ and $g(x_1)<g(x_2), \forall\ x_1>x_2$, then the least integral value of α for which $f(g(\alpha^2-2\alpha))>f(g(3\alpha-4))$ is ..... .

106. If the function $f(x)=\frac{t+3x-x^2}{x-4}$, where t is a parameter, has a minimum and a maximum, then the greatest value of t is ..... .

107. If $f(x)=(x-a)(x-b)$ for $a, b\in R$, then minimum number of roots of equation $\pi(f'(x))^2\cos(\pi f(x))+\sin(\pi f(x))\cdot f''(x)=0$ in (α, β), where $f(\alpha)=3=f(\beta)$ is ..... . (here, $\alpha<a<b<\beta$)

108. If absolute maximum value of $f(x)=\frac{1}{|x-4|+1}+\frac{1}{|x+8|+1}$ is $\frac{p}{q}$, (p, q are coprime) the $(p-q)$ is ..... .

Monotonicity, Maxima and Minima Exercise 7 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

109. The least value of $\alpha\in R$ for which $4\alpha x^2+\frac{1}{x}\geq 1$, for all $x>0$, is **[One Correct Option 2016 Adv.]**

(a) $\frac{1}{64}$ (b) $\frac{1}{32}$

(c) $\frac{1}{27}$ (d) $\frac{1}{25}$

110. The number of points in $(-\infty, \infty)$ for which $x^2-x\ \sin x-\cos x=0$, is **[One Correct Option, 2013 Adv.]**

(a) 6 (b) 4

(c) 2 (d) 0

111. Let $f: R\to(0, \infty)$ and $g: R\to R$ be twice differentiable functions such that f'' and g'' are continuous funcitons of R. Suppose $f'(2)=g(2)=0, f''(2)\neq 0$ and $g'(2)\neq 0$. If $\lim_{x\to 2}\frac{f(x)g(x)}{f'(x)g'(x)}=1$, then **[More than One Correct option, 2016 Adv.]**

(a) f has a local minimum at $x=2$

(b) f has a local maximum at $x=2$

(c) $f''(2)>f(2)$

(d) $f(x)-f''(x)=0$ for atleast one $x\in R$

112. If $f:(0, \infty)\to R$ be given by $f(x)=\int_{1/x}^{x}e^{-\left(t+\frac{1}{t}\right)}\frac{dt}{t}$.

Then, **[More than One Correct Option, 2014 Adv.]**

(a) $f(x)$ is monotonically increasing on $[1, \infty)$

(b) $f(x)$ is monotonically decreasing on $[0,1)$

(c) $f(x)+f\left(\frac{1}{x}\right)=0, \forall x\in(0, \infty)$

(d) $f(2^x)$ is an odd function of x on R

113. The function $f(x)=2|x|+|x+2|-||x+2|-2|x||$ has a local minimum or a local maximum at x is equal to **[More than One Correct Option, 2013 Adv.]**

(a) -2 (b) $\frac{-2}{3}$

(c) 2 (d) 2/3

114. A rectangular sheet of fixed perimeter with sides having their lengths in the ratio 8 : 15 is converted into an open rectangular box by folding after removing squares of equal area from all four corners. If the total area of removed squares is 100, the resulting box has maximum volume. The lengths of the sides of the rectangular sheet are **[More than One Correct Option, 2013 Adv.]**

(a) 24 (b) 32 (c) 45 (d) 60

115. A vertical line passing through the point $(h, 0)$ intersects the ellipse $\frac{x^2}{4}+\frac{y^2}{3}=1$ at the points P and Q. If the tangents to the ellipse at P and Q meet at the point R. If $\Delta(h)$ = area of the ΔPQR, $\Delta_1=\max_{1/2\leq h\leq 1}\Delta(h)$ and $\Delta_2=\min_{1/2\leq h\leq 1}\Delta(h)$, then $\frac{8}{\sqrt{5}}\Delta_1-8\Delta_2$ is equal to **[Integer Type Question, 2013 Adv.]**

116. Let f, g and h be real-valued functions defined on the interval [0, 1] by $f(x)=e^{x^2}+e^{-x^2}$, $g(x)=xe^{x^2}+e^{-x^2}$ and $h(x)=x^2e^{x^2}+e^{-x^2}$. If a, b and c denote respectively, the absolute maximum of f, g and h on [0, 1], then **[One Correct Option, 2010]**

(a) $a=b$ and $c\neq b$ (b) $a=c$ and $a\neq b$

(c) $a\neq b$ and $c\neq b$ (d) $a=b=c$

117. The total number of local maxima and local minima of the function $f(x)=\begin{cases}(2+x)^3, & -3<x\le -1\\ x^{\frac{2}{3}}, & -1<x<2\end{cases}$ is **[One Correct Option, 2008]**

(a) 0 (b) 1 (c) 2 (d) 3

118. If the function $g:(-\infty,\infty)\to\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$ is given by $g(u)=2\tan^{-1}(e^u)-\frac{\pi}{2}$. Then, g is **[One Correct Option, 2008)**

(a) even and is strictly increasing in $(0,\infty)$
(b) odd and is strictly decreasing in $(-\infty,\infty)$
(c) odd and is strictly increasing in $(-\infty,\infty)$
(d) neither even nor odd but is strictly increasing in $(-\infty,\infty)$

119. The second degree polynomial $f(x)$, satisfying $f(0)=0$, $f(1)=1$, $f'(x)>0\ \forall x\in(0,1)$ **[One Correct Option, 2005]**

(a) $f(x)=\phi$
(b) $f(x)=ax+(1-a)x^2, \forall\ a\in(0,\infty)$
(c) $f(x)=ax+(1-a)x^2, a\in(0,2)$
(d) No such polynomial

120. If $f(x)=x^3+bx^2+cx+d$ and $0<b^2<c$, then in $(-\infty,\infty)$ **[One Correct Option, 2004]**

(a) $f(x)$ is strictly increasing function
(b) $f(x)$ has a local maxima
(c) $f(x)$ is strictly decreasing function
(d) $f(x)$ is bounded

121. If $f(x)=x^2+2bx+2c^2$ and $g(x)=-x^2-2cx+b^2$, such that $\min f(x)>\max g(x)$, then the relation between b and c, is **[One Correct Option, 2003]**

(a) No real value of b and c (b) $0<c<b\sqrt{2}$
(c) $|c|<|b|\sqrt{2}$ (d) $|c|>|b|\sqrt{2}$

122. The length of a longest interval in which the function $3\sin x-4\sin^3 x$ is increasing, is **[One Correct Option, 2002]**

(a) $\frac{\pi}{3}$ (b) $\frac{\pi}{2}$ (c) $\frac{3\pi}{2}$ (d) π

123. The maximum value of $(\cos\alpha_1)\cdot(\cos\alpha_2)\cdot\ldots\cdot(\cos\alpha_n)$, under the restrictions $0\le\alpha_1,\alpha_2\ldots,\alpha_n\le\frac{\pi}{2}$ and $(\cot\alpha_1)\cdot(\cot\alpha_2)\cdot\ldots\cdot(\cot\alpha_n)=1$ is **[One Correct Option, 2001]**

(a) $\frac{1}{2^{n/2}}$ (b) $\frac{1}{2^n}$ (c) $\frac{1}{2n}$ (d) 1

124. If $f(x)=\begin{cases}e^x, & 0\le x\le 1\\ 2-e^{x-1}, & 1<x\le 2\\ x-e, & 2<x\le 3\end{cases}$ and $g(x)=\int_0^x f(t)\,dt$, $x\in[1,3]$, then **[More than One Correct Option, 2006]**

(a) $g(x)$ has local maxima at $x=1+\log_e 2$ and local minima at $x=e$
(b) $f(x)$ has local maxima at $x=1$ and local minima at $x=2$
(c) $g(x)$ has no local minima
(d) $f(x)$ has no local maxima

125. If $f(x)$ is a cubic polynomial which has local maximum at $x=-1$. If $f(2)=18$, $f(1)=-1$ and $f'(x)$ has local minimum at $x=0$, then **[More than One Correct Option, 2006]**

(a) the distance between $(-1, 2)$ and $(a, f(a))$, where $x=a$ is the point of local minima, is $2\sqrt{5}$
(b) $f(x)$ is increasing for $x\in[1,2\sqrt{5}]$
(c) $f(x)$ has local minima at $x=1$
(d) the value of $f(0)=5$

126. Consider the function $f:(-\infty,\infty)\to(-\infty,\infty)$ defined by $f(x)=\frac{x^2-ax+1}{x^2+ax+1}; 0<a<2$. Which of the following is true ? **[Passage Based Question, 2008]**

(a) $(2+a)^2 f''(1)+(2-a)^2 f''(-1)=0$
(b) $(2-a)^2 f''(1)-(2+a)^2 f''(-1)=0$
(c) $f'(1)\,f'(-1)=(2-a)^2$
(d) $f'(1)\,f'(-1)=-(2+a)^2$

127. Which of the following is true? **[Passage Based Question, 2008]**

(a) $f(x)$ is decreasing on $(-1, 1)$ and has a local minimum at $x=1$
(b) $f(x)$ is increasing on $(-1, 1)$ and has a local maximum at $x=1$
(c) $f(x)$ is increasing on $(-1, 1)$ but has neither a local maximum nor a local minimum at $x=1$
(d) $f(x)$ is decreasing on $(-1, 1)$ but has neither a local maximum nor a local minimum at $x=1$

128. Let $g(x)=\int_0^{e^x}\frac{f'(t)}{1+t^2}dt$. Which of the following is true? **[Passage Based Question, 2008]**

(a) $g'(x)$ is positive on $(-\infty, 0)$ and negative on $(0,\infty)$
(b) $g'(x)$ is negative on $(-\infty, 0)$ and positive on $(0,\infty)$
(c) $g'(x)$ changes sign on both $(-\infty, 0)$ and $(0,\infty)$
(d) $g'(x)$ does not change sign $(-\infty,\infty)$

129. For the circle $x^2+y^2=r^2$, find the value of r for which the area enclosed by the tangents drawn from the point $P(6, 8)$ to the circle and the chord of contact is maximum. **[Subjective Type Question, 2003]**

130. Find a point on the curve $x^2+2y^2=6$ whose distance from the line $x+y=7$, is minimum. **[Subjective Type Question, 2003]**

131. Let $f:R\to R$ be defined as $f(x)=|x|+|x^2-1|$. Total number of points at which f attains either a local maximum or a local minimum is **[Integer Type Question, 2012]**

132. Let $p(x)$ be a real polynomial of least degree which has a local maximum at $x=1$ and a local minimum at $x=3$. If $p(1)=6$ and $p(3)=2$, then $p'(0)$ is equal to **[Integer Type Question, 2012]**

133. Let f be a function defined on R (the set of all real numbers) such that $f'(x) = 2010(x-2009)(x-2010)^2 (x-2011)^3 (x-2012)^4, \forall x \in R$. If g is a function defined on R with values in the interval $(0, \infty)$ such that $f(x) = \ln(g(x)), \forall x \in R$, then the number of points in R at which g has a local maximum is ..... .

[Integer Type Question, 2010]

134. The maximum value of the expression $\frac{1}{\sin^2\theta + 3\sin\theta\cos\theta + 5\cos^2\theta}$ is ..... .

[Integer Type Question, 2010]

135. The maximum value of the function $f(x) = 2x^3 - 15x^2 + 36x - 48$ on the set $A = \{x \mid x^2 + 20 \le 9x\}$ is ... .

[Integer Type Question, 2009]

(ii) JEE Main & AIEEE

136. A wire of length 2 units is cut into two parts which are bent respectively to form a square of side = x units and a circle of radius = r units. If the sum of the areas of the square and the circle so formed is minimum, then

[2016 JEE Main]

(a) $2x = (\pi + 4)r$ (b) $(4 - \pi)x = \pi r$

(c) $x = 2r$ (d) $2x = r$

137. If $x = -1$ and $x = 2$ are extreme points of $f(x) = \alpha \log|x| + \beta x^2 + x$, then **[2014 JEE Main]**

(a) $\alpha = -6, \beta = \frac{1}{2}$ (b) $\alpha = -6, \beta = -\frac{1}{2}$

(c) $\alpha = 2, \beta = -\frac{1}{2}$ (d) $\alpha = 2, \beta = \frac{1}{2}$

138. Let $a, b \in R$ be such that the function f given by $f(x) = \log|x| + bx^2 + ax, x \neq 0$ has extreme values at $x = -1$ and $x = 2$.

Statement I f has local maximum at $x = -1$ and at $x = 2$.

Statement II $a = \frac{1}{2}$ and $b = \frac{-1}{4}$ **[2012 AIEEE]**

(a) Statement I is false, Statement II is true

(b) Statement I is true, Statement II is true; Statement II is a correct explanation of Statement I

(c) Statement I is true, Statement II is true; Statement II is not a correct explanation of Statement I

(d) Statement I is true, Statement II is false

Solutions

1. Since, f is non-decreasing and g is non-increasing, so h is a non-increasing function. Now, $h(1) = 1$

$\Rightarrow$ $h(x)$ is a constant function

$\Rightarrow$ $h(2) = 1$

2. Since, maximum or minimum distance between two curve always measure along common normal. AP is perpendicular on the tangent drawn to the curve.

3. f is continuous at 0 and $f'(0-) > 0$ and $f'(0+) < 0$. Thus, f has a local maximum at 0.

4. Here, $f(x) = \int_1^x (t-a)^{2n}(t-b)^{2m+1}dt,\ a \neq b$

$f'(x) = (x-a)^{2n}(x-b)^{2m+1}$.

Obviously, $f'(a-),\ f'(a+) > 0$

while $f'(b-) < 0$ and $f'(b+) > 0$

Hence, $x = b$ is a point of local minima.

5. $f'(x) = x^{n-1}[(n+1)x + an]$.

If n is even then, $f'(0-) < 0$ and $f'(0+) > 0$

Hence, 0 is a point of minimum when n is even.

6. $f'(x) = 4x - \frac{4}{x^3} = \frac{4}{x^3}(x^4 - 1) = \frac{4}{x^3}(x-1)(x+1)(x^2+1)$

$\Rightarrow$ $f'(x) = 0$ at $x = 1$ and -1

$f''(x) = 4 + \frac{12}{x^4} > 0$ for $x = \pm 1$

$\Rightarrow$ $x = 1$ and -1 are points of local minima.

7. Since, $y_{\min} = \frac{1}{e^{1/e}} > \frac{1}{e}$. So, graph always lie above the line $y = x$.

Hence, $0 < x < 1$ is correct answer.

8. $y^2 - y + a = \left(y - \frac{1}{2}\right)^2 + a - \frac{1}{4}$

Since, $-\sqrt{2} \le \sin x + \cos x \le \sqrt{2}$, given equation will have no real value of x for any y, if $a - \frac{1}{4} > \sqrt{2}$

i.e. $a \in \left(\sqrt{2} + \frac{1}{4}, \infty\right)$

$\Rightarrow$ $a \in (\sqrt{3}, \infty)$ $\left[\text{as } \sqrt{2} + \frac{1}{4} < \sqrt{3}\right]$

9. $f(x) = 1 - \frac{2e^{-x^2}}{e^{x^2} + e^{-x^2}} = 1 - \frac{2}{e^{2x^2} + 1}$

As $x \to +\infty,\ f(x) \to 1$

As $x \to -\infty,\ f(x) \to 1$

$\Rightarrow f(x)$ is increasing as well as decreasing in some intervals. Since, the range of $f(x)$ is $[0, 1)$ which does not coincide with the co-domain R and hence f is not an onto function.

10. Let $f(x) = ax^2 + bx + c > 0,\ \forall\ x \in R$

$\Rightarrow$ $b^2 - 4ac < 0$ and $a > 0$ ... (i)

Now, $g(x) = f(x) - f'(x) + f''(x)$

$= (ax^2 + bx + c) - (2ax + b) + 2a$

$= ax^2 + (b - 2a)x + (2a - b + c)$

$\Rightarrow$ $\Delta = (b-2a)^2 - 4a(2a - b + c)$

$= (b^2 - 4ac) - 4a^2 < 0$ [using Eq. (i)]

$\Rightarrow$ $g(x) > 0,\ \forall\ x \in R$

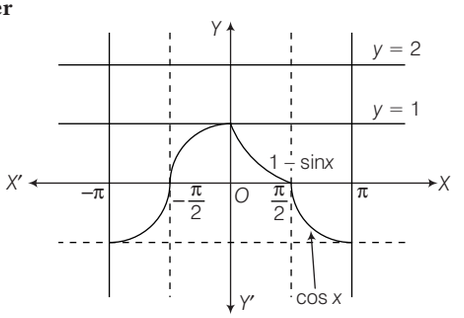
11. We have, $f(x) = \min\{1, \cos x, 1 - \sin x\}$

$$f(x) = \begin{cases} \cos x, & -\pi \le x \le 0 \\ 1 - \sin x, & 0 < x \le \frac{\pi}{2} \\ \cos x, & \frac{\pi}{2} < x \le \pi \end{cases} \Rightarrow f'(x) = \begin{cases} -\sin x, & -\pi \le x \le 0 \\ -\cos x, & 0 < x \le \frac{\pi}{2} \\ -\sin x, & \frac{\pi}{2} < x \le \pi \end{cases}$$

Therefore, $f'(0) = 0$

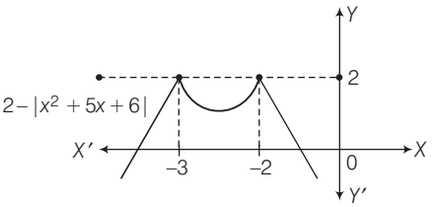
Hence, $f(x)$ has local maximum at 0 and $f(x)$ is not differentiable at $x = 0$ and $\frac{\pi}{2}$

Aliter



From the graph it is clear that $f(x)$ is not differentiable at $x = 0, \frac{\pi}{2}$ and $f(x)$ has occurs local maximum at $x = 0$.

12. $f(x)$ will have maxima only, if $a^2 + 1 \ge 2 \Rightarrow |a| \ge 1$

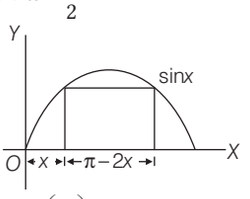


13. $ax^n = -x^2 - bx - c$. For $a = -1$ and $b = c = 0$ and $n = 2$, it will have infinite solutions.

14. $A = \text{Area} = \sin x(\pi - 2x)$ (as $l = \pi - 2x,\ b = \sin x$)

$\frac{dA}{dx} = (\pi - 2x)\cos x - 2\sin x = 0 \Rightarrow \tan x = \frac{\pi}{2} - x$

Let $f(x) = \tan x + x - \frac{\pi}{2}$

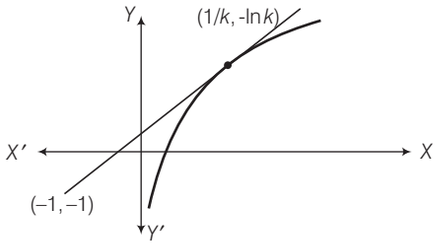


$f\left(\frac{\pi}{6}\right)$ is negative, $f\left(\frac{\pi}{4}\right)$ is positive.

So, one root lies between $\left(\frac{\pi}{6}, \frac{\pi}{4}\right)$.

15. $f(x)+1=k(x+1)$ always passes through $(-1,-1)$. Clearly, its maximum slope can go upto ∞. For minimum slope this line should touch $y=\ln x$.

$\frac{dy}{dx}=\frac{1}{x}=k$. So, $\left(\frac{1}{k},-\ln k\right)$ is point of tangency.



Now, $\frac{-\ln k+1}{\frac{1}{k}+1}=k \quad \Rightarrow \quad -\ln k+1=k+1$

$\Rightarrow \quad -\ln k=k$

Let $f(x)=k+\ln k$

$f\left(\frac{1}{e}\right)=\frac{1}{e}-1$ [negative]

$f\left(\frac{1}{\sqrt{e}}\right)=\frac{1}{\sqrt{e}}-\frac{1}{2}$ [positive]

So, one root must lie between $\frac{1}{e}$ and $\frac{1}{\sqrt{e}}$.

16. $f(x)=f'(x)\times f'''(x)$ is satisfied only by the polynomial of degree 4. Since, $f(x)=0$ satisfies $x=1,2,3$ only. It is clear that one of the roots is repeated twice.

$\Rightarrow \quad f'(1)f'(2)f'(3)=0$

17. $\frac{d^2y}{dx^2}=k\log x \Rightarrow \frac{dy}{dx}=k(x\log x-x)+A$

$=kx(\log x-1)+A$

$=k\left[(\log x-1)\frac{x^2}{2}-\frac{x^2}{4}\right]+Ax+B$

$=k\frac{x^2}{4}(2\log x-3)+Ax+B$

$\Rightarrow y=c_1(2\log x-3)x^2+c_2x+c_3$

18. $f'(x)=3\sec^2\left[\left(\tan x-\frac{1}{3}\right)^2+\frac{11}{9}\right]>0$ for all x in its domain.

19. $\lim\limits_{x\to k^-} f(x)=\lim\limits_{h\to 0}3+h=3 \Rightarrow f(k)=3$

and $\lim\limits_{x\to k^+} f(x)=\lim\limits_{h\to 0} a^2-2+\frac{\sin h}{h}=a^2-2+1$

Since, $f(x)$ has minimum at $x=k$

$f(k^-)>f(k)$

and $f(k^+)>f(k) \Rightarrow \alpha^2-2+1>3$

$|a|>2$

20. Let $f(x)=mx+b$

$\because \quad f(1)\le f(2) \Rightarrow m\ge 0$, similarly

$f(3)\ge f(4) \Rightarrow m\le 0 \Rightarrow m=0$

$\therefore \quad f(0)=f(5)=5$

21. Let $P(x)$ is of degree n, then

$\Rightarrow \quad 2n=n+2$ [as $P(x^2)=x^2P(x)$]

$\Rightarrow \quad n=2$

$P(x)=ax^2+bx+c$ form

$P(0)=-2$

$\Rightarrow \quad c=-2$ ...(i)

$P(1)=0$

$\Rightarrow \quad a+b+c=0$ ...(ii)

$P'\left(\frac{3}{2}\right)=0 \quad \Rightarrow \quad 3a+b=0$

$\Rightarrow \quad \frac{a}{b}=\frac{-1}{3} \quad \Rightarrow P(x)=-x^2+3x-2$

Hence, maximum $P(x)=-\frac{1}{4}$

22. In $[0,1]$, $[x^2-x+1]=0$

$\ln\left[1,\frac{1+\sqrt{5}}{2}\right)$, $[x^2-x+1]=1 \Rightarrow x^2=-4(y-a)$

Put $y=0$, $x^2=4(a-1) \Rightarrow 4a>1$

Put $y=1$, $x^2=4(a-1) \Rightarrow a<1$

$\Rightarrow \quad \frac{1}{4}<a<1.$

23. Clearly, $f'(a)=0$, $f'(c)=0$, $f'(e)=0$, $x=b$ and $x=d$ two points of inflexion $f'''(x)>0$, $d<x<e$.

$x=e$ is point of local minima.

24. $g(x)=f(x^2-2x-1)+f(5-x^2+2x)$

$=2x^4-8x^3-4x^2+24x+18$

$g'(x)=8x^3-24x^2-8x+24$

$g'(x)=0 \quad \Rightarrow \quad x=-1,1,3$

We observe that $g(x)\ge \min\{g(-1),g(1),g(3)\}=0$

$\therefore \quad g(x)\ge 0, \forall\ x\in R$

25. Using the fact that every set of natural numbers have the smallest element.

$\therefore$ $f(f(1))$ is the smallest element in $\{f(f(1)),f(2),f(f(2)),\ldots\}$

Same argument implies that $f(1)=1$

Repeating the argument for $f\{n\ge 2\}\to\{n\ge 2\}$, we get $f(2)=2$

$\therefore$ Clearly, $f(x)=x$

26. $\frac{1}{2}=|2ax-3|+|ax+1|+|5-ax|\ge|2ax-3-(ax+1)+5-ax|=1$

which is impossible.

27. Given, $\int_0^x 2xf^2(t)dt=\left(\int_0^x 2f(x-t)dt\right)^2$

$\Rightarrow \quad x\cdot\int_0^x f^2(t)dt=2\left(\int_0^x f(t)dt\right)^2$, using $\int_0^a f(x)dx$

$=\int_0^a f(a-x)dx$

Differentiating, we get

$x\cdot f^2(x)+\int_0^x f^2(t)dt=4\int_0^x f(t)dt\cdot f(x)$

[using Leibnitz rule]

$\Rightarrow \quad x^2f^2(x)+x\cdot\int_0^x f^2(t)dt=4x\cdot f(x)\cdot\int_0^x f(t)dt$

$$\Rightarrow \quad x^2 f^2(x) + 2\left(\int_0^x f(t)\,dt\right)^2 = 4x\,f(x)\cdot\int_0^x f(t)\,dt$$

$$\Rightarrow \quad 2\left(\int_0^x f(t)\,dt\right)^2 - 4x\cdot f(x)\cdot\int_0^x f(t)\,dt + x^2 f^2(x) = 0$$

$$\int_0^x f(t)\,dt = \frac{4x\,f(x) \pm \sqrt{16x^2 f^2(x) - 8x^2 f^2(x)}}{4} \qquad \left(\begin{matrix}\because ax^2 + bx + c = 0\\ \Rightarrow x = \dfrac{-b \pm \sqrt{d}}{2a}\end{matrix}\right)$$

$$\Rightarrow \qquad \sqrt{2}\int_0^x f(t)\,dt = (\sqrt{2} \pm 1)\,x\,f(x)$$

Again, differentiating, we get

$$\sqrt{2}\,f(x) = (\sqrt{2}\pm 1)(f(x) + x\,f'(x))$$

$$\Rightarrow \quad \sqrt{2}\,f(x) = (\sqrt{2}\pm 1)\,f(x) + (\sqrt{2}\pm 1)\,x\cdot f'(x)$$

$$\Rightarrow \quad \pm\,f(x) = (\sqrt{2}\pm 1)\cdot x\,f'(x)$$

$$\Rightarrow \quad \int \pm\frac{1}{\sqrt{2}\pm 1}\cdot\frac{1}{x}\,dx = \int\frac{f'(x)}{f(x)}\,dx$$

$$\Rightarrow \quad \pm(\sqrt{2}\pm 1)\cdot\log x = \log|f(x)| + C, \text{ as } f(1) = 1 \Rightarrow C = 0$$

$$\Rightarrow \quad f(x) = x^{\sqrt{2}\pm 1}$$

$$\therefore \quad f(x) = x^{\sqrt{2}+1} \qquad [\text{as } f'(x) > 0]$$

$$\therefore \quad f(n^{\sqrt{2}-1}) = n \qquad \ldots(\text{i})$$

Now, let $a_n = \cot\theta_n$

$$\Rightarrow \quad a_{n+1} = \cot\left(\frac{\theta_n}{2}\right)$$

$$\Rightarrow \quad \theta_{n+1} = \frac{1}{2}\theta_n$$

$$\because \quad \theta_0 = \pi/2$$

$$\Rightarrow \quad \theta_1 = \frac{1}{2}\left(\frac{\pi}{2}\right),\ \theta_2 = \frac{1}{2^2}\left(\frac{\pi}{2}\right)$$

$$\Rightarrow \quad \theta_n = \frac{1}{2^n}\times\frac{\pi}{2} \qquad \therefore\ a_n = \cot\left(\frac{\pi}{2^{n+1}}\right)$$

$$\Rightarrow \quad \lim_{n\to\infty}\frac{a_n}{2^{n-1}} = \frac{1}{2^{-1}\cdot\pi/2} = 4/\pi$$

28. We have, $f(x) = |x|^m|x-1|^n$

$$f(x) = \begin{cases}(-1)^{m+n}x^m\cdot(x-1)^n, & \text{if} \quad x < 0\\ (-1)^n x^m(x-1)^n, & \text{if} \quad 0 \le x < 1\\ x^m(x-1)^n, & \text{if} \quad x \ge 1\end{cases}$$

Let, $g(x) = x^m(x-1)^n$, then

$$g'(x) = mx^{m-1}\cdot(x-1)^n + n\,x^m\cdot(x-1)^{n-1}$$

$$= x^{m-1}\cdot(x-1)^{n-1}\cdot(m(x-1) + n\cdot x) = 0$$

Now, $f'(x) = 0$

$\Rightarrow \quad g'(x) = 0$

$$\Rightarrow \quad x = 0 \text{ or } \frac{m}{m+n} \text{ or } 1.$$

$$f(0) = 0,\ f(1) = 0$$

$$f\left(\frac{m}{m+n}\right) = (-1)^n\cdot\frac{m^m\cdot n^n\cdot(-1)^n}{(m+n)^{m+n}} \qquad \left[\text{as, } 0 < \frac{m}{m+1} < 1\right]$$

$$\therefore \text{ Maximum value} = \frac{m^m\cdot n^n}{(m+n)^{m+n}}$$

29. Let $f(x) = \dfrac{\ln(\ln x)}{\ln x} \Rightarrow f'(x) = \dfrac{1-\ln(\ln x)}{x(\ln x)^2} < 0,\ \forall\ x > e^e$

So, $f(x)$ is increasing in $(1, e^e)$ and decreasing in (e^e, ∞).

Therefore, $x > y$

$$\Rightarrow \quad (\ln x)^{\ln y} < (\ln y)^{\ln x},\ \forall\ x, y \in (e^e, \infty) \quad \text{and} \quad x < y$$

$$\Rightarrow \quad (\ln x)^{\ln y} < (\ln y)^{\ln x},\ \forall\ x, y \in (1, e^e)$$

30. $\lim\limits_{x\to a}[f(x)]$ can exist only when $f(x)$ either increases or decreases at both sides of the point $x = a$.

Since, $\lim\limits_{x\to a} f(x) = \lim\limits_{x\to a}[f(x)]$

So, this can occur only when $\lim\limits_{x\to a} f(x)$ is an integer.

31. $f(x) = 2x^3 - 3(2+\lambda)x^2 + 12\lambda x$

$$\Rightarrow \quad f'(x) = 6x^2 - 6(2+\lambda)\,x + 12\lambda$$

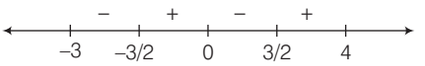
$$\Rightarrow \quad f'(x) = 0 \ \Rightarrow\ x = 2, \lambda$$

If $f(x)$ has exactly one local maximum and exactly one local minimum, then $\lambda \neq 2.1$

32. $h(x) = 3f\left(\dfrac{x^2}{3}\right) + f(3-x^2) \ \Rightarrow\ h'(x) = 2x\left(f'\left(\dfrac{x^2}{3}\right) - f'(3-x^2)\right)$

$$\Rightarrow \quad f'\left(\frac{x^2}{3}\right) > f'(3-x^2),\ \forall\ x \text{ such that } \frac{x^2}{3} > 3 - x^2 \Rightarrow x^2 > \frac{9}{4}$$

$$\Rightarrow \quad f'\left(\frac{x^2}{3}\right) < f'(3-x^2),\ \forall\ x \text{ such that } x^2 < \frac{9}{4}$$



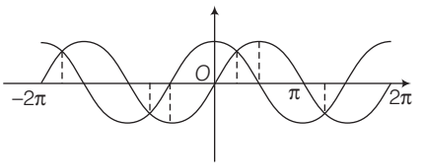
using number line rule

$$\Rightarrow\ h(x) \text{ increases in } \left(-\frac{3}{2}, 0\right)\cup\left(\frac{3}{2}, 4\right)$$

and $h(x)$ decreases in $\left(-3, -\dfrac{3}{2}\right)\cup\left(0, \dfrac{3}{2}\right)$

33. $f'(x) = \dfrac{\cos x - \sin x}{1 + (\sin x + \cos x)^2} \ge 0 \Rightarrow \cos x \ge \sin x$

$$\Rightarrow \quad x \in \left[-2\pi, -\frac{7\pi}{4}\right]\cup\left[-\frac{3\pi}{4}, \frac{\pi}{4}\right]\cup\left[\frac{5\pi}{4}, 2\pi\right]$$



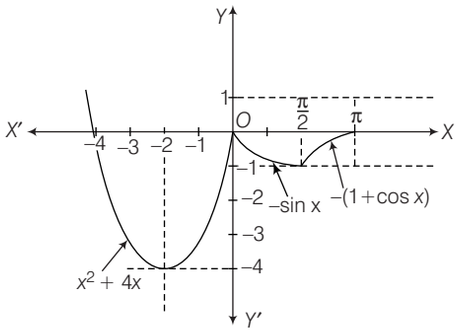
34. Applying $C_1 \to C_1 + C_2$, we get $\begin{vmatrix}2 & \cos^2 x & \sin 2x\\ 2 & 1+\cos^2 x & \sin 2x\\ 1 & \cos^2 x & 1+\sin 2x\end{vmatrix}$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, we get

$$\begin{vmatrix}2 & \cos^2 x & \sin 2x\\ 0 & 1 & 0\\ -1 & 0 & 1\end{vmatrix} = 2 + \sin 2x$$

Since, the maximum value of $\sin 2x$ is 1 and minimum value of $\sin 2x$ is (-1). Therefore, $\alpha = 3,\ \beta = 1$.

35.



From above figure clearly options (a), (b) and (c) are correct.

36. $f(x) = \sqrt{a^2b^2 + b^2 - b^2a^2}\sin(x + \alpha) + c$

$= b\sin(x + \alpha) + c$, where $\tan\alpha = \dfrac{\sqrt{1-a^2}}{a}$

$f_{\max} = b + c$

$f_{\min} = -b + c$

$(f(x))_{\max} - (f(x))_{\min} = 2b$

Also, at $x = -\cos^{-1}a$, $f(x) = c$.

37. $f'(x) = \dfrac{n \cdot x^{n-1}}{(\ln x^n)} - \dfrac{1 \cdot mx^{m-1}}{(\ln x^m)}$,

Clearly, (c) and (d) are the answers.

38. $f(x)$ occurs maximum at $x = \dfrac{3}{2}$

$g(x)$ occurs maximum at $x = \dfrac{-b}{2}$

$\therefore \qquad \dfrac{3}{2} = \dfrac{-b}{2} \Rightarrow b = -3$

39. $h(x) = \dfrac{\ln(f(x)\cdot g(x))}{\ln a} = \dfrac{\ln a^{\{a^{|x|}\ \text{sgn}\ x\} + [a^{|x|}\cdot \text{sgn}\ x]}}{\ln a}$

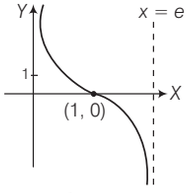
$= \{a^{|x|}\cdot \text{sgn}\ x\} + [a^{|x|}\cdot \text{sgn}\ x] = a^{|x|}\ \text{sgn}\ x$

$$= \begin{cases} a^x & \text{for } x > 0 \\ 0 & \text{for } x = 0 \\ -a^{-x} & \text{for } x < 0 \end{cases} \qquad [\because \{y\} + [y] = y]$$

$\Rightarrow h(x)$ is an odd function.

40. $f(x) = \ln(1 - \ln x)$, Domain $(0, e)$

$$f'(x) = -\frac{1}{(1-\ln x)}\cdot\frac{1}{x} < 0$$



$\Rightarrow$ Decreasing, $\forall\ x$ in its domain

$\Rightarrow$ (a) and (b) are incorrect.

$f'(1) = -1 \Rightarrow$ (c) is also incorrect.

Also, $f(1) = 0$, $\lim\limits_{x\to e} \to -\infty$, $\lim\limits_{x\to 0^+} f(x) \to \infty$

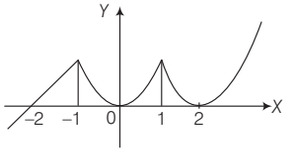
$$f''(x) = \frac{-\ln x}{x^2(1-\ln x)^2}$$

$f''(1) = 0$ which is a point of inflection as shown in graph

Y-axis and $x = e$ are two asymptotes.

41. f is obvious continuous, $\forall\ x \in R$ and not derivable at -1 and 1.

$f'(x)$ changes sign 4 times at $-1, 0, 1, 2$



Local maxima at 1 and -1.

Local minima at $x = 0$ and 2.

42. $f(x) = \int_0^{\pi}\cos t\cos(x - t)\,dt$ ...(i)

$= \int_0^{\pi} -\cos t\cdot\cos(x - \pi + t)\,dt$

$f(x) = \int_0^{\pi} -\cos t\cdot\cos(x + t)\,dt$ ...(ii)

On adding Eqs. (i) and (ii), we get

$2f(x) = \int_0^{\pi}\cos t\,(2\cos x\cdot\cos t)\,dt$

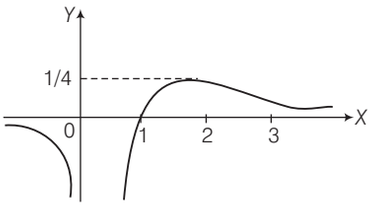
$2f(x) = 2\cos x\int_0^{\pi/2}\cos^2 t\,dt$

$f(x) = \dfrac{\pi\cos x}{2}$ Now, verify.

Only (a) and (b) are correct.

Aliter Convert the integer and into sum of two cosine functions.

43. $f'(x) = \dfrac{2-x}{x^3}$ and $f''(x) = \dfrac{x-3}{x^4}$ Now, interpret



44. We have, $\lim\limits_{a\to x}\dfrac{af(x) - xf(a)}{a - x}$ $\left[\dfrac{0}{0}\text{form}\right]$

$\Rightarrow \lim\limits_{a\to x}\dfrac{f(x) - xf'(a)}{1} = 2$

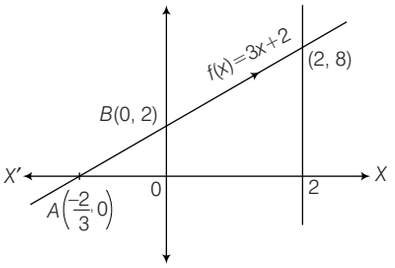
$\Rightarrow f(x) - xf'(x) = 2$

$\Rightarrow \dfrac{f'(x)}{f(x)-2} = \dfrac{1}{x}$

On integrating both sides w.r.t. x, we get

$$\int\frac{f'(x)}{f(x)-2}dx = \int\frac{1}{x}dx$$

$\Rightarrow \quad \log(f(x)-2) = \log x + \log c$



$\Rightarrow \quad f(x) = cx + 2$

As, $f(1) = 5$, so $5 = c + 2 \Rightarrow c = 3$

Hence, $f(x) = 3x + 2$

Clearly, area $(\Delta OAB) = \frac{1}{2}\left(\frac{2}{3}\right)(2) = \frac{2}{3}$

Also, $\int_0^2 (3x+2)\,dx = \left(\frac{3x^2}{2} + 2x\right)_0^2$

$= 6 + 4 = 10$

45. Given, $2(F(x) - f(x)) = f^2(x)$ and $\frac{d\,F(x)}{dx} = f(x)$ ...(i)

$\therefore \quad F(x) = \frac{f^2(x)}{2} + f(x)$

$\Rightarrow \quad F'(x) = f(x)\cdot f'(x) + f'(x)$

$\therefore \quad f(x) = f(x)\cdot f'(x) + f'(x)$, using $F'(x) = f(x)$

$\Rightarrow \quad f'(x) = \frac{f(x)}{1+f(x)}$, as $f(0,\infty) \to (0,\infty)$

$\therefore \quad f'(x) > 0$

Hence, f is strictly increasing and $\lim_{x\to\infty} \frac{f(x)}{x} = \lim_{x\to\infty} \frac{f'(x)}{1}$

[using L'Hospital's rule]

$= \lim_{x\to\infty}\left(1 + \frac{1}{1+f(x)}\right)$, as $x \to \infty; f(x) \to \infty$

$\therefore \quad \lim_{x\to 0} \frac{f(x)}{x} = 1$

46. If $b < 0$, then $f(0) = b < 0, f(1) = b < 0$

$\therefore \quad 0,\ 1$ lies between the roots, Statement I is false.

47. $x = 2$ is a point of local minima.

48. $\phi'(x) = 3\sin x + 4\cos x > 0$

$\phi(x)$ is increasing in $\left[\frac{\pi}{6}, \frac{\pi}{3}\right]$.

$\therefore\ f(x)$ attain maximum value at $x = \frac{\pi}{3}$.

49. Let $g(x) = f(x)\cdot f'(x)$

$\Rightarrow\ g'(x) > 0$ in $[a, b]$.

50. Let $g(x) = \sqrt{x} - \sqrt{x-1},\ x > 1$

$\Rightarrow g'(x) = \frac{1}{2\sqrt{x}} - \frac{1}{2\sqrt{x-1}} = \frac{1}{2}\left(\frac{\sqrt{x-1} - \sqrt{x}}{\sqrt{x(x-1)}}\right)$

$= \frac{-1}{2\sqrt{x}\sqrt{x-1}(\sqrt{x} + \sqrt{x-1})} < 0, \forall\ x > 1$

Hence, $g(x)$ is a decreasing function.

$\Rightarrow \quad c + 1 > c$

$g(c+1) < g(c)$

$\Rightarrow \quad f(u) < f(v)$

51. Let $h(x) = f(x) - \sin x$ or $x \in \left[0, \frac{\pi}{2}\right]$

$\Rightarrow \quad h(0) = h\left(\frac{\pi}{2}\right) = 0$

According to Rolle's theorem for atleast one $c \in \left(0, \frac{\pi}{2}\right)$.

$h'(c) = f'(c) - \sin c = 0$

for $x \in \left[\frac{\pi}{2}, \frac{3\pi}{2}\right], h\left(\frac{\pi}{2}\right) = h\left(\frac{5\pi}{2}\right) = 0$

According to Rolle's theorem for atleast one $d \in \left(\frac{\pi}{2}, \frac{3\pi}{2}\right)$.

$h'(d) = f'(d) - \cos d = 0$

for $x \in [c, d],\ h'(c) = h'(d) = 0$

According to Rolle's theorem for atleast one $x \in (c, d)$.

$h'(x) = f''(x) + \sin x = 0$

$\Rightarrow\ |f''(x)| \le 1$ for atleast one $x \in \left(0, \frac{3\pi}{2}\right)$.

52. Statements I and II both are true but Statement II does not explain Statement I.

53. Statement II is true as $f'(a)^+ = f'(a)^-, \forall\ a \in I$.

Statement I is true and is obtained from differentiable rule.

54. Statement II is correct as $y = f(x)$ is odd and hence Statement I is correct.

Sol. **(Q. Nos. 55 to 57)**

Here, we have $f'(x) = \frac{-2x}{(1+x^2)^2}$ and $f''(x) = \frac{6x^2 - 2}{(1+x^2)^3}$

$\therefore\ f'(x)$ is maximum at $x = -\frac{1}{\sqrt{3}}$

If m is greatest, then $m = \frac{3\sqrt{3}}{8}$

y-coordinate of the point of contact is $\frac{3}{4}$.

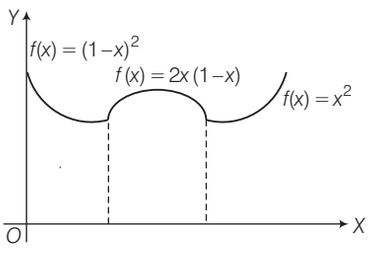
$\therefore$ Equation of the tangent is $y - \frac{3}{4} = \frac{3\sqrt{3}}{8}\left(x + \frac{1}{\sqrt{3}}\right)$

$\therefore \quad a = -\sqrt{3}$ and $b = \frac{9}{8}$

55. (d) **56.** (a) **57.** (a)

Sol. **(Q. Nos. 58 to 60)**

We draw the graphs of $f_1(x) = x^2$, $f_2(x) = (1-x)^2$ and $f_3(x) = 2x(1-x)$. Here, $f(x)$ is redefined as



$$f(x)=\begin{cases}(1-x)^2, & 0\le x<\dfrac{1}{3}\\ 2x(1-x), & \dfrac{1}{3}\le x\le\dfrac{2}{3}\\ x^2, & \dfrac{2}{3}<x\le 1\end{cases}$$

Interval of increase of $f(x)$ is $\left(\frac{1}{3},\frac{1}{2}\right)\cup\left(\frac{2}{3},1\right)$.

Interval of decrease of $f(x)$ is $\left(0,\frac{1}{3}\right)\cup\left(\frac{1}{2},\frac{2}{3}\right)$.

Clearly, Rolle's theorem is applicable on $\left[\frac{1}{3},\frac{2}{3}\right]$, where $f(x)=2x(1-x)$.

$\Rightarrow$ $f'(c)=2-4c=0 \Rightarrow c=\frac{1}{2}$

$\Rightarrow$ $a+b+c=\frac{1}{3}+\frac{2}{3}+\frac{1}{2}=\frac{3}{2}$

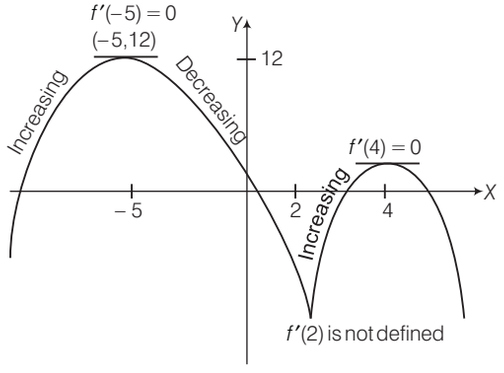
Sol. **(Q. Nos. 78 to 80)**

From given statements (i) to (v), one of the graph of $f(x)$ can be plotted as

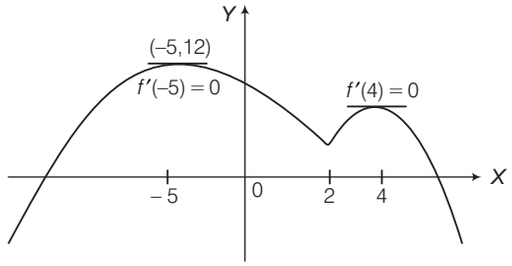


78. Since, $f'(2)$ is not defined and continuous for $x\in R$.

$\Rightarrow y=f(x)$ must have a geometrically sharp corner at $x=2$.

79. At $x=-5$, $f'(x)$ changes from positive to negative and at $x=4$, $f'(x)$ change sign for positive to negative, hence maxima at $x=-5$ and 4. f is continuous and $f'(2)$ is not defined, hence $x=2$ must be geometrical sharp corner.

80. Clearly, one of the graph of $f(x)$ is



Sol. **(Q. Nos. 81 to 83)**

$$f(x)=e^{(p+1)x}-e^x=e^x(e^{px}-1)$$

$$f'(x)=e^x(e^{px}-1)+e^x\cdot pe^{px}$$

$$=e^x[(p+1)e^{px}-1]=0 \qquad [e^x\neq 0]$$

$\Rightarrow$ $e^{px}=\dfrac{1}{p+1}\Rightarrow px=-\log_e(p+1)$

$$x=-\frac{\log_e(p+1)}{p} \qquad \text{...(i)}$$

Now, $f''(x)=(p+1)^2e^{(p+1)x}-e^x$

$$=e^x[(p+1)^2e^{px}-1]$$

$\therefore$ $f''\left(-\dfrac{\log(p+1)}{p}\right)=e^x[(p+1)-1]>0$

Hence, $x=s_p=-\dfrac{\log_e(p+1)}{p}$

$$g(t)=\int_t^{t+1}(e^{px}\cdot e^x-e^x)e^t\cdot e^{-x}\,dx=e^t\int_t^{t+1}(e^{px}-1)\,dx$$

On integrating, we get

$$g(t)=e^t\cdot\left(\frac{e^{px}}{p}-x\right)_t^{t+1}=e^t\left[\frac{e^{pt}(e^p-1)}{p}-1\right]$$

$\therefore$ $g(t)=\dfrac{(e^p-1)e^{(p+1)t}}{p}-e^t$

$$g'(t)=(p+1)\frac{(e^p-1)}{p}e^{(p+1)t}-e^t=0$$

$\Rightarrow$ $\dfrac{(p+1)(e^p-1)}{p}e^{pt}=1\Rightarrow e^{pt}=\dfrac{p}{(p+1)(e^p-1)}$

$$pt=\log_e\left(\frac{p}{(p+1)(e^p-1)}\right)$$

$\therefore$ $t=-\dfrac{1}{p}\log\left(\dfrac{(p+1)(e^p-1)}{p}\right)=t_p$

Also, $s_p-t_p=\dfrac{1}{p}\log\left(\dfrac{(p+1)(e^p-1)}{p}\right)-\dfrac{\log(p+1)}{p}$

$$=\frac{1}{p}\log\left(\frac{e^p-1}{p}\right)$$

Hence, $\lim\limits_{p\to 0^+}(s_p-t_p)=\lim\limits_{p\to 0^+}\dfrac{1}{p}\log\left(\dfrac{e^p-1}{p}\right)$

$$=\lim_{p\to 0}\frac{\log\left(1+\dfrac{e^p-p-1}{p}\right)}{\left(\dfrac{e^p-p-1}{p}\right)\cdot p}\cdot\left(\frac{e^p-p-1}{p}\right)=\lim_{p\to 0^+}\left(\frac{e^p-p-1}{p^2}\right)=\frac{1}{2}$$

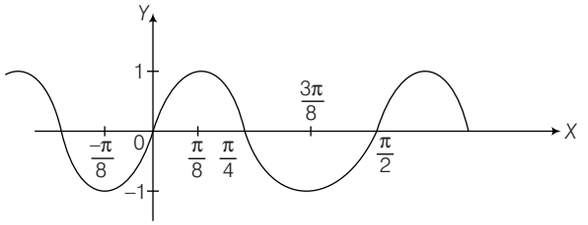
81. (c) ***82.*** (c) ***83.*** (b)

Sol. (Q. Nos. 84 to 86)

84. Here, $h(x) = f^2(x) + g^2(x)$

$= (\sin 3x + \cos x)^2 + (\cos 3x + \sin x)^2 = 2 + 2\sin 4x$

Graph of $y = \sin 4x$



Clearly, $h(x)$ is periodic function with period $\pi/2$ and from above graph, the length of a longest interval in which the function $y = h(x)$ is increasing $= \pi/8 - (-\pi/8) = \pi/4$

85. We have, $h(x) = 4$

$\Rightarrow \quad 2 + 2\sin 4x = 4 \Rightarrow \sin 4x = 1$

$\therefore \quad 4x = 2n\pi + \pi/2 = (4n+1)\pi/2$

$\Rightarrow \quad x = (4n+1)\pi/8, n \in I$

86. We have, $f(x) = g(x)$

$\Rightarrow \quad \sin 3x + \cos x = \cos 3x + \sin x$

$\Rightarrow \quad \sin 3x - \sin x = \cos 3x - \cos x$

$\Rightarrow \quad 2\sin x(\cos 2x + \sin 2x) = 0$

$\Rightarrow \quad$ either $\sin x = 0$ or $\tan 2x = -1$

$\Rightarrow \quad x = 0, \pi, 3\pi/8, 7\pi/8$

$\therefore$ Number of solution = 4

Sol. (Q. Nos. 87 to 89)

87. We have, $h''(x) = 6x - 4$

$\Rightarrow \quad h'(x) = 3x^2 - 4x + c$

As, $h'(1) = 0 \Rightarrow 0 = -1 + c$ or $c = 1$

So, $h'(x) = 3x^2 - 4x + 1$

$\Rightarrow \quad h(x) = x^3 - 2x^2 + x + k$

Also, $h(1) = 5 \Rightarrow k = 5$

$\therefore \quad h(x) = x^3 - 2x^2 + x + 5$

Now, $h'(2) = 5$

$\therefore$ The equation of tangent at $m(2, 7)$ to $y = h(x)$, is

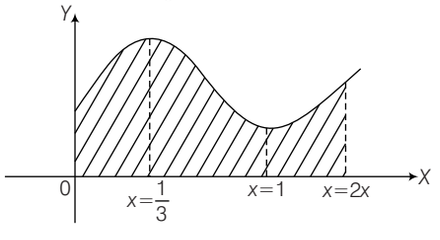
$(g - 7) = 5(x - 2)$

$\Rightarrow \quad 5x - y = 3$

88. Also, $g(f(x)) = 0, \forall\, x \in R$

$\therefore$ Required area $= \int_0^2 h(x)\,dx = \left(\frac{x^4}{4} - \frac{2x^3}{3} + \frac{x^2}{2} + 5x\right)_0^2$

$= 4 - \frac{16}{3} + 2 + 10 = 32/3$



89. Also, range of $f(g(x)) = \{-1, 0, 1\}$

$\therefore \quad \sqrt{f(g(x))} \in \{0, 1\}$

Hence, range of $\sin^{-1}\sqrt{(fog)(x)} \in \{0, \pi/2\}$

Sol. (Q. Nos. 90 to 92)

We have, $g(x) = x^3 + g''(1)x^2 + \{3g'(1) - g''(1) - 1\}x + 3g'(1)$

Let $\quad g'(1) = a,\ g''(1) = b$, then

$g(x) = x^3 + bx^2 + (3a - b - 1)x + 3a$

Differentiating both sides w.r.t. x, we get

$g'(x) = 3x^2 + 2bx + (3a - b - 1)$

Put $x = 1$,

$\Rightarrow \quad g'(1) = 3 + 2b + 3a - b - 1 \qquad [\because g'(1) = a]$

$\Rightarrow \quad a = b + 3a + 2$ or $2a + b = -2 \qquad$ ...(i)

Again differentiating, we get

$g''(x) = 6x + 2b$

Put $x = 1$,

$\Rightarrow \quad g''(1) = 6 + 2b \qquad [\therefore g''(1) = b]$

$\Rightarrow \quad b = 6 + 2b$

$\Rightarrow \quad b = -6 \qquad$ ...(ii)

From Eq. (i), $a = 2$

$\therefore \quad g(x) = x^3 - 6x^2 + 11x + 6$

Given, $\quad f(x) = x\,g(x) - 12x + 1$

$= x^4 - 6x^3 + 11x^2 + 6x - 12x + 1$

$= x^4 - 6x^3 + 11x^2 - 6x + 1$

$= (x^2+1)^2 - 2x^2 + 11x^2 - 6x^3 - 6x$

$= (x^2+1)^2 - 6x(x^2+1) + (3x)^2$

$= (x^2 + 1 - 3x)^2 = \{h(x)\}^2$, given

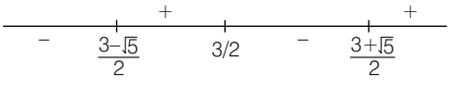
$\because \quad h(0) = 1$

$\therefore \quad h(x) = x^2 - 3x + 1$

90. $f(x) = (x^2 - 3x + 1)^2$

$\because \quad f'(x) = 2(x^2 - 3x + 1)(2x - 3) = 0$

$\Rightarrow \quad x = \frac{3}{2}, \frac{3 \pm \sqrt{5}}{2}$



Clearly, $f(x)$ has local maxima at $x = 3/2$ and local minima at $x = \frac{3 \pm \sqrt{5}}{2}$

$\therefore \quad f(x)$ has exactly one local maxima and two local minima

91. We have,

$g(x) = x^3 - 6x^2 + 11x + 6$

$g'(x) = 3x^2 - 12x + 11$

$= 3(x-2)^2 - 1 = 3[(x-2)^2 - 1/3]$

$\therefore \quad g'(x) > 0 \Rightarrow x \in \left(-\infty, 2 - \frac{1}{\sqrt{3}}\right) \cup \left(2 + \frac{1}{\sqrt{3}}, \infty\right)$

and $\quad g'(x) < 0 \Rightarrow x \in \left(2 - \frac{1}{\sqrt{3}}, 2 + \frac{1}{\sqrt{3}}\right)$

$\therefore$ $g(x)$ monotonically increases for
$x \in \left(-\infty, 2-\frac{1}{\sqrt{3}}\right) \cup \left(2+\frac{1}{\sqrt{3}}, \infty\right)$ and monotonically decreases for $x \in \left(2-\frac{1}{\sqrt{3}}, 2+\frac{1}{\sqrt{3}}\right)$

For $x \in [1, 3]$

$$g(x) = (x-1)(x-2)(x-3)+12$$

$\Rightarrow$ $g(1) = 12$ and $g(3) = 12$

$\therefore$ By Rolle's theorem in $[1, 3]$, we have $g'(c) = 0$

$\Rightarrow$ $c = 2 \pm \frac{1}{\sqrt{3}}$ [both $\in (1, 3)$]

$\therefore$ There exists two distinct tangents to the curve $y = g(x)$ which are parallel to the chord joining $(1, g(1))$ and $(3, g(3))$.

For $x \in [0, 4]$

$$g(0) = 6 \text{ and } g(4) = 18$$

$\therefore$ By LMVT

$$g'(c) = \frac{g(4)-g(0)}{4-0} = \frac{18-6}{4} = 3$$

$\therefore$ $3c^2 - 12c + 11 = 3$

$\Rightarrow$ $3c^2 - 12c + 8 = 0$

$\Rightarrow$ $c = 2 \pm 2/\sqrt{3}$ [both $\in (0, 4)$]

$\therefore$ There exists exactly two distinct lagrange's mean value in $(0, 4)$ for $y = g(x)$.

92. We have, $h(x) = x^2 - 3x + 1 = \left(x - \frac{3}{2}\right)^2 - \frac{5}{4}$

The curve $y = h(x)$ is an upward parabola, intersecting X-axis at two distinct points.

$\therefore$ $h(x)$ has exactly one critical point (i.e. the vertex) and no point of inflexion.

Also, $h(x) = 0$

$\Rightarrow$ $x = \frac{3 \pm \sqrt{5}}{2}$ [both $\in (0, 3)$]

$\therefore$ $h(x) = 0$ has exactly two distinct zeroes in $(0, 3)$.

93. (A) $y = 10 - (10 - x)$, $-1 \le x \le 3$
$= x$

$\therefore$ Maximum value $= 3$

(B) Equation of tangent at $(t^2, 2t)$

$$ty = x + t^2$$

this tangent means Y-axis at $Q(0, t)$

Here, $QS \times PQ = t \times \left(\frac{-1}{t}\right) = -1$

Area of triangle $PQS, \Delta = \frac{1}{2}\begin{vmatrix} t^2 & 2t & 1 \\ 0 & t & 1 \\ 1 & 0 & 1 \end{vmatrix}$

$\Rightarrow$ $\Delta = \frac{1}{2}[3t^2 + t]$

for $\in [0, 2]$, $\frac{d\Delta}{dt} \ge 0$

Δ is maximum at $t = 2$

$\therefore$ max $\Delta = \frac{1}{2}[2^3 + 2] = 5$

(C) Let $y = \left(1+\frac{1}{a}\right)\left(1+\frac{1}{b}\right) = \left(1+\frac{1}{1-b}\right)\left(1+\frac{1}{b}\right)$

$\Rightarrow b^2(y-1) + b(1-y) + 2 = 0$

Then, $(1-y)^2 - 8(y-1) \le 0$

$\Rightarrow$ $1 \le \sqrt{y} \le 3$

(D) $y = \frac{x+2}{2x^2+3x+6}$

$\Rightarrow$ $2yx^2 + (3y-1)x + 6y - 2 = 0$

$(3y-1)^2 - 4 \times 2y(6y-2) \ge 0$

$\Rightarrow$ $(3y-1)(13y+1) \le 0$

$\Rightarrow$ $\frac{-1}{13} \le y \le \frac{1}{3}$

94. (A) $3^x = t \Rightarrow Q(t) = 2t^3 - 4t^2 + 2t$ in $t \in \left[\frac{1}{3}, 3\right]$

$\Rightarrow Q'(t) < 0$ in $\left(\frac{1}{3}, 1\right)$ and $Q'(t) > 0$ in $(1, 3) \Rightarrow Q(t)_{\min} = Q(1) = 0$

(B) Take $x^2 + x = t \Rightarrow Q(t) = t(t-2) \Rightarrow Q(t)_{\min} = -1$

(C) $\int_{-1}^{3} |x-2|\,dx = 5$ and $\int_{-1}^{3} [x]dx = 2 \Rightarrow I = 3$

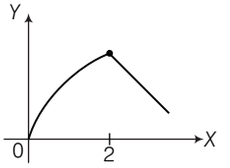
(D) Period of $\sin 36x = \frac{\pi}{18}$

Period of $\tan 42x = \frac{\pi}{42} \Rightarrow p = \frac{\pi}{6}$

95. (A) $f'(x) = 8x(x-1)(x+1)$ [positive factor]

$\Rightarrow$ Local maxima at $x = 0$

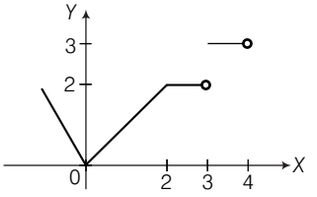
(B) Clearly, we see (p), (r), (s)



(C) $f\left(\frac{1}{2}\right)^- > f\left(\frac{1}{2}\right) < f\left(\frac{1}{2}\right)^+$

Also, $f(x)$ is non-differentiable at $x = \frac{1}{2}$

$\Rightarrow$ Clearly, we see (p), (s).



(D) Clearly, we see (q), (s).

96. (A) $f'(x) = -\pi \sin \pi x + 10 + 6x + 3x^2$

$= 3(x+1)^2 + 7 - \pi \sin \pi x > 0$ for all x

$\therefore$ $f(x)$ is minimum in $-2 \le x \le 3$. So, the absolute minimum

$= f(-2) = -15$

(B) $f'(x) = 2x + 1$. Therefore, for $-1 \le x < -\frac{1}{2}$, we get $f'(x) < 0$ and for $-\frac{1}{2} < x \le 1$, we get $f'(x) > 0$

$\therefore$ $f(x)$ is minimum decrease in $f\left[-1, -\frac{1}{2}\right]$.

and minimum decrease in $\left(-\frac{1}{2}, 1\right]$.

$\therefore$ $\min f(x) = f\left(-\frac{1}{2}\right) = \left(-\frac{1}{2}\right)^2 + \left(-\frac{1}{2}\right) + 1 = \frac{3}{4}$

(C) $f'(x) = 4(x^2 - 1)$. So, for $0 \le x < 1$, we get $f'(x) < 0$, i.e. $f(x)$ is monotonically decreasing and for $1 < x \le 2$, we get $f'(x) > 0$, $f(x)$ is monotonically increasing.

$\therefore$ $\min f(x) = f(1) = \frac{4}{3} - 4 = -\frac{8}{3}$.

(D) $f'(x) = -12 + 18x - 6x^2$

$= -6(x^2 - 3x + 2) = -6(x-1)(x-2)$

$\therefore$ $f'(x) > 0$, if $1 < x < 2$

and $f'(x) < 0$, if $2 < x \le 4$

$\therefore$ $f(x)$ is monotonically increasing in $1 < x < 2$ and monotonically decreasing in $2 < x \le 4$.

$\therefore$ Absolute maximum = The greatest among $\{f(1), f(2)\}$

= The greatest among $\{1, 2\} = 2$

97. $\frac{dT}{dt} = k(T-5)^2$

$$\frac{dT}{(T-5)^2} = k\,dt$$

$\Rightarrow$ $$\frac{(T-5)^{-1}}{-1} = kt + c$$

$\therefore$ $-(40-5)^{-1} = c$ i.e. $c = -\frac{1}{35}$

$\therefore$ $$-\frac{1}{T-5} = kt - \frac{1}{35}$$

After 15 min

$$-\frac{1}{30-5} = 15k - \frac{1}{35}$$

$\therefore$ $k = \frac{1}{15}\left(\frac{1}{35} - \frac{1}{25}\right) = \frac{-10}{15 \times 35 \times 25} = \frac{-2}{75 \times 35}$

Temperature after 60 min is given by

$$-\frac{1}{T-5} = 60\left(\frac{-2}{75 \times 35}\right) - \frac{1}{35}$$

$\Rightarrow$ $$\frac{1}{T-5} = \frac{120 + 75}{75 \times 35} + 5 = \frac{195}{75 \times 35}$$

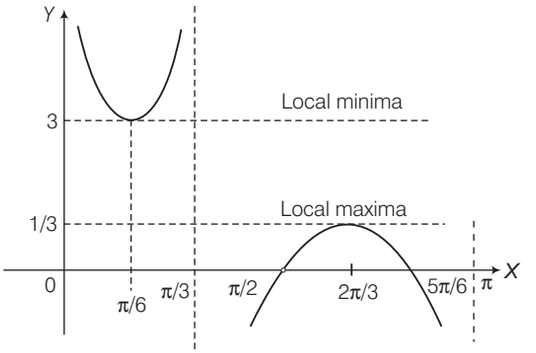
$\Rightarrow$ $T = \frac{75 \times 35}{195} + 5 = \frac{5 \times 35}{13} + 5 = \frac{175}{13} + 5$

$\Rightarrow$ $[T] = 18$

$\therefore$ $[T]/2 = 18/2 = 9$

98. $y = \frac{2\sin\left(x + \frac{\pi}{6}\right)\cos x}{2\sin x \cos\left(x + \frac{\pi}{6}\right)} = \frac{\sin\left(2x + \frac{\pi}{6}\right) + \sin\frac{\pi}{6}}{\sin\left(2x + \frac{\pi}{6}\right) - \sin\frac{\pi}{6}}$

$= 1 + \frac{1}{\sin\left(2x + \frac{\pi}{6}\right) - \sin\frac{\pi}{6}}$



y is minimum, if $2x + \frac{\pi}{6} = \frac{\pi}{2} \Rightarrow x = \frac{\pi}{6}$

$\Rightarrow$ $y_{\min} = 1 + 2 = 3$

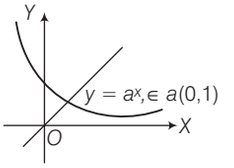
99. Let $A = (t, t^2)$, $m_{OA} = t$, $m_{AB} = -\frac{1}{t}$

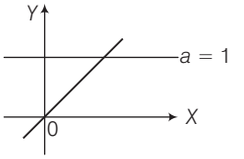
Equation of AB, $y - t^2 = -\frac{1}{t}(x - t)$

Put $x = 0, h = t^2 + 1$

Now, $\lim_{x \to 0}(h) = \lim_{t \to 0}(1 + t^2) = 1$ [as $x \to 0$, then $t \to 0$]

100. For $0 < a \le 1$ the line always intersects $y = a^x$



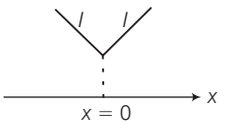


For $a > 1$ say $a = e$ consider $f(x) = e^x - x$

$f'(x) = e^x - 1$

$f'(x) > 0$ for $x > 0$ and $f'(x) < 0$ for $x < 0$

$\therefore f(x)$ is increasing ($\uparrow$) for $x > 0$ and decreasing ($\downarrow$) for $x < 0$



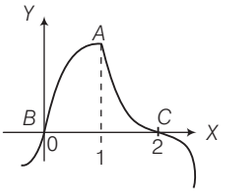
$y = e^x$ always lies above $y = x$, i.e. $e^x - x \ge 1$ for $a > 1$, hence never intersects $\Rightarrow a \in (0, 1]$

101. $\frac{dy}{dx} = -\frac{4\cos x}{\sin^2 x} + \frac{\cos x}{(1-\sin x)^2} = 0$ gives $\sin x = \frac{2}{3}$

note that $f(x) \to \infty$ as $x \to 0^+$ or $x \to \frac{\pi^-}{2}$ and between two maxima, we have a minima.

So, $a = \frac{4}{2/3} + \frac{1}{1-2/3} = 9$

102.



A, B, C are the 3 critical points of $y = f(x)$.

103. Only at A and E, $f(x) = 0$ but does not change sign.

104. Note that f is defined for $x > 0$

$$f'(x) = \frac{1}{2}\cos 2x = 0 \quad \Rightarrow \quad x = n\pi \pm \frac{\pi}{4}$$

105. Obviously, f is increasing and g is decreasing in (x_1, x_2), hence $f(g(\alpha^2 - 2\alpha)) > f(g(3\alpha - 4))$ as f is increasing

$\Rightarrow \quad g(\alpha^2 - 2\alpha) > g(3\alpha - 4)$

$\therefore \quad \alpha^2 - 2\alpha < 3\alpha - 4$ as g is decreasing.

$$\alpha^2 - 5\alpha + 4 < 0$$

$\Rightarrow \quad (\alpha - 1)(\alpha - 4) < 0 \quad \Rightarrow \quad \alpha \in (1, 4)$

106. $f(x) = \frac{t + 3x - x^2}{x - 4}$, $f'(x) = \frac{(x-4)(3-2x) - (t + 3x - x^2)}{(x-4)^2}$

For maximum or minimum, $f'(x) = 0$

$$-2x^2 + 11x - 12 - t - 3x + x^2 = 0$$

$$-x^2 + 8x - (12 + t) = 0$$

For one M and m, $D > 0$

$$64 - 4(12 + t) > 0$$

$$16 - 12 - t > 0 \quad \Rightarrow \quad 4 > t \text{ or } t < 4$$

Hence, the greatest value of t is 3.

107. Let $g(x) = f'(x)\sin(\pi f(x))$ ...(i)

$\therefore \; g'(x) = \pi(f'(x))^2 \cos[\pi f(x)] + \sin(\pi f(x)) \cdot f''(x)$ ...(ii)

Here, $g(a) = 0 = g(b)$

and $g(\alpha) = g(\beta) = 0$

$$g\left(\frac{\alpha + \beta}{2}\right) = 0$$

$\therefore$ According to Rolle's theorem,

$g'(x) = 0$ has atleast one root in $(\alpha, a), \left(a, \frac{a+b}{2}\right), \left(\frac{a+b}{2}, b\right)$ and (b, β), i.e. minimum of 4 roots.

108. Let $g(x) = \frac{1}{|x-4|+1}$

$\Rightarrow \quad g(x+12) = \frac{1}{|x+8|+1}$

When $x < -8$ both $g(x)$ and $g(x+12)$ are increasing, hence maximum value can't occur in this interval.

Similarly, for $x \in (4, \infty)$ both $g(x)$ and $g(x+12)$ are decreasing, hence maximum value can't occur in this interval.

So, now for all values of $x \in (-8, 4)$

$$f(x) = \frac{1}{x+9} + \frac{1}{5-x}$$

$\Rightarrow \quad f'(x) = -\frac{1}{(x+9)^2} + \frac{1}{(5-x)^2} = \frac{(x+9)^2 - (5-x)^2}{(x+9)^2(5-x)^2}$

$\therefore \quad f'(x) = \frac{14(2x+4)}{(x+9)^2(5-x)^2}$

$\therefore$ Minimum at $x = -2$, and maximum occurs at $x = +4$ or $x = -8$.

Here, $f(4) = f(-8) = \frac{14}{13} = \frac{p}{q}$

$\therefore \quad (p - q) = 1$

109. Here, to find the least value of $\alpha \in R$, for which $4\alpha x^2 + \frac{1}{x} \geq 1$, for all $x > 0$.

i.e. to find the minimum value of α when $y = 4\alpha x^2 + \frac{1}{x}$; $x > 0$ attains minimum value of α.

$\therefore \quad \frac{dy}{dx} = 8\alpha x - \frac{1}{x^2}$ ...(i)

Now, $\frac{d^2y}{dx^2} = 8\alpha + \frac{2}{x^3}$ ...(ii)

When $\frac{dy}{dx} = 0$, then $8x^3\alpha = 1$

At $x = \left(\frac{1}{8\alpha}\right)^{1/3}$, $\frac{d^2y}{dx^2} = 8\alpha + 16\alpha = 24\alpha$, Thus, y attains minimum when

$$x = \left(\frac{1}{8\alpha}\right)^{1/3}; \; \alpha > 0.$$

$\therefore \; y$ attains minimum when $x = \left(\frac{1}{8\alpha}\right)^{1/3}$.

i.e. $4\alpha\left(\frac{1}{8\alpha}\right)^{2/3} + (8\alpha)^{1/3} \geq 1$

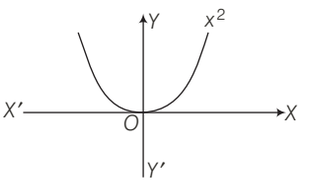
$\Rightarrow \quad \alpha^{1/3} + 2\alpha^{1/3} \geq 1$

$\Rightarrow \quad 3\alpha^{1/3} \geq 1 \Rightarrow \alpha \geq \frac{1}{27}$

Hence, the least value of α is $\frac{1}{27}$.

110. **Plan** The given equation contains algebraic and trigonometric functions called transcendental equation. To solve transcendental equations we should always plot the graph for LHS and RHS.

Here, $x^2 = x\sin x + \cos x$



Let $f(x) = x^2$ and $g(x) = x\sin x + \cos x$

We know that, the graph for $f(x) = x^2$

To plot, $g(x) = x\sin x + \cos x$

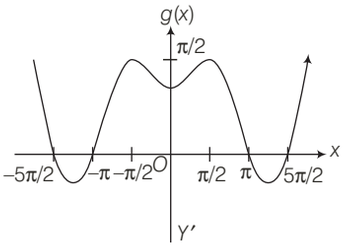
$g'(x) = x\cos x + \sin x - \sin x$

$g'(x) = x\cos x$ ...(i)

$g''(x) = -x\sin x + \cos x$ ...(ii)

Put $g'(x) = 0 \Rightarrow x\cos x = 0$

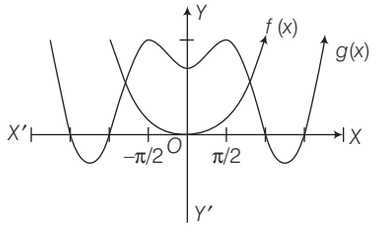
$\therefore$ $x = 0, \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}, \frac{7\pi}{2}$



At $x = 0, \frac{3\pi}{2}, \frac{7\pi}{2}, ..., f''(x) > 0$, so minimum

At $x = \frac{\pi}{2}, \frac{5\pi}{2}, \frac{9\pi}{2}, ..., f'(x) < 0$, so maximum

So, graph of $f(x)$ and $g(x)$ are shown as



So, number of solutions are 2.

111. Here, $\lim_{x\to 2} \frac{f(x)\cdot g(x)}{f'(x)\cdot g'(x)} = 1$

$\Rightarrow \lim_{x\to 2} \frac{f(x)g'(x) + f'(x)g(x)}{f''(x)g'(x) + f'(x)g''(x)} = 1$ [using L'Hospital's rule]

$\Rightarrow \frac{f(2)g'(2) + f'(2)g(2)}{f''(2)g'(2) + f'(2)g''(2)} = 1$

$\Rightarrow \frac{f(2)g'(2)}{f''(2)g'(2)} = 1$ [$\because f'(2) = g(2) = 0$]

$\Rightarrow f(2) = f''(2)$ ...(i)

$\therefore$ $f(x) - f''(x) = 0$ for atleast one $x \in R$.

$\Rightarrow$ Option (d) is correct.

Also, $f: R \to (0, \infty)$

$\Rightarrow f(2) > 0$

$\therefore f''(2) = f(2) > 0$ [from Eq. (i)]

Since, $f'(2) = 0$ and $f''(2) > 0$

$\therefore f(x)$ attains local minimum at $x = 2$.

$\Rightarrow$ Option (a) is correct.

112. Given, $f(x) = \int_{\frac{1}{x}}^{x} \frac{e^{-\left(t+\frac{1}{t}\right)}}{t} dt$

$$f'(x) = 1\cdot \frac{e^{-\left(x+\frac{1}{x}\right)}}{x} - \left(\frac{-1}{x^2}\right)\frac{e^{-\left(\frac{1}{x}+x\right)}}{1/x}$$

$$= \frac{e^{-\left(x+\frac{1}{x}\right)}}{x} + \frac{e^{-\left(x+\frac{1}{x}\right)}}{x} = \frac{2e^{-\left(x+\frac{1}{x}\right)}}{x}$$

As $f'(x) > 0, \forall x \in (0, \infty)$

$\therefore$ $f(x)$ is monotonically increasing on $(0, \infty)$.

$\Rightarrow$ Option (a) is correct and option (b) is wrong.

Now, $f(x) + f\left(\frac{1}{x}\right) = \int_{1/x}^{x} \frac{e^{-\left(t+\frac{1}{t}\right)}}{t} dt + \int_{x}^{1/x} \frac{e^{-\left(t+\frac{1}{t}\right)}}{t} dt$

$= 0, \forall x \in (0, \infty)$

Now, let $g(x) = f(2^x) = \int_{2^{-x}}^{2^x} \frac{e^{-\left(t+\frac{1}{t}\right)}}{t} dt$

$$g(-x) = f(2^{-x}) = \int_{2^x}^{2^{-x}} \frac{e^{-\left(t+\frac{1}{t}\right)}}{t} dt = -g(x)$$

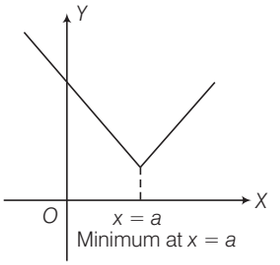
$\therefore$ $f(2^x)$ is an odd function of x on R.

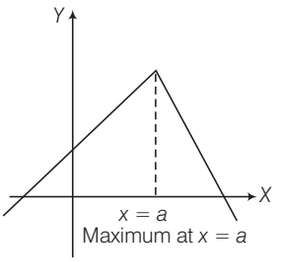
113. **Plan**

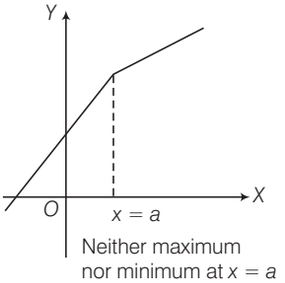
We know that, $|x| = \begin{cases} x, & \text{if } x \geq 0 \\ -x, & \text{if } x < 0 \end{cases}$

$\Rightarrow$ $|x - a| = \begin{cases} x - a, & \text{if } x \geq a \\ -(x - a), & \text{if } x < a \end{cases}$

and for non-differentiable continuous function, the maximum or minimum can be checked with graph as





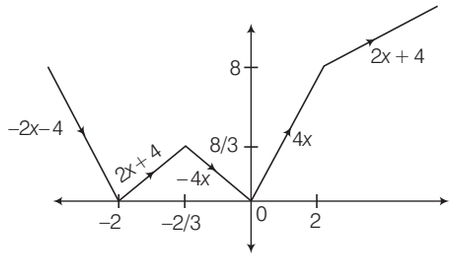


Here, $f(x) = 2|x| + |x + 2| - ||x + 2| - 2|x||$

$$= \begin{cases} -2x - (x + 2) + (x - 2), & \text{if when } x \leq -2 \\ -2x + x + 2 + 3x + 2, & \text{if when } -2 < x \leq -2/3 \\ -4x, & \text{if when } -\frac{2}{3} < x \leq 0 \\ 4x, & \text{if when } 0 < x \leq 2 \\ 2x + 4, & \text{if when } x > 2 \end{cases}$$

$$= \begin{cases} -2x-4, & \text{if} \quad x \le -2 \\ 2x+4, & \text{if} \quad -2 < x \le -2/3 \\ -4x, & \text{if} \quad -\frac{2}{3} < x \le 0 \\ 4x, & \text{if} \quad 0 < x \le 2 \\ 2x+4, & \text{if} \quad x > 2 \end{cases}$$

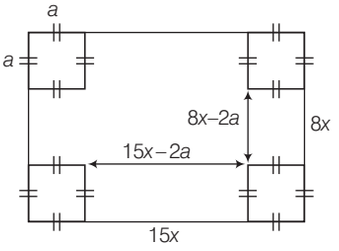
Graph for $y = f(x)$ is shown as



114. **Plan** The problem is based on the concept to maximise volume of cuboid, i.e. to form a function of volume, say $f(x)$ find $f'(x)$ and $f''(x)$.

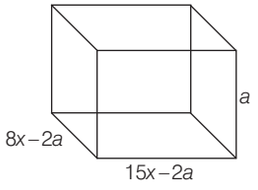
Put $f'(x) = 0$ and check $f''(x)$ to be + ve or − ve for minimum and maximum, respectively.

Here, $l = 15x - 2a$, $b = 8x - 2a$ and $h = a$



$\therefore$ Volume $= (8x - 2a)(15x - 2a)a$

$$V = 2a \cdot (4x - a)(15x - 2a) \qquad \ldots(i)$$



On differentiating Eq. (i) w.r.t. a, we get

$$\frac{dv}{da} = 6a^2 - 46ax + 60x^2$$

Again, differentiating, we get $\dfrac{d^2v}{da^2} = 12a - 46x$

Here, $\left(\dfrac{dv}{da}\right) = 0$

$\Rightarrow$ $6x^2 - 23x + 15 = 0$

At $a = 5$, $x = 3, \dfrac{5}{6}$

$\Rightarrow$ $\left(\dfrac{d^2v}{da^2}\right) = 2(30 - 23x)$

At $x = 3, \left(\dfrac{d^2v}{da^2}\right) = 2(30 - 69) < 0$

$\therefore$ Maximum when $x = 3$, also at $x = \dfrac{5}{6}$

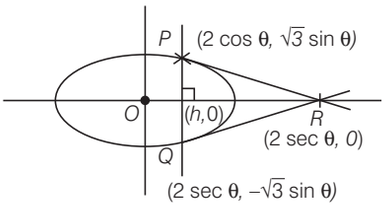
$\Rightarrow$ $\left(\dfrac{d^2v}{da^2}\right) > 0$

$\therefore$ At $x = 5/6$, volume is minimum.

Thus, sides are $8x = 24$ and $15x = 45$

115. **Plan** As to maximise or minimise area of triangle, we should find area in terms of parametric coordinates and use second derivative test.

Here, tangent at $P(2\cos\theta, \sqrt{3}\sin\theta)$ is



$$\frac{x}{2}\cos\theta + \frac{y}{\sqrt{3}}\sin\theta = 1$$

$\therefore$ $R(2\sec\theta, 0)$

$\Rightarrow$ $\Delta =$ Area of ΔPQR

$$= \frac{1}{2}(2\sqrt{3}\sin\theta)(2\sec\theta - 2\cos\theta)$$

$$= 2\sqrt{3} \cdot \sin^3\theta / \cos\theta \qquad \ldots(i)$$

Since, $\dfrac{1}{2} \le h \le 1$

$\therefore$ $\dfrac{1}{2} \le 2\cos\theta \le 1$

$\Rightarrow$ $\dfrac{1}{4} \le \cos\theta \le \dfrac{1}{2}$ $\qquad \ldots(ii)$

$$\therefore \frac{d\Delta}{d\theta} = \frac{2\sqrt{3}\{\cos\theta \cdot 3\sin^2\theta\cos\theta - \sin^3\theta(-\sin\theta)\}}{\cos^2\theta}$$

$$= \frac{2\sqrt{3}\cdot\sin^2\theta}{\cos^2\theta}[3\cos^2\theta + \sin^2\theta] = \frac{2\sqrt{3}\sin^2\theta}{\cos^2\theta}\cdot[2\cos^2\theta + 1]$$

$$= 2\sqrt{3}\tan^2\theta(2\cos^2\theta + 1) > 0$$

When $\dfrac{1}{4} \le \cos\theta \le \dfrac{1}{2}$,

$\therefore$ $\Delta_1 = \Delta_{\max}$ occurs at $\cos\theta = \dfrac{1}{4} = \left(\dfrac{2\sqrt{3}\cdot\sin^3\theta}{\cos\theta}\right)$

When $\cos\theta = \dfrac{1}{4} = \dfrac{45\sqrt{5}}{8}$

$\Delta_2 = \Delta_{\min}$ occurs at $\cos\theta = \dfrac{1}{2} = \left(\dfrac{2\sqrt{3}\sin^3\theta}{\cos\theta}\right)$

When $\cos\theta = \dfrac{1}{2} = \dfrac{9}{2}$

$\therefore$ $\dfrac{8}{\sqrt{5}}\Delta_1 - 8\Delta_2 = 45 - 36 = 9$

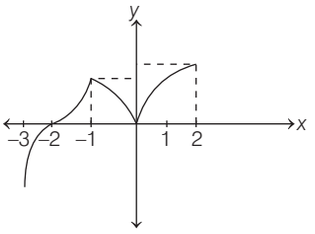
116. Given function, $f(x) = e^{x^2} + e^{-x^2}$, $g(x) = xe^{x^2} + e^{-x^2}$ and $h(x) = x^2e^{x^2} + e^{-x^2}$ are strictly increasing on $[0, 1]$.

Hence, at $x = 1$, the given function attains absolute maximum all equal to $e + 1/e$.

$\Rightarrow$ $a = b = c$

117. Given, $f(x) = \begin{cases} (2+x)^3, & \text{if } -3 < x \le -1 \\ x^{2/3}, & \text{if } -1 < x < 2 \end{cases}$

$\Rightarrow$ $f'(x) = \begin{cases} 3(x+2)^2, & \text{if } -3 < x < -1 \\ \frac{2}{3}x^{-\frac{1}{3}}, & \text{if } -1 < x < 2 \end{cases}$



Clearly, $f'(x)$ changes its sign at $x = -1$ from +ve to –ve and so $f(x)$ has local maxima at $x = -1$.

Also, $f'(0)$ does not exist but $f'(0^-) < 0$ and $f'(0^+) > 0$. It can only be inferred that $f(x)$ has a possibility of a minima at $x = 0$. Hence, the given function has one local maxima at $x = -1$ and one local minima at $x = 0$.

118. Given, $g(u) = 2\tan^{-1}(e^u) - \frac{\pi}{2}$ for $u \in (-\infty, \infty)$

$$g(-u) = 2\tan^{-1}(e^{-u}) - \frac{\pi}{2} = 2(\cot^{-1}(e^u)) - \frac{\pi}{2}$$

$$= 2\left(\frac{\pi}{2} - \tan^{-1}(e^u)\right) - \frac{\pi}{2}$$

$$= \pi/2 - 2\tan^{-1}(e^u) = -g(u)$$

$\therefore$ $g(-u) = -g(u)$

$\Rightarrow$ $g(u)$ is an odd function.

We have, $g(u) = 2\tan^{-1}(e^u) - \pi/2$

$$g'(u) = \frac{2e^u}{1 + e^{2u}}$$

$g'(u) > 0, \forall\ x \in R$ $\quad [\because e^u > 0]$

So, $g'(u)$ is increasing for all $x \in R$.

119. Let $f(x) = bx^2 + ax + c$

$\because$ $f(0) = 0 \Rightarrow c = 0$

and $f(1) = 1 \Rightarrow a + b = 1$

$\therefore$ $f(x) = ax + (1 - a)x^2$

Also, $f'(x) > 0$, for $x \in (0, 1)$

$\Rightarrow$ $a + 2(1 - a)x > 0$

$\Rightarrow$ $a(1 - 2x) + 2x > 0$

$\Rightarrow$ $a > \frac{2x}{2x - 1} \Rightarrow 0 < a < 2$, since $x \in (0, 1)$

$\therefore$ $f(x) = ax + (1 - a)x^2$, $0 < a < 2$

120. Given, $f(x) = x^3 + bx^2 + cx + d$

$\Rightarrow$ $f'(x) = 3x^2 + 2bx + c$

As we know that, if $ax^2 + bx + c > 0, \forall x$, then $a > 0$ and $D < 0$.

Now, $D = 4b^2 - 12c = 4(b^2 - c) - 8c$

[where, $b^2 - c < 0$ and $c > 0$]

$\therefore$ $D = (-\text{ve})$ or $D < 0$

$\Rightarrow f'(x) = 3x^2 + 2bx + c > 0\ \forall x \in (-\infty, \infty)$ [as $D < 0$ and $a > 0$]

Hence, $f(x)$ is strictly increasing function.

121. Given $f(x) = x^2 + 2bx + 2c^2$ and $g(x) = -x^2 - 2cx + b^2$

Then, $f(x)$ is minimum and $g(x)$ is maximum at $\left(x = \frac{-b}{4a} \text{ and } f(x) = \frac{-D}{4a}\right)$, respectively.

$\therefore$ $\min f(x) = \frac{-(4b^2 - 8c^2)}{4} = (2c^2 - b^2)$

and $\max g(x) = -\frac{(4c^2 + 4b^2)}{4(-1)} = (b^2 + c^2)$

Now, $\min f(x) > \max g(x)$

$\Rightarrow$ $2c^2 - b^2 > b^2 + c^2 \Rightarrow c^2 > 2b^2 \Rightarrow |c| > \sqrt{2}|b|$

122. Let $f(x) = 3\sin x - 4\sin^3 x = \sin 3x$

The longest interval in which $\sin x$ is increasing is of length π. So, the length of largest interval in which $f(x) = \sin 3x$ is increasing is $\frac{\pi}{3}$.

123. Given, $\cot\alpha_1 \cdot \cot\alpha_2 \cdot \ldots \cdot \cot\alpha_n = 1$

$\Rightarrow$ $\frac{\cos\alpha_1}{\sin\alpha_1} \cdot \frac{\cos\alpha_2}{\sin\alpha_2} \cdot \frac{\cos\alpha_3}{\sin\alpha_3} \cdot \ldots \cdot \frac{\cos\alpha_n}{\sin\alpha_n} = 1$

Let $\cos\alpha_1 \cdot \cos\alpha_2 \cdot \cos\alpha_3 \cdot \ldots \cdot \cos\alpha_n = k$ ...(i)

and $\sin\alpha_1 \cdot \sin\alpha_2 \cdot \sin\alpha_3 \cdot \ldots \cdot \sin\alpha_n = k$ ... (ii)

Again, on multiplying Eqs. (i) and (ii), we get

$(\cos\alpha_1 \cdot \cos\alpha_2 \cdot \cos\alpha_3 \cdot \ldots \cdot \cos\alpha_n)$

$\times (\sin\alpha_1 \cdot \sin\alpha_2 \cdot \sin\alpha_3 \cdot \ldots \cdot \sin\alpha_n) = k^2$

$$k^2 = \frac{1}{2 \times 2 \times \ldots n \text{ times}} (2\sin\alpha_1\cos\alpha_1)$$

$$(2\sin\alpha_2\cos\alpha_2)\ldots(2\sin\alpha_n\cos\alpha_n)$$

$\Rightarrow$ $k^2 = \frac{1}{2^n}(\sin 2\alpha_1)(\sin 2\alpha_2) \ldots (\sin 2\alpha_n)$

$$\le \frac{1}{2^n}\sin 2\alpha_i \le 1, \forall 1 \le i < n \Rightarrow k \le \frac{1}{2^{n/2}}$$

124. Given, $f(x) = \begin{cases} e^x, & \text{if } 0 \le x \le 1 \\ 2 - e^{x-1}, & \text{if } 1 < x \le 2 \\ x - e, & \text{if } 2 < x \le 3 \end{cases}$

and $g(x) = \int_0^x f(t)\,dt$

$\Rightarrow$ $g'(x) = f(x)$

Put $g'(x) = 0 \Rightarrow x = 1 + \log_e 2$ and $x = e$.

Also, $g''(x) = \begin{cases} e^x, & \text{if } 0 \le x \le 1 \\ -e^{x-1}, & \text{if } 1 < x \le 2 \\ 1, & \text{if } 2 < x \le 3 \end{cases}$

At $x = 1 + \log_e 2$, $g''(1 + \log_e 2) = -e^{\log_e 2} < 0$, $g(x)$ has a local maximum.

Also, at $x = e$,

$g''(e) = 1 > 0$, $g(x)$ has a local minima.

$\because$ $f(x)$ is discontinuous at $x = 1$, then we get local maxima at $x = 1$ and local minima at $x = 2$.

Hence, (a) and (b) are correct answers.

125. Since, $f(x)$ has local maxima at $x = -1$ and $f'(x)$ has local minima at $x = 0$.

$\therefore$ $f''(x) = \lambda x$

On integrating, we get

$$f'(x) = \lambda \frac{x^2}{2} + c \qquad [\because f'(-1) = 0]$$

$$\Rightarrow \quad \frac{\lambda}{2} + c = 0 \Rightarrow \lambda = -2c \qquad \ldots(i)$$

Again, integrating on both sides, we get

$$f(x) = \lambda \frac{x^3}{6} + cx + d$$

$$\Rightarrow \quad f(2) = \lambda\left(\frac{8}{6}\right) + 2c + d = 18 \qquad \ldots(ii)$$

and $$f(1) = \frac{\lambda}{6} + c + d = -1 \qquad \ldots(iii)$$

From Eqs. (i), (ii) and (iii), we get

$$f(x) = \frac{1}{4}(19x^3 - 57x + 34)$$

$$\therefore \quad f'(x) = \frac{1}{4}(57x^2 - 57) = \frac{57}{4}(x-1)(x+1)$$

For maxima or minima, put $f'(x) = 0$

$$\Rightarrow \quad x = 1, -1$$

Now $$f''(x) = \frac{1}{4}(114x)$$

At $x = 1$, $f''(x) > 0$, minima

At $x = -1$, $f''(x) < 0$, maxima

$\therefore$ $f(x)$ is increasing for $[1, 2\sqrt{5}]$.

$\therefore$ $f(x)$ has local maxima at $x = -1$ and $f(x)$ has local minima at $x = 1$.

Also, $$f(0) = 34/4$$

Hence, (b) and (c) are the correct answers.

126. $$f(x) = \frac{(x^2 + ax + 1) - 2ax}{x^2 + ax + 1} = 1 - \frac{2ax}{x^2 + ax + 1}$$

$$f'(x) = -\left[\frac{(x^2 + ax + 1)\cdot 2a - 2ax(2x + a)}{(x^2 + ax + 1)^2}\right]$$

$$= -\left[\frac{-2ax^2 + 2a}{(x^2 + ax + a)^2}\right] = 2a\left[\frac{(x^2 - 1)}{(x^2 + ax + 1)^2}\right] \qquad \ldots(i)$$

$$f''(x) = 2a\left[\frac{(x^2 + ax + 1)^2(2x) - 2(x^2 - 1)(x^2 + ax + 1)(2x + a)}{(x^2 + ax + 1)^4}\right]$$

$$= 2a\left[\frac{2x(x^2 + ax + 1) - 2(x^2 - 1)(2x + a)}{(x^2 + ax + 1)^3}\right] \qquad \ldots(ii)$$

Now, $$f''(1) = \frac{4a(a+2)}{(a+2)^3} = \frac{4a}{(a+2)^2}$$

and $$f''(-1) = \frac{4a(a-2)}{(2-a)^3} = \frac{-4a}{(a-2)^2}$$

$\therefore$ $(2 + a)^2 f''(1) + (2 - a)^2 f''(-1) = 4a - 4a = 0$

127. When $x \in (-1, 1)$,

$$x^2 < 1$$

$\Rightarrow x^2 - 1 < 0$

$\therefore$ $f'(x) < 0$, $f(x)$ is decreasing.

Also, at $x = 1$, $f''(1) = \frac{4a}{(a+2)^2} > 0$ $\qquad [\because 0 < a < 2]$

So, $f(x)$ has local minimum at $x = 1$.

128. $$g'(x) = \frac{f'(e^x)}{1 + (e^x)^2}\cdot e^x = 2a\left[\frac{e^{2x} - 1}{(e^{2x} + ae^x + 1)^2}\right]\left(\frac{e^x}{1 + e^{2x}}\right)$$

$g'(x) = 0$, if $e^{2x} - 1 = 0$,

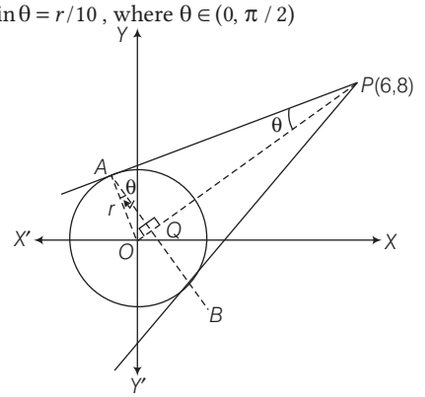
i.e. $$x = 0$$

If $$x < 0, e^{2x} < 1$$

$$\Rightarrow \quad g'(x) < 0$$

129. To maximize area of ΔAPB, we know that, $OP = 10$

and $\sin\theta = r/10$, where $\theta \in (0, \pi/2)$ $\qquad \ldots$ (i)



$\therefore$ $$\text{Area} = \frac{1}{2}(2AQ)(PQ)$$

$$= AQ \cdot PQ = (r\cos\theta)(10 - OQ)$$

$$= (r\cos\theta)(10 - r\sin\theta)$$

$$= 10\sin\theta\cos\theta(10 - 10\sin^2\theta) \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow \quad A = 100\cos^3\theta\sin\theta$$

$$\Rightarrow \quad \frac{dA}{d\theta} = 100\cos^4\theta - 300\cos^2\theta\cdot\sin^2\theta$$

Put $$\frac{dA}{d\theta} = 0$$

$$\Rightarrow \quad \cos^2\theta = 3\sin^2\theta$$

$$\Rightarrow \quad \tan\theta = 1/\sqrt{3}$$

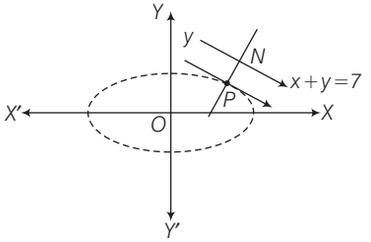
$$\Rightarrow \quad \theta = \pi/6$$

At which $\frac{dA}{d\theta} < 0$, thus when $\theta = \pi/6$, area is maximum

From Eq. (i), $r = 10\sin\frac{\pi}{6} = 5$ units

130. Let us take a point $P(\sqrt{6}\cos\theta, \sqrt{3}\sin\theta)$ on $\frac{x^2}{6}+\frac{y^2}{3}=1$.

Now, to minimise the distance from P to given straight line $x+y=7$, shortest distance exists along the common normal.



Slope of normal at $P=\frac{a^2/x_1}{b^2/y_1}=\frac{\sqrt{6}\sec\theta}{\sqrt{6}\,\mathrm{cosec}\,\theta}=\sqrt{2}\tan\theta=1$

So, $\cos\theta=\sqrt{\frac{2}{3}}$ and $\sin\theta=\frac{1}{\sqrt{3}}$

Hence, required point is $P(2,1)$.

131. **Plan**

(i) Local maximum and local minimum are those points at which $f'(x)=0$, when defined for all real numbers.

(ii) Local maximum and local minimum for piecewise functions are also been checked at sharp edges.

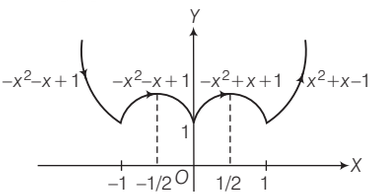
Description of Situation $y=|x|=\begin{cases}x, & \text{if } x\geq 0\\ -x, & \text{if } x<0\end{cases}$

Also, $y=|x^2-1|=\begin{cases}(x^2-1), & \text{if } x\leq -1 \text{ or } x\geq 1\\ (1-x^2), & \text{if } -1\leq x\leq 1\end{cases}$

$$y=|x|+|x^2-1|=\begin{cases}-x+1-x^2, & \text{if } x\leq -1\\ -x+1-x^2, & \text{if } -1\leq x\leq 0\\ x+1-x^2, & \text{if } 0\leq x\leq 1\\ x+x^2-1, & \text{if } x\geq 1\end{cases}$$

$$=\begin{cases}-x^2-x+1, & \text{if } x\leq -1\\ -x^2-x+1, & \text{if } -1\leq x\leq 0\\ -x^2+x+1, & \text{if } 0\leq x\leq 1\\ x^2+x-1, & \text{if } x\geq 1\end{cases}$$

which could be graphically shown as



Thus, $f(x)$ attains maximum at $x=\frac{1}{2},\frac{-1}{2}$ and $f(x)$ attains minimum at $x=-1,0,1$.

$\Rightarrow$ Total number of points = 5

132. **Plan** If $f(x)$ is least degree polynomial having local maximum and local minimum at α and β.

Then, $f'(x)=\lambda(x-\alpha)(x-\beta)$

Here, $p'(x)=\lambda(x-1)(x-3)=\lambda(x^2-4x+3)$

On integrating both sides between 1 to 3, we get

$$\int_1^3 p'(x)\,dx=\int_1^3\lambda(x^2-4x+3)\,dx$$

$$\Rightarrow\quad (p(x))_1^3=\lambda\left(\frac{x^3}{3}-2x^2+3x\right)_1^3$$

$$\Rightarrow\quad p(3)-p(1)=\lambda\left((9-18+9)-\left(\frac{1}{3}-2+3\right)\right)$$

$$\Rightarrow\quad 2-6=\lambda\left\{\frac{-4}{3}\right\}\quad\Rightarrow\quad\lambda=3$$

$$\Rightarrow\quad p'(x)=3(x-1)(x-3)$$

$$\therefore\quad p'(0)=9$$

133. Let $g(x)=e^{f(x)},\ \forall\ x\in R\ \Rightarrow\ g'(x)=e^{f(x)}\cdot f'(x)$

$\Rightarrow f'(x)$ changes its sign from positive to negative in the neighbourhood of $x=2009$

$\Rightarrow f(x)$ has local maxima at $x=2009$.

So, the number of local maximum is one.

134. Let $f(\theta)=\frac{1}{\sin^2\theta+3\sin\theta\cos\theta+5\cos^2\theta}$

Again let, $g(\theta)=\sin^2\theta+3\sin\theta\cos\theta+5\cos^2\theta$

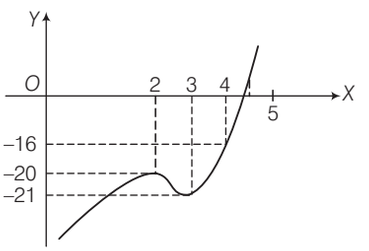
$$=\frac{1-\cos2\theta}{2}+5\left(\frac{1+\cos2\theta}{2}\right)+\frac{3}{2}\sin2\theta$$

$$=3+2\cos2\theta+\frac{3}{2}\sin2\theta$$

$$\therefore\quad g(\theta)_{\min}=3-\sqrt{4+\frac{9}{4}}=3-\frac{5}{2}=\frac{1}{2}$$

$\therefore$ Maximum value of $f(\theta)=\frac{1}{1/2}=2$

135. Given, $A=\{x|x^2+20\leq 9x\}=\{x|x\in[4,5]\}$



Now, $f'(x)=6(x^2-5x+6)$

Put $f'(x)=0\ \Rightarrow\ x=2,3$

$f(2)=-20,\ f(3)=-21,\ f(4)=-16,\ f(5)=7$

From graph, maximum value of $f(x)$ on set A is $f(5)=7$.

136. According to given information, we have

Perimeter of square + Perimeter of circle = 2 units

$$\Rightarrow\quad 4x+2\pi r=2$$

$$\Rightarrow\quad r=\frac{1-2x}{\pi}\qquad\ldots(i)$$

Now, let A be the sum of the areas of the square and the circle.

Then, $A=x^2+\pi r^2=x^2+\pi\frac{(1-2x)^2}{\pi^2}$

$$\Rightarrow\quad A(x)=x^2+\frac{(1-2x)^2}{\pi}$$

Now, for minimum value of $A(x)$, $\frac{dA}{dx} = 0$

$$\Rightarrow \quad 2x + \frac{2(1-2x)}{\pi} \cdot (-2) = 0 \Rightarrow \quad x = \frac{2-4x}{\pi}$$

$$\Rightarrow \qquad \pi x + 4x = 2$$

$$\Rightarrow \qquad x = \frac{2}{\pi + 4} \qquad \text{...(ii)}$$

Now, from Eq. (i), we get

$$r = \frac{1 - 2 \cdot \frac{2}{\pi + 4}}{\pi} = \frac{\pi + 4 - 4}{\pi(\pi + 4)} = \frac{1}{\pi + 4} \qquad \text{...(iii)}$$

From Eqs. (ii) and (iii), we get $x = 2r$

137. Here, $x = -1$ and $x = 2$ are extreme points of $f(x) = \alpha \log|x| + \beta x^2 + x$, then

$$f'(x) = \frac{\alpha}{x} + 2\beta x + 1$$

$$\therefore \quad f'(-1) = -\alpha - 2\beta + 1 = 0 \qquad \text{...(i)}$$

[at extreme point, $f'(x) = 0$]

and $\quad f'(-2) = \frac{\alpha}{2} + 4\beta + 1 = 0 \qquad$ ...(ii)

On solving Eqs. (i) and (ii), we get

$$\alpha = 2, \beta = -\frac{1}{2}$$

138. Given

(i) A function f, such that

$$f(x) = \log|x| + bx^2 + ax, x \neq 0$$

(ii) The function f has extrema at $x = -1$ and $x = 2$, *i.e.,* $f'(-1) = f'(2) = 0$ and $f''(-1) \neq 0 \neq f''(2)$.

Now, given function f is given by

$$f(x) = \log|x| + bx^2 + ax$$

$$\Rightarrow \qquad f'(x) = \frac{1}{x} + 2bx + a \Rightarrow \quad f''(x) = \frac{-1}{x^2} + 2b$$

Since, f has extrema at $x = -1$ and $x = 2$.

Hence, $\qquad f'(-1) = 0 = f'(2)$

$$f'(-1) = 0$$

$$\Rightarrow \qquad a - 2b = 1 \qquad \text{...(i)}$$

and $\qquad f'(2) = 0$

$$\Rightarrow \qquad a + 4b = \frac{-1}{2} \qquad \text{...(ii)}$$

On solving Eqs. (i) and (ii), we get

$$a = \frac{1}{2} \quad \text{and} \quad b = \frac{-1}{4}$$

$$\Rightarrow \qquad f''(x) = \frac{-1}{x^2} + \frac{-1}{2} = -\left(\frac{x^2 + 2}{2x^2}\right)$$

$$\Rightarrow \quad f''(-1) < 0 \quad \text{and } f''(2) < 0$$

Hence, f has local maxima at both $x = -1$ and $x = 2$.

Hence, Statement I is correct.

Also, while solving for Statement I, we found the values of a and b, which justify that Statement II is also correct.

However, Statement II does not explain Statement I in any way.

PREFACE

"YOU CAN DO ANYTHING IF YOU SET YOUR MIND TO IT, I TEACH CALCULUS TO JEE ASPIRANTS BUT BELIEVE THE MOST IMPORTANT FORMULA IS COURAGE + DREAMS = SUCCESS"

It is a matter of great pride and honour for me to have received such an overwhelming response to the previous editions of this book from the readers. In a way, this has inspired me to revise this book thoroughly as per the changed pattern of JEE Main & Advanced. I have tried to make the contents more relevant as per the needs of students, many topics have been re-written, a lot of new problems of new types have been added in etcetc. All possible efforts are made to remove all the printing errors that had crept in previous editions. The book is now in such a shape that the students would feel at ease while going through the problems, which will in turn clear their concepts too.

A Summary of changes that have been made in Revised & Enlarged Edition

- Theory has been completely updated so as to accommodate all the changes made in JEE Syllabus & Pattern in recent years.
- The most important point about this new edition is, now the whole text matter of each chapter has been divided into small sessions with exercise in each session. In this way the reader will be able to go through the whole chapter in a systematic way.
- Just after completion of theory, Solved Examples of all JEE types have been given, providing the students a complete understanding of all the formats of JEE questions & the level of difficulty of questions generally asked in JEE.
- Along with exercises given with each session, a complete cumulative exercises have been given at the end of each chapter so as to give the students complete practice for JEE along with the assessment of knowledge that they have gained with the study of the chapter.
- Last 10 Years questions asked in JEE Main & Adv, IIT-JEE & AIEEE have been covered in all the chapters.

However I have made the best efforts and put my all calculus teaching experience in revising this book. Still I am looking forward to get the valuable suggestions and criticism from my own fraternity i.e. the fraternity of JEE teachers.

I would also like to motivate the students to send their suggestions or the changes that they want to be incorporated in this book.

All the suggestions given by you all will be kept in prime focus at the time of next revision of the book.

Amit M. Agarwal

CONTENTS

1. Indefinite Integral 1-82

Learning Part

Session 1
- Fundamental of Indefinite Integral

Session 2
- Methods of Integration

Session 3
- Some Special Integrals

Session 4
- Integration by Parts

Session 5
- Integration Using Partial Fractions

Session 6
- Indirect and Derived Substitutions

Session 7
- Euler's Substitution, Reduction Formula and Integration Using Differentiation

Practice Part
- JEE Type Examples
- Chapter Exercises

2. Definite Integral 83-164

Learning Part

Session 1
- Integration Basics
- Geometrical Interpretation of Definite Integral
- Evaluation of Definite Integrals by Substitution

Session 2
- Properties of Definite Integral

Session 3
- Applications of Piecewise Function Property

Session 4
- Applications of Even-Odd Property and Half the Integral Limit Property

Session 5
- Applications of Periodic Functions and Newton-Leibnitz's Formula

Session 6
- Integration as Limit of a Sum
- Applications of Inequality
- Gamma Function
- Beta Function
- Walli's Formula

Practice Part
- JEE Type Examples
- Chapter Exercises

3. Area of Bounded Regions 165-232

Learning Part

Session 1
- Sketching of Some Common Curves
- Some More Curves Which Occur Frequently in Mathematics in Standard Forms
- Asymptotes
- Areas of Curves

Session 2
- Area Bounded by Two or More Curves

Practice Part
- JEE Type Examples
- Chapter Exercises

4. Differential Equations 233-308

Learning Part

Session 1
- Solution of a Differential Equation

Session 2
- Solving of Variable Seperable Form
- Homogeneous Differential Equation

Session 3
- Solving of Linear Differential Equations
- Bernoulli's Equation
- Orthogonal Trajectory

Session 4
- Exact Differential Equations

Session 5
- Solving of First Order & Higher Degrees
- Application of Differential Equations
- Application of First Order Differential Equations

Practice Part

- Chapter Exercises

SYLLABUS

JEE MAIN

Integral Calculus

Integral as an anti - derivative. Fundamental integrals involving algebraic, trigonometric, exponential and logarithmic functions. Integration by substitution, by parts and by partial fractions. Integration using trigonometric identities.

Evaluation of simple integrals of the type

$$\int \frac{dx}{x^2 \pm a^2}, \quad \int \frac{dx}{\sqrt{x^2 \pm a^2}}, \quad \int \frac{dx}{a^2 - x^2}, \quad \int \frac{dx}{\sqrt{a^2 - x^2}},$$

$$\int \frac{dx}{ax^2 + bx + c}, \quad \int \frac{dx}{\sqrt{ax^2 + bx + c}}, \quad \int \frac{(px + q)\,dx}{ax^2 + bx + c},$$

$$\int \frac{(px + q)\,dx}{\sqrt{ax^2 + bx + c}}, \quad \int \sqrt{a^2 \pm x^2}\,dx \quad \text{and} \quad \int \sqrt{x^2 - a^2}\,dx$$

Integral as limit of a sum. Fundamental Theorem of Calculus. Properties of definite integrals. Evaluation of definite integrals, determining areas of the regions bounded by simple curves in
standard form.

Differential Equations

Ordinary differential equations, their order and degree. Formation of differential equations. Solution of differential equations by the method of separation of variables, solution of homogeneous and linear differential equations of the type $\frac{dy}{dx} + p(x)y = q(x)$

JEE ADVANCED

Integral Calculus

Integration as the inverse process of differentiation, indefinite integrals of standard functions, definite integrals and their properties, application of the Fundamental Theorem of Integral Calculus.

Integration by parts, integration by the methods of substitution and partial fractions, application of definite integrals to the determination of areas involving simple curves.

Formation of ordinary differential equations, solution of homogeneous differential equations, variables separable method, linear first order differential equations.

Arihant on Your Mobile !
Exercises with the symbol can be practised on your mobile. See inside cover page to activate for free.

It was in this aspect that the process of integration was treated by Leibnitz, the symbol of $\int$ being regarded as the initial letter of the word sum, in the same way as the symbol of differentiation d is the initial letter in the word difference.

Definition

If f and g are functions of x such that $g'(x) = f(x)$, then the function g is called a anti-derivative (or primitive function or simply integral) of f w.r.t. x. It is written symbolically, $\int f(x)\,dx = g(x)$, where, $\frac{d}{dx} g(x) = f(x)$

Remarks

1. In other words, $\int f(x)\,dx = g(x)$ iff $g'(x) = f(x)$
2. $\int f(x)\,dx = g(x) + c$, where c is constant, $[\because (g(x) + C)' = g'(x) = f(x)]$ and C is called constant of integration.

Example 1 If $\frac{d}{dx}[x^{n+1} + c] = (n+1)\,x^n$, then find $\int x^n\,dx$.

Sol. As, $\frac{d}{dx}[x^{n+1} + C] = (n+1)\,x^n$

$\Rightarrow$ $(x^{n+1} + C)$ is anti-derivative or integral of $(n+1)\,x^n$.

$\therefore$ $\int x^n\,dx = \frac{x^{n+1}}{n+1} + C$

Example 2 If $\frac{d}{dx}(\sin x + c) = \cos x$, then find $\int \cos x\,dx$.

Sol. As, $\frac{d}{dx}(\sin x + C) = \cos x$

$\Rightarrow \sin x + C$ is anti-derivative or integral of $\cos x$.

$\therefore$ $\int \cos x\,dx = (\sin x) + C$

Session 1

Fundamental of Indefinite Integral

Fundamental of Indefinite Integral

Since, $\frac{d}{dx}\{g(x)\} = f(x)$

$\Leftrightarrow$ $\int f(x)\,dx = g(x) + C$

Therefore, based upon this definition and various standard differentiation formulas, we obtain the following integration formulae

(i) $\frac{d}{dx}\left(\frac{x^{n+1}}{n+1}\right) = x^n, n \neq -1 \Rightarrow \int x^n\,dx = \frac{x^{n+1}}{n+1} + C, n \neq -1$

(ii) $\frac{d}{dx}(\log|x|) = \frac{1}{x} \Rightarrow \int \frac{1}{x}\,dx = \log|x| + C$, when $x \neq 0$

(iii) $\frac{d}{dx}(e^x) = e^x \Rightarrow \int e^x\,dx = e^x + C$

(iv) $\frac{d}{dx}\left(\frac{a^x}{\log_e a}\right) = a^x, a > 0, a \neq 1$

$\Rightarrow \int a^x\,dx = \frac{a^x}{\log_e a} + C$

(v) $\frac{d}{dx}(-\cos x) = \sin x \Rightarrow \int \sin x\,dx = -\cos x + C$

(vi) $\frac{d}{dx}(\sin x) = \cos x \Rightarrow \int \cos x\,dx = \sin x + C$

(vii) $\frac{d}{dx}(\tan x) = \sec^2 x \Rightarrow \int \sec^2 x\,dx = \tan x + C$

(viii) $\frac{d}{dx}(-\cot x) = \operatorname{cosec}^2 x \Rightarrow \int \operatorname{cosec}^2 x\,dx = -\cot x + C$

(ix) $\frac{d}{dx}(\sec x) = \sec x \tan x$

$\Rightarrow \int \sec x \tan x\,dx = \sec x + C$

(x) $\frac{d}{dx}(-\operatorname{cosec} x) = \operatorname{cosec} x \cot x$

$\Rightarrow \int \operatorname{cosec} x \cot x\,dx = -\operatorname{cosec} x + C$

(xi) $\frac{d}{dx}(\log|\sin x|) = \cot x$

$\Rightarrow \int \cot x\,dx = \log|\sin x| + C$

(xii) $\frac{d}{dx}(-\log|\cos x|)=\tan x$

$\Rightarrow \int \tan x\,dx=-\log|\cos x|+C$

(xiii) $\frac{d}{dx}(\log|\sec x+\tan x|)=\sec x$

$\Rightarrow \int \sec x\,dx=\log|\sec x+\tan x|+C$

(xiv) $\frac{d}{dx}(\log|\operatorname{cosec} x-\cot x|)=\operatorname{cosec} x$

$\Rightarrow \int \operatorname{cosec} x\,dx=\log|\operatorname{cosec} x-\cot x|+C$

(xv) $\frac{d}{dx}\left(\sin^{-1}\frac{x}{a}\right)=\frac{1}{\sqrt{a^2-x^2}}$

$\Rightarrow \int \frac{dx}{\sqrt{a^2-x^2}}=\sin^{-1}\left(\frac{x}{a}\right)+C$

(xvi) $\frac{d}{dx}\left(\cos^{-1}\frac{x}{a}\right)=\frac{-1}{\sqrt{a^2-x^2}}$

$\Rightarrow \int \frac{-1}{\sqrt{a^2-x^2}}dx=\cos^{-1}\left(\frac{x}{a}\right)+C$

(xvii) $\frac{d}{dx}\left(\frac{1}{a}\tan^{-1}\frac{x}{a}\right)=\frac{1}{a^2+x^2}$

$\Rightarrow \int \frac{dx}{a^2+x^2}=\frac{1}{a}\tan^{-1}\left(\frac{x}{a}\right)+C$

(xviii) $\frac{d}{dx}\left(\frac{1}{a}\cot^{-1}\frac{x}{a}\right)=\frac{-1}{a^2+x^2}$

$\Rightarrow \int \frac{-1}{a^2+x^2}dx=\frac{1}{a}\cot^{-1}\left(\frac{x}{a}\right)+C$

(xix) $\frac{d}{dx}\left(\frac{1}{a}\sec^{-1}\frac{x}{a}\right)=\frac{1}{x\sqrt{x^2-a^2}}$

$\Rightarrow \int \frac{dx}{x\sqrt{x^2-a^2}}=\frac{1}{a}\sec^{-1}\left(\frac{x}{a}\right)+C$

(xx) $\frac{d}{dx}\left(\frac{1}{a}\operatorname{cosec}^{-1}\frac{x}{a}\right)=\frac{-1}{x\sqrt{x^2-a^2}}$

$\Rightarrow \int \frac{-dx}{x\sqrt{x^2-a^2}}=\frac{1}{a}\operatorname{cosec}^{-1}\left(\frac{x}{a}\right)+C$

Example 3 Evaluate

(i) $\int \frac{x^2+5x-1}{\sqrt{x}}dx$ (ii) $\int (x^2+5)^3\,dx$

Sol. (i) $I=\int \frac{x^2+5x-1}{\sqrt{x}}dx=\int\left(\frac{x^2}{x^{1/2}}+\frac{5x^1}{x^{1/2}}-\frac{1}{x^{1/2}}\right)dx$

$=\int (x^{3/2}+5x^{1/2}-x^{-1/2})\,dx$

$\left[\text{using}\int x^n\,dx=\frac{x^{n+1}}{n+1}+C\right]$

$=\frac{x^{3/2+1}}{3/2+1}+\frac{5x^{1/2+1}}{1/2+1}-\frac{x^{-1/2+1}}{-1/2+1}+C$

$\Rightarrow \quad I=\frac{2}{5}x^{5/2}+\frac{2}{3}\cdot 5x^{3/2}-2x^{1/2}+C$

(ii) $I=\int (x^2+5)^3\,dx$ [using $(a+b)^3=a^3+3a^2b+3ab^2+b^3$]

$I=\int (x^6+15x^4+75x^2+125)\,dx$

$I=\frac{x^7}{7}+\frac{15x^5}{5}+\frac{75x^3}{3}+125x+C$

$I=\frac{x^7}{7}+3x^5+25x^3+125x+C$

Example 4 Evaluate

(i) $\int \tan^2 x\,dx$ (ii) $\int \frac{dx}{\sin^2 x\cos^2 x}$

(iii) $\int \frac{\sin^6 x+\cos^6 x}{\sin^2 x\cos^2 x}dx$ (iv) $\int \frac{\cos x-\cos 2x}{1-\cos x}dx$

Sol. (i) $I=\int \tan^2 x\,dx \Rightarrow I=\int(\sec^2 x-1)\,dx$

$I=\int \sec^2 x\,dx-\int 1\,dx$ [using $\int \sec^2 x dx=\tan x+C$]

$\Rightarrow I=\tan x-x+C$

(ii) $I=\int \frac{1}{\sin^2 x\cos^2 x}dx$

$I=\int \frac{\sin^2 x+\cos^2 x}{\sin^2 x\cos^2 x}dx$ [Using $\sin^2 x+\cos^2 x=1$]

$I=\int \frac{\sin^2 x}{\sin^2 x\cos^2 x}dx+\int \frac{\cos^2 x}{\sin^2 x\cos^2 x}dx$

$I=\int \sec^2 x\,dx+\int \operatorname{cosec}^2 x\,dx$

$I=\tan x-\cot x+C$

(iii) $I=\int \frac{\sin^6 x+\cos^6 x}{\sin^2 x\cos^2 x}dx$

$I=\int \frac{(\sin^2 x)^3+(\cos^2 x)^3}{\sin^2 x\cos^2 x}dx$

[using $(a+b)^3=a^3+b^3+3ab(a+b)$]

$I=\int \frac{(\sin^2 x+\cos^2 x)^3-3\sin^2 x\cos^2 x(\sin^2 x+\cos^2 x)}{\sin^2 x\cos^2 x}dx$

$I=\int \frac{1-3\sin^2 x\cos^2 x}{\sin^2 x\cos^2 x}dx$

$$I = \int \frac{1}{\sin^2 x \cos^2 x}\,dx - \int 3\,dx$$

$$I = \int \frac{(\sin^2 x + \cos^2 x)}{\sin^2 x \cos^2 x}\,dx - 3x + C$$

$$I = \int \sec^2 x\,dx + \int \operatorname{cosec}^2 x\,dx - 3x + C$$

$$I = \tan x - \cot x - 3x + C$$

(iv) $I = \int \frac{\cos x - \cos 2x}{1 - \cos x}\,dx$ [using $\cos 2x = 2\cos^2 x - 1$.]

$$I = \int \frac{\cos x - (2\cos^2 x - 1)}{1 - \cos x}\,dx$$

$$= \int \frac{-2\cos^2 x + \cos x + 1}{1 - \cos x}\,dx$$

$$\Rightarrow I = \int \frac{-(2\cos x + 1)(\cos x - 1)}{-(\cos x - 1)}\,dx$$

[as $-2\cos^2 x + \cos x - 1 = -(2\cos x + 1)\cdot(\cos x - 1)$]

$$\Rightarrow I = \int (2\cos x + 1)\,dx$$

$$\therefore \quad I = 2\sin x + x + C$$

Remark

In rational algebraic functions if the degree of numerator is greater than or equal to degree of denominator, then always divide the numerator by denominator and use the result of integration.

Example 5 Evaluate

(i) $\int \frac{x^3}{x+2}\,dx$ (ii) $\int \frac{x^2}{x^2+5}\,dx$

Sol. (i) $I = \int \frac{x^3}{x+2}\,dx = \int \frac{x^3 + 8 - 8}{x+2}\,dx$

$$I = \int \left(\frac{(x^3 + 2^3)}{x+2} - \frac{8}{x+2} \right) dx$$

$$\Rightarrow I = \int \left(\frac{(x+2)(x^2 - 2x + 4)}{x+2} - \frac{8}{x+2} \right) dx$$

$$I = \int \left(x^2 - 2x + 4 - \frac{8}{x+2} \right) dx$$

$$\therefore \quad I = \frac{x^3}{3} - x^2 + 4x - 8\log|x+2| + C$$

(ii) $I = \int \frac{x^2}{x^2+5}dx = \int \frac{x^2+5-5}{x^2+5}dx = \int \left(\frac{x^2+5}{x^2+5} - \frac{5}{x^2+5} \right) dx$

$$I = \int \left(1 - \frac{5}{x^2+5} \right) dx = x - 5\int \frac{dx}{x^2 + (\sqrt{5})^2}$$

$$I = x - \frac{5}{\sqrt{5}} \tan^{-1}\left(\frac{x}{\sqrt{5}} \right) + C$$

$$I = x - \sqrt{5}\tan^{-1}\left(\frac{x}{\sqrt{5}} \right) + C$$

Example 6 *Evaluate*

(i) $\int 5^{\log_e x}\,dx$ (ii) $\int 2^{\log_4 x}\,dx$

Sol. (i) $I = \int 5^{\log_e x}\,dx = \int x^{\log_e 5}\,dx$ [Using $a^{\log_e b} = b^{\log_c a}$]

$$= \frac{x^{\log_e 5 + 1}}{(\log_e 5 + 1)} + C$$

$$\therefore \quad \int 5^{\log_e x}\,dx = \frac{x^{\log_e 5 + 1}}{\log_e 5 + 1} + C$$

(ii) $I = \int 2^{\log_4 x}\,dx = \int 2^{\log_{2^2} x}\,dx = \int 2^{1/2 \log_2 x}\,dx$

$$\left[\text{using } \log_{b^n} x = \frac{1}{n}\log_b x \right]$$

$$= \int 2^{\log_2 \sqrt{x}}\,dx = \int \sqrt{x}\,dx \qquad [\text{using } a^{\log_a b} = b]$$

$$= \frac{x^{3/2}}{3/2} + C$$

$$\therefore \quad \int 2^{\log_4 x}\,dx = \frac{2}{3}x^{3/2} + C$$

Example 7 Evaluate $\int \frac{(\sqrt{x}+1)(x^2 - \sqrt{x})}{x\sqrt{x} + x + \sqrt{x}}\,dx$.

Sol. Here, $I = \int \frac{(\sqrt{x}+1)\cdot\sqrt{x}(x^{3/2} - 1)}{\sqrt{x}(x + \sqrt{x} + 1)}\,dx$

$$\therefore \quad I = \int \frac{(\sqrt{x}+1)[(\sqrt{x})^3 - 1^3]}{(x + \sqrt{x} + 1)}\,dx$$

$$= \int \frac{(\sqrt{x}+1)(\sqrt{x}-1)(x + \sqrt{x} + 1)}{(x + \sqrt{x} + 1)}\,dx$$

[Using, $a^3 - b^3 = (a-b)(a^2 + ab + b^2)$]

$$= \int (x - 1)\,dx = \frac{x^2}{2} - x + C$$

Example 8 Evaluate

(i) $\int \frac{1 + 2x^2}{x^2(1 + x^2)}\,dx$ (ii) $\int \frac{x^6 - 1}{(x^2 + 1)}\,dx$

Sol. (i) Here, $I = \int \frac{1 + 2x^2}{x^2(1 + x^2)}\,dx = \int \frac{1 + x^2 + x^2}{x^2(1 + x^2)}\,dx$

$$= \int \frac{1 + x^2}{x^2(1 + x^2)}\,dx + \int \frac{x^2}{x^2(1 + x^2)}\,dx$$

$$= \int \frac{1}{x^2}\,dx + \int \frac{1}{1 + x^2}\,dx = -\frac{1}{x} + \tan^{-1} x + C$$

(ii) Here, $I = \int \frac{x^6 - 1}{x^2 + 1}\,dx = \int \frac{x^6 + 1 - 2}{x^2 + 1}\,dx$

$$= \int \frac{(x^2)^3 + 1^3}{x^2 + 1}\,dx - \int \frac{2}{x^2 + 1}\,dx$$

$$I=\int\frac{(x^2+1)(x^4-x^2+1)}{(x^2+1)}\,dx-2\int\frac{dx}{x^2+1}$$

[Using, $a^3+b^3=(a+b)(a^2-ab+b^2)$]

$$=\int(x^4-x^2+1)\,dx-2\int\frac{1}{x^2+1}\,dx$$

$$=\frac{x^5}{5}-\frac{x^3}{3}+x-2\tan^{-1}x+C$$

Example 9 Evaluate

(i) $\int\left(\frac{1-x^{-2}}{x^{1/2}-x^{-1/2}}-\frac{2}{x^{3/2}}+\frac{x^{-2}-x}{x^{1/2}-x^{-1/2}}\right)dx$

(ii) $\int\left(\frac{x^{-6}-64}{4+2x^{-1}+x^{-2}}\cdot\frac{x^2}{4-4x^{-1}+x^{-2}}-\frac{4x^2(2x+1)}{1-2x}\right)dx$

Sol. (i) Here, $I=\int\left(\frac{1-x^{-2}}{x^{1/2}-x^{-1/2}}-\frac{2}{x^{3/2}}+\frac{x^{-2}-x}{x^{1/2}-x^{-1/2}}\right)dx$

$$=\int\left(\frac{(1-x^{-2})+(x^{-2}-x)}{x^{1/2}-x^{-1/2}}-\frac{2}{x^{3/2}}\right)dx$$

$$=\int\left(\frac{1-x}{\sqrt{x}-\frac{1}{\sqrt{x}}}-\frac{2}{x^{3/2}}\right)dx=\int\left(\frac{1-x}{\frac{x-1}{\sqrt{x}}}-\frac{2}{x^{3/2}}\right)dx$$

$$=\int(-\sqrt{x}-2x^{-3/2})\,dx$$

$$=\left(-\frac{x^{3/2}}{3/2}-2\cdot\frac{x^{-1/2}}{-1/2}\right)+C=-\frac{2}{3}x^{3/2}+\frac{4}{\sqrt{x}}+C$$

(ii) Here

$$I=\int\left(\frac{x^{-6}-64}{4+2x^{-1}+x^{-2}}\cdot\frac{x^2}{4-4x^{-1}+x^{-2}}-\frac{4x^2(2x+1)}{1-2x}\right)dx$$

$$=\int\left(\frac{\frac{1-64x^6}{x^6}}{\frac{4x^2+2x+1}{x^2}}\cdot\frac{x^2}{\frac{4x^2-4x+1}{x^2}}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

$$=\int\left(\frac{1-(4x^2)^3}{x^6\cdot(4x^2+2x+1)}\cdot\frac{x^6}{(4x^2-4x+1)}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

$$=\int\left(\frac{(1-4x^2)(1+4x^2+16x^4)}{(4x^2+2x+1)(4x^2-4x+1)}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

$$=\int\left(\frac{(1-4x^2)\cdot(4x^2+2x+1)(4x^2-2x+1)}{(4x^2+2x+1)(2x-1)^2}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

[using, $16x^4+4x^2+1=16x^4+8x^2+1-4x^2$

$=(4x^2+1)^2-(2x)^2=(4x^2+1+2x)$]

$$=\int\left(\frac{(1-2x)(1+2x)(4x^2-2x+1)}{(1-2x)^2}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

$$=\int\left(\frac{(1+2x)\cdot(4x^2-2x+1)}{(1-2x)}-\frac{4x^2(2x+1)}{(1-2x)}\right)dx$$

$$=\int\frac{(2x+1)\{4x^2-2x+1-4x^2\}\,dx}{1-2x}$$

$$=\int\frac{(2x+1)(1-2x)}{(1-2x)}\,dx$$

$$=\int(2x+1)\,dx=x^2+x+C$$

Example 10 Evaluate

(i) $\int\frac{1}{\sin(x-a)\cos(x-b)}\,dx$

(ii) $\int\frac{1}{\cos(x-a)\cos(x-b)}\,dx$

Sol. (i) $I=\int\frac{1}{\sin(x-a)\cos(x-b)}\,dx$

$$I=\frac{\cos(a-b)}{\cos(a-b)}\cdot\int\frac{dx}{\sin(x-a)\cos(x-b)}$$

$$=\frac{1}{\cos(a-b)}\cdot\int\frac{\cos\{(x-b)-(x-a)\}}{\sin(x-a)\cos(x-b)}\,dx$$

$$=\frac{1}{\cos(a-b)}\cdot\int\left\{\frac{\cos(x-b)\cdot\cos(x-a)}{\sin(x-a)\cos(x-b)}+\frac{\sin(x-b)\cdot\sin(x-a)}{\sin(x-a)\cos(x-b)}\right\}dx$$

$$=\frac{1}{\cos(a-b)}\int\{\cot(x-a)+\tan(x-b)\}\,dx$$

$$=\frac{1}{\cos(a-b)}\{\log|\sin(x-a)|-\log|\cos(x-b)|\}+C$$

$$=\frac{1}{\cos(a-b)}\log_e\left|\frac{\sin(x-a)}{\cos(x-b)}\right|+C$$

(ii) $I=\int\frac{1}{\cos(x-a)\cos(x-b)}\,dx$

$$=\frac{1}{\sin(a-b)}\int\frac{\sin(a-b)}{\cos(x-a)\cos(x-b)}dx$$

$$=\frac{1}{\sin(a-b)}\int\frac{\sin\{(x-b)-(x-a)\}}{\cos(x-a)\cos(x-b)}\,dx$$

$$=\frac{1}{\sin(a-b)}\int\left\{\frac{\sin(x-b)\cos(x-a)}{\cos(x-a)\cos(x-b)}-\frac{\cos(x-b)\sin(x-a)}{\cos(x-a)\cos(x-b)}\right\}dx$$

$$=\frac{1}{\sin(a-b)}\int\{\tan(x-b)-\tan(x-a)\}\,dx$$

$$=\frac{1}{\sin(a-b)}[-\log|\cos(x-b)|+\log|\cos(x-a)|]+C$$

$$=\frac{1}{\sin(a-b)}\left[\log\left|\frac{\cos(x-a)}{\cos(x-b)}\right|\right]+C$$

Example 11 Evaluate $\int \frac{\sin(x+a)}{\sin(x+b)}\,dx$.

Sol. Let $I = \int \frac{\sin(x+a)}{\sin(x+b)}\,dx$. Put $x + b = t \Rightarrow dx = dt$

$$\therefore \quad I = \int \frac{\sin(t-b+a)}{\sin t}\,dt$$

$$= \int \left\{ \frac{\sin t \cos(a-b)}{\sin t} + \frac{\cos t \sin(a-b)}{\sin t} \right\} dt$$

$$= \cos(a-b)\int 1\,dt + \sin(a-b)\int \cot(t)\,dt$$

$$= t\cos(a-b) + \sin(a-b)\log|\sin t| + C$$

$$= (x+b)\cos(a-b) + \sin(a-b)\log|\sin(x+b)| + C$$

Example 12

(i) If $f'(x) = \frac{x}{2} + \frac{2}{x}$ and $f(1) = \frac{5}{4}$, then find $f(x)$.

(ii) The gradient of the curve is given by $\frac{dy}{dx} = 2x - \frac{3}{x^2}$.

The curve passes through (1, 2) find its equation.

Sol. (i) Given, $f'(x) = \frac{x}{2} + \frac{2}{x}$,

On integrating both sides w.r.t. x,

we get $\int f'(x)\,dx = \int \left(\frac{x}{2} + \frac{2}{x}\right) dx$

$$\Rightarrow \quad f(x) = \frac{1}{2}\cdot\frac{x^2}{2} + 2\log|x| + c \qquad \text{...(i)}$$

Now, as $f(1) = \frac{5}{4}$ (called as initial value problem

i.e. when $x = 1, y = \frac{5}{4}$ or $f(1) = \frac{5}{4}$)

Putting, $x = 1$ in Eq. (i),

$$f(1) = \frac{1}{4} + 2\log|1| + C, \text{ but } f(1) = \frac{5}{4}$$

$$\therefore \quad \frac{5}{4} = \frac{1}{4} + C \Rightarrow C = 1$$

$$\Rightarrow \quad f(x) = \frac{x^2}{4} + 2\log|x| + 1$$

(ii) Given, $\frac{dy}{dx} = 2x - \frac{3}{x^2}$ or $dy = \left(2x - \frac{3}{x^2}\right) dx$,

On integrating both sides w.r.t. x, we get

$$\int dy = \int \left(2x - \frac{3}{x^2}\right) dx$$

$$\Rightarrow \quad y = \frac{2x^2}{2} + \frac{3}{x} + C$$

Since, curve passes through (1, 1).

$$\Rightarrow \quad 1 = 1 + 3 + C \Rightarrow C = -3$$

$$\therefore \quad f(x) = x^2 + \frac{3}{x} - 3$$

Important Points Related to Integration

1. $\int k\,f(x)\,dx = k\int f(x)\,dx$, where k is constant. i.e. the integral of the product of a constant and a function = the constant × integral of the function

2. $\int \{f_1(x) \pm f_2(x) \pm \ldots \pm f_n(x)\}\,dx$

$$= \int f_1(x)\,dx \pm \int f_2(x)\,dx \pm \ldots \pm \int f_n(x)\,dx.$$

i.e. the integral of the sum or difference of a finite number of functions is equal to the sum or difference of the integrals of the various functions.

3. **Geometrical interpretation of constant of integration** By adding C means the graph of function would shift in upward or downward direction along y-axis as C is +ve or − ve respectively.

e.g. $$y = \int x\,dx = \frac{x^2}{2} + C$$

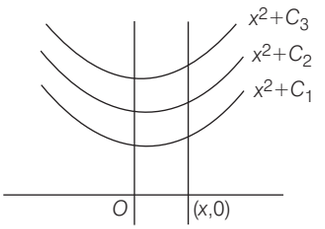

Figure. 1.1

$$\therefore \quad y = \int f(x)\,dx = F(x) + C$$

$$\Rightarrow \quad F'(x) = f(x);\ F'(x_1) = f(x_1)$$

Hence, $y = \int f(x)\,dx$ denotes a family of curves such that the slope of the tangent at $x = x_1$ on every member is same i.e. $F'(x_1) = f(x)$ [when x_1 lies in the domain of $f(x)$]

Hence, anti-derivative of a function is not unique. If $g_1(x)$ and $g_2(x)$ are two anti-derivatives of a function $f(x)$ on $[a, b]$, then they differ only by a constant.

i.e. $$g_1(x) - g_2(x) = C$$

Anti-derivative of a continuous function is differentiable.

4. If $f(x)$ is continuous, then

$$\int f(x)\,dx = F(x) + C$$

$$\Rightarrow \quad F'(x) = f(x)$$

$\Rightarrow$ always exists and is continuous.

$$\Rightarrow \quad F'(x)$$

5. If integral is discontinuous at $x = x_1$, then its anti-derivative at $x = x_1$ need not be discontinuous.
   e.g. $\int x^{-1/3} dx$. Here, $x^{-1/3}$ is discontinuous at $x = 0$. But $\int x^{-1/3} dx = \frac{3}{2} x^{2/3} + C$ is continuous at $x = 0$.
6. Anti-derivative of a periodic function need not be a periodic function. e.g. $f(x) = \cos x + 1$ is periodic but $\int (\cos x + 1)\, dx = \sin x + x + C$ is a periodic.

Daily Life Applications

The Derivative			The Integral		
Function	**Its derivative function**	**In symbols**	**Function**	**It's Anti-derivative Function**	**In symbols**
Distance (s)	Velocity (v)	$v = \frac{ds}{dt}$	Velocity	Distance	$s = \int v(t)\, dt$
Velocity (v)	Acceleration (a)	$a = \frac{dv}{dt}$	Acceleration	Velocity	$v = \int a(t)\, dt$
Mass (μ)	Liner Density (ρ)	$\rho = \frac{d\mu}{dx}$	Linear Density	Mass	$\mu = \int \rho(x)\, dx$
Population (P)	Instantaneous growth	$\frac{dP}{dt}$	Instantaneous Growth	Population	$\rho = \int \left(\frac{dP}{dt}\right) dt$
Cost (C)	Marginal cost (MC)	$\text{MC} = \frac{dC}{dq}$	Marginal Cost	Cost	$C(q) = \int \left(\frac{dC}{dq}\right) dq$
Revenue (R)	Marginal Revenue (MR)	$\text{MR} = \frac{dR}{dq}$	Marginal Revenue	Revenue	$R(q) = \int \left(\frac{dR}{dq}\right) dq$

Here, q is quantity of products.

Exercise for Session 1

- Evaluate the following integration

1. $\int \frac{dx}{\sqrt{x+1} - \sqrt{x}}$
2. $\int \frac{x^2 + 3}{x^6 (x^2 + 1)} dx$
3. $\int \frac{(1+x)^2}{x(1+x^2)} dx$
4. $\int \frac{x^4}{1+x^2} dx$
5. $\int \frac{x^4 + x^2 + 1}{2(1+x^2)} dx$
6. $\int \frac{(x^2 + \sin^2 x)\sec^2 x}{(1+x^2)} dx$
7. $\int \frac{x^2}{(a+bx)^2} dx$
8. $\int 2^x \cdot e^x \cdot dx$
9. $\int \frac{e^{3x} + e^{5x}}{e^x + e^{-x}} dx$
10. $\int (e^{a \log x} + e^{x \log a})\, dx$
11. $\int \frac{1 + \cos 4x}{\cot x - \tan x} dx$
12. $\int \tan x \tan 2x \tan 3x\, dx$
13. $\int \frac{\sin 4x}{\sin x} dx$
14. $\int \cos^3 x\, dx$
15. $\int \sin^3 x \cos^3 x\, dx$

Session 2

Methods of Integration

Methods of Integration

If the integral is not a derivative of a simple function, then the corresponding integrals cannot be found directly. In order to find the integral of complex problems.

e.g. $\int \frac{\sin x}{x}\,dx, \int \frac{\cos x}{x}\,dx, \int \frac{1}{\log x}\,dx$

Some Integrals which Cannot be Found

Any function continuous on an interval (a, b) has an anti-derivative in that interval. In other words, there exists a function $F(x)$ such that $F'(x) = f(x)$.

However, not every anti-derivative $F(x)$, even when it exists, is expressible in closed form in terms of elementary functions such as polynomials, trigonometric, logarithmic, exponential functions etc. Then, we say that such anti-derivatives or integrals "cannot be found''.

Some typical examples are

(i) $\int \frac{\sin x}{x}\,dx$ (ii) $\int \frac{\cos x}{x}\,dx$

(iii) $\int \frac{1}{\log x}\,dx$ (iv) $\int \sqrt{1-k^2\sin^2 x}\,dx$

(v) $\int \sqrt{\sin x}\,dx$ (vi) $\int \sin(x^2)\,dx$

(vii) $\int \cos(x^2)\,dx$ (viii) $\int x\tan x\,dx$

(ix) $\int e^{-x^2}\,dx$ (x) $\int e^{x^2}\,dx$

(xi) $\int \frac{x^2}{1+x^5}\,dx$ (xii) $\int \sqrt[3]{1+x^2}\,dx$

(xiii) $\int \sqrt{1+x^3}\,dx$ etc.

Integration by Substitution

(or by change of the independent variable)

If $g(x)$ is a continuously differentiable function, then to evaluate integrals of the form,

$$I = \int f(g(x)).g'(x)\,dx,$$

we substitute $g(x) = t$ and $g'(x)\,dx = dt$

The substitution reduces the integral to $\int f(t)\,dt$. After evaluating this integral we substitute back the value of t.

Example 13 Prove that

$$\int (ax+b)^n\,dx = \frac{(ax+b)^{n+1}}{(n+1)a} + C, n \neq 1.$$

Sol. Putting, $ax + b = t$, we get

$$adx = dt \text{ or } dx = \frac{1}{a}dt$$

$$\therefore \quad I = \int (ax+b)^n\,dx = \int t^n \cdot \frac{dt}{a} = \frac{1}{a}\cdot\frac{t^{n+1}}{n+1} + C$$

$$= \frac{1}{a(n+1)}(ax+b)^{n+1}dx + C.$$

Remarks

1. If $\int f(x)\,dx = g(x) + C$, then $\int f(ax+b)\,dx = \frac{1}{a}g(ax+b) + C$

2. If $\int \frac{1}{x}\,dx = \log|x| + C$, then $\int \frac{1}{ax+b}\,dx = \frac{1}{a}\log|ax+b| + C$

Thus, in any fundamental integral formulae given in article fundamental integration formulae if in place of x we have $(ax + b)$, then same formula is applicable but we must divide by coefficient of x or derivative of $(ax + b)$ i.e. a.

Here is the list of some of frequently used formulae

(i) $\int (ax+b)^n\,dx = \frac{(ax+b)^{n+1}}{a(n+1)} + C, n \neq -1$

(ii) $\int \frac{1}{ax+b}\,dx = \frac{1}{a}\log|ax+b| + C$

(iii) $\int e^{ax+b}\,dx = \frac{1}{a}e^{ax+b} + C$

(iv) $\int a^{bx+c}\,dx = \frac{1}{b}\cdot\frac{a^{bx+c}}{\log a} + C$

(v) $\int \sin(ax+b)\,dx = -\frac{1}{a}\cos(ax+b) + C$

(vi) $\int \cos(ax+b)\,dx = \frac{1}{a}\sin(ax+b) + C$

(vii) $\int \sec^2(ax+b)\,dx = \frac{1}{a}\tan(ax+b) + C$

(viii) $\int \text{cosec}^2\,(ax+b)\,dx = -\frac{1}{a}\cot(ax+b)+C$

(ix) $\int \sec(ax+b)\tan(ax+b)\,dx = \frac{1}{a}\sec(ax+b)+C$

(x) $\int \text{cosec}\,(ax+b)\cot(ax+b)\,dx = -\frac{1}{a}\text{cosec}\,(ax+b)+C$

(xi) $\int \tan(ax+b)\,dx = -\frac{1}{a}\log|\cos(ax+b)|+C$

(xii) $\int \cot(ax+b)\,dx = \frac{1}{a}\log|\sin(ax+b)|+C$

(xiii) $\int \sec(ax+b)dx = \frac{1}{a}\log|\sec(ax+b)+\tan(ax+b)|+C$

(xiv) $\int \text{cosec}(ax+b)\,dx = \frac{1}{a}\log|\text{cosec}(ax+b)-\cot(ax+b)|+C$

Example 14 Evaluate

(i) $\int \frac{1}{\sqrt{3x+4}-\sqrt{3x+1}}\,dx$ (ii) $\int \frac{8x+13}{\sqrt{4x+7}}\,dx.$

(iii) $\int (7x-2)\sqrt{3x+2}\,dx.$ (iv) $\int \frac{2+3x^2}{x^2(1+x^2)}\,dx.$

Sol. (i) Here, $I = \int \frac{dx}{\sqrt{3x+4}-\sqrt{3x+1}}$

$$= \int \frac{(\sqrt{3x+4}+\sqrt{3x+1})}{(\sqrt{3x+4}-\sqrt{3x+1})(\sqrt{3x+4}+\sqrt{3x+1})}\,dx$$

$$= \int \frac{(\sqrt{3x+4}+\sqrt{3x+1})}{(3x+4)-(3x+1)}\,dx$$

$$= \frac{1}{3}\int \sqrt{3x+4}\,dx + \frac{1}{3}\int \sqrt{3x+1}\,dx$$

$$= \frac{1}{3}\left\{\frac{(3x+4)^{3/2}}{3/2\times 3}\right\} + \frac{1}{3}\left\{\frac{(3x+1)^{3/2}}{3/2\times 3}\right\} + C$$

Using, $\int (ax+b)^n\,dx = \frac{(ax+b)^{n+1}}{(n+1)\,a}+C$

$$= \frac{2}{27}[(3x+4)^{3/2}+(3x+1)^{3/2}]+C$$

(ii) Here, $I = \int \frac{8x+13}{\sqrt{4x+7}}\,dx = \int \frac{8x+14-1}{\sqrt{4x+7}}\,dx$

$$= \int \frac{2(4x+7)-1}{\sqrt{4x+7}}dx$$

$$= 2\int \frac{4x+7}{\sqrt{4x+7}}\,dx - \int \frac{dx}{\sqrt{4x+7}}$$

$$= 2\int (\sqrt{4x+7})dx - \int (4x+7)^{-1/2}dx$$

$$= 2\left(\frac{(4x+7)^{3/2}}{3/2\times 4}\right) - \left(\frac{(4x+7)^{1/2}}{1/2\times 4}\right)+C$$

$$= \frac{1}{3}(4x+7)^{3/2} - \frac{1}{2}(4x+7)^{1/2}+C$$

(iii) Here, $I = \int (7x-2)\sqrt{3x+2}\,dx = 7\int \left(x-\frac{2}{7}\right)\sqrt{3x+2}\,dx$

$$= \frac{7}{3}\int \left(3x-\frac{6}{7}\right)\sqrt{3x+2}\,dx$$

$$= \frac{7}{3}\int \left(3x+2-2-\frac{6}{7}\right)\sqrt{3x+2}\,dx$$

$$= \frac{7}{3}\int (3x+2)\sqrt{3x+2}\,dx - \frac{20}{3}\int \sqrt{3x+2}\,dx$$

$$= \frac{7}{3}\int (3x+2)^{3/2}\,dx - \frac{20}{3}\int \sqrt{3x+2}\,dx$$

$$= \frac{7}{3}\left(\frac{(3x+2)^{5/2}}{\frac{5}{2}\times 3}\right) - \frac{20}{3}\left(\frac{(3x+2)^{3/2}}{\frac{3}{2}\times 3}\right)+C$$

$$= \frac{14}{45}(3x+2)^{5/2} - \frac{40}{27}(3x+2)^{3/2}+C$$

(iv) Here, $I = \int \frac{(2+3x^2)\,dx}{x^2(1+x^2)} = \int \frac{2+2x^2+x^2}{x^2(1+x^2)}\,dx$

$$= \int \left(\frac{2(1+x^2)}{x^2(1+x^2)} + \frac{x^2}{x^2(1+x^2)}\right)dx$$

$$= \int \left(\frac{2}{x^2}+\frac{1}{1+x^2}\right)dx = 2\int x^{-2}dx + \int \frac{1}{1+x^2}\,dx$$

$$= 2\cdot\frac{x^{-1}}{-1} + \tan^{-1}x + C = -\frac{2}{x} + \tan^{-1}x + C$$

Example 15 Evaluate

(i) $\int \frac{\sin(\log x)}{x}\,dx$ (ii) $\int \left(\frac{3\sin x+4\cos x}{4\sin x-3\cos x}\right)dx$

(iii) $\int \frac{e^{m\tan^{-1}x}}{1+x^2}\,dx$ (iv) $\int x\sin(4x^2+7)\,dx$

Sol. (i) $I = \int \frac{\sin(\log x)}{x}\,dx$

We know that, $\frac{d}{dx}(\log x) = \frac{1}{x}$

Thus, let $\log x = t$

$\Rightarrow \quad \frac{1}{x}\,dx = dt$ ...(i)

$\therefore \quad I = \int \sin(t)\,dt = -\cos(t)+C$

$= -\cos(\log x)+C$ [using Eq. (i)]

(ii) $I = \int \frac{3\sin x+4\cos x}{4\sin x-3\cos x}\,dx$

We know, $\frac{d}{dx}(4\sin x-3\cos x) = (4\cos x+3\sin x)$

Thus, let $4\sin x-3\cos x = t$ ...(i)

$\Rightarrow \quad (4\cos x+3\sin x)\,dx = dt$

$$\therefore \quad I = \int \frac{dt}{t} = \log|t| + C$$

$$= \log|4\sin x - 3\cos x| + C \quad \text{[using Eq. (i)]}$$

(iii) $I = \int \frac{e^{m\tan^{-1}x}}{1+x^2}\,dx$ Let $m\tan^{-1}x = t$

$$\Rightarrow \quad \frac{m}{1+x^2}\,dx = dt \quad \Rightarrow \quad \frac{1}{1+x^2}\,dx = \frac{1}{m}\,dt$$

$$\therefore \quad I = \int e^t \cdot \frac{dt}{m} \quad \Rightarrow \quad I = \frac{1}{m}\int e^t\,dt$$

$$I = \frac{1}{m}e^t + C = \frac{1}{m}e^{m\tan^{-1}x} + C$$

(iv) $I = \int x\sin(4x^2+7)\,dx$

Let $4x^2 + 7 = t \Rightarrow 8x\,dx = dt \Rightarrow x\,dx = \frac{1}{8}dt$

$$\therefore \quad I = \int \sin(t)\frac{dt}{8} = -\frac{1}{8}\cos(t) + C$$

$$= -\frac{1}{8}\cos(4x^2+7) + C$$

Remarks

While solving product of trignometric, it is expedient to use the following trigonometric identities

1. $\sin mx\cos nx = \frac{1}{2}\{\sin(m-n)x + \sin(m+n)x\}$
2. $\cos mx\sin nx = \frac{1}{2}\{\sin(m+n)x - \sin(m-n)x\}$
3. $\sin mx\sin nx = \frac{1}{2}\{\cos(m-n)x - \cos(m+n)x\}$
4. $\cos mx\cos nx = \frac{1}{2}\{\cos(m-n)x + \cos(m+n)x\}$

Example 16 Evaluate

(i) $\int \cos 4x\cos 7x\,dx$ (ii) $\int \cos x\cos 2x\cos 5x\,dx$

Sol. When calculating such integrals it is advisable to use the trigonometric product formulae.

(i) $\int \cos 4x\cos 7x\,dx$

Here, $\cos 4x\cos 7x = \frac{1}{2}(\cos 3x + \cos 11x)$,

$[\text{using } \cos mx\cdot\cos nx = \frac{1}{2}\{\cos(m-n)x + \cos(m+n)x\}]$

$$\therefore \quad I = \int \cos 4x\cos 7x\,dx = \frac{1}{2}\int(\cos 3x + \cos 11x)\,dx$$

$$= \frac{1}{2}\int \cos 3x\,dx + \frac{1}{2}\int \cos 11x\,dx$$

$$= \frac{\sin 3x}{6} + \frac{\sin 11x}{22} + C$$

(ii) $\int \cos x\cos 2x\cos 5x\,dx$,

We have $(\cos x\cos 2x)\cos 5x = \frac{1}{2}(\cos x + \cos 3x)\cos 5x$,

$[\text{using } \cos mx.\cos nx = \frac{1}{2}\{\cos(m-n)x + \cos(m+n)x\}]$

$$= \frac{1}{4}\{2\cos x\cos 5x + 2\cos 3x\cos 5x\}$$

$$= \frac{1}{4}\{(\cos 4x + \cos 6x) + (\cos 2x + \cos 8x)\}$$

$$\therefore \quad \cos x\cos 2x\cos 5x = \frac{1}{4}\{\cos 2x + \cos 4x + \cos 6x + \cos 8x\}$$

$$\therefore \quad I = \int(\cos x\cos 2x\cos 5x)\,dx$$

$$= \frac{1}{4}\int(\cos 2x + \cos 4x + \cos 6x + \cos 8x)\,dx$$

$$= \frac{\sin 2x}{8} + \frac{\sin 4x}{16} + \frac{\sin 6x}{24} + \frac{\sin 8x}{32} + C$$

Example 17 Evaluate

(i) $\int \sin x\cos x\cdot\cos 2x\cdot\cos 4x\,dx$

(ii) $\int \frac{1-\tan^2 x}{1+\tan^2 x}\,dx$ (iii) $\int \frac{1+\cos^2 x}{1+\cos 2x}\,dx$

(iv) $\int \frac{\cos 2x}{\cos^2 x\sin^2 x}\,dx$ (v) $\int \frac{\sec 2x - 1}{\sec 2x + 1}\,dx$

Sol. (i) Here, $I = \int \sin x\cos x\cdot\cos 2x\cos 4x\,dx$

$$= \frac{1}{2}\int 2\sin x\cdot\cos x\cdot\cos 2x\cdot\cos 4x\,dx$$

$[\text{using, } \sin 2x = 2\sin x\cdot\cos x]$

$$= \frac{1}{2\times 2}\int 2\sin 2x\cdot\cos 2x\cdot\cos 4x\cdot dx$$

$$= \frac{1}{4}\int \sin 4x\cdot\cos 4x\,dx = \frac{1}{2\times 4}\int 2\sin 4x\cos 4x\,dx$$

$$= \frac{1}{8}\int \sin 8x\,dx = \frac{-\cos 8x}{64} + C$$

(ii) Here, $I = \int \frac{1-\tan^2 x}{1+\tan^2 x}\,dx$

$$\therefore \quad I = \int \cos 2x\,dx \qquad \text{Using, } \cos 2x = \frac{1-\tan^2 x}{1+\tan^2 x}$$

$$= \frac{\sin 2x}{2} + c$$

(iii) Here, $I = \int \frac{1+\cos^2 x}{1+\cos 2x}\,dx$,

$$= \int \frac{1+\cos^2 x}{1+2\cos^2 x - 1}\,dx = \int \frac{1+\cos^2 x}{2\cos^2 x}\,dx$$

$[\text{Using, } \cos 2x = 2\cos^2 x - 1]$

$$= \frac{1}{2}\int(\sec^2 x + 1)\,dx = \frac{1}{2}(\tan x + x) + C$$

(iv) Here, $I = \int \frac{\cos 2x}{\cos^2 x\cdot\sin^2 x}\,dx$

$$I = \int \frac{(\cos^2 x - \sin^2 x)\,dx}{\cos^2 x\cdot\sin^2 x}$$

$[\text{Using, } \cos 2x = \cos^2 x - \sin^2 x]$

$$= \int \left(\frac{1}{\sin^2 x} - \frac{1}{\cos^2 x} \right) dx$$

$$= \int (\operatorname{cosec}^2 x - \sec^2 x)\, dx = -\cot x - \tan x + C$$

(v) Here, $I = \int \frac{\sec 2x - 1}{\sec 2x + 1} \cdot dx = \int \frac{1 - \cos 2x}{1 + \cos 2x}\, dx,$

We get, $I = \int \frac{2\sin^2 x}{2\cos^2 x}\, dx$

[using, $1 - \cos 2x = 2\sin^2 x$ and $1 + \cos 2x = 2\cos^2 x$]

$$= \int \tan^2 x \cdot dx$$

As, $\tan^2 x = \sec^2 x - 1$

$\therefore \quad I = \int (\sec^2 x - 1)\, dx = \tan x - x + C$

Example 18 ***Evaluate***

$$I = \int \left(\frac{\cot^2 2x - 1}{2\cot 2x} - \cos 8x \cdot \cot 4x \right) dx.$$

Sol. Here, $I = \int \left(\frac{\cot^2 2x - 1}{2\cot 2x} - \cos 8x \cdot \cot 4x \right) dx$

$$I = \int (\cot 4x - \cos 8x \cdot \cot 4x)\, dx$$

$$\left[\text{using } \cot 2A = \frac{\cot^2 A - 1}{2\cot A} \right]$$

$$= \int \cot 4x (1 - \cos 8x)\, dx$$

[using $1 - \cos 2A = 2\sin^2 A$]

$$= \int \cot 4x \cdot 2\sin^2 (4x)\, dx$$

$$= \int \frac{\cos 4x}{\sin 4x} \cdot 2\sin^2 4x\, dx$$

$$= \int 2\sin 4x \cdot \cos 4x\, dx,$$

using $\sin 2A = 2\sin A \cos A$

$$= \int \sin 8x\, dx = \frac{-\cos 8x}{8} + C$$

Exercise for Session 2

- Solve the following integration

1. $\int \frac{dx}{1 + \sin x}$

2. $\int \frac{\cos x - \sin x}{\cos x + \sin x} \cdot (2 + 2\sin 2x)\, dx$

3. $\int (3\sin x \cos^2 x - \sin^3 x)\, dx$

4. $\int \cos x^\circ\, dx$

5. $\int \frac{\sin x + \cos x}{\sqrt{1 + \sin 2x}} \cdot dx$, here $(\sin x + \cos x) > 0$

6. $\int \frac{\cos 2x - \cos 2\alpha}{\cos x - \cos \alpha} \cdot dx$

7. $\int \frac{\sin^3 x + \cos^3 x}{\sin^2 x \cdot \cos^2 x}\, dx$

8. $\int \sec^2 x \cdot \operatorname{cosec}^2 x\, dx$

9. $\int \sqrt{1 - \sin 2x}\, dx$

10. $\int \frac{\sin^6 x + \cos^6 x}{\sin^2 x \cdot \cos^2 x}\, dx$

11. $\int \left(\sin^2 \left(\frac{9\pi}{8} + \frac{x}{4} \right) - \sin^2 \left(\frac{7\pi}{8} + \frac{x}{4} \right) \right) dx$

12. $\int \frac{\cos 4x + 1}{\cot x - \tan x}\, dx$

13. $\int \left(\sin \alpha \cdot \sin (x - \alpha) + \sin^2 \left(\frac{x}{2} - \alpha \right) \right) dx$

14. $\int \frac{\sin 2x + \sin 5x - \sin 3x}{\cos x + 1 - 2\sin^2 2x}\, dx$

15. $\int \frac{\cos^4 x + \sin^4 x}{\sqrt{1 + \cos 4x}}\, dx$, here $\cos 2x > 0$

Session 3

Some Special Integrals

Some Special Integrals

(i) $\int \frac{dx}{x^2+a^2} = \frac{1}{a}\tan^{-1}\left(\frac{x}{a}\right)+C$

(ii) $\int \frac{dx}{x^2-a^2} = \frac{1}{2a}\log\left|\frac{x-a}{x+a}\right|+C$

(iii) $\int \frac{dx}{a^2-x^2} = \frac{1}{2a}\log\left|\frac{a+x}{a-x}\right|+C$

(iv) $\int \frac{dx}{\sqrt{a^2-x^2}} = \sin^{-1}\left(\frac{x}{a}\right)+C$

(v) $\int \frac{dx}{\sqrt{a^2+x^2}} = \log|x+\sqrt{x^2+a^2}|+C$

(vi) $\int \frac{dx}{\sqrt{x^2-a^2}} = \log|x+\sqrt{x^2-a^2}|+C$

(vii) $\int \sqrt{a^2-x^2}\,dx = \frac{1}{2}x\sqrt{a^2-x^2}+\frac{1}{2}a^2\sin^{-1}\left(\frac{x}{a}\right)+C$

(viii) $\int \sqrt{a^2+x^2}\,dx$

$= \frac{1}{2}x\sqrt{a^2+x^2}+\frac{1}{2}a^2\log|x+\sqrt{a^2+x^2}|+C$

(ix) $\int \sqrt{x^2-a^2}\,dx$

$= \frac{1}{2}x\sqrt{x^2-a^2}-\frac{1}{2}a^2\log|x+\sqrt{x^2-a^2}|+C$

Some Important Substitutions

Expression	Substitution
a^2+x^2	$x = a\tan\theta$ or $a\cot\theta$
a^2-x^2	$x = a\sin\theta$ or $a\cos\theta$
x^2-a^2	$x = a\sec\theta$ or $a\operatorname{cosec}\theta$
$\sqrt{\frac{a-x}{a+x}}$ or $\sqrt{\frac{a+x}{a-x}}$	$x = a\cos 2\theta$
$\sqrt{\frac{x-\alpha}{\beta-x}}$ or $\sqrt{(x-\alpha)(x-\beta)}$	$x = \alpha\cos^2\theta+\beta\sin^2\theta$

Application of these Formulae

The above standard integrals are very important. Given below are integrals which are applications of these.

Type I

(i) $\int \frac{dx}{ax^2+bx+c}$ (ii) $\int \frac{dx}{\sqrt{ax^2+bx+c}}$

(iii) $\int \sqrt{ax^2+bx+c}\,dx$

If ax^2+bx+c can be factorised, then the integration is easily done by the method of partial fractions (explained later). If the denominator cannot be factorised, then express it as the sum or difference of two squares by the method of completing the square

$$ax^2+bx+c = a\left(x^2+\frac{b}{a}x+\frac{c}{a}\right) = a\left\{\left(x+\frac{b}{2a}\right)^2+\left(\frac{c}{a}\right)-\frac{b^2}{4a^2}\right\}$$

make the substitution $x+\frac{b}{2a}=t$.

Example 19 Evaluate

(i) $\int \frac{1}{x^2-x+1}dx$ (ii) $\int \frac{1}{2x^2+x-1}dx$

(iii) $\int \frac{1}{\sqrt{x^2-2x+3}}dx$ (iv) $\int \sqrt{2x^2-3x+1}\,dx$

Sol. (i) $I = \int \frac{dx}{x^2-x+1}$,

completing x^2-x+1 into perfect square.

$$= \int \frac{dx}{x^2-x+1/4-1/4+1} = \int \frac{dx}{(x-1/2)^2+3/4}$$

$$\therefore\ I = \int \frac{dx}{(x-1/2)^2+(\sqrt{3}/2)^2}$$

$$= \frac{1}{\sqrt{3}/2}\tan^{-1}\left(\frac{x-1/2}{\sqrt{3}/2}\right)+C$$

$$\therefore I = \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{2x-1}{\sqrt{3}}\right)+C$$

$$\left[\text{using } \int \frac{1}{x^2+a^2}dx = \frac{1}{a}\tan^{-1}\left(\frac{x}{a}\right)+C\right]$$

(ii) $I = \int \frac{1}{2x^2+x-1}dx = \frac{1}{2}\int \frac{1}{x^2+x/2-1/2}dx$

$$= \frac{1}{2}\int \frac{1}{x^2+x/2+1/16-1/16-1/2}dx$$

$$= \frac{1}{2}\int \frac{dx}{(x+1/4)^2 - 9/16} = \frac{1}{2}\int \frac{dx}{(x+1/4)^2 - (3/4)^2}$$

$$= \frac{1}{2}\cdot\frac{1}{2(3/4)}\log\left|\frac{x+1/4-3/4}{x+1/4+3/4}\right| + C$$

$$\left[\text{using}\int\frac{dx}{x^2-a^2} = \frac{1}{2a}\log\left|\frac{x-a}{x+a}\right| + C\right]$$

$$= \frac{1}{3}\log\left|\frac{x-1/2}{x+1}\right| + C$$

$$\therefore \quad I = \frac{1}{3}\log\left|\frac{2x-1}{2(x+1)}\right| + C$$

(iii) $I = \int \frac{dx}{\sqrt{x^2-2x+3}} = \int \frac{dx}{\sqrt{x^2-2x+1-1+3}}$

$$= \int \frac{dx}{\sqrt{(x-1)^2+(\sqrt{2})^2}}$$

$$= \log|(x-1) + \sqrt{(x-1)^2+(\sqrt{2})^2}|$$

$$\left[\text{using}\int\frac{dx}{\sqrt{x^2+a^2}} = \log|x+\sqrt{x^2+a^2}| + C\right]$$

$$\therefore \quad I = \log|(x-1)+\sqrt{x^2-2x+3}| + C$$

(iv) $I = \int(\sqrt{2x^2-3x+1})\,dx = \sqrt{2}\int(\sqrt{x^2-3x/2+1/2})\,dx$

$$= \sqrt{2}\int(\sqrt{x^2-3x/2+9/16-9/16+1/2})\,dx$$

$$= \sqrt{2}\int(\sqrt{(x-3/4)^2-1/16})\,dx$$

$$= \sqrt{2}\left\{\begin{matrix}\frac{1}{2}(x-3/4)\sqrt{(x-3/4)^2-1/16} \\ -\frac{1}{16\times 2}\log|(x-3/4)+\sqrt{(x-3/4)^2-1/16}\end{matrix}\right\} + C$$

$$= \sqrt{2}\left\{\begin{matrix}\frac{1}{8}(4x-3)\sqrt{x^2-3x/2+1/2} \\ -\frac{1}{32}\log|(x-3/4)+\sqrt{x^2-3x/2+1/2}\end{matrix}\right\} + C$$

Example 20 Evaluate

(i) $\int \frac{1}{\sqrt{1-e^{2x}}}\,dx$ (ii) $\int \frac{2x}{\sqrt{1-x^2-x^4}}\,dx$

(iii) $\int \frac{a^x}{\sqrt{1-a^{2x}}}\,dx$ (iv) $\int \sqrt{\frac{x}{a^3-x^3}}\,dx$

Sol. (i) Here, $I = \int \frac{dx}{\sqrt{1-e^{2x}}}$

Let, $1 - e^{2x} = t^2$

Then, $-2e^{2x}dx = 2t\,dt$

$$\Rightarrow \quad dx = -\frac{-t\,dt}{e^{2x}},$$

$$dx = \frac{t\,dt}{t^2-1} = \int \frac{1}{\sqrt{t^2}}\cdot\frac{t}{t^2-1}\,dt$$

$$I = \int\frac{dt}{t^2-1} = \frac{1}{2\cdot 1}\log\left|\frac{t-1}{t+1}\right| + C$$

$$= \frac{1}{2}\log\left|\frac{\sqrt{1-e^{2x}}-1}{\sqrt{1-e^{2x}}+1}\right| + C$$

(ii) Here, $I = \int \frac{2x}{\sqrt{1-x^2-x^4}}\,dx$

Let, $x^2 = t, 2x\,dx = dt$

$$\therefore \quad I = \int\frac{dt}{\sqrt{1-t-t^2}} = \int\frac{dt}{\sqrt{1+\frac{1}{4}-\frac{1}{4}-t-t^2}}$$

$$I = \int\frac{dt}{\sqrt{5/4-(t+1/2)^2}} = \int\frac{dt}{\sqrt{(\sqrt{5}/2)^2-(t+1/2)^2}}$$

$$= \sin^{-1}\left(\frac{t+1/2}{\sqrt{5}/2}\right) + C = \sin^{-1}\left(\frac{2x^2+1}{\sqrt{5}}\right) + C$$

(iii) Here, $I = \int \frac{a^x}{\sqrt{1-a^{2x}}}\,dx$. Let, $a^x = t$

$$\therefore \quad a^x \log a\,dx = dt, \; a^x\,dx = \frac{dt}{\log a}$$

$$\therefore \quad I = \int\frac{1}{\sqrt{1-t^2}}\cdot\frac{dt}{\log a} = \frac{1}{\log a}\cdot\sin^{-1}(t) + C$$

$$I = \frac{1}{\log a}\sin^{-1}(a^x) + C$$

(iv) Here, $I = \int\sqrt{\frac{x}{a^3-x^3}}\,dx = \int\frac{x^{1/2}\,dx}{\sqrt{(a^{3/2})^2-(x^{3/2})^2}}$

Let, $x^{3/2} = t, \frac{3}{2}x^{1/2}\,dx = dt, x^{1/2}\,dx = \frac{2}{3}dt$

$$= \int\frac{\frac{2}{3}dt}{\sqrt{(a^{3/2})^2-(t)^2}}$$

$$= \frac{2}{3}\cdot\sin^{-1}\left(\frac{t}{a^{3/2}}\right) + C = \frac{2}{3}\sin^{-1}\left(\frac{x^{3/2}}{a^{3/2}}\right) + C$$

Example 21 Evaluate

(i) $\int \frac{\cos x}{\sqrt{\sin^2 x - 2\sin x - 3}}\,dx$. (ii) $\int\sqrt{\frac{\sin(x-\alpha)}{\sin(x+\alpha)}}\,dx$.

(iii) $\int \frac{2\sin 2x - \cos x}{6-\cos^2 x - 4\sin x}\,dx$.

Sol. (i) Let $I = \int \frac{\cos x\, dx}{\sqrt{\sin^2 x - 2\sin x - 3}}$

Put $\sin x = t \quad \therefore \cos x\, dx = dt$

$$\Rightarrow I = \int \frac{dt}{\sqrt{t^2 - 2t - 3}} = \int \frac{dt}{\sqrt{t^2 - 2t + 1 - 1 - 3}}$$

$$I = \int \frac{dt}{\sqrt{(t-1)^2 - (2)^2}}$$

$$= \log|(t-1) + \sqrt{(t-1)^2 - (2)^2}| + C$$

$$\therefore \quad I = \log|(\sin x - 1) + \sqrt{\sin^2 x - 2\sin x - 3}| + C$$

(ii) Let $I = \int \sqrt{\frac{\sin(x-\alpha)}{\sin(x+\alpha)}}\, dx$

$$I = \int \sqrt{\frac{\sin(x-\alpha)}{\sin(x+\alpha)} \times \frac{\sin(x-\alpha)}{\sin(x-\alpha)}}\, dx$$

$$= \int \frac{\sin(x-\alpha)}{\sqrt{\sin^2 x - \sin^2 \alpha}}\, dx$$

$$I = \int \frac{\sin x \cos\alpha - \cos x \sin\alpha}{\sqrt{\sin^2 x - \sin^2 \alpha}}\, dx$$

$$= \cos\alpha \int \frac{\sin x\, dx}{\sqrt{\sin^2 x - \sin^2 \alpha}} - \sin\alpha \int \frac{\cos x\, dx}{\sqrt{\sin^2 x - \sin^2 \alpha}}$$

$$= \cos\alpha \int \frac{\sin x\, dx}{\sqrt{1 - \cos^2 x - \sin^2 \alpha}} - \sin\alpha \int \frac{\cos x\, dx}{\sqrt{\sin^2 x - \sin^2 \alpha}}$$

$$= \cos\alpha \int \frac{\sin x\, dx}{\sqrt{\cos^2\alpha - \cos^2 x}} - \sin\alpha \int \frac{\cos x\, dx}{\sqrt{\sin^2 x - \sin^2 \alpha}}$$

In the first part, put $\cos x = t$, so that $-\sin x\, dx = dt$ and in second part, put $\sin x = u$, so that $\cos x\, dx = du$

$$\therefore \quad I = -\cos\alpha \int \frac{dt}{\sqrt{\cos^2\alpha - t^2}} - \sin\alpha \int \frac{du}{\sqrt{u^2 - \sin^2\alpha}}$$

$$= -\cos\alpha \cdot \sin^{-1}\left(\frac{t}{\cos\alpha}\right) - \sin\alpha \cdot \log |u - \sqrt{(u^2 - \sin^2\alpha)}| + C$$

$$= -\cos\alpha \cdot \sin^{-1}\left(\frac{\cos x}{\cos\alpha}\right) - \sin\alpha \cdot \log |\sin x - \sqrt{\sin^2 x - \sin^2\alpha}| + C$$

(iii) $I = \int \frac{2\sin 2x - \cos x}{6 - \cos^2 x - 4\sin x}\, dx$

$$= \int \frac{(4\sin x - 1)\cos x}{6 - (1 - \sin^2 x) - 4\sin x}\, dx$$

$$= \int \frac{(4\sin x - 1)\cos x}{\sin^2 x - 4\sin x + 5}\, dx$$

Put $\sin x = t$, so that $\cos x\, dx = dt$

$$\therefore \quad I = \int \frac{(4t-1)\, dt}{(t^2 - 4t + 5)} \qquad \ldots(i)$$

Now, let $\quad (4t - 1) = \lambda(2t - 4) + \mu$

Comparing coefficients of like powers of t, we get

$$2\lambda = 4, -4\lambda + \mu = -1$$

$$\Rightarrow \quad \lambda = 2, \mu = 7 \qquad \ldots(ii)$$

$$\therefore I = \int \frac{2(2t-4) + 7}{t^2 - 4t + 5}\, dt \qquad \text{[using Eqs. (i) and (ii)]}$$

$$= 2\int \frac{2t - 4}{t^2 - 4t + 5}\, dt + 7\int \frac{dt}{t^2 - 4t + 5}$$

$$= 2\log|t^2 - 4t + 5| + 7\int \frac{dt}{t^2 - 4t + 4 - 4 + 5}$$

$$= 2\log|t^2 - 4t + 5| + 7\int \frac{dt}{(t-2)^2 + (1)^2}$$

$$= 2\log|t^2 - 4t + 5| + 7\tan^{-1}(t-2) + C$$

$$= 2\log|\sin^2 x - 4\sin x + 5| + 7\tan^{-1}(\sin x - 2) + C$$

Type II

(i) $\int \frac{(px+q)\, dx}{ax^2 + bx + c}$ (ii) $\int \frac{(px+q)}{\sqrt{ax^2 + bx + c}}\, dx$

(iii) $\int (px+q)\sqrt{ax^2 + bx + c}\, dx$

The linear factor $(px + q)$ is expressed in terms of the derivative of the quadratic factor $ax^2 + bx + c$ together with a constant as $px + q = \frac{\lambda d}{dx}(ax^2 + bx + c) + \mu$

$$\Rightarrow \quad px + q = \lambda(2ax + b) + \mu$$

Here, we have to find λ and μ and replace $(px + q)$ by $\{\lambda(2ax + b) + \mu\}$ in (i), (ii) and (iii).

Example 22 Evaluate

(i) $\int \sqrt{\frac{a-x}{a+x}}\, dx$ (ii) $\int x\sqrt{\frac{a^2 - x^2}{a^2 + x^2}}\, dx$

Sol. (i) Let $I = \int \sqrt{\frac{a-x}{a+x}}\, dx$

$$I = \int \sqrt{\frac{a-x}{a+x} \times \frac{a-x}{a-x}}\, dx = \int \frac{a-x}{\sqrt{a^2 - x^2}}\, dx$$

$$I = \int \frac{a}{\sqrt{a^2 - x^2}}\, dx - \int \frac{x}{\sqrt{a^2 - x^2}}\, dx$$

$$= a \cdot \sin^{-1}\left(\frac{x}{a}\right) + \int \frac{t\, dt}{t}$$

Put $\quad a^2 - x^2 = t^2 \Rightarrow -2x\, dx = 2t\, dt \Rightarrow x\, dx = -t\, dt$

$$= a \cdot \sin^{-1}\left(\frac{x}{a}\right) + t + C$$

$$= a \cdot \sin^{-1}\left(\frac{x}{a}\right) + \sqrt{a^2 - x^2} + C$$

(ii) Let $I = \int x \sqrt{\frac{a^2 - x^2}{a^2 + x^2}}\, dx$

Put $x^2 = t \Rightarrow 2x\, dx = dt$

$$\therefore \quad I = \int \sqrt{\frac{a^2 - t}{a^2 + t}} \cdot \frac{dt}{2} = \frac{1}{2}\int \sqrt{\frac{a^2 - t}{a^2 + t} \cdot \frac{a^2 - t}{a^2 - t}}\, dt$$

$$= \frac{1}{2}\int \frac{a^2 - t}{\sqrt{a^4 - t^2}}\, dt$$

$$= \frac{1}{2} a^2 \int \frac{dt}{\sqrt{(a^2)^2 - (t)^2}} - \frac{1}{2}\int \frac{t\, dt}{\sqrt{a^4 - t^2}}$$

$$= \frac{1}{2} a^2 \cdot \sin^{-1}\left(\frac{t}{a^2}\right) + \frac{1}{4}\int \frac{du}{\sqrt{u}},$$

where $a^4 - t^2 = u \implies -2t\, dt = du$

$$= \frac{1}{2} a^2 \cdot \sin^{-1}\left(\frac{t}{a^2}\right) + \frac{1}{4} \cdot \left(\frac{u^{1/2}}{1/2}\right) + C$$

[where $t = x^2$ and $u = a^4 - x^4$]

$$= \frac{1}{2} a^2 \cdot \sin^{-1}\left(\frac{x^2}{a^2}\right) + \frac{1}{2} \cdot \sqrt{a^4 - x^4} + C$$

Integrals of the Form $\int \frac{k(x)}{ax^2 + bx + c}\, dx$, where $k(x)$ is a Polynomial of Degree Greater than 2

To evaluate this type of integrals we divide the numerator by denominator and express the integral as

$Q(x) + \frac{R(x)}{ax^2 + bx + c}$, where $R(x)$ is a linear function of x.

Example 23 Evaluate

(i) $\int x \sqrt{1 + x - x^2}\, dx$ (ii) $\int (x + 1) \sqrt{1 - x - x^2}\, dx$

Sol. (i) Let $I = \int x \sqrt{1 + x - x^2}\, dx$

Put $x = \lambda \left\{\frac{d}{dx}(1 + x - x^2)\right\} + \mu$

Then, comparing the coefficients of like powers of x, we get

$1 = -2\lambda$ and $\lambda + \mu = 0 \Rightarrow \lambda = -1/2, \mu = 1/2$

$\therefore \quad I = \int x \sqrt{1 + x - x^2}\, dx$

$$= \int \left\{-\frac{1}{2}(1 - 2x) + \frac{1}{2}\right\} \sqrt{1 + x - x^2}\, dx$$

$$= -\frac{1}{2}\int (1 - 2x) \sqrt{1 + x - x^2}\, dx + \frac{1}{2}\int \sqrt{1 + x - x^2}\, dx$$

$$= -\frac{1}{2}\int \sqrt{t}\, dt + \frac{1}{2}\int \sqrt{-(x^2 - x + \frac{1}{4} - \frac{1}{4} - 1)}\, dx$$

[where $t = 1 + x - x^2$]

$$= -\frac{1}{2}\left(\frac{t^{3/2}}{3/2}\right) + \frac{1}{2}\int \sqrt{\left(\frac{\sqrt{5}}{2}\right)^2 - \left(x - \frac{1}{2}\right)^2}\, dx$$

$$= -\frac{1}{3} t^{3/2} + \frac{1}{2}$$

$$\left[\frac{(x - 1/2)}{2}\sqrt{\left(\frac{\sqrt{5}}{2}\right)^2 - \left(x - \frac{1}{2}\right)^2} + \frac{1}{2}\left(\frac{\sqrt{5}}{2}\right)^2 \sin^{-1}\left(\frac{x - 1/2}{\sqrt{5}/2}\right)\right] + C$$

$$= -\frac{1}{3}(1 + x - x^2)^{3/2}$$

$$+ \frac{1}{2}\left[\frac{(x - 1/2)}{2}\sqrt{1 + x - x^2} + \frac{5}{8}\sin^{-1}\left(\frac{2x - 1}{\sqrt{5}}\right)\right] + C$$

(ii) Let $I = \int (x + 1) \sqrt{1 - x - x^2}\, dx$

Put, $(x + 1) = \lambda \cdot \left(\frac{d}{dx}(1 - x - x^2)\right) + \mu$

Then, $(x + 1) = \lambda(-1 - 2x) + \mu$ comparing the coefficients of like powers of x, we get $-2\lambda = 1$ and $\mu - \lambda = 1 \Rightarrow \lambda = -1/2$ and $\mu = 1/2$.

$\therefore \quad (x + 1) = -\frac{1}{2}(-1 - 2x) + \frac{1}{2}$

So, $\int (x + 1) \sqrt{1 - x - x^2}\, dx = \int \left\{-\frac{1}{2}(-1 - 2x) + \frac{1}{2}\right\} \sqrt{1 - x - x^2}\, dx$

$$= -\frac{1}{2}\int (-1 - 2x) \sqrt{1 - x - x^2}\, dx + \frac{1}{2}\int \sqrt{1 - x - x^2}\, dx$$

$$= -\frac{1}{2}\int (-1 - 2x) \sqrt{1 - x - x^2}\, dx + \frac{1}{2}\int \sqrt{\left\{1 - \left(x^2 + x + \frac{1}{4} - \frac{1}{4}\right)\right\}}\, dx$$

$$= -\frac{1}{2}\sqrt{t}\, dt + \frac{1}{2}\int \sqrt{(\sqrt{5}/2)^2 - (x + 1/2)^2}\, dx$$

[where $t = 1 + x - x^2$]

$$= -\frac{1}{2}\left(\frac{t^{3/2}}{3/2}\right) + \frac{1}{2}\left\{\frac{1}{2}\left(x + \frac{1}{2}\right)\sqrt{1 - x - x^2} + \frac{1}{2} \cdot \frac{5}{4}\sin^{-1}\left(\frac{x + 1/2}{\sqrt{5}/2}\right)\right\} + C$$

$$= -\frac{1}{3}(1 - x - x^2)^{3/2} + \frac{1}{8}(2x + 1)\sqrt{1 - x - x^2} + \frac{5}{16}\sin^{-1}\left(\frac{2x + 1}{\sqrt{5}}\right) + C$$

Example 24 Evaluate $\int \frac{x^2+x+3}{x^2-x-2}\,dx$.

Sol. Let $I = \int \frac{x^2+x+3}{x^2-x-2}\,dx$

$\therefore \quad I = \int \left(1 + \frac{2x+5}{x^2-x-2}\right) dx$

$\Rightarrow \quad I = \int 1\,dx + \int \frac{2x+5}{x^2-x-2}\,dx$

$I = x + \int \frac{2x+5}{x^2-x-2}\,dx$

Put, $2x+5 = \lambda\left\{\frac{d}{dx}(x^2-x-2)\right\} + \mu$. Then, obtaining $2x+5 = \lambda(2x-1) + \mu$, comparing the coefficients of like terms. We get, $2 = 2\lambda$ and $5 = \mu - \lambda$

$\therefore \quad \lambda = 1$ and $\mu = 6$

$\therefore \quad I = x + \int \frac{\lambda(2x-1)+\mu}{x^2-x-2}\,dx$

$= x + \int \frac{2x-1}{x^2-x-2}\,dx + 6\int \frac{1}{x^2-x-2}\,dx$

$= x + \int \frac{1}{t}\,dt + 6\int \frac{1}{x^2-x+\frac{1}{4}-\frac{1}{4}-2}$

[where $t = x^2 - x - 2$]

$= x + \log|t| + 6\int \frac{dx}{(x-1/2)^2-(3/2)^2}\,dx$

$= x + \log|x^2-x-2| + 6\cdot\frac{1}{2(3/2)}\log\left|\frac{x-\frac{1}{2}-\frac{3}{2}}{x-\frac{1}{2}+\frac{3}{2}}\right| + C$

$= x + \log|x^2-x-2| + 2\cdot\log\left|\frac{x-2}{x+1}\right| + C$

Integrals of the Type

1. $\int \frac{ax^2+bx+c}{(px^2+qx+r)}\,dx$
2. $\int \frac{(ax^2+bx+c)}{\sqrt{px^2+qx+r}}\,dx$
3. $\int (ax^2+bx+c)\sqrt{px^2+qx+r}\,dx$

In above cases; substitute

$$ax^2+bx+c = \lambda(px^2+qx+r) + \mu\left\{\frac{d}{dx}(px^2+qx+r)\right\} + \gamma.$$

Find λ, μ and γ. These integrations reduces to integration of three independent functions.

Example 25 ***Evaluate*** $\int \frac{2x^2+5x+4}{\sqrt{x^2+x+1}}\,dx$.

Sol. Let $I = \int \frac{2x^2+5x+4}{\sqrt{x^2+x+1}}\,dx$

Put $2x^2+5x+4 = \lambda(x^2+x+1) + \mu\left\{\frac{d}{dx}(x^2+x+1)\right\} + \gamma$

or $2x^2+5x+4 = \lambda(x^2+x+1) + \mu(2x+1) + \gamma$

Comparing the coefficients of like terms, we get

$2 = \lambda, \quad 5 = \lambda + 2\mu, \quad 4 = \lambda + \mu + \gamma$

$\therefore \quad \lambda = 2, \quad \mu = 3/2, \quad \gamma = 1/2$

Hence, the above integral reduces to

$I = \int \frac{2x^2+5x+4}{\sqrt{x^2+x+1}}\,dx$

$= \int \left(2\cdot\frac{(x^2+x+1)}{\sqrt{x^2+x+1}} + \frac{3}{2}\cdot\frac{(2x+1)}{\sqrt{x^2+x+1}} + \frac{1}{2}\cdot\frac{1}{\sqrt{x^2+x+1}}\right) dx$

$= 2\int \sqrt{x^2+x+1}\,dx + \frac{3}{2}\int \frac{dt}{\sqrt{t}} + \frac{1}{2}\int \frac{dx}{\sqrt{x^2+x+1}}$

[where $t = x^2 + x + 1$]

$= 2\int \sqrt{(x+1/2)^2+(\sqrt{3}/2)^2}\,dx + \frac{3}{2}\cdot\frac{t^{1/2}}{1/2} + \frac{1}{2}\int \frac{dx}{\sqrt{(x+1/2)^2+(\sqrt{3}/2)^2}}$

$= 2\left[\frac{1}{2}\left(x+\frac{1}{2}\right)\sqrt{x^2+x+1} + \frac{1}{2}\cdot\frac{3}{4}\cdot\log\left|\left(x+\frac{1}{2}\right)+\sqrt{x^2+x+1}\right|\right]$

$+ 3\sqrt{x^2+x+1} + \frac{1}{2}\log\left|\left(x+\frac{1}{2}\right)+\sqrt{x^2+x+1}\right| + C$

$\therefore \quad I = \left(x+\frac{1}{2}\right)\sqrt{x^2+x+1} + \frac{3}{4}\log\left\{\left(x+\frac{1}{2}\right)+\sqrt{x^2+x+1}\right\}$

$+ 3\sqrt{x^2+x+1} + \frac{1}{2}\log\left\{\left(x+\frac{1}{2}\right)+\sqrt{x^2+x+1}\right\} + C$

$\Rightarrow I = \left(x+\frac{7}{2}\right)\sqrt{x^2+x+1} + \frac{5}{4}\log\left\{\left(x+\frac{1}{2}\right)+\sqrt{x^2+x+1}\right\} + C$

Trigonometric Integrals

(a) Integrals of the Form

$$\int \frac{1}{a\cos^2 x + b\sin^2 x}\,dx, \int \frac{1}{a+b\sin^2 x}\,dx, \int \frac{1}{a+b\cos^2 x}\,dx,$$

$$\int \frac{1}{(a\sin x + b\cos x)^2}\,dx, \int \frac{1}{a+b\sin^2 x + c\cos^2 x}\,dx$$

To evaluate this type of integrals, divide numerator and denominator both by $\cos^2 x$, replace $\sec^2 x$, if any, in denominator by $(1+\tan^2 x)$ and put $\tan x = t$. So that $\sec^2 x\, dx = dt$.

Example 26 Evaluate

(i) $\int \frac{1}{4\sin^2 x + 9\cos^2 x}\, dx$ (ii) $\int \frac{\sin x}{\sin 3x}\, dx$

Sol. (i) $I = \int \frac{dx}{4\sin^2 x + 9\cos^2 x}$

Here, dividing numerator and denominator by $\cos^2 x$. We get

$$I = \int \frac{\sec^2 x}{4\tan^2 x + 9} dx$$

Put $\tan x = t$

$\Rightarrow \sec^2 x\, dx = dt$

$$\therefore \quad I = \int \frac{dt}{4t^2+9} = \frac{1}{4}\int \frac{dt}{t^2 + (3/2)^2}$$

$$= \frac{1}{4}\cdot\frac{1}{3/2}\tan^{-1}\left(\frac{t}{3/2}\right) + C$$

$$I = \frac{1}{6}\tan^{-1}\left(\frac{2\tan x}{3}\right) + C$$

(ii) Let $I = \int \frac{\sin x}{\sin 3x}\, dx = \int \frac{\sin x}{3\sin x - 4\sin^3 x}\, dx$

$$I = \int \frac{dx}{3 - 4\sin^2 x}$$

Dividing numerator and denominator by $\cos^2 x$, we get

$$I = \int \frac{\sec^2 x\, dx}{3\sec^2 x - 4\tan^2 x} = \int \frac{\sec^2 x\, dx}{3(1+\tan^2 x) - 4\tan^2 x}$$

$$I = \int \frac{\sec^2 x\, dx}{3 - \tan^2 x}$$

Let $\tan x = t \Rightarrow \sec^2 x\, dx = dt$

$$\therefore \quad I = \int \frac{dt}{(\sqrt{3})^2 - (t)^2} = \frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{3}+t}{\sqrt{3}-t}\right| + C$$

$$I = \frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{3}+\tan x}{\sqrt{3}-\tan x}\right| + C$$

(b) Integrals of the Form

$$\int \frac{1}{a\sin x + b\cos x}\, dx, \int \frac{1}{a + b\sin x}\, dx,$$

$$\int \frac{1}{a + b\cos x}\, dx, \int \frac{1}{a\sin x + b\cos x + c}\, dx$$

To evaluate this type of integrals we put

$\sin x = \frac{2\tan x/2}{1+\tan^2 x/2}$ and $\cos x = \frac{1-\tan^2 x/2}{1+\tan^2 x/2}$ and replace $\tan x/2 = t$, by performing these steps the integral reduces to the form $\int \frac{1}{at^2+bt+c}\, dt$ which can be evaluated by methods discussed earlier.

Example 27 Evaluate

(i) $\int \frac{dx}{2 + \sin x + \cos x}$ (ii) $\int \frac{dx}{\sqrt{3}\sin x + \cos x}$

Sol. For this type we use, $\sin x = \frac{2\tan x/2}{1+\tan^2 x/2}$,

$$\cos x = \frac{1-\tan^2 x/2}{1+\tan^2 x/2}.$$

(i) Let $I = \int \frac{dx}{2 + \sin x + \cos x}$

$$= \int \frac{dx}{2 + \frac{2\tan x/2}{1+\tan^2 x/2} + \frac{1-\tan^2 x/2}{1+\tan^2 x/2}}$$

$$= \int \frac{\sec^2 \frac{x}{2}\, dx}{2 + 2\tan^2 \frac{x}{2} + 2\tan\frac{x}{2} + 1 - \tan^2\frac{x}{2}}$$

$$I = \int \frac{\sec^2 \frac{x}{2}\, dx}{\tan^2 \frac{x}{2} + 2\tan\frac{x}{2} + 3}$$

Put $\tan\frac{x}{2} = t$

$$\Rightarrow \frac{1}{2}\sec^2\frac{x}{2}\, dx = dt = \int \frac{2\, dt}{t^2+2t+3} = 2\int \frac{dt}{t^2+2t+1+2}$$

$$= 2\int \frac{dt}{(t+1)^2 + (\sqrt{2})^2}$$

$$= 2\cdot\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{t+1}{\sqrt{2}}\right) + C$$

$$I = \sqrt{2}\tan^{-1}\left(\frac{\tan x/2 + 1}{\sqrt{2}}\right) + C$$

(ii) Let $I = \int \frac{dx}{\sqrt{3}\sin x + \cos x}$

$$= \int \frac{dx}{\frac{\sqrt{3}\cdot 2\tan x/2}{1+\tan^2 x/2} + \frac{1-\tan^2 x/2}{1+\tan^2 x/2}}$$

$$= \int \frac{\sec^2 \frac{x}{2}\, dx}{2\sqrt{3}\tan\frac{x}{2} + 1 - \tan^2\frac{x}{2}}$$

Put $\tan\frac{x}{2}=t \Rightarrow \frac{1}{2}\sec^2\frac{x}{2}\,dx=dt$

$$\therefore \quad I=\int\frac{2dt}{-t^2+2\sqrt{3}t+1}=2\int\frac{dt}{-t^2+2\sqrt{3}t-3+3+1}$$

$$=2\int\frac{dt}{4-(t-\sqrt{3})^2}=2\int\frac{dt}{(2)^2-(t-\sqrt{3})^2}$$

$$=2\cdot\frac{1}{2(2)}\log\left|\frac{2+t-\sqrt{3}}{2-t+\sqrt{3}}\right|+C$$

$$\therefore \quad I=\frac{1}{2}\log\left|\frac{2-\sqrt{3}+\tan x/2}{2+\sqrt{3}-\tan x/2}\right|+C$$

(c) Alternative Method to Evaluate the Integrals of the Form

$$\int\frac{1}{a\sin x+b\cos x}\,dx$$

To evaluate this type of integrals we substitute $a=r\cos\theta$, $b=r\sin\theta$ and so

$$r=\sqrt{a^2+b^2},\quad \theta=\tan^{-1}\left(\frac{b}{a}\right)$$

$$\therefore \quad a\sin x+b\cos x=r\sin(x+\theta)$$

So, $$\int\frac{1}{a\sin x+b\cos x}\,dx=\frac{1}{r}\int\frac{1}{\sin(x+\theta)}\,dx$$

$$=\frac{1}{r}\int\operatorname{cosec}(x+\theta)\,dx=\frac{1}{r}\log\left|\tan\left(\frac{x}{2}+\frac{\theta}{2}\right)\right|+C$$

$$\therefore \quad \int\frac{1}{a\sin x+b\cos x}\,dx=\frac{1}{\sqrt{a^2+b^2}}\log\left|\tan\left(\frac{x}{2}+\frac{1}{2}\tan^{-1}\frac{b}{a}\right)\right|+C$$

Example 28 Evaluate $\int\frac{1}{\sqrt{3}\sin x+\cos x}\,dx$.

Sol. Let $\sqrt{3}=r\sin\theta$ and $1=r\cos\theta$.

Then, $r=\sqrt{(\sqrt{3})^2+(1)^2}=2$ and $\tan\theta=\frac{\sqrt{3}}{1}\Rightarrow\theta=\frac{\pi}{3}$

$$\therefore \quad I=\int\frac{1}{\sqrt{3}\sin x+\cos x}\,dx$$

$$=\int\frac{1}{r\sin\theta\sin x+r\cos\theta\cos x}\,dx$$

$$=\frac{1}{r}\int\frac{dx}{\cos(x-\theta)}=\frac{1}{r}\int\sec(x-\theta)\,dx$$

$$=\frac{1}{r}\log\left|\tan\left(\frac{\pi}{4}+\frac{x}{2}-\frac{\theta}{2}\right)\right|+C$$

$$=\frac{1}{2}\log\left|\tan\left(\frac{\pi}{4}+\frac{x}{2}-\frac{\pi}{6}\right)\right|+C$$

$$=\frac{1}{2}\log\left|\tan\left(\frac{x}{2}+\frac{\pi}{12}\right)\right|+C$$

(d) Integrals of the Form

$$\int\frac{p\cos x+q\sin x+r}{a\cos x+b\sin x+c}\,dx,\ \int\frac{p\cos x+q\sin x}{a\cos x+b\sin x}\,dx$$

Rule for (i) In this integral express numerator as,

λ (denominator) + μ (diffn. of denominator) + γ.

Find λ,μ and γ by comparing coefficients of $\sin x, \cos x$ and constant term and split the integral into sum of three integrals.

$$\lambda\int dx+\mu\int\frac{\text{d.c. of (denominator)}}{\text{denominator}}\,dx+\gamma\int\frac{dx}{a\sin x+b\cos x+c}$$

Rule for (ii) Express numerator as λ (denominator) + μ (differentiation of denominator) and find λ and μ as above.

Example 29 Evaluate $\int\frac{(2+3\cos x)}{\sin x+2\cos x+3}\,dx$.

Sol. Write the numerator = λ (denominator) + μ (d.c. of denominator) + γ

$$\Rightarrow \quad 2+3\cos x=\lambda(\sin x+2\cos x+3)+\mu(\cos x-2\sin x)+\gamma$$

Comparing the coefficients of $\sin x$, $\cos x$ and constant terms, we get

$$0=\lambda-2\mu,\ 3=2\lambda+\mu,\ 2=3\lambda+\gamma$$

$$\Rightarrow \quad \lambda=6/5,\ \mu=3/5,\ \gamma=-8/5$$

Hence, $$I=\frac{6}{5}\int 1\,dx+\frac{3}{5}\int\frac{\cos x-2\sin x}{\sin x+2\cos x+3}\,dx-\frac{8}{5}\int\frac{dx}{\sin x+2\cos x+3}$$

$$=\frac{6}{5}\cdot x+\frac{3}{5}\log|\sin x+2\cos x+3|-\frac{8}{5}I_3 \qquad \ldots(i)$$

Where, $I_3=\int\frac{dx}{\sin x+2\cos x+3}$

$$=\int\frac{dx}{\frac{2\tan x/2}{1+\tan^2 x/2}+\frac{2(1-\tan^2 x/2)}{1+\tan^2 x/2}+3}$$

$$=\int\frac{\sec^2\frac{x}{2}\,dx}{2\tan\frac{x}{2}+2-2\tan^2\frac{x}{2}+3+3\tan^2\frac{x}{2}}$$

$$=\int\frac{\sec^2\frac{x}{2}\,dx}{\tan^2\frac{x}{2}+2\tan\frac{x}{2}+5},\quad \text{let } \tan\frac{x}{2}=t$$

$$\Rightarrow \quad \frac{1}{2}\sec^2\frac{x}{2}\,dx = dt = \int \frac{2dt}{t^2+2t+5} = 2\int \frac{dt}{(t+1)^2+2^2}$$

$$I_3 = 2\cdot\frac{1}{2}\cdot\tan^{-1}\left(\frac{t+1}{2}\right) = \tan^{-1}\left(\frac{\tan\frac{x}{2}+1}{2}\right) \quad ...(ii)$$

From Eqs. (i) and (ii),

$$I = \frac{6}{5}x + \frac{3}{5}\log|\sin x + 2\cos x + 3| - \frac{8}{5}\tan^{-1}\left|\left(\frac{\tan\frac{x}{2}+1}{2}\right)\right| + C$$

Example 30 The value of $\int\{1+\tan x\cdot\tan(x+A)\}\,dx$ is equal to

(a) $\cot A\cdot\log\left|\dfrac{\sec x}{\sec(x+A)}\right| + C$

(b) $\tan A\cdot\log|\sec(x+A)| + C$

(c) $\cot A\cdot\log\left|\dfrac{\sec(x+A)}{\sec(x)}\right| + C$

(d) None of the above

Sol. Let $I = \int\{1+\tan x\cdot\tan(x+A)\}\,dx$

$$= \int\left\{1+\frac{\sin x\cdot\sin(x+A)}{\cos x\cdot\cos(x+A)}\right\}dx$$

$$= \int\frac{\cos x\cdot\cos(x+A)+\sin x\cdot\sin(x+A)}{\cos x\cdot\cos(x+A)}\,dx$$

$$= \int\frac{\cos(x+A-x)\,dx}{\cos x\cdot\cos(x+A)}$$

$$= \cos A\cdot\int\frac{dx}{\cos x\cdot\cos(x+A)}$$

Multiplying and dividing by $\sin A$, we get

$$= \cot A\cdot\int\frac{\sin A\,dx}{\cos x\cdot\cos(x+A)}$$

$$= \cot A\cdot\int\frac{\sin(x+A-x)\,dx}{\cos x\cdot\cos(x+A)}$$

$$= \cot A\cdot\int\left\{\frac{\sin(x+A)\cdot\cos x}{\cos x\cos(x+A)} - \frac{\cos(x+A)\cdot\sin x}{\cos x\cdot\cos(x+A)}\right\}dx$$

$$= \cot A\cdot\{\int\tan(x+A)dx - \int\tan x\,dx\}$$

$$= \cot A\cdot\{\log|\sec(x+A)| - \log|\sec x|\} + C$$

Hence, (c) is the correct answer.

Example 31 The value of $\int\frac{\sqrt{\cos 2x}}{\sin x}\,dx$, is equal to

(a) $\log\left|\cot x+\sqrt{\cot^2 x-1}\right| + \sqrt{2}\log\left|\cos x + \sqrt{\cos^2 x - 1/2}\right| + C$

(b) $-\log\left|\cot x+\sqrt{\cot^2 x-1}\right| + \sqrt{2}\log\left|\cos x + \sqrt{\cos^2 x - 1/2}\right| + C$

(c) $\log\left|\cot x+\sqrt{\cot^2 x-1}\right| + 2\log\left|\cos x + \sqrt{\cos^2 x - 1/2}\right| + C$

(d) $-\log\left|\cot x+\sqrt{\cot^2 x-1}\right| + 2\log\left|\cos x + \sqrt{\cos^2 x - 1/2}\right| + C$

Sol. Let $I = \int\frac{\sqrt{\cos 2x}}{\sin x}\,dx = \int\frac{\cos 2x}{\sin x\sqrt{\cos 2x}}\,dx$

$$= \int\frac{1-2\sin^2 x}{\sin x\sqrt{\cos 2x}}\,dx$$

$$= \int\frac{1}{\sin x\sqrt{\cos^2 x - \sin^2 x}}\,dx - 2\int\frac{\sin x}{\sqrt{2\cos^2 x - 1}}\,dx$$

$$= \int\frac{\operatorname{cosec}^2 x}{\sqrt{\cot^2 x - 1}}\,dx - \frac{2}{\sqrt{2}}\int\frac{\sin x}{\sqrt{\cos^2 x - 1/2}}\,dx$$

$$= -\int\frac{dt}{\sqrt{t^2-1}} - \sqrt{2}\int\frac{-ds}{\sqrt{s^2-(1/\sqrt{2})^2}}$$

[where $t = \cot x$ and $s = \cos x$]

$$= -\log|t+\sqrt{t^2-1}| + \sqrt{2}\log|s+\sqrt{s^2-1/2}| + C$$

$$= -\log|\cot x+\sqrt{\cot^2 x-1}| + \sqrt{2}\log|\cos x + \sqrt{\cos^2 x - 1/2}| + C$$

Hence, (b) is the correct answer.

Exercise for Session 3

■ Evaluate the following integrals

1. $\int \frac{x\,dx}{9-16x^4}$

2. $\int \frac{x^2}{9+16x^6}\,dx$

20. $\int \sqrt{\frac{\cos x-\cos^3 x}{(1-\cos^3 x)}}\,dx$

21. Evaluate $\int \frac{3\sin x+2\cos x}{3\cos x+2\sin x}\,dx$

22. Evalute $\int (2x-4)\sqrt{4+3x-x^2}dx$.

23. $\int \frac{(2x^2+5x+9)dx}{(x+1)\sqrt{x^2+x+1}}$

24. The value of $\int \frac{dx}{\sec x+\operatorname{cosec} x}$, is equal to

(a) $\left\{(\sin x+\cos x)+\frac{1}{\sqrt{2}}\log\left|\frac{\tan x/2-1-\sqrt{2}}{\tan x/2-1+\sqrt{2}}\right|\right\}+C$

(b) $2\left\{(\sin x+\cos x)+\frac{1}{\sqrt{2}}\log\left|\frac{\tan x/2-1-\sqrt{2}}{\tan x/2-1+\sqrt{2}}\right|\right\}+C$

(c) $\frac{1}{2}\left\{(\sin x-\cos x)+\frac{1}{\sqrt{2}}\log\left|\frac{\tan x/2-1-\sqrt{2}}{\tan x-1+\sqrt{2}}\right|\right\}+C$

(d) None of these

Session 4

Integration by Parts

Integration by Parts

Theorem If u and v are two functions of x, then

$$\int uv\,dx = u\int v\,dx - \int\left\{\frac{du}{dx}\int v\,dx\right\}dx$$

i.e. The integral of product of two functions = (first function) × (integral of second function) − integral of (differential of first function × integral of second function).

Proof For any two functions $f(x)$ and $g(x)$, we have

$$\frac{d}{dx}\{f(x)\cdot g(x)\} = f(x)\cdot\frac{d}{dx}\{g(x)\} + g(x)\cdot\frac{d}{dx}\{f(x)\}$$

$$\therefore \int\left(f(x)\cdot\frac{d}{dx}\{g(x)\}+g(x)\cdot\frac{d}{dx}\{f(x)\}\right)dx = \int f(x)\cdot g(x)\,dx$$

$$\Rightarrow \int\left(f(x)\cdot\frac{d}{dx}\{g(x)\}\right)dx + \int\left(g(x)\cdot\frac{d}{dx}\{f(x)\}\right)dx = \int f(x)\cdot g(x)dx$$

$$\Rightarrow \int\left(f(x)\cdot\frac{d}{dx}\{g(x)\}\right)dx = \int f(x)\cdot g(x)\,dx - \int\left(g(x)\cdot\frac{d}{dx}\{f(x)\}\right)dx$$

Let $f(x) = u$ and $\frac{d}{dx}\{g(x)\} = v$

So that, $g(x) = \int v\,dx$

$$\therefore \int uv\,dx = u\cdot\int v\,dx - \int\left\{\frac{du}{dx}\cdot\int v\,dx\right\}\cdot dx$$

Remarks

While applying the above rule, care has to be taken in the selection of first function (u) and selection of second function (v). Normally we use the following methods :

1. If in the product of the two functions, one of the functions is not directly integrable (e.g. $\log|x|$, $\sin^{-1}x$, $\cos^{-1}x$, $\tan^{-1}x$, ..., etc.) Then, we take it as the first function and the remaining function is taken as the second function. i.e. In the integration of $\int x\tan^{-1}x\,dx$, $\tan^{-1}x$ is taken as the first function and x as the second function.
2. If there is no other function, then unity is taken as the second function. e.g. In the integration of $\int\tan^{-1}x\,dx$, $\tan^{-1}x$ is taken as first function and 1 as the second function.
3. If both of the function are directly integrable, then the first function is chosen in such a way that the derivative of the function thus obtained under integral sign is easily integrable.

Usually we use the following preference order for selecting the first function. (Inverse, Logarithmic, Algebraic, Trigonometric, Exponent).

In above stated order, the function on the left is always chosen as the first function. This rule is called as **ILATE**.

Example 32 Evaluate

(i) $\int\sin^{-1}x\,dx$ (ii) $\int\log_e|x|\,dx$

Sol. (i) $I = \int\sin^{-1}x\,dx = \int\underset{\text{I}}{\sin^{-1}x}\cdot\underset{\text{II}}{1}\,dx$

Here, we know by definition of integration by parts that order of preference is taken according to ILATE. So, '$\sin^{-1}x$' should be taken as first and '1' as the second function to apply by parts.

Applying integration by parts, we get

$$I = \sin^{-1}x\cdot(x) - \int\frac{1}{\sqrt{1-x^2}}\cdot x\,dx$$

$$= x\cdot\sin^{-1}x + \frac{1}{2}\int\frac{dt}{t^{1/2}}$$

Let $1-x^2 = t$

$$-2x\,dx = dt \Rightarrow x\,dx = -\frac{1}{2}dt$$

$$= x\sin^{-1}x + \frac{1}{2}\cdot\frac{t^{1/2}}{1/2} + C$$

$$I = x\sin^{-1}x + \sqrt{1-x^2} + C$$

$$\therefore \int\sin^{-1}x\,dx = x\sin^{-1}x + \sqrt{1-x^2} + C$$

(ii) $I = \int\log_e|x|\,dx = \int\underset{\text{I}}{\log_e|x|}\cdot\underset{\text{II}}{1}\,dx$

Applying integration by parts, we get

$$= \log|x|\cdot x - \int\frac{1}{x}\cdot x\,dx$$

$$= x\log|x| - \int 1\,dx$$

$$I = x\log|x| - x + C$$

Example 33 Evaluate

(i) $\int x\cos x\,dx$ (ii) $\int x^2\cos x\,dx$

Sol. (i) $\int x\cos x\,dx$, $I = \int\underset{\text{I}}{x}\,\underset{\text{II}}{\cos x}\,dx$

Applying integration by parts,

$$I = x\left(\int \cos x\, dx\right) - \int \left\{\frac{d}{dx}(x)\right\}\left\{\int (\cos x)\, dx\right\} dx$$

$$I = x \sin x - \int 1 \cdot \sin x\, dx = x \sin x + \cos x + C$$

(ii) $I = \underset{\text{I}}{\int x^2} \underset{\text{II}}{\cos x}\, dx$

Applying integration by parts,

$$I = x^2\left(\int \cos x\, dx\right) - \int \left\{\frac{d}{dx}(x^2)\right\} \cdot \{\int \cos x\} dx$$

$$= x^2 \sin x - \int 2x \cdot (\sin x)\, dx$$

$$= x^2 \sin x - 2\int x\,(\sin x)\, dx$$

We again have to integrate $\int x \sin x\, dx$ using integration by parts,

$$= x^2 \cdot \sin x - 2 \int \underset{\text{I}}{x} \cdot \underset{\text{II}}{\sin x}\, dx$$

$$= x^2 \sin x - 2\left\{x\left(\int \sin x\, dx\right) - \int \left(\frac{dx}{dx}\right)\left(\int \sin x\, dx\right) dx\right\}$$

$$= x^2 \sin x - 2\{-x \cos x - \int 1 \cdot (-\cos x)\, dx\}$$

$$I = x^2 \sin x + 2x \cos x - 2 \sin x + C$$

Example 34 Evaluate $\int \frac{\sin^{-1}\sqrt{x} - \cos^{-1}\sqrt{x}}{\sin^{-1}\sqrt{x} + \cos^{-1}\sqrt{x}}\, dx$.

Sol. Let $I = \int \frac{\sin^{-1}\sqrt{x} - \cos^{-1}\sqrt{x}}{\sin^{-1}\sqrt{x} + \cos^{-1}\sqrt{x}}\, dx$

$$= \int \frac{\sin^{-1}\sqrt{x} - (\pi/2 - \sin^{-1}\sqrt{x})}{\pi/2}\, dx$$

$[\because \sin^{-1}\theta + \cos^{-1}\theta = \pi/2]$

$$\Rightarrow \quad I = \frac{2}{\pi}\int (2\sin^{-1}\sqrt{x} - \pi/2)\, dx$$

$$= \frac{4}{\pi}\int \sin^{-1}\sqrt{x}\, dx - \int 1\, dx$$

$$I = \frac{4}{\pi}\int \sin^{-1}\sqrt{x}\, dx - x + C \qquad \ldots(i)$$

Let $x = \sin^2\theta$, then $dx = 2\sin\theta\cos\theta\, d\theta = \sin 2\theta\, d\theta$

$$\therefore \quad \int \sin^{-1}\sqrt{x}\, dx = \int \underset{\text{I}}{\theta} \cdot \underset{\text{II}}{\sin 2\theta}\, d\theta$$

Applying integration by parts

$$\int \sin^{-1}\sqrt{x}\, dx = -\theta \cdot \frac{\cos 2\theta}{2} + \int \frac{1}{2}\cos 2\theta\, d\theta$$

$$= \frac{-\theta}{2} \cdot \cos 2\theta + \frac{1}{4}\sin 2\theta$$

$$= \frac{-1 \cdot \theta}{2} \cdot (1 - 2\sin^2\theta) + \frac{1}{2} \cdot \sin\theta \cdot \sqrt{1 - \sin^2\theta}$$

$$= \frac{-1}{2}\sin^{-1}\sqrt{x}\,(1 - 2x) + \frac{1}{2} \cdot \sqrt{x}\,\sqrt{1 - x} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$I = \frac{4}{\pi}\left\{\frac{-1}{2}(\sin^{-1}\sqrt{x})(1 - 2x) + \frac{1}{2}\sqrt{x}\sqrt{1 - x}\right\} - x + C$$

$$= \frac{2}{\pi}\{\sqrt{x - x^2} - (1 - 2x)\sin^{-1}\sqrt{x}\} - x + C$$

Integral of Form $\int e^x \{f(x) + f'(x)\} dx$

Theorem Prove that

$$\int e^x \{f(x) + f'(x)\}\, dx = e^x f(x) + C$$

Proof We have, $\int e^x \{f(x) + f'(x)\}\, dx$

$$= \int \underset{\text{II}}{e^x} \cdot \underset{\text{I}}{f(x)}\, dx + \int e^x \cdot f'(x)\, dx$$

$$= f(x) \cdot e^x - \int f'(x) \cdot e^x dx + \int e^x \cdot f'(x)\, dx + C$$

$$= f(x) \cdot e^x + C$$

Thus, to evaluate the integrals of the type

$$\int e^x \{f(x) + f'(x)\}\, dx,$$

we first express the integral as the sum of two integrals $\int e^x f(x)\, dx$ and $\int e^x f'(x)\, dx$ and then integrate the integral involving $e^x f(x)$ as integral by parts taking e^x as second function.

Remark

The above theorem is also true, if we have e^{kx} in place of e^x

i.e. $\int e^{kx}\{f(kx) + f'(kx)\}\, dx = e^{kx} f(kx) + C$

General Concept

$$\int e^{g(x)} \{f(x)g'(x) + f'(x)\}\, dx$$

Proof $I = \int \underset{\text{II}}{e^{g(x)}}\, \underset{\text{I}}{f(x)}\, \underset{\text{II}}{g'(x)}\, dx + \underbrace{\int e^{g(x)} f'(x)\, dx}_{\text{as it is}}$

Using, $\int e^{g(x)} \cdot g'(x)\, dx = e^{g(x)}$, we get

$$= f(x) \cdot e^{g(x)} - \int f'(x) \cdot e^{g(x)} dx + \int e^{g(x)} \cdot f'(x)\, dx$$

$$= f(x) \cdot e^{g(x)} + C$$

e.g. $$= \int e^{(x\sin x + \cos x)}\left(\frac{x^2\cos^2 x - (x\sin x + \cos x)}{x^2}\right) dx$$

$$\Rightarrow \quad \int e^{(x\sin x + \cos x)}\left(\cos^2 x - \frac{x\sin x + \cos x}{x^2}\right) dx$$

$$\Rightarrow \int e^{(x\sin x+\cos x)}\left(x\cos x\left(\frac{\cos x}{x}\right)+\left(\frac{\cos x}{x}\right)'\right)dx$$

$$\Rightarrow e^{(x\sin x+\cos x)}\cdot\frac{\cos x}{x}+C$$

e.g. $$=\int e^{\tan x}(\sin x-\sec x)\,dx$$

$$=\int e^{\tan x}\sin x\,dx-\int e^{\tan x}\sec x\,dx$$

$$\Rightarrow -e^{\tan x}\cdot\cos x+\int e^{\tan x}\sec^2 x\cos x dx-\int e^{\tan x}\sec x dx$$

$$\Rightarrow -e^{\tan x}\cdot\cos x$$

Example 35 Evaluate

(i) $\int e^x\left(\frac{1+\sin x\cos x}{\cos^2 x}\right)dx$ (ii) $\int e^{2x}\left(\frac{1+\sin 2x}{1+\cos 2x}\right)dx$

Sol. (i) $I=\int e^x\left(\frac{1+\sin x\cos x}{\cos^2 x}\right)dx$

$$I=\int e^x\left\{\frac{1}{\cos^2 x}+\frac{\sin x\cos x}{\cos^2 x}\right\}dx$$

$$I=\int e^x\{\tan x+\sec^2 x\}\,dx$$

$$I=\int \underset{\text{II}}{e^x}\cdot\underset{\text{I}}{\tan x}\,dx+\int e^x(\sec^2 x)\,dx$$

$$I=\tan x\cdot e^x-\int\sec^2 x\cdot e^x\,dx+\int e^x\cdot\sec^2 x\,dx+C$$

$$I=e^x\tan x+C$$

(ii) $I=\int e^{2x}\left\{\frac{1+\sin 2x}{1+\cos 2x}\right\}dx$

$$=\int e^{2x}\left\{\frac{1+2\sin x\cos x}{2\cos^2 x}\right\}dx$$

$$=\int e^{2x}\left\{\frac{1}{2\cos^2 x}+\frac{2\sin x\cos x}{2\cos^2 x}\right\}dx$$

$$=\int e^{2x}\left\{\frac{1}{2}\sec^2 x+\tan x\right\}dx$$

$$=\int \underset{\text{II}}{e^{2x}}\cdot\underset{\text{I}}{\tan x}\,dx+\frac{1}{2}\int e^{2x}\cdot\sec^2 x\,dx$$

$$=\tan x\cdot\frac{e^{2x}}{2}-\int\sec^2 x\cdot\frac{e^{2x}}{2}dx+\frac{1}{2}\int e^{2x}\cdot\sec^2 x\,dx$$

$$I=\frac{1}{2}e^{2x}\cdot\tan x+C$$

Example 36 ***Evaluate*** $\int e^x\left(\frac{1-x}{1+x^2}\right)^2 dx$.

Sol. $I=\int e^x\left(\frac{1-x}{1+x^2}\right)^2 dx=\int e^x\frac{(1-2x+x^2)}{(1+x^2)^2}dx$

$$=\int e^x\left\{\frac{1+x^2}{(1+x^2)^2}-\frac{2x}{(1+x^2)^2}\right\}dx$$

$$=\int e^x\left\{\frac{1}{1+x^2}-\frac{2x}{(1+x^2)^2}\right\}dx\left[\text{as}\,\frac{d}{dx}\left(\frac{1}{1+x^2}\right)=-\frac{2x}{(1+x^2)^2}\right]$$

$$=\frac{e^x}{1+x^2}+C$$

$$\therefore \quad I=\frac{e^x}{1+x^2}+C$$

Integrals of the Form $\int e^{ax}\sin bx\,dx, \int e^{ax}\cos bx\,dx$

Let $$I=\int e^{ax}(\sin bx)\,dx$$

Then, $$I=\int \underset{\text{I}}{\sin bx}\cdot\underset{\text{II}}{e^{ax}}\,dx$$

$$=\sin bx\cdot\left(\frac{e^{ax}}{a}\right)-\int b\cos bx\cdot\frac{e^{ax}}{a}dx$$

$$=\frac{1}{a}\sin bx\cdot e^{ax}-\frac{b}{a}\left\{\cos bx\cdot\frac{e^{ax}}{a}-\int(-b\sin bx)\cdot\frac{e^{ax}}{a}dx\right\}$$

$$=\frac{1}{a}\sin bx\cdot e^{ax}-\frac{b}{a^2}\cos bx\cdot e^{ax}-\frac{b^2}{a^2}\int\sin bx\cdot e^{ax}\,dx$$

$$I=\frac{1}{a}\sin bx\cdot e^{ax}-\frac{b}{a^2}\cos bx\cdot e^{ax}-\frac{b^2}{a^2}I$$

$$\therefore \quad I+\frac{b^2}{a^2}I=\frac{1\cdot e^{ax}}{a^2}\cdot(a\sin bx-b\cos bx)$$

$$\Rightarrow \quad I\left(\frac{a^2+b^2}{a^2}\right)=\frac{e^{ax}}{a^2}(a\sin bx-b\cos bx)$$

or $$I=\frac{e^{ax}}{a^2+b^2}(a\sin bx-b\cos bx)+C$$

Thus, $\int e^{ax}\sin bx\,dx=\frac{e^{ax}}{a^2+b^2}(a\sin bx-b\cos bx)+C$

Similarly, $\int e^{ax}\cos bx\,dx=\frac{e^{ax}}{a^2+b^2}(a\cos bx+b\sin bx)+C$

Aliter Use Euler's equation

Let $P=\int e^{ax}\cos bx\,dx$ and $Q=\int e^{ax}\sin bx\,dx$

Hence, $P+iQ=\int e^{ax}\cdot e^{ibx}\,dx=\int e^{(a+ib)x}\,dx$

$$P+iQ=\frac{1}{a+ib}e^{(a+ib)x}=\frac{a-ib}{a^2+b^2}e^{ax}(\cos bx+i\sin bx)$$

$$= \frac{(ae^{ax}\cos bx + be^{ax}\sin bx) - i(ae^{ax}\sin bx - be^{ax}\cos bx)}{a^2 + b^2}$$

$$\therefore \quad P = \frac{e^{ax}(a\cos bx + b\sin bx)}{a^2 + b^2}$$

$$Q = \frac{e^{ax}(a\sin bx - b\cos bx)}{a^2 + b^2}$$

Example 37 *Evaluate*

(i) $\int e^x \cos^2 x\, dx$

(ii) $\int \sin(\log x)\, dx$

Sol. (i) $I = \int e^x \cdot \cos^2 x\, dx = \int e^x \cdot \left\{\frac{1 + \cos 2x}{2}\right\} dx$

$$I = \frac{1}{2}\int e^x\, dx + \frac{1}{2}\int \cos 2x \cdot e^x\, dx$$

$$I = \frac{1}{2}e^x + \frac{1}{2}I_1 \qquad \ldots(i)$$

where, $I_1 = \int \cos 2x \cdot e^x\, dx$

$$I_1 = \int \underset{\text{I}}{\cos 2x} \cdot \underset{\text{II}}{e^x}\, dx = \cos 2x \cdot e^x - \int -2\sin 2x \cdot e^x\, dx$$

$$= e^x \cdot \cos 2x + 2\int \underset{\text{I}}{\sin 2x} \cdot \underset{\text{II}}{e^x}\, dx$$

$$= e^x \cdot \cos 2x + 2\{\sin 2x \cdot e^x - \int 2\cos 2x \cdot e^x\, dx\}$$

$$= e^x \cdot \cos 2x + 2\sin 2x \cdot e^x - 4I_1$$

$$\therefore \quad I_1 = \frac{1}{5}\{e^x \cos 2x + 2\sin 2x\, e^x\} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$I = \frac{1}{2}e^x + \frac{1}{2}\cdot\frac{1}{5}\{e^x \cos 2x + 2\sin 2x \cdot e^x\}$$

$$I = \frac{1}{2}e^x + \frac{1}{10}e^x\{\cos 2x + 2\sin 2x\} + C$$

(ii) $I = \int \sin(\log x)\, dx$

Let $\log x = t$

$\Rightarrow \quad x = e^t$ or $dx = e^t\, dt$

$$\therefore \quad I = \int \underset{\text{I}}{(\sin t)} \cdot \underset{\text{II}}{e^t}\, dt = \sin t \cdot e^t - \int \underset{\text{I}}{\cos t} \cdot \underset{\text{II}}{e^t}\, dt$$

$$I = \sin t \cdot e^t - \{\cos t \cdot e^t - \int -\sin t \cdot e^t\, dt\}$$

$$I = e^t \cdot \sin t - e^t \cdot \cos t - I$$

$$\therefore \quad I = \frac{1}{2}e^t(\sin t - \cos t) + C$$

$$I = \frac{x}{2}\{\sin(\log x) - \cos(\log x)\} + C$$

Example 38 *Evaluate* $\int \frac{x^2 dx}{(x\sin x + \cos x)^2}$.

Sol. Let $I = \int \frac{x^2}{(x\sin x + \cos x)^2}\, dx$

Multiplying and dividing it by $(x\cos x)$, we get

$$I = \int \underset{\text{I}}{(x\sec x)} \cdot \underset{\text{II}}{\frac{(x\cos x)}{(x\sin x + \cos x)^2}}\, dx$$

$$I = x\sec x \cdot \int \frac{x\cos x}{(x\sin x + \cos x)^2}\, dx$$

$$- \int \left\{\frac{d}{dx}(x\sec x)\right\}\left\{\int \frac{x\cos x}{(x\sin x + \cos x)^2}\, dx\right\} dx$$

$$= x\sec x \cdot \frac{-1}{(x\sin x + \cos x)}$$

$$- \int (x\sec x\tan x + \sec x) \cdot \frac{-1}{(x\sin x + \cos x)}\, dx$$

$$= \frac{-x\sec x}{(x\sin x + \cos x)} + \int \frac{(x\sin x + \cos x)}{\cos^2 x \cdot (x\sin x + \cos x)}\, dx$$

$$= \frac{-x\sec x}{(x\sin x + \cos x)} + \int \sec^2 x\, dx$$

$$I = \frac{-x\sec x}{(x\sin x + \cos x)} + \tan x + C$$

Example 39 The value of $\int \sqrt{\frac{3-x}{3+x}} \cdot \sin^{-1}\left(\frac{1}{\sqrt{6}}\sqrt{3-x}\right) dx$, is equal to

(a) $\frac{1}{4}\left\{-3\left(\cos^{-1}\left(\frac{x}{3}\right)\right)^2 + 2\sqrt{9-x^2}\cdot\cos^{-1}\left(\frac{x}{3}\right) + 2x\right\} + C$

(b) $\frac{1}{4}\left\{-3\left(\cos^{-1}\left(\frac{x}{3}\right)\right)^2 + 2\sqrt{9-x^2}\sin^{-1}\left(\frac{x}{3}\right) + 2x\right\} + C$

(c) $\frac{1}{4}\left\{-3\left(\sin^{-1}\left(\frac{x}{3}\right)\right)^2 + 2\sqrt{9-x^2}\sin^{-1}\left(\frac{x}{3}\right) + 2x\right\} + C$

(d) None of the above

Sol. Here, $I = \int \sqrt{\frac{3-x}{3+x}} \cdot \sin^{-1}\left(\frac{1}{\sqrt{6}}\sqrt{3-x}\right) dx$

Put $\quad x = 3\cos 2\theta$

$\Rightarrow \quad dx = -6\sin 2\theta\, d\theta$

$$\therefore \quad I = \int \sqrt{\frac{3-3\cos 2\theta}{3+3\cos 2\theta}} \cdot \sin^{-1}\left(\frac{1}{\sqrt{6}}\sqrt{3-3\cos 2\theta}\right)(-6\sin 2\theta)\, d\theta$$

$$= \int \frac{\sin\theta}{\cos\theta} \cdot \sin^{-1}(\sin\theta) \cdot (-6\sin 2\theta)\, d\theta$$

$$= -6\int \theta \cdot (2\sin^2\theta)\, d\theta = -6\int \theta(1 - \cos 2\theta)\, d\theta$$

$$= -6\left\{\frac{\theta^2}{2} - \int \theta \cos 2\theta \, d\theta\right\}$$

$$= -6\left\{\frac{\theta^2}{2} - \left(\theta \frac{\sin 2\theta}{2} - \int 1 \cdot \left(\frac{\sin 2\theta}{2}\right) d\theta\right)\right\}$$

$$= -3\theta^2 + 6\left\{\frac{\theta \sin 2\theta}{2} + \frac{\cos 2\theta}{4}\right\} + C$$

$$= \frac{1}{4}\left\{-3\left(\cos^{-1}\left(\frac{x}{3}\right)\right)^2 + 2\sqrt{9-x^2} \cdot \cos^{-1}\left(\frac{x}{3}\right) + 2x\right\} + C$$

Hence, (a) is the correct answer.

Example 40 The value of $\int \frac{\sec x\,(2+\sec x)}{(1+2\sec x)^2}\,dx$, is equal to

(a) $\frac{\sin x}{2+\cos x} + C$ (b) $\frac{\cos x}{2+\cos x} + C$

(c) $\frac{-\sin x}{2+\sin x} + C$ (d) $\frac{\cos x}{2+\sin x} + C$

Sol. Let $I = \int \frac{\sec x\,(2+\sec x)}{(1+2\sec x)^2}\,dx = \int \frac{2\cos x + 1}{(\cos x + 2)^2}\,dx$

$$= \int \frac{\cos x\,(\cos x + 2) + \sin^2 x}{(2+\cos x)^2}\,dx$$

$$= \int \frac{\cos x}{2+\cos x}\,dx + \int \frac{\sin^2 x}{(2+\cos x)^2}\,dx$$

$$= \int \underset{\text{II}}{\cos x} \cdot \underset{\text{I}}{\frac{1}{(2+\cos x)}}\,dx + \int \frac{\sin^2 x}{(2+\cos x)^2}\,dx$$

Applying integration by parts to first by taking $\cos x$ as second function, keeping $\int \frac{\sin^2 x}{(2+\cos x)^2}\,dx$ as it is.

$$\therefore \quad I = \frac{1}{2+\cos x} \cdot (\sin x) - \int \sin x \cdot \frac{\sin x}{(2+\cos x)^2}\,dx + \int \frac{\sin^2 x}{(2+\cos x)^2}\,dx$$

$$\therefore \quad I = \frac{\sin x}{2+\cos x} + C$$

Hence, (a) is the correct answer.

Example 41 The value of $\int \log\left(\sqrt{1-x} + \sqrt{1+x}\right) dx$, is equal to

(a) $x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) + \frac{1}{2}x - \frac{1}{2}\sin^{-1}(x) + C$

(b) $x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) + \frac{1}{2}x + \frac{1}{2}\sin^{-1}(x) + C$

(c) $x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}x + \frac{1}{2}\sin^{-1}(x) + C$

(d) None of the above

Sol. Here, we have only one function. This can be solved easily by applying integration by parts taking unity as second function.

If we take $u = \log\left(\sqrt{1-x} + \sqrt{1+x}\right)$ as the first function and $v = 1$ as the second function.

Then,

$$I = \int 1 \cdot \log\left(\sqrt{1-x} + \sqrt{1+x}\right) dx$$

$$= \{\log\left(\sqrt{1-x} + \sqrt{1+x}\right)\} \cdot x - \int \frac{1}{\sqrt{1-x} + \sqrt{1+x}} \left(-\frac{1}{2\sqrt{1-x}} + \frac{1}{2\sqrt{1+x}}\right) \cdot x\,dx$$

$$= x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}\int \frac{\sqrt{1-x} - \sqrt{1+x}}{\sqrt{1-x} + \sqrt{1+x}} \cdot \frac{1}{\sqrt{1-x^2}} \cdot x\,dx$$

$$= x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}\int \frac{(1-x) + (1+x) - 2\sqrt{1-x^2}}{(1-x) - (1+x)} \cdot \frac{1}{\sqrt{1-x^2}} \cdot 2x\,dx$$

$$= x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}\int \frac{\sqrt{1-x^2} - 1}{\sqrt{1-x^2}}\,dx$$

$$= x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}\int 1\,dx + \frac{1}{2}\int \frac{1}{\sqrt{1-x^2}}\,dx$$

$$= x \log\left(\sqrt{1-x} + \sqrt{1+x}\right) - \frac{1}{2}x + \frac{1}{2}\sin^{-1} x + C$$

Hence, (c) is the correct answer.

Example 42 The value of $\int e^x \left(\frac{x^4+2}{(1+x^2)^{5/2}}\right) dx$, is equal to

(a) $\frac{e^x\,(x+1)}{(1+x^2)^{3/2}}$ (b) $\frac{e^x\,(1-x+x^2)}{(1+x^2)^{3/2}}$

(c) $\frac{e^x\,(1+x)}{(1+x^2)^{3/2}}$ (d) None of these

Sol. Let $I = \int e^x \left(\frac{x^4+2}{(1+x^2)^{5/2}}\right) dx$

$$= \int e^x \left(\frac{1}{(1+x^2)^{1/2}} + \frac{1-2x^2}{(1+x^2)^{5/2}}\right) dx$$

$$= \int e^x \left(\frac{1}{(1+x^2)^{1/2}} - \frac{x}{(1+x^2)^{3/2}} + \frac{x}{(1+x^2)^{3/2}} + \frac{1-2x^2}{(1+x^2)^{5/2}}\right) dx$$

$$= \frac{e^x}{(1+x^2)^{1/2}} + \frac{xe^x}{(1+x^2)^{3/2}} + C = \frac{e^x\,\{1+x^2+x\}}{(1+x^2)^{3/2}} + C$$

Hence, (d) is the correct answer.

Example 43 If $\int (\sin 3\theta + \sin\theta)\, e^{\sin\theta} \cos\theta\, d\theta = (A\sin^3\theta + B\cos^2\theta + C\sin\theta + D\cos\theta + E)\, e^{\sin\theta} + F$, then

(a) $A = -4, B = 12$ (b) $A = -4, B = -12$

(c) $A = 4, B = 12$ (d) $A = 4, B = -12$

Sol. Let $I = \int (\sin 3\theta + \sin\theta)\, e^{\sin\theta} \cdot \cos\theta\, d\theta$

$= \int (3\sin\theta - 4\sin^3\theta) \cdot e^{\sin\theta} \cdot \cos\theta\, d\theta;$

Put $\sin\theta = t \Rightarrow \cos\theta\, d\theta = dt$

$= \int (3t - 4t^3)\, e^t\, dt$ ...(i)

As, $I = (A\sin^3\theta + B\cos^2\theta + C\sin\theta + D\cos\theta + E)e^{\sin\theta} + F$

$= (A\sin^3\theta - B\sin^2\theta + C\sin\theta + D\cos\theta + B + E)e^{\sin\theta} + F$

When, $\sin\theta = t$

$I = (At^3 - Bt^2 + Ct + B + E)\, e^t + F$

as by Eq. (i) $D = 0$ ...(ii)

From Eqs. (i) and (ii),

$\int (3t - 4t^3)\, e^t\, dt = \underbrace{(At^3 - Bt^2 + Ct + B + E)}_{f(t)}\, e^t + F,$

differentiating both sides

$(3t - 4t^3)\, e^t = (At^3 - Bt^2 + Ct + B + E)e^t + (3At^2 - 2Bt + C)e^t$

$\Rightarrow \quad A = -4$ and $3A = B \Rightarrow B = -12$

Hence, (b) is the correct answer.

Example 44 The value of $\int e^{(x\sin x + \cos x)} \cdot \left(\frac{x^4\cos^3 x - x\sin x + \cos x}{x^2\cos^2 x}\right) dx$, is equal to

(a) $e^{(x\sin x + \cos x)} \cdot \left(x + \frac{1}{x\cos x}\right) + C$

(b) $e^{(x\sin x + \cos x)} \cdot \left(x\cos x + \frac{1}{x}\right) + C$

(c) $e^{(x\sin x + \cos x)} \cdot \left(x - \frac{1}{x\cos x}\right) + C$

(d) None of the above

Sol. Let $I = \int e^{(x\sin x + \cos x)} \cdot \left(\frac{x^4\cos^3 x - x\sin x + \cos x}{x^2\cos^2 x}\right) dx$

$= \int (x \cdot e^{(x\sin x + \cos x)} \cdot x\cos x)\, dx - \int e^{(x\sin x + \cos x)} \cdot \left(\frac{x\sin x - \cos x}{(x\cos x)^2}\right) dx$

Applying integration by parts

$= \{x \cdot e^{(x\sin x + \cos x)} - \int e^{(x\sin x + \cos x)}\, dx\} - \left\{e^{(x\sin x + \cos x)} \cdot \frac{1}{x\cos x} - \int e^{(x\sin x + \cos x)}\, dx\right\}$

$= e^{(x\sin x + \cos x)} \left(x - \frac{1}{x\cos x}\right) + C$

Hence, (c) is the correct answer.

Example 45 ***Evaluate*** $\int \sin^{-1}\left\{\frac{2x+2}{\sqrt{4x^2+8x+13}}\right\} dx.$

[IIT JEE 2001]

Sol. Here, $I = \int \sin^{-1}\left(\frac{2x+2}{\sqrt{4x^2+8x+13}}\right) dx$

$= \int \sin^{-1}\left(\frac{2x+2}{\sqrt{(2x+2)^2+3^2}}\right) dx$

Put $2x + 2 = 3\tan\theta \Rightarrow 2\, dx = 3\sec^2\theta\, d\theta$

$= \int \sin^{-1}\left(\frac{3\tan\theta}{3\sec\theta}\right)\frac{3}{2}\sec^2\theta\, d\theta = \frac{3}{2}\int \theta\sec^2\theta\, d\theta$

$= \frac{3}{2}\{\theta\tan\theta - \int \tan\theta\, d\theta\}$

$= \frac{3}{2}\{\theta\tan\theta - \log|\sec\theta|\} + C$

$\Rightarrow I = \frac{3}{2}\left\{\frac{2x+2}{3}\tan^{-1}\left(\frac{2x+2}{3}\right) - \log\left(\sqrt{1 + \left(\frac{2x+2}{3}\right)^2}\right)\right\} + C$

$= \frac{3}{2}\left\{\frac{2}{3}(x+1)\tan^{-1}\left(\frac{2}{3}(x+1)\right) - \log\sqrt{4x^2+8x+13}\right\} + C$

$\Rightarrow I = (x+1)\tan^{-1}\left(\frac{2}{3}(x+1)\right) - \frac{3}{4}\log(4x^2+8x+13) + C$

Example 46 ***Evaluate*** $\int \frac{x^2(x\sec^2 x + \tan x)\, dx}{(x\tan x + 1)^2}.$

Sol. Here, $I = \int x^2 \cdot \frac{x\sec^2 x + \tan x}{(x\tan x + 1)^2}\, dx$

$= x^2\left(-\frac{1}{(x\tan x + 1)}\right) - \int 2x \cdot \left(-\frac{1}{(x\tan x + 1)}\right) dx$ ...(i)

$\left[\text{using } \int \frac{x\sec^2 x + \tan x}{(x\tan x + 1)^2}\, dx = \int \frac{dt}{t^2} = -\frac{1}{t} = -\frac{1}{(x\tan x + 1)}\right]$

$\Rightarrow I = -\left(\frac{x^2}{x\tan x + 1}\right) + \int \frac{2x(\cos x)}{x\sin x + \cos x}\, dx$

[put, $x\sin x + \cos x = u$

$\Rightarrow (x\cos x + \sin x - \cos x)\, dx = du$]

$\Rightarrow \quad I = -\frac{x^2}{(x\tan x + 1)} + 2\int \frac{du}{u}$

$= -\frac{x^2}{x\tan x + 1} + 2\log|u| + C$

$= -\frac{x^2}{x\tan x + 1} + 2\log|x\sin x + \cos x| + C$

Exercise for Session 4

Session 5

Integration Using Partial Fraction

This section deals with the integration of general algebraic rational functions, of the form $\frac{f(x)}{g(x)}$, where $f(x)$ and $g(x)$ are both polynomials. We already have seen some examples of this form. For example, we know how to integrate functions of the form $\frac{1}{Q(x)}$ or $\frac{L(x)}{Q(x)}$ or $\frac{P(x)}{Q(x)}$ where $L(x)$ is a linear factor, $Q(x)$ is a quadratic factor and $P(x)$ is a polynomial of degree $n \geq 2$. We intend to generalise that previous discussion in this section.

We are assuming the scanario where $g(x)$ (the denominator) is decomposible into linear or quadratic factors. These are the only cases relevant to us right now. Any linear or quadratic factor in $g(x)$ might also occur repeatedly.

Thus, $g(x)$ could be of the following general forms.

- $g(x) = L_1(x)L_2(x)\ldots L_n(x)$ (n linear factors)
- $g(x) = L_1(x)\ldots L_r^k(x)\ldots L_n(x)$ (n linear factors; the rth factor is repeated k times)
- $g(x) = L_1^{k_1}(x)L_2^{k_2}(x)\ldots L_n^{k_n}(x)$ (n linear factors, the ith factor is repeated k_i times)
- $g(x) = L_1(x)L_2(x)\ldots L_n(x)Q(x)Q_2(x)\ldots Q_m(x)$ (n linear factors and m quadratic factors)
- $g(x) = \ldots Q_r^k(x)\ldots$ (a particular quadratic factor repeats more than once)
- A combination of any of the above

Suppose that the degree of $g(x)$ is n and that of $f(x)$ is m. If $m \geq n$,we can always divide $f(x)$ by $g(x)$ to obtain a quotient $q(x)$ and a remainder $r(x)$ whose degree would be less than n.

$$\frac{f(x)}{g(x)} = q(x) + \frac{r(x)}{g(x)} \qquad \ldots(\text{i})$$

If $m < n$, $\frac{f(x)}{g(x)}$ is termed a proper rational function.

The partial fraction expansion technique says that a proper rational function can be expressed as a sum of simpler rational functions each possessing one of the factors of $g(x)$. The simpler rational functions are called partial fractions.

From now on, we consider only proper rational functions. If $\frac{f(x)}{g(x)}$ is not proper, we make it proper $\left(\frac{r(x)}{g(x)}\right)$ by the procedure described in (1) above. Let us consider a few examples.

Let $g(x)$ be a product of non-repeated, linear factors :

$$g(x) = L_1(x)L_2(x)\ldots L_n(x)$$

Then, we can expand $\frac{f(x)}{g(x)}$ in terms of partial fractions as

$$\frac{f(x)}{g(x)} = \frac{A_1}{L_1(x)} + \frac{A_2}{L_2(x)} + \ldots + \frac{A_n}{L_n(x)}$$

where the $A_i's$ are all constants that need to be determined.

Suppose $f(x) = x + 1$ and $g(x) = (x-1)(x-2)(x-3)$. Let us write down the partial fraction expansion of $\frac{f(x)}{g(x)}$:

$$\frac{f(x)}{g(x)} = \frac{x+1}{(x-1)(x-2)(x-3)} = \frac{A}{x-1} + \frac{B}{x-2} + \frac{C}{x-3}$$

We need to determine A, B and C. Cross multiplying in the expression above, we obtain :

$$(x+1) = A(x-2)(x-3) + B(x-1)(x-3) + C(x-1)(x-2)$$

A, B, C can now be determined by comparing coefficients on both sides. More simply since this relation that we have obtained should held true for all x,we substitute those values of x that would straight way give us the required values of A, B and C. These values are obviously the roots of $g(x)$.

$$\begin{aligned}
x = 1 \quad &\Rightarrow \quad 2 = A(-1)(-2) + B(0) + C(0) \\
&\Rightarrow \quad A = 1 \\
x = 2 \quad &\Rightarrow \quad 3 = A(0) + B(1)(-1) + C(0) \\
&\Rightarrow \quad B = -3 \\
x = 3 \quad &\Rightarrow \quad 4 = A(0) + B(0) + C(2)(1) \\
&\Rightarrow \quad C = 2
\end{aligned}$$

Thus, $A = 1$, $B = -3$ and $C = 2$.

We can therefore write $\frac{f(x)}{g(x)}$ as a sum of partial fractions.

$$\frac{f(x)}{g(x)} = \frac{1}{x-1} - \frac{3}{x-2} + \frac{2}{x-3}$$

Integrating $\frac{f(x)}{g(x)}$ is now a simple matter of integrating the partial fractions. This was our sole motive in writing such an expansion, so that integration could be carried out easily. In the example above :

$$\int \frac{f(x)}{g(x)}\,dx = \ln(x-1) - 3\ln(x-2) + 2\ln(x-3) + C$$

Now, suppose that $g(x)$ contains all linear factors, but a particular factor, say $L_1(x)$, is repeated k times.

Thus, $g(x) = L_1^k(x)L_2(x)\ldots L_n(x)$

$\frac{f(x)}{g(x)}$ can now be expanded into partial fractions as follows

$$\frac{f(x)}{g(x)} = \underbrace{\frac{A_1}{L_1(x)} + \frac{A_2}{L_1^2(x)} + \frac{A_3}{L_1^3(x)} + \ldots \frac{A_k}{L_1^k(x)}}_{k \text{ partial fractions corresponding to } L_1(x)} + \frac{B_2}{L_2(x)} + \ldots + \frac{B_n}{L_n(x)}$$

This means that we will have k terms corresponding to $L_1(x)$. The rest of the linear factors will have single corresponding terms in the expansion. Here are some examples.

$\Rightarrow$ $\dfrac{1}{(x-1)^2(x-2)}$

can be expanded as $\dfrac{A}{x-1} + \dfrac{B}{(x-1)^2} + \dfrac{C}{x-2}$

$\Rightarrow$ $\dfrac{1}{(x-1)^3(x-2)(x-3)}$

can be expanded as

$\Rightarrow$ $\dfrac{A}{x-1} + \dfrac{B}{(x-1)^2} + \dfrac{C}{(x-1)^3} + \dfrac{D}{(x-2)} + \dfrac{C}{(x-3)}$

$\Rightarrow$ $\dfrac{1}{(x-1)^2(x+5)^3}$

can be expanded as

$$\frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{C}{(x+5)} + \frac{D}{(x+5)^2} + \frac{E}{(x+5)^3}$$

Example 47 $\frac{2x+1}{(x+1)(x-2)}$ into partial fractions

Sol. Here, $\frac{2x+1}{(x+1)(x-2)}$ has $Q(x) = (x+1)(x-2)$ i.e linear and non-repeated roots.

$\therefore$ $\dfrac{2x+1}{(x+1)(x-2)} = \dfrac{A}{x+1} + \dfrac{B}{x-2}$

$\Rightarrow$ $(2x+1) = A(x-2) + B(x+1)$

On putting, $x = 2$ we get

$$5 = A(0) + B(3) \;\Rightarrow\; B = \frac{5}{3}$$

Again, let $x = -1$

$\Rightarrow$ $2(-1) + 1 = A(-1-2) + B(0)$

$\therefore$ $A = \dfrac{1}{3}$.

$\therefore$ $\dfrac{2x+1}{(x+1)(x-2)} = \dfrac{1/3}{x+1} + \dfrac{5/3}{x-2}$

Example 48 Resolve $\frac{1}{(x-1)(x+2)(2x+3)}$ into partial fractions.

Sol. Let $\dfrac{1}{(x-1)(x+2)(2x+3)} = \dfrac{A}{x-1} + \dfrac{B}{x+2} + \dfrac{C}{2x+3}$,

where A, B, C are constants.

$1 = A(x+2)(2x+3) + B(x-1)(2x+3) + C(x-1)(x+2)\ldots$(i)

For finding A, let $x - 1 = 0$ or $x = 1$ in Eq. (i), we get

$1 = A(1+2)(2+3) + B(0) + C(0)$

$\therefore$ $A = \dfrac{1}{15}$

Similarly, for getting B, let $x + 2 = 0$ or $x = -2$ in Eq. (i), we get

$1 = A(0) + B(-2-1)(-4+3) + C(0)$

$\Rightarrow$ $B = \dfrac{1}{3}$

For getting C, let $2x + 3 = 0$ or $x = -3/2$ in Eq. (i), we get

$$1 = A(0) + B(0) + C\left(-\frac{3}{2} - 1\right)\left(-\frac{3}{2} + 2\right)$$

$\Rightarrow$ $C = -\dfrac{4}{5}$

Hence, $\dfrac{1}{(x-1)(x+2)(2x+3)} = \dfrac{1}{15(x-1)} + \dfrac{1}{3(x+2)} - \dfrac{4}{5(2x+3)}$

Example 49 Resolve $\frac{3x^3 + 2x^2 + x + 1}{(x+1)(x+2)}$ into partial fractions.

Sol. This is not a proper fraction. Hence, by division process it is to be expressed as the sum of an integral polynomial and a fraction.

Now, $3x^3 + 2x^2 + x + 1 = 3x(x^2 + 3x + 2)$

$\qquad - 7(x^2 + 3x + 2) + (16x + 15)$

So, the given polynomial

$$\frac{3x^3 + 2x^2 + x + 1}{(x+1)(x+2)} = (3x - 7) + \frac{(16x+15)}{(x+1)(x+2)} \quad \ldots(i)$$

Now, the second term is proper fraction hence it can be expressed as a sum of partial fractions.

$$\frac{16x+15}{(x+1)(x+2)} = \frac{A}{x+1} + \frac{B}{x+2}$$

To find A put $x+1=0$, *ie*, $x=-1$ in the fraction except in the factor $(x+1)$.

$$\therefore \quad \frac{16(-1)+15}{(-1+2)}=A \quad \Rightarrow \quad A=-1 \qquad \text{...(ii)}$$

To find B put $x+2=0$, *ie*, $x=-2$ in the fraction except in the factor $(x+2)$.

$$\therefore \quad \frac{16(-2)+15}{(-2+1)}=B \quad \Rightarrow \quad B=17 \qquad \text{...(iii)}$$

$$\Rightarrow \text{The given expression} = (3x-7)-\frac{1}{x+1}+\frac{17}{x+2}$$

[using Eqs. (i), (ii) and (iii)]

Case II When the denominator $g(x)$ is expressible as the product of the linear factors such that some of them are repeating. (Linear and Repeated)

Let $Q(x)=(x-a)^k(x-a_1)(x-a_2)\ldots(x-a_r)$. Then, we assume that

$$\frac{P(x)}{Q(x)}=\frac{A_1}{(x-a)}+\frac{A_2}{(x-a)^2}+\ldots+\frac{A_k}{(x-a)^k}+\frac{B_1}{(x-a_1)}+\frac{B_2}{(x-a_2)}+\ldots+\frac{B_r}{(x-a_r)}$$

Example 50 Expression $\frac{x+5}{(x-2)^2}$ has repeated (twice) linear factors in denominator, so find partial fractions.

Sol. Let $\quad \frac{x+5}{(x-2)^2}=\frac{A}{(x-2)}+\frac{B}{(x-2)^2}$

$$\therefore \quad (x+5)=A(x-2)+B$$

Comparing the like terms, $A=1, -2A+B=5$ or $B=7$

$$\therefore \quad \frac{x+5}{(x-2)^2}=\frac{1}{(x-2)}+\frac{7}{(x-2)^2}$$

Example 51 Resolve $\frac{3x-2}{(x-1)^2(x+1)(x+2)}$ into partial fractions.

Sol. Let $\frac{3x-2}{(x-1)^2(x+1)(x+2)}$

$$=\frac{A}{(x-1)}+\frac{B}{(x-1)^2}+\frac{C}{(x+1)}+\frac{D}{(x+2)}$$

$$\therefore 3x-2=A(x-1)(x+1)(x+2)+B(x+1)(x+2)+C(x-1)^2(x+2)+D(x-1)^2(x+1)$$

Putting $(x-1)=0$, we get $B=1/6$,

Putting $(x+1)=0$, we get $C=-5/4$

Putting $(x+2)=0$, we get $D=8/9$

Now, equating the coefficient of x^3 on both the sides, we get

$$0=A+C+D \quad \Rightarrow \quad A=\frac{5}{4}-\frac{8}{9}=\frac{13}{36}$$

$$\therefore \frac{3x-2}{(x-1)^2(x+1)(x+2)}=\frac{13}{36(x-1)}+\frac{1}{6(x-1)^2}-\frac{5}{4(x+1)}+\frac{8}{9(x+2)}$$

Case III When some of the factors in denominator are quadratic but non-repeating. Corresponding to each quadratic factor ax^2+bx+c, we assume the partial fraction of the type $\frac{Ax+B}{ax^2+bx+c}$, where A and B are constants to be determined by comparing coefficients of similar powers of x in numerator of both the sides.

Example 52 ***Resolve*** $\frac{2x+7}{(x+1)(x^2+4)}$ ***into partial fractions.***

Sol. Let $\quad \frac{2x+7}{(x+1)(x^2+4)}=\frac{A}{x+1}+\frac{Bx+C}{x^2+4}$

$$\therefore \quad 2x+7=A(x^2+4)+(Bx+C)(x+1)$$

Put $\quad x=-1$

$$\therefore \quad 5=5A \text{ or } A=1$$

Comparing the terms, $\quad 0=A+B \quad \Rightarrow \quad B=-1$

$$7=4A+C \quad \Rightarrow \quad C=3$$

$$\therefore \quad \frac{2x+7}{(x+1)(x^2+4)}=\frac{1}{x+1}+\frac{(-x+3)}{x^2+4}$$

Aliter To obtain values of A, B and C from

$$2x+7=A(x^2+4)+(Bx+C)(x+1)$$

i.e., $\quad 2x+7=(A+B)x^2+(B+C)x+4A+C$

Equating the coefficients of identical powers of x, we get

$$A+B=0, B+C=2 \text{ and } 4A+C=7.$$

Solving, we get $A=1, B=-1, C=3$

Example 53 ***Find the partial fraction*** $\frac{2x+1}{(3x+2)(4x^2+5x+6)}$.

Sol. Let $\frac{2x+1}{(3x+2)(4x^2+5x+6)}=\frac{A}{(3x+2)}+\frac{Bx+C}{(4x^2+5x+6)}$,

then $2x+1=A(4x^2+5x+6)+(Bx+C)(3x+2)$

where A, B, C are constants.

For A, let $\quad 3x+2=0$,

i.e., $\quad x=-2/3$

$$2\left(-\frac{2}{3}\right)+1=A\left\{4\cdot\frac{4}{9}-\frac{10}{3}+6\right\}+\left\{B\left(-\frac{2}{3}\right)+C\right\}(0)$$

$$-\frac{1}{3}=A\left(\frac{40}{9}\right) \Rightarrow \quad A=-\frac{3}{40}$$

Comparing coefficients of x^2 and constant term on both the sides for B and C, we get

$$4A + 3B = 0,$$

$$\therefore \quad B = -\frac{4}{3}A \quad \Rightarrow \quad B = \frac{1}{10} \quad \text{and} \quad 6A + 2C = 1,$$

$$\therefore \quad C = \frac{1-6A}{2} \quad \Rightarrow C = \frac{29}{40}$$

$$\therefore \frac{2x+1}{(3x+2)(4x^2+5x+6)} = \frac{-3}{40(3x+2)} + \frac{\left(x+\frac{29}{4}\right)}{10(4x^2+5x+6)}$$

Case IV When some of the factors of the denominator are quadratic and repeating. For every quadratic repeating factor of the type $(ax^2+bx+c)^k$, we assume :

$$\frac{A_1x+A_2}{ax^2+bx+c} + \frac{A_3\,x+A_4}{(ax^2+bx+c)^2} + \ldots + \frac{A_{2k-1}\,x+A_{2k}}{(ax^2+bx+c)^k}$$

Example 54 Resolve $\dfrac{2x^4+2x^2+x+1}{x(x^2+1)^2}$ into partial fractions.

Sol. Let $\dfrac{2x^4+2x^2+x+1}{x(x^2+1)^2} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+1} + \dfrac{Dx+E}{(x^2+1)^2}$

or $2x^4+2x^2+x+1 = A(x^2+1)^2 + (Bx+C)\,x(x^2+1) + (Dx+E)\,x$

Comparing coefficients of x^4, x^3, x^2, x and constant term

$$\therefore \quad A+B=2, C=0, 2A+D+B=2, E=1, A=1$$

$\therefore$ we get $A=1, B=1, C=0, D=-1, E=1$

Hence, the partial fraction,

$$\frac{2x^4+2x^2+x+1}{x(x^2+1)^2} = \frac{1}{x} + \frac{x}{1+x^2} + \frac{1-x}{(1+x^2)^2}$$

Example 55 Evaluate the following integrals:

(i) $\displaystyle\int \frac{(1-x^2)\,dx}{x(1-2x)}$ (ii) $\displaystyle\int \frac{3x-1}{(x-2)^2}\,dx$

(iii) $\displaystyle\int \frac{x^2+x+1}{x^2(x+2)}\,dx$ (iv) $\displaystyle\int \frac{8dx}{(x+2)(x^2+4)}$

Sol. (i) Let, $\dfrac{1-x^2}{x(1-2x)} = \dfrac{1}{2} + \dfrac{A}{x} + \dfrac{B}{(1-2x)}$

$$\Rightarrow \quad (1-x^2) = \frac{1}{2}x(1-2x) + A(1-2x) + B(x)$$

On putting $x=0$ and $x=\dfrac{1}{2}$, we get

$$1 = A \text{ and } 1 - \frac{1}{4} = B \cdot \frac{1}{2} \Rightarrow A = 1, B = \frac{3}{2}$$

$$\therefore \quad \int \frac{1-x^2}{x(1-2x)}\,dx = \int \left(\frac{1}{2} + \frac{1}{x} + \frac{3}{2(1-2x)}\right) dx$$

$$= \frac{1}{2}x + \log|x| + \frac{3}{2}\frac{\log|1-2x|}{-2} + C$$

$$= \frac{1}{2}x + \log|x| - \frac{3}{4}\log|1-2x| + C.$$

(ii) Let, $\dfrac{3x-1}{(x-2)^2} = \dfrac{A}{(x-2)} + \dfrac{B}{(x-2)^2}$

$$\Rightarrow \quad 3x-1 = A(x-2) + B, \qquad \ldots(i)$$

On putting $x=2$ in Eq. (i), we get $B=5$.

On equating coefficients of x on both sides of (i), we get $A=3$,

$$\therefore \quad \int \frac{3x-1}{(x-2)^2}\,dx = \int \left(\frac{3}{(x-2)} + \frac{5}{(x-2)^2}\right) dx$$

$$= 3\log|x-2| - \frac{5}{x-2} + C$$

(iii) Let, $\dfrac{x^2+x+1}{x^2(x+2)} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x+2}$

$$\Rightarrow \quad x^2+x+1 = Ax(x+2) + B(x+2) + C(x^2) \quad \ldots(i)$$

On putting, $x=-2$ and $x=0$ in Eq. (i), we get

$$C = 3/4 \text{ and } B = 1/2$$

On equation Coefficient of x^2 on both sides of (i), we get $1 = A + C \Rightarrow A = 1/4$.

$$\therefore \quad \int \frac{x^2+x+1}{x^2(x+2)}\,dx = \int \left(\frac{1/4}{x} + \frac{1/2}{x^2} + \frac{3/4}{x+2}\right) dx$$

$$= \frac{1}{4}\log|x| - \frac{1}{2x} + \frac{3}{4}\log|x+2| + C$$

(iv) Let, $\dfrac{8}{(x+2)(x^2+4)} = \dfrac{A}{x+2} + \dfrac{Bx+C}{x^2+4}$

$$\Rightarrow \quad 8 = A(x^2+4) + (Bx+C)(x+2) \qquad \ldots(i)$$

On putting $x=-2$ in Eq. (i), we get $A=1$.

On equating coefficient of x^2 on both sides we get,

$$0 = A + B \Rightarrow B = -1$$

On equating constant term on both sides, we get,

$$8 = 4A + 2C \Rightarrow C = 2$$

$$\therefore \quad \int \frac{8}{(x+2)(x^2+4)}\,dx = \int \left(\frac{1}{x+2} + \frac{(-x+2)}{x^2+4}\right) dx$$

$$= \int \frac{1}{x+2}\,dx - \frac{1}{2}\int \frac{2x\,dx}{x^2+4} + 2\int \frac{dx}{x^2+4}$$

$$= \log|x+2| - \frac{1}{2}\log|x^2+4| + 2\cdot\frac{1}{2}\tan^{-1}\left(\frac{x}{2}\right) + C.$$

Example 56 Evaluate $\displaystyle\int \frac{1}{\sin x - \sin 2x}\,dx$.

Sol. Let $I = \displaystyle\int \frac{1}{\sin x - \sin 2x}\,dx = \int \frac{1}{\sin x - 2\sin x\cos x}\,dx$

$$= \int \frac{1}{\sin x(1-2\cos x)}\,dx = \int \frac{\sin x}{\sin^2 x(1-2\cos x)}\,dx$$

$$= \int \frac{\sin x}{(1-\cos^2 x)(1-2\cos x)}\,dx$$

(put $\cos x = t \Rightarrow -\sin x\,dx = dt$)

$$\therefore \quad I = \int \frac{-dt}{(1-t^2)(1-2t)} = \int \frac{-1}{(1-t)(1+t)(1-2t)}\,dt \quad ...(i)$$

Here, in Eq. (i) we have linear and non-repeated factors thus we use partial fractions for;

$$\frac{-1}{(1-t)(1+t)(1-2t)} = \frac{A}{(1-t)} + \frac{B}{(1+t)} + \frac{C}{(1-2t)}$$

or $-1 = A(1+t)(1-2t) + B(1-t)(1-2t) + C(1-t)(1+t)$ ...(ii)

Putting $(t+1) = 0$ or $t = -1$, we get

$$-1 = B(2)(1+2) \Rightarrow B = -\frac{1}{6}$$

Putting $(1-t) = 0$ or $t = 1$, we get

$$-1 = A(2)(-1) \quad \Rightarrow \quad A = \frac{1}{2}$$

Putting $(1-2t) = 0$ or $t = 1/2$, we get

$$-1 = C\left(1-\frac{1}{2}\right)\left(1+\frac{1}{2}\right) \Rightarrow C = -\frac{4}{3}$$

$$\therefore \quad \frac{-1}{(1-t)(1+t)(1-2t)} = \frac{1}{2(1-t)} - \frac{1}{6(1+t)} - \frac{4}{3(1-2t)}$$

So, Eq. (i) reduces to

$$I = \frac{1}{2}\int \frac{1}{1-t}\,dt - \frac{1}{6}\int \frac{1}{1+t}\,dt - \frac{4}{3}\int \frac{1}{1-2t}\,dt$$

$$= -\frac{1}{2}\log|1-t| - \frac{1}{6}\log|1+t| - \frac{4}{3}\times -\frac{1}{2}\log|1-2t| + C$$

$$= -\frac{1}{2}\log|1-\cos x| - \frac{1}{6}\log|1+\cos x| + \frac{2}{3}\log|1-2\cos x| + C$$

Example 57 Evaluate $\int \frac{(1-x\sin x)\,dx}{x(1-x^3 e^{3\cos x})}$.

Sol. Here, $I = \int \frac{(1-x\sin x)\,dx}{x(1-(xe^{\cos x})^3)}$

Put $xe^{\cos x} = t$

$\Rightarrow \quad (xe^{\cos x}\cdot(-\sin x) + e^{\cos x})\,dx = dt$

$$\therefore \quad I = \int \frac{dt}{t(1-t^3)} = \int \frac{dt}{t(1-t)(1+t+t^2)}$$

$$= \int\left(\frac{A}{t} + \frac{B}{1-t} + \frac{Ct+D}{1+t+t^2}\right)dt$$

Comparing coefficients, we get

$$A = 1, B = \frac{1}{3}, C = -\frac{2}{3}, D = -\frac{1}{3}$$

$$\therefore \quad I = \int \frac{dt}{t} + \frac{1}{3}\int \frac{dt}{1-t} + \int \frac{\left(-\frac{2}{3}t - \frac{1}{3}\right)}{1+t+t^2}\,dt$$

$$= \log|t| - \frac{1}{3}\log|1-t| - \frac{1}{3}\log|1+t+t^2|$$

[where, $t = xe^{\cos x}$]

Example 58 Evaluate $\int \sin 4x \cdot e^{\tan^2 x}\,dx$.

Sol. The given integral could be written as,

$$I = \int 4\sin x\cdot\cos x\cdot\cos 2x\cdot e^{\tan^2 x}dx$$

$$= 4\int \tan x\cdot\cos^2 x(\cos^2 x - \sin^2 x)\cdot e^{\tan^2 x}dx$$

$$= 4\int \tan x\cdot\cos^4 x(1-\tan^2 x)\cdot e^{\tan^2 x}\,dx$$

$$= 4\int \frac{\tan x}{(\sec^2 x)^2}\cdot(1-\tan^2 x)\cdot e^{\tan^2 x}\,dx$$

Put $\tan^2 x = t$

$\Rightarrow \quad 2\tan x\cdot\sec^2 x\,dx = dt$

$$\Rightarrow \quad I = 4\int \frac{(1-t)e^t}{(1+t)^3}\cdot\frac{dt}{2} = 2\int \frac{(1-t)e^t}{(1+t)^3}\,dt$$

$$= 2\left\{\int \frac{2e^t - (1+t)e^t}{(1+t)^3}dt\right\}$$

$$= 2\left\{\int e^t\frac{2}{(1+t)^3} - \frac{1}{(1+t)^2}\right\}dt$$

$$= -2\frac{1}{(1+t)^2}e^t + C$$

[using $\int e^x(f(x)) + f'(x))dx = e^x.f(x) + c$]

$$= -\frac{2e^{\tan^2 x}}{(1+\tan^2 x)^2} + C$$

$$I = -2\cos^4 x\cdot e^{\tan^2 x} + C$$

Example 59 Solve $\int \frac{1+x\cos x}{x(1-x^2e^{2\sin x})}\,dx$.

Sol. Let $I = \int \frac{1+x\cos x}{x(1-x^2e^2\sin x)}\,dx$

Put $(x\,e^{\sin x}) = t$

Differentiating both the sides, we get

$(x\,e^{\sin x}\cdot\cos x + e^{\sin x})\,dx = dt$

$\Rightarrow \quad e^{\sin x}(x\cos x + 1)\,dx = dt$

$$\Rightarrow \quad I = \int \frac{dt}{t(1-t^2)}$$

$$= \int \frac{dt}{t(1-t)(1+t)} \qquad \text{[using partial fraction]}$$

$$= \int\left\{\frac{1}{t} + \frac{1}{2(1-t)} - \frac{1}{2(1+t)}\right\}dt$$

$$= \log|t| - \frac{1}{2}\log|1-t| - \frac{1}{2}\log|1+t| + C$$

$$= \log|x\,e^{\sin x}| - \frac{1}{2}\log|1-x^2e^{2\sin x}| + C$$

Example 60 Evaluate;

$$\int \frac{1}{x}\{\log e^{ex} \cdot \log e^{e^2x} \cdot \log e^{e^3x}\}\, dx$$

Sol. We have,

$$I = \int \frac{1}{x}\{\log e^{ex} \cdot \log e^{e^2x} \cdot \log_e e^3 x\}\, dx$$

$$= \int \frac{1}{x}\left\{\frac{1}{\log e^{ex}} \cdot \frac{1}{\log e^{e^2x}} \cdot \frac{1}{\log e^{e^3x}}\right\} dx$$

$$= \int \frac{dx}{x\{\log e^{e} + \log e^{x}\}\{\log e^{e^2} + \log e^{x^2}\}\{\log e^{e^3} + \log x^2\}}$$

$$= \int \frac{dx}{x\{1 + \log e^{x}\}\{2 + \log e^{x}\}\{3 + \log e^{x}\}}$$

Put $\log e^x = t \Rightarrow \frac{1}{x}dx = dt$

$$I = \int \frac{dt}{(1+t)(2+t)(3+t)} = \int\left(\frac{1}{2}\cdot\frac{1}{(1+t)} - \frac{1}{(2+t)} + \frac{1}{(3+t)}\right)dt$$

[using partial fraction]

$$= \frac{1}{2}\log|1+t| - \log|2+t| + \log|3+t| + C.$$

$$= \frac{1}{2}\log|1+\log e^x| - \log|2+\log e^x| + \log|3+\log e^x| + C.$$

Exercise for Session 5

- Evaluate the following Integrals :

1. $\int \frac{x^2}{(x-1)(x-2)(x-3)}\, dx$

2. $\int \frac{dx}{1+x^3}$

3. $\int \frac{dx}{x(x^n+1)}$

4. $\int \frac{2x}{(x^2+1)(x^2+3)}$

5. $\int \frac{\cos x}{(1+\sin x)(2+\sin x)}\, dx$

6. $\int \frac{dx}{\sin x\,(3+2\cos x)}\, dx$

7. $\int \frac{\sec x}{1+\operatorname{cosec} x}\, dx$

8. $\int \frac{\tan x + \tan^3 x}{1+\tan^3 x}\, dx$

9. $\int \frac{dx}{x\,|6(\log x)^2 + 7\log x + 2|}$

10. $\int \frac{\tan^{-1}}{x^2}.\, dx$

Session 6

Indirect and Derived Substitutions

Indirect and Derived Substitutions

(i) Indirect Substitution

If the integral is of the form $f(x)\cdot g(x)$, where $g(x)$ is a function of the integral of $f(x)$, then put integral of $f(x)=t$.

Example 61 The value of $\int \frac{d(x^2+1)}{\sqrt{x^2+2}}$, is

(a) $2\sqrt{x^2+2}+C$ (b) $\sqrt{x^2+2}+C$

(c) $x\sqrt{x^2+2}+C$ (d) None of these

Sol. Here, $I=\int \frac{d(x^2+1)}{\sqrt{x^2+2}}$

We know, $d(x^2+1)=2x\,dx$

$\therefore \quad I=\int \frac{2x\,dx}{\sqrt{x^2+2}}$

Put, $x^2+2=t^2$

$\therefore \quad 2x\,dx=2t\,dt \Rightarrow I=\int \frac{2t\,dt}{t}=2t+C$

$\Rightarrow \quad I=2\sqrt{x^2+2}+C$

Hence, (a) is the correct answer.

Example 62 If $\int \frac{(\sqrt{x})^5}{(\sqrt{x})^7+x^6}dx=a\log\left(\frac{x^k}{1+x^k}\right)+c$, then a and k are

(a) $2/5, 5/2$ (b) $1/5, 2/5$

(c) $5/2, 1/2$ (d) $2/5, 1/2$

Sol. Here, $I=\int \frac{(\sqrt{x})^5}{(\sqrt{x})^7+x^6}dx = \int \frac{dx}{(\sqrt{x})^2+(\sqrt{x})^7}$

$$=\int \frac{dx}{x^{7/2}\left\{1+\frac{1}{x^{5/2}}\right\}},$$

Put $\frac{1}{x^{5/2}}=y \Rightarrow -\frac{5}{2x^{7/2}}dx=dy$

$$I=-\frac{2}{5}\int \frac{dy}{1+y}$$

$$=-\frac{2}{5}\log|1+y|+C=\frac{2}{5}\log\left|\frac{1}{1+y}\right|+C$$

$$=\frac{2}{5}\log\left|\frac{x^{5/2}}{x^{5/2}+1}\right|+C \quad \text{...(i)}$$

where, $I=a\log\left(\frac{x^k}{1+x^k}\right)+C$ (given) ...(ii)

$\therefore$ From Eqs. (i) and (ii), we get

$$a\log\left(\frac{x^k}{1+x^k}\right)+C=\frac{2}{5}\log\left(\frac{x^{5/2}}{1+x^{5/2}}\right)+C$$

$\Rightarrow \quad a=2/5$ and $k=5/2$

Hence, (a) is the correct answer.

Example 63 Evaluate $\int \frac{5x^4+4x^5}{(x^5+x+1)^2}dx$.

Sol. Here, $I=\int \frac{5x^4+4x^5}{(x^5+x+1)^2}dx=\int \frac{x^4(5+4x)}{x^{10}\left(1+\frac{1}{x^4}+\frac{1}{x^5}\right)^2}dx$

$$=\int \frac{5/x^6+4/x^5}{\left(1+\frac{1}{x^4}+\frac{1}{x^5}\right)^2}dx$$

Put $1+\frac{1}{x^4}+\frac{1}{x^5}=t$

$\Rightarrow \quad \left(-\frac{4}{x^5}-\frac{5}{x^6}\right)dx=dt$

$$I=\int -\frac{dt}{t^2}=\frac{1}{t}+C=\frac{1}{1+\frac{1}{x^4}+\frac{1}{x^5}}+C$$

$$=\frac{x^5}{x^5+x+1}+C$$

Example 64 For any natural number m, evaluate $\int (x^{3m}+x^{2m}+x^m)(2x^{2m}+3x^m+6)^{1/m}\,dx,\ x>0$

[IIT JEE 2002]

Sol. Here, $I=\int (x^{3m}+x^{2m}+x^m)(2x^{2m}+3x^m+6)^{1/m}\,dx$

$$=\int (x^{3m}+x^{2m}+x^m)\frac{(2x^{3m}+3x^{2m}+6x^m)^{1/m}}{x}dx$$

$$=\int (x^{3m-1}+x^{2m-1}+x^{m-1})(2x^{3m}+3x^{2m}+6x^m)^{1/m}dx \quad \text{...(i)}$$

Put $2x^{3m} + 3x^{2m} + 6x^m = t$

$\Rightarrow \quad 6m\,(x^{3m-1} + x^{2m-1} + x^{m-1})\,dx = dt$

$\therefore$ Eq. (i) becomes,

$$I = \int t^{1/m}\,\frac{dt}{6m} = \frac{1}{6m}\cdot\frac{t^{(1/m)+1}}{(1/m)+1} + C$$

$$I = \frac{1}{6\,(m+1)}\{2x^{3m} + 3x^{2m} + 6x^m\}^{\frac{m+1}{m}} + C$$

Example 65 $\int \frac{x\,dx}{\sqrt{1+x^2+\sqrt{(1+x^2)^3}}}$ is equal to

(a) $\frac{1}{2}\ln(1+\sqrt{1+x^2}) + C$ (b) $2\sqrt{1+\sqrt{1+x^2}} + C$

(c) $2(1+\sqrt{1+x^2}) + C$ (d) None of these

Sol. $\int \frac{x\,dx}{\sqrt{(1+x^2)}\sqrt{1+\sqrt{1+x^2}}}$

Put $1+\sqrt{1+x^2} = t^2 \;\Rightarrow\; \frac{2x}{2\sqrt{1+x^2}}\,dx = 2t\,dt$

$\therefore \quad \frac{x\,dx}{\sqrt{1+x^2}} = 2t\,dt$

$\therefore \quad I = \int \frac{2t\,dt}{t} = 2t + C = 2\sqrt{1+\sqrt{1+x^2}} + C$

Hence, (b) is the correct answer.

Example 66 $\int \frac{(2x+1)}{(x^2+4x+1)^{3/2}}\,dx$

(a) $\frac{x^3}{(x^2+4x+1)^{1/2}} + C$ (b) $\frac{x}{(x^2+4x+1)^{1/2}} + C$

(c) $\frac{x^2}{(x^2+4x+1)^{1/2}} + C$ (d) $\frac{1}{(x^2+4x+1)^{1/2}} + C$

Sol. $\int \frac{2x+1}{(x^2+4x+1)^{3/2}}\,dx = \int \frac{2x+1}{x^3\left(1+\frac{4}{x}+\frac{1}{x^2}\right)^{3/2}}\,dx$

$$= \int \frac{2x^{-2}+x^{-3}}{\left(1+\frac{4}{x}+\frac{1}{x^2}\right)^{3/2}}\,dx$$

Now, put $\frac{1}{x^2}+\frac{4}{x}+1 = t^2 \;\Rightarrow\; \left(-\frac{2}{x^3}-\frac{4}{x^2}\right)dx = 2t\,dt$

$\therefore \quad I = \int \frac{-t\,dt}{t^3} = \frac{1}{t} + C$

$$= \frac{x}{\sqrt{x^2+4x+1}} + C$$

Hence, (b) is the correct answer.

Example 67 *The evaluation of* $\int \frac{p\,x^{p+2q-1} - qx^{q-1}}{x^{2p+2q} + 2x^{p+q} + 1}\,dx$ *is*

(a) $-\frac{x^p}{x^{p+q}+1} + C$ (b) $\frac{x^q}{x^{p+q}+1} + C$

(c) $-\frac{x^q}{x^{p+q}+1} + C$ (d) $\frac{x^p}{x^{p+q}+1} + C$

Sol. Here, $I = \int \frac{px^{p+2q-1} - qx^{q-1}}{x^{2p+2q} + 2x^{p+q} + 1}$

$$\int \frac{px^{p+2q-1} - qx^{q-1}}{(x^{p+q}+1)^2}\,dx = \int \frac{px^{p-1} - qx^{-q-1}}{(x^p + x^{-q})^2}\,dx$$

Taking x^q as x^{2q} common from denominator and take it in numerator.

Put $x^p + x^{-q} = t \;\Rightarrow\; (px^{p-1} - qx^{-q-1})\,dx = dt$

$\therefore \quad I = \int \frac{dt}{t^2} = -\frac{1}{t} + C = -\left(\frac{x^q}{x^{p+q}+1}\right) + C$

Hence, (c) is the correct answer.

Example 68 $\int \frac{x^2(1-\ln x)}{\ln^4 x - x^4}\,dx$ is equal to

(a) $\frac{1}{2}\ln\left(\frac{x}{\ln x}\right) - \frac{1}{4}\ln(\ln^2 x - x^2) + C$

(b) $\frac{1}{4}\ln\left(\frac{\ln x - x}{\ln x + x}\right) - \frac{1}{2}\tan^{-1}\left(\frac{\ln x}{x}\right) + C$

(c) $\frac{1}{4}\ln\left(\frac{\ln x + x}{\ln x - x}\right) + \frac{1}{2}\tan^{-1}\left(\frac{\ln x}{x}\right) + C$

(d) $\frac{1}{4}\left(\ln\left(\frac{\ln x - x}{\ln x + x}\right) + \tan^{-1}\left(\frac{\ln x}{x}\right)\right) + C$

Sol. Here, $I = \int \frac{x^2(1-\ln x)}{\ln x^4 x - x^4}$

$$I = \int \frac{x^2(1-\ln x)}{x^4\left(\left(\frac{\ln x}{x}\right)^4 - 1\right)}\,dx = \int \frac{1-\ln x}{x^2\left(\left(\frac{\ln x}{x}\right)^4 - 1\right)}\,dx$$

Put $\frac{\ln x}{x} = t \;\Rightarrow\; \frac{1-\ln x}{x^2} = dt$

$$I = \int \frac{dt}{(t^4-1)} = \int \frac{dt}{(t^2+1)(t^2-1)}$$

$$= \frac{1}{2}\int \frac{(t^2+1)-(t^2-1)}{(t^2+1)(t^2-1)}\,dt$$

$$I = \frac{1}{2}\left(\int \frac{dt}{t^2-1} - \int \frac{dt}{t^2+1}\right) = \frac{1}{2}\left(\frac{1}{2}\ln\frac{t-1}{t+1} - \tan^{-1}t\right)$$

$$= \frac{1}{4}\ln\left(\frac{\ln x - x}{\ln x + x}\right) - \frac{1}{2}\tan^{-1}\left(\frac{\ln x}{x}\right) + C$$

Hence, (b) is the correct answer.

Example 69 $\int \frac{x^2-1}{x^3\sqrt{2x^4-2x^2+1}}\,dx$ is equal to

[IIT JEE 2006]

(a) $\frac{\sqrt{2x^4-2x^2+1}}{x^2}+C$ (b) $\frac{\sqrt{2x^4-2x^2+1}}{x^3}+C$

(c) $\frac{\sqrt{2x^4-2x^2+1}}{x}+C$ (d) $\frac{\sqrt{2x^4-2x^2+1}}{2x^2}+C$

Sol. Let $I = \int \frac{x^2-1}{x^3\sqrt{2x^4-2x^2+1}}\,dx$

$$= \int \frac{x^2-1}{x^5}\cdot\frac{dx}{\sqrt{2-\frac{2}{x^2}+\frac{1}{x^4}}}$$

$$= \frac{1}{4}\int \frac{\frac{4}{x^3}-\frac{4}{x^5}}{\sqrt{2-\frac{2}{x^2}+\frac{1}{x^4}}}\,dx = \frac{1}{4}\cdot 2\sqrt{2-\frac{2}{x^2}+\frac{1}{x^4}}$$

$$\left(\because \int \frac{f'(x)}{\sqrt{f(x)}}\,dx = 2\sqrt{f(x)}+C\right)$$

$$= \frac{\sqrt{2x^4-2x^2+1}}{2x^2}+C$$

Hence, (d) is the correct answer.

Example 70 ***Let*** $f(x)=\frac{x}{(1+x^n)^{1/n}}$ ***for*** $n\geq 2$ ***and*** $g(x)=\underbrace{fofo\ldots of}_{n\text{ times}}(x)$, ***then*** $\int x^{n-2}\,g(x)\,dx$ ***equals to***

[IIT JEE 2007]

(a) $\frac{1}{n(n-1)}(1+nx^n)^{1-\frac{1}{n}}+C$ (b) $\frac{1}{n-1}(1+nx^n)^{1-\frac{1}{n}}+C$

(c) $\frac{1}{n(n+1)}(1+nx^n)^{1+\frac{1}{n}}+C$ (d) $\frac{1}{n+1}(1+nx^n)^{1+\frac{1}{n}}+C$

Sol. $\because$ $f(x)=\frac{x}{(1+x^n)^{1/n}}$

$\therefore$ $f(f(x))=\frac{y}{(1+x^n)^{1/n}}$,

Where, $y=\frac{x}{(1+x^n)^{1/n}}=\frac{x}{(1+2x^n)^{1/n}}$

Similarly, $f(f(f(x)))=\frac{x}{(1+3x^n)^{1/n}}$

and $\underbrace{(fofofo\ldots of)}_{n\text{ times}}(x)=g(x)=\frac{x}{(1+nx^n)^{1/n}}$

$$\therefore \int x^{n-2}g(x)\,dx = \int \frac{x^{n-1}}{(1+nx^n)^{1/n}}\,dx$$

$$= \frac{1}{n^2}\int n^2\cdot x^{n-1}\cdot(1+nx^n)^{-1/n}\,dx$$

$$= \frac{1}{n^2}\cdot\frac{(1+nx^n)^{1-\frac{1}{n}}}{1-\frac{1}{n}}+C$$

$$= \frac{(1+nx^n)^{1-\frac{1}{n}}}{n(n-1)}+C$$

Hence, (a) is the correct answer.

Derived Substitutions

Some times it is useful to write the integral as a sum of two related integrals which can be evaluated by making suitable substitutions.

Examples of such integrals are

Type I

(a) Algebraic Twins

$$\int \frac{2x^2}{x^4+1}\,dx = \int \frac{x^2+1}{x^4+1}\,dx + \int \frac{x^2-1}{x^4+1}\,dx$$

$$\int \frac{2}{x^4+1}\,dx = \int \frac{x^2+1}{x^4+1}\,dx - \int \frac{x^2-1}{x^4+1}\,dx$$

$$\int \frac{2x^2}{x^4+1+kx^2}\,dx, \int \frac{2}{(x^4+1+kx^2)}\,dx$$

(b) Trigonometric Twins

$$\int \sqrt{\tan x}\,dx, \int \sqrt{\cot x}\,dx,$$

$$\int \frac{1}{(\sin^4 x+\cos^4 x)}\,dx, \int \frac{1}{\sin^6 x+\cos^6 x}\,dx,$$

$$\int \frac{\pm\sin x\pm\cos x}{a+b\sin x\cos x}\,dx$$

Method of evaluating these integral are illustrated by mean of the following examples :

Integral of the Form

1. $\int f\left(x+\frac{1}{x}\right)\left(1-\frac{1}{x^2}\right)dx$

Put $x+\frac{1}{x}=t \Rightarrow \left(1-\frac{1}{x^2}\right)dx = dt$

2. $\int f\left(x-\frac{1}{x}\right)\left(1+\frac{1}{x^2}\right)dx.$

   Put $x-\frac{1}{x}=t \Rightarrow \left(1+\frac{1}{x^2}\right)dx=dt$

3. $\int \frac{x^2+1}{x^4+kx^2+1}\,dx.$

   Divide numerator and denominator by x^2.

4. $\int \frac{x^2-1}{x^4+kx^2+1}\,dx$

   Divide numerator and denominator by x^2.

Example 71 Evaluate $\int \frac{5}{1+x^4}\,dx.$

Sol. Let $I=\int \frac{5}{1+x^4}\,dx=\frac{5}{2}\int \frac{2}{1+x^4}\,dx$

$$=\frac{5}{2}\left[\int \frac{1+x^2}{1+x^4}\,dx+\int \frac{1-x^2}{1+x^4}\,dx\right]$$

$$=\frac{5}{2}\left[\int \frac{x^2+1}{x^4+1}\,dx-\int \frac{x^2-1}{x^4+1}\,dx\right]$$

Remark

Here, dividing Numerator and Denominator by x^2 and converting Denominator into perfect square so as to get differential in Numerator

i.e. $$I=\frac{5}{2}\left[\int \frac{1+1/x^2}{x^2+1/x^2}\,dx-\int \frac{1-1/x^2}{x^2+1/x^2}\,dx\right]$$

$$=\frac{5}{2}\left[\int \frac{1+1/x^2}{(x-1/x)^2+2}\,dx-\int \frac{1-1/x^2}{(x+1/x)^2-2}\,dx\right]$$

$$=\frac{5}{2}\left[\int \frac{dt}{t^2+(\sqrt{2})^2}-\int \frac{du}{u^2-(\sqrt{2})^2}\right],$$

$$[\text{where } t=x-\frac{1}{x} \text{ and } u=x+\frac{1}{x}]$$

$$=\frac{5}{2}\left[\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{t}{\sqrt{2}}\right)-\frac{1}{2\sqrt{2}}\log\left|\frac{u-\sqrt{2}}{u+\sqrt{2}}\right|\right]+C$$

$$\therefore \quad I=\frac{5}{2}\left[\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{x-1/x}{\sqrt{2}}\right)-\frac{1}{2\sqrt{2}}\log\left|\frac{x+\frac{1}{x}-\sqrt{2}}{x+\frac{1}{x}+\sqrt{2}}\right|\right]+C$$

Example 72 Evaluate $\int \frac{1}{x^4+5x^2+1}\,dx.$

Sol. Let $I=\frac{1}{2}\int \frac{2}{x^4+5x^2+1}\,dx$

$$\Rightarrow I=\frac{1}{2}\int \frac{1+x^2}{x^4+5x^2+1}\,dx+\frac{1}{2}\int \frac{1-x^2}{x^4+5x^2+1}\,dx$$

$$=\frac{1}{2}\int \frac{1+1/x^2}{x^2+5+1/x^2}\,dx-\frac{1}{2}\int \frac{1-1/x^2}{x^2+5+1/x^2}\,dx$$

[(dividing Numerator and Denominator by x^2)]

$$=\frac{1}{2}\int \frac{(1+1/x^2)}{(x-1/x)^2+7}\,dx-\frac{1}{2}\int \frac{(1-1/x^2)}{(x+1/x)^2+3}\,dx$$

$$=\frac{1}{2}\int \frac{dt}{t^2+(\sqrt{7})^2}-\frac{1}{2}\int \frac{du}{u^2+(\sqrt{3})^2}$$

where $t=x-\frac{1}{x}$ and $u=x+\frac{1}{x}$

$$\therefore \quad I=\frac{1}{2}\cdot\frac{1}{\sqrt{7}}\left(\tan^{-1}\frac{t}{\sqrt{7}}\right)-\frac{1}{2}\cdot\frac{1}{\sqrt{3}}\left(\tan^{-1}\frac{u}{\sqrt{3}}\right)+C$$

$$=\frac{1}{2}\left[\frac{1}{\sqrt{7}}\tan^{-1}\left(\frac{x-1/x}{\sqrt{7}}\right)-\frac{1}{\sqrt{3}}\tan^{-1}\left(\frac{x+1/x}{\sqrt{3}}\right)\right]+C$$

Example 73 Evaluate $\int \sqrt{\tan x}\,dx.$

Sol. Here $I=\int \sqrt{\tan x}\,dx$

Put $\tan x=t^2$

$$\Rightarrow \sec^2 x\,dx=2t\,dt \quad \Rightarrow dx=\frac{2t\,dt}{1+t^4}$$

$$\therefore \quad I=\int t\cdot\frac{2t}{1+t^4}\,dt=\int \frac{2t^2}{t^4+1}\,dt$$

$$=\int \frac{t^2+1}{t^4+1}\,dt+\int \frac{t^2-1}{t^4+1}\,dt$$

$$=\int \frac{1+1/t^2}{t^2+1/t^2}\,dt+\int \frac{1-1/t^2}{t^2+1/t^2}\,dt$$

$$=\int \frac{1+1/t^2}{(t-1/t)^2+2}\,dt+\int \frac{1-1/t^2}{(t+1/t)^2-2}\,dt$$

$$I=\int \frac{ds}{s^2+(\sqrt{2})^2}+\int \frac{dr}{r^2-(\sqrt{2})^2}, \left[s=t-\frac{1}{t} \text{ and } r=t+\frac{1}{t}\right]$$

$$=\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{s}{\sqrt{2}}\right)+\frac{1}{2\sqrt{2}}\log\left|\frac{r-\sqrt{2}}{r+\sqrt{2}}\right|+C$$

$$=\frac{1}{\sqrt{2}}\left[\tan^{-1}\left(\frac{t-1/t}{\sqrt{2}}\right)+\frac{1}{2}\log\left(\frac{t+\frac{1}{t}-\sqrt{2}}{t+\frac{1}{t}+\sqrt{2}}\right)\right]+C$$

[(where $t=\sqrt{\tan x}$)]

Example 74 Evaluate $\int \frac{4}{\sin^4 x+\cos^4 x}\,dx.$

Sol. Let $I=4\int \frac{dx}{\sin^4 x+\cos^4 x}$

Dividing numerator and denominator by $\cos^4 x$, we get

$$I = 4\int \frac{\sec^4 x}{\tan^4 x + 1}\,dx$$

$$I = 4\int \frac{\sec^2 x\,(1+\tan^2 x)}{1+\tan^4 x}\,dx$$

Put $\tan x = t \Rightarrow \sec^2 x\,dx = dt$

$$\therefore \quad I = 4\int \frac{t^2+1}{t^4+1}\,dt$$

$$= 4\int \frac{1+1/t^2}{t^2+1/t^2}\,dt = 4\int \frac{1+1/t^2}{(1-1/t)^2+2}\,dt$$

Again, put $z = t - \frac{1}{t}$

$$\therefore \quad I = 4\int \frac{dz}{z^2+2} = \frac{4}{\sqrt{2}}\tan^{-1}\left(\frac{z}{\sqrt{2}}\right)+C$$

$$I = 2\sqrt{2}\tan^{-1}\left(\frac{\tan x - 1/\tan x}{\sqrt{2}}\right)+C$$

Example 75 The value of $\int \frac{(ax^2-b)\,dx}{x\sqrt{c^2x^2-(ax^2+b)^2}}$, is equal to

(a) $\frac{1}{c}\sin^{-1}\left(ax\frac{b}{x}\right)+k$ (b) $c\sin^{-1}\left(ax+\frac{b}{x}\right)+k$

(c) $\sin^{-1}\left[\frac{ax+b/x}{c}\right]+k$ (d) None of these

Sol. Here, $I = \int \frac{(ax^2-b)\,dx}{x\sqrt{c^2x^2-(ax^2+b)^2}} = \int \frac{\left(a-\frac{b}{x^2}\right)dx}{\sqrt{c^2-\left(ax+\frac{b}{x}\right)^2}}$

Put $ax + \frac{b}{x} = t$

$$\therefore \quad \left(a-\frac{b}{x^2}\right)dx = dt$$

$$I = \int \frac{dt}{\sqrt{c^2-t^2}} = \sin^{-1}\left(\frac{t}{c}\right)+k$$

$$\Rightarrow \quad \sin^{-1}\left(\frac{ax+b/x}{c}\right)+k$$

Hence (c) is the correct answer.

Example 76 $\int \frac{x^x\,(x^{2x}+1)(\ln x+1)}{x^{4x}+1}\,dx$

Sol. $I = \int \frac{x^x\,(x^{2x}+1)(\ln x+1)}{x^{4x}+1}\,dx$

Put $x^x = y \Rightarrow x^x(\ln x+1)\,dx = dy$

$$I = \int \frac{y^2+1}{y^4+1}\,dy = \int \frac{1+\frac{1}{y^2}}{y^2+\frac{1}{y^2}}\,dy = \int \frac{1+\frac{1}{y^2}}{\left(y-\frac{1}{y}\right)^2+2}\,dy$$

Put, $y - \frac{1}{y} = t \Rightarrow \left(1+\frac{1}{y^2}\right)dy = dt$

$$I = \int \frac{dt}{t^2+2} = \frac{1}{\sqrt{2}}\left(\tan^{-1}\frac{t}{\sqrt{2}}\right)+C$$

$$= \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{y-\frac{1}{y}}{\sqrt{2}}\right)+C = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{x^x-\frac{1}{x^x}}{\sqrt{2}}\right)+C$$

Example 77 Evaluate

$$\int \frac{(x^2-1)\,dx}{(x^4+3x^2+1)\tan^{-1}\left(x+\frac{1}{x}\right)}.$$

Sol. Here $I = \int \frac{(x^2-1)}{(x^4+x^3+1)\tan^{-1}\left(x+\frac{1}{x}\right)}$

The given integral can be written as

$$I = \int \frac{(1-1/x^2)\,dx}{(x^2+3+1/x^2)\tan^{-1}\left(x+\frac{1}{x}\right)}$$

(dividing numerator and denominator by x^2)

$$I = \int \frac{(1-1/x^2)\,dx}{\{(x+1/x)^2+1\}\tan^{-1}\left(x+\frac{1}{x}\right)}$$

Put, $x + \frac{1}{x} = t \Rightarrow \left(1-\frac{1}{x^2}\right)dx = dt$

$$\therefore \quad I = \int \frac{dt}{(t^2+1)\cdot\tan^{-1}(t)} \qquad \ldots(i)$$

Now, make one more substitution

$\tan^{-1} t = u$. Then, $\frac{dt}{t^2+1} = du$

$\therefore$ Eq. (i) becomes, $I = \int \frac{du}{u} = \log|u| + C$

$\Rightarrow I = \log|\tan^{-1} t| + C = \log|\tan^{-1}(x+1/x)| + C$

Example 78 $\int \frac{(x^{-7/6}-x^{5/6})\,dx}{x^{1/3}(x^2+x+1)^{1/2}-x^{1/2}(x^2+x+1)^{1/3}}$

Sol. $I = \int \frac{x^{7/6}(x^{-7/6}-x^{5/6})\,dx}{x^{7/6}\cdot x^{1/3}(x^2+x+1)^{1/2}-x^{1/2}\cdot x^{7/6}(x^2+x+1)^{1/3}}$

$$= \int \frac{(1-x^2)\,dx}{x^{3/2}(x^2+x+1)^{1/2}-x^{5/3}(x^2+x+1)^{1/3}}$$

$$= \int \frac{-\left(1-\frac{1}{x^2}\right)dx}{\left(x+\frac{1}{x}+1\right)^{1/2}-\left(x+\frac{1}{x}+1\right)^{1/3}} \left[\begin{array}{l}\text{Putting } x+\frac{1}{x}=t \\ \Rightarrow \left(1-\frac{1}{x^2}\right)dx = dt\end{array}\right]$$

$$= -\int \frac{dt}{(t+1)^{1/2}-(t+1)^{1/3}}$$

Substitute, $(t+1) = u^6$

$$= -\int \frac{6u^5\,du}{u^3-u^2} = -6\int \frac{u^3}{u-1}\,du,$$

Put $u-1=z$

$$dz = -6\int \frac{(z+1)^3}{z}\,dz$$

$$= -6\int \frac{z^3+3z^2+3z+1}{z}\,dz$$

$$= -6\int \left(z^2+3z+3+\frac{1}{z}\right)dz$$

$$= -6\left\{\frac{z^3}{3}+\frac{3z^2}{2}+3z+\log|z|\right\}+C$$

where, $z = \left(x+\frac{1}{x}+1\right)^{1/6}-1$

Example 79 The value of $\int \{\{[x]\}\}\,dx$, where {.} and [.] denotes fractional part of x and greatest integer function, is equal to

(a) 0 (b) 1 (c) 2 (d) –1

Sol. Let $I = \int \{\{[x]\}\}\,dx$

where, $[x] =$ Integer and we know $\{n\} = 0; n \in$ Integer.

$\therefore \quad I = \int 0\,dx = 0$

Hence, (a) is the correct answer.

Type II

Integration of Some Special Irrational Algebraic Functions

In this case we shall discuss four integrals of the form $\int \frac{\phi(x)}{P\sqrt{Q}}\,dx$, where P and Q are polynomial functions of x and $\phi(x)$ is polynomial in x.

(a) Integrals of the Form $\int \frac{\phi(x)}{P\sqrt{Q}}\,dx$, where P and Q are both linear of x

To evaluate this type of integrals we put $Q = t^2$, i.e. to evaluate integrals of the form $\int \frac{1}{(ax+b)\sqrt{cx+d}}\,dx$, put $cx+d = t^2$.

The following examples illustrate the procedure :

Example 80 Evaluate $\int \frac{1}{(x+1)\sqrt{x-2}}\,dx$.

Sol. Let $I = \int \frac{1}{(x+1)\sqrt{x-2}}\,dx$

Here, P and Q both are linear, so we put $Q = t^2$

i.e. $x-2 = t^2$

So that $dx = 2t\,dt$

$$\therefore \quad I = \int \frac{1}{(t^2+2+1)\sqrt{t^2}}\cdot 2t\,dt = 2\int \frac{dt}{t^2+3}$$

$$= 2\times\frac{1}{\sqrt{3}}\tan^{-1}\left(\frac{t}{\sqrt{3}}\right)+C$$

$$\therefore \quad I = \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{\sqrt{x-2}}{\sqrt{3}}\right)+C$$

(b) Integrals of the Form $\int \frac{\phi(x)}{P\sqrt{Q}}\,dx$, where P is a quadratic expression and Q is a linear expression

To evaluate this type of integrals we put $Q = t^2$ i.e. to evaluate the integrals of the form

$$\int \frac{1}{(ax^2+bx+c)\sqrt{px+q}}\,dx$$

put $px+q = t^2$.

Example 81 ***Evaluate*** $\int \frac{x+2}{(x^2+3x+3)\sqrt{x+1}}\,dx$.

Sol. Let $I = \int \frac{x+2}{(x^2+3x+3)\sqrt{x+1}}\,dx$

Put $x+1 = t^2 \Rightarrow dx = 2t\,dt$

$$\therefore \quad I = \int \frac{(t^2-1)+2}{\{(t^2-1)^2+3(t^2-1)+3\}\sqrt{t^2}}\cdot(2t)\,dt$$

$$= 2\int \frac{t^2+1}{t^4+t^2+1}\,dt = 2\int \frac{1+1/t^2}{t^2+1+1/t^2}\,dt$$

$$= 2\int \frac{1+1/t^2}{(t-1/t)^2+(\sqrt{3})^2}\,dt = 2\int \frac{du}{u^2+(\sqrt{3})^2} \qquad \left[\text{where } u = t-\frac{1}{t}\right]$$

$$= \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{u}{\sqrt{3}}\right)+C$$

$$\therefore \quad I = \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{t^2-1}{\sqrt{3}t}\right)+C$$

$$= \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{x}{\sqrt{3(x+1)}}\right)+C$$

(c) Integral of the Form $\int \frac{1}{(ax+b)} \cdot \frac{dx}{\sqrt{px^2+qx+r}}$, where in $\int \frac{dx}{P\sqrt{Q}}$ P is linear and Q is a quadratic put, $ax+b=\frac{1}{t}$.

Example 82 Evaluate $\int \frac{dx}{(x-1)\sqrt{x^2+x+1}}$.

Sol. Let $I=\int \frac{dx}{(x-1)\sqrt{x^2+x+1}}$

Put $x-1=\frac{1}{t} \Rightarrow dx=-\frac{1}{t^2}dt$

$$\therefore \quad I=\int \frac{-1/t^2\,dt}{1/t\sqrt{\left(\frac{1}{t}+1\right)^2+\left(\frac{1}{t}+1\right)+1}}$$

$$=-\int \frac{dt}{\sqrt{3t^2+3t+1}}=-\frac{1}{\sqrt{3}}\int \frac{dt}{\sqrt{\left(t+\frac{1}{2}\right)^2+\frac{1}{12}}}$$

$$=-\frac{1}{\sqrt{3}}\log\left|(t+1/2)+\sqrt{(t+1/2)^2+1/12}\right|+C$$

$$=-\frac{1}{\sqrt{3}}\log\left|\left(\frac{1}{x-1}+\frac{1}{2}\right)+\sqrt{\frac{12\left(\frac{1}{x-1}+\frac{1}{2}\right)^2+1}{12}}\right|+C$$

(d) Integrals of the Form $\int \frac{dx}{P\sqrt{Q}}$, where P and Q both are pure quadratic expression in x, i.e. $P=ax^2+b$ and $Q=cx^2+d$, i.e. $\int \frac{dx}{(ax^2+b)\sqrt{cx^2+d}}$.

To evaluate this type of integrals of the form we put $x=\frac{1}{t}$

Example 83 Evaluate $\int \frac{dx}{(1+x^2)\sqrt{1-x^2}}$.

Sol. Let $I=\int \frac{dx}{(1+x^2)\sqrt{1-x^2}}$

Put $x=\frac{1}{t}$, so that $dx=-\frac{1}{t^2}\,dt$

$$\therefore \quad I=\int \frac{-1/t^2\,dt}{(1+1/t^2)\sqrt{1-1/t^2}}=-\int \frac{t\,dt}{(t^2+1)\sqrt{t^2-1}}$$

Again, $t^2=u \Rightarrow 2t\,dt=du$.

$=-\frac{1}{2}\int \frac{du}{(u+1)\sqrt{u-1}}$ which reduces to the form $\int \frac{dx}{P\sqrt{Q}}$ where both P and Q are linear so that we put $u-1=z^2$ so that $du=2z\,dz$

$$\therefore \quad I=-\frac{1}{2}\int \frac{2z\,dz}{(z^2+1+1)\sqrt{z^2}}=-\int \frac{dz}{(z^2+2)}$$

$$I=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{z}{\sqrt{2}}\right)+C$$

$$I=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\sqrt{u-1}}{\sqrt{2}}\right)+C$$

$$=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\sqrt{t^2-1}}{\sqrt{2}}\right)+C$$

$$=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\sqrt{1-x^2}}{\sqrt{2}x}\right)+C$$

Aliter Put $x=\cos\theta, dx=-\sin\theta\,d\theta$

$$\therefore \quad I=-\int \frac{\sin\theta\,d\theta}{(1+\cos^2\theta)\sin\theta}=-\int \frac{d\theta}{1+\cos^2\theta}$$

$$=-\int \frac{\sec^2\theta\,d\theta}{\sec^2\theta+1}=-\int \frac{\sec^2\theta\,d\theta}{\tan^2\theta+2}$$

Put $\tan\theta=t. \Rightarrow \sec^2\theta\,d\theta=dt$

$$\therefore \quad I=-\int \frac{dt}{t^2+2}=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{t}{\sqrt{2}}\right)+C$$

$$=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\tan\theta}{\sqrt{2}}\right)+C$$

$$=-\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\sqrt{1-x^2}}{\sqrt{2}\,x}\right)+C \quad \left[\begin{array}{l}\text{where, } \cos\theta=x \\ \qquad \sin\theta=\sqrt{1-x^2} \\ \therefore \quad \tan\theta=\frac{\sqrt{1-x^2}}{x}\end{array}\right]$$

Example 84 Evaluate

$$I=\int \frac{(x-1)\sqrt{x^4+2x^3-x^2+2x+1}}{x^2(x+1)}\,dx.$$

Sol. Here, $I=\int \frac{(x^2-1)\sqrt{x^4+2x^3-x^2+2x+1}}{x^2(x+1)^2}\,dx$

$$=\int \frac{\left(1-\frac{1}{x^2}\right)\sqrt{x^2\left(x^2+2x-1+\frac{2}{x}+\frac{1}{x^2}\right)}}{\frac{x^2(x^2+2x+1)}{x^2}}\,dx$$

$$=\int \frac{\left(1-\frac{1}{x^2}\right)\sqrt{\left(x^2+\frac{1}{x^2}\right)+2\left(x+\frac{1}{x}\right)-1}}{\left(x+\frac{1}{x}+2\right)}\,dx$$

Put $x+\frac{1}{x}=t$, i.e. $\left(1-\frac{1}{x^2}\right)dx=dt$

$$=\int \frac{\sqrt{(t^2-2)}+2t-1}{(t+2)}\,dt=\int \frac{\sqrt{t^2+2t-3}}{(t+2)}\,dt$$

$$= \int \frac{t^2 + 2t - 3}{(t+2)\sqrt{t^2+2t-3}}\, dt$$

$$= \int \frac{t(t+2)}{(t+2)\sqrt{t^2+2t-3}}\, dt - 3\int \frac{dt}{(t+2)\sqrt{t^2+2t-3}}$$

$$I = I_1 - 3I_2 \quad \text{...(i)}$$

Where, $I_1 = \int \frac{t\, dt}{\sqrt{t^2+2t-3}}$ and $I_2 = \int \frac{dt}{(t+2)\sqrt{t^2+2t-3}}$

$$\therefore \quad I_1 = \int \frac{t\, dt}{\sqrt{(t+1)^2 - 4}}$$

Put, $t + 1 = z = \int \frac{(z-1)\, dz}{\sqrt{z^2 - 2^2}}$

$$= \int \frac{z dz}{\sqrt{z^2-2^2}} - \int \frac{dz}{\sqrt{z^2-2^2}}$$

$$= \sqrt{z^2-2^2} - \log|z + \sqrt{z^2-4}|$$

$$= \sqrt{t^2+2t-3} - \log|(t+1) + \sqrt{t^2+2t+3}| \quad \text{...(ii)}$$

Also, $I_2 = \int \frac{dy}{y^2 \cdot \frac{1}{y}\sqrt{\left(\frac{1}{y}-2\right)^2 + 2\left(\frac{1}{y}-2\right) - 3}}$

Put $t + 2 = \frac{1}{y} = \int \frac{dy}{\sqrt{1-2y-3y^2}} = \frac{1}{\sqrt{3}} \int \frac{dy}{\sqrt{\left(\frac{2}{3}\right)^2 - \left(y + \frac{1}{3}\right)^2}}$

$$= \frac{1}{\sqrt{3}} \sin^{-1}\left(\frac{y + \frac{1}{3}}{\frac{2}{3}}\right) = \frac{1}{\sqrt{3}} \sin^{-1}\left(\frac{5+t}{2+t}\right) \quad \text{...(iii)}$$

$$\therefore \quad I = \sqrt{t^2+2t-3} - \log(t + 1 + \sqrt{t^2+2t-3}) - \sqrt{3} \sin^{-1}\left(\frac{t+5}{t+2}\right)$$

where, $t = x + \frac{1}{x}$

(e) Integrals of the Form $\int \frac{dx}{(x-k)^r \sqrt{ax^2 + bx + c}}$, where $r \geq 2$ and $r \in I$

Here, we substitute, $x - k = \frac{1}{t}$

Example 85 Evaluate $\int \frac{dx}{(x-3)^3 \sqrt{x^2 - 6x + 10}}$.

Sol. Substitute $(x-3) = \frac{1}{t} \Rightarrow dx = -\frac{1}{t^2}\, dt$

We get, $\int \frac{dx}{(x-3)^3 \sqrt{x^2 - 6x + 10}}$

$$= \int \frac{-1/t^2\, dt}{1/t^3 \sqrt{(1/t+3)^2 - 6(1/t+3) + 10}}$$

$$= -\int \frac{t^2\, dt}{\sqrt{1+t^2}} = \int \frac{dt}{\sqrt{1+t^2}} - \int \sqrt{1+t^2}\, dt$$

$$= \log|t + \sqrt{1+t^2}| - \frac{t}{2}\sqrt{1+t^2} - \frac{1}{2}\log|t + \sqrt{1+t^2}| + C$$

$$= \frac{1}{2}\log|t + \sqrt{1+t^2}| - \frac{t}{2}\sqrt{1+t^2} + C$$

$$= \frac{1}{2}\left[\log\left|\frac{1 + \sqrt{x^2 - 6x + 10}}{|x-3|}\right| - \frac{\sqrt{x^2-6x+10}}{|x-3|^2}\right] + C$$

(f) Integrals of the Form $\int \frac{ax^2 + bx + c}{(dx+e)\sqrt{fx^2 + gx + h}}\, dx$

Here, we write

$$ax^2 + bx + c = A_1(dx+e)(2fx+g) + B_1(dx+e) + C_1$$

Where A_1, B_1 and C_1 are constants which can be obtained by comparing the coefficients of like terms on both the sides.

Example 86 ***Evaluate*** $\int \frac{2x^2 + 5x + 9}{(x+1)\sqrt{x^2+x+1}}\, dx$.

Sol. Let $2x^2 + 5x + 9 = A(x+1)(2x+1) + B(x+1) + C$

or $2x^2 + 5x + 9 = x^2(2A) + x(3A + B) + (A + B + C)$

$\Rightarrow \quad A = 1, B = 2, C = 6$

Thus, $\int \frac{2x^2 + 5x + 9}{(x+1)\sqrt{x^2+x+1}}\, dx$

$$= \int \frac{(x+1)(2x+1)}{(x+1)\sqrt{x^2+x+1}}\, dx + 2\int \frac{x+1}{(x+1)\sqrt{x^2+x+1}}\, dx + 6\int \frac{dx}{(x+1)\sqrt{x^2+x+1}}$$

$$= \int \frac{2x+1}{\sqrt{x^2+x+1}}\, dx + 2\int \frac{dx}{\sqrt{x^2+x+1}} + 6\int \frac{dx}{(x+1)\sqrt{x^2+x+1}}$$

$$= \int \frac{du}{\sqrt{u}} + 2\int \frac{dx}{\sqrt{(x+1/2)^2 + (3/4)}} + 6\int \frac{-dt}{\sqrt{t^2 - t + 1}}$$

[where $u = x^2 + x + 1$ and $\frac{1}{t} = x + 1$]

$$= 2\sqrt{x^2+x+1} + 2 \cdot 1 \log|(x + 1/2) + \sqrt{x^2+x+1}| - 6\int \frac{dt}{\sqrt{(t-1/2)^2 + 3/4}}$$

$$= 2\sqrt{x^2+x+1} + 2\log\left|\left(x + \frac{1}{2}\right) + \sqrt{x^2+x+1}\right| - 6\log\left|\left(t - \frac{1}{2}\right) + \sqrt{t^2-t+1}\right| + C$$

$$= 2\sqrt{x^2+x+1} + 2\log\left|\left(x + \frac{1}{2}\right) + \sqrt{x^2+x+1}\right| - 6\log\left|\frac{1 - x + \sqrt{x^2+x+1}}{2(x+1)}\right| + C$$

Type III

Integration of Type $\int (\sin^m x \cdot \cos^n x)\, dx$

(i) Where m, n belongs to natural number.
(ii) If one of them is odd, then substitute for term of even power.
(iii) If both are odd, substitute either of them.
(iv) If both are even, use trigonometric identities only.
(v) If m and n are rational numbers and $\left(\frac{m+n-2}{2}\right)$ is a negative integer, then substitute $\cot x = p$ or $\tan x = p$ which so ever is found suitable.

Example 87 Evaluate $\int \sin^3 x \cdot \cos^5 x\, dx$.

Sol. $I = \int \sin^3 x \cdot \cos^5 x\, dx$

Let $\cos x = t \quad \Rightarrow \quad -\sin x\, dx = dt$

$$I = -\int (1 - t^2) \cdot t^5 dt$$

$$I = \int t^7\, dt - \int t^5\, dt = \frac{t^8}{8} - \frac{t^6}{6} + C$$

$$I = \frac{\cos^8 x}{8} - \frac{\cos^6 x}{6} + C$$

Aliter $I = \int R^3 (1 - R^2)^2\, dR,$

if $\sin x = R,\ \cos x\, dx = dR$

$$I = \int R^3\, dR - \int 2R^5\, dR + \int R^7 dR$$

$$I = \frac{\sin^4 x}{4} - \frac{2\sin^6 x}{6} + \frac{\sin^8 x}{8} + C$$

Remark

This problem can also be handled by successive reduction or by trigonometrical identities. Answers will be in different form but identical with modified constant of integration.

Example 88 Evaluate $\int \sin^{-11/3} x \cdot \cos^{-1/3} x\, dx$.

Sol. Here, $\int \sin^{-11/3} x \cdot \cos^{-1/3} x\, dx$ i.e. $\left(\frac{-\frac{11}{3} - \frac{1}{3} - 2}{2} = -3\right)$

$$\therefore \quad I = \int \frac{\cos^{-1/3} x}{\sin^{-1/3} x \cdot \sin^4 x}\, dx = \int (\cot^{-1/3} x)(\operatorname{cosec}^2 x)^2 dx$$

$$I = \int (\cot^{-1/3} x)(1 + \cot^2 x) \operatorname{cosec}^2 x\, dx$$

$$= -\int t^{-1/3} (1 + t^2)\, dt \ = -\int (t^{-1/3} + t^{5/3})\, dt$$

[Put $\cot x = t, \Rightarrow -\operatorname{cosec}^2 x\, dx = dt$]

$$= -\left\{\frac{3}{2} t^{2/3} + \frac{3}{8} t^{8/3}\right\} + C$$

$$= -\left\{\frac{3}{2} (\cot^{2/3} x) + \frac{3}{8} (\cot^{8/3} x)\right\} + C$$

Example 89 Evaluate $\int \frac{dx}{2\sin x + \sec x}$.

Sol. Let $I = \int \frac{dx}{2\sin x + \sec x} = \int \frac{\cos x\, dx}{\sin 2x + 1} = \frac{1}{2}\int \frac{2\cos x\, dx}{1 + \sin 2x}$

$$= \frac{1}{2}\int \frac{(\cos x + \sin x) + (\cos x - \sin x)}{(\sin^2 + \cos^2 x + 2\sin x \cos x)}\, dx$$

$$= \frac{1}{2}\int \frac{\cos x + \sin x}{(\sin x + \cos x)^2}\, dx + \frac{1}{2}\int \frac{(\cos x - \sin x)}{(\sin x + \cos x)^2}\, dx$$

$$= \frac{1}{2}\int \frac{dx}{\sin x + \cos x} + \frac{1}{2}\int \frac{dv}{v^2}, \text{ where, } v = \sin x + \cos x$$

$$= \frac{1}{2\sqrt{2}}\int \frac{dx}{\frac{1}{\sqrt{2}}\sin x + \frac{1}{\sqrt{2}}\cos x} - \frac{1}{2v} + C$$

$$= \frac{1}{2\sqrt{2}}\int \frac{dx}{\sin\left(x + \frac{\pi}{4}\right)} - \frac{1}{2(\sin x + \cos x)} + C$$

$$= \frac{1}{2\sqrt{2}} \log\left|\operatorname{cosec}\left(x + \frac{\pi}{4}\right) - \cot\left(x + \frac{\pi}{4}\right)\right| - \frac{1}{2(\sin x + \cos x)} + C$$

Type IV

Integrals of the Form $\int x^m (a + bx^n)^P dx$

Case I If $P \in N$. We expand using binomial and integrate.

Case II If $P \in I^-$ (*ie*, negative integer), write $x = t^k$, where k is the LCM of m and n.

Case III If $\frac{m+1}{n}$ is an integer and $P \leftrightarrow$ fraction, put $(a + b\, x^n) = t^k$, where k is denominator of the fraction P.

Case IV If $\left(\frac{m+1}{n} + P\right)$ is an integer and $P \in$ fraction.

We put $(a + b\, x^n) = t^k x^n$, where k is denominator of the fraction P.

Example 90 Evaluate $\int x^{1/3} (2 + x^{1/2})^2\, dx$.

Sol. $I = \int x^{1/3} (2 + x^{1/2})^2\, dx$

Since, P is natural number.

$$\therefore \quad I = \int x^{1/3} (4 + x + 4x^{1/2})\, dx$$

$$= \int (4x^{1/3} + x^{4/3} + 4x^{5/6})\, dx$$

$$= \frac{4x^{4/3}}{4/3} + \frac{x^{7/3}}{7/3} + \frac{4x^{11/6}}{11/6} + C$$

$$= 3x^{4/3} + \frac{3}{7} x^{7/3} + \frac{24}{11} x^{11/6} + C$$

Example 91 Evaluate $\int x^{-2/3}\,(1+x^{2/3})^{-1}\,dx$.

Sol. If we substitute $x = t^3$ (as we know $P \in$ negative integer)

$\therefore$ Let $x = t^k$, where k is the LCM of m and n.

$\therefore \quad x = t^3 \Rightarrow dx = 3t^2\,dt$

or $\quad I = \int \frac{3t^2}{t^2(1+t^2)}\,dt = 3\int \frac{dt}{t^2+1} = 3\tan^{-1}(t) + C$

$\Rightarrow \quad I = 3\tan^{-1}(x^{1/3}) + C$

Example 92 Evaluate $\int x^{-2/3}\,(1+x^{1/3})^{1/2}\,dx$.

Sol. If we substitute $1 + x^{1/3} = t^2$, then $\frac{1}{3x^{2/3}}\,dx = 2t\,dt$

$\therefore \quad I = \int \frac{t \cdot 6t\,dt}{1} = 6\int t^2\,dt = 2t^3 + C$

or $\quad I = 2(1 + x^{1/3})^{3/2} + C$

Example 93 Evaluate $\int \sqrt{x}\,(1+x^{1/3})^4\,dx$.

Sol. Here, $m = \frac{1}{2}$ and $n = \frac{1}{3}$

Put $\quad x = t^6 \Rightarrow dx = 6t^5\,dt$

$\Rightarrow \quad I = \int t^3\,(1+t^2)^4\,6t^5\,dt$

$\Rightarrow \quad I = 6\int t^8\,(1 + 4t^2 + 6t^4 + 4t^6 + t^8)\,dt$

$$= 6\int (t^8 + 4t^{10} + 6t^{12} + 4t^{14} + t^{16})\,dt$$

$$= 6\left\{\frac{t^9}{9} + \frac{4t^{11}}{11} + \frac{6t^{13}}{13} + \frac{4t^{15}}{15} + \frac{t^{17}}{17}\right\} + C$$

$$I = 6\left\{x^{2/3} + \frac{4}{11}x^{11/6} + \frac{6}{13}x^{13/6} + \frac{4}{15}x^{5/2} + \frac{1}{17}x^{17/6}\right\} + C$$

Example 94 Evaluate $\int x^5\,(1+x^3)^{2/3}\,dx$.

Sol. Here, $\int x^5\,(1+x^3)^{2/3}\,dx$ have $m = 5, n = 3$ and $p = \frac{2}{3}$

$\therefore \quad \frac{m+1}{n} = \frac{6}{3} = 2$ [an integer]

So, we substitute $1 + x^3 = t^2$ and $3x^2\,dx = 2t\,dt$

$$\therefore \int x^5(1+x^3)^{2/3}dx = \int x^3\,(1+x^3)^{2/3}x^2dx$$

$$= \int (t^2-1)\,(t^2)^{2/3}\,\frac{2}{3}\,t\,dt$$

$$= \frac{2}{3}\int (t^2-1)\,t^{7/3}dt = \frac{2}{3}\int (t^{13/3} - t^{7/3})\,dt$$

$$= \frac{2}{3}\left\{\frac{3}{16}t^{16/3} - \frac{3}{10}t^{10/3}\right\} + C$$

$$= \frac{1}{8}(1+x^3)^{8/3} - \frac{1}{5}(1+x^3)^{5/3} + C$$

Example 95 Evaluate $\int x^{-11}\,(1+x^4)^{-1/2}\,dx$.

Sol. Here, $\left(\frac{m+1}{n} + p\right) = \left[\frac{-11+1}{4} - \frac{1}{2}\right] = -3$

If we substitute $(1 + x^4) = t^2\,x^4$,

then $1 + \frac{1}{x^4} = t^2$ and $\frac{-4}{x^5}\,dx = 2t\,dt$

$$\therefore \quad I = \int \frac{dx}{x^{11}\,(1+x^4)^{1/2}} = \int \frac{dx}{x^{11}\cdot x^2\,(1+1/x^4)^{1/2}}$$

$$= \int \frac{dx}{x^{13}\,(1+1/x^4)^{1/2}} = -\frac{1}{4}\int \frac{2t\,dt}{x^8\,t}$$

$$= -\frac{1}{2}\int (t^2-1)^2\,dt = -\frac{1}{2}\int (t^4 - 2t^2 + 1)\,dt$$

$$= -\frac{1}{2}\left[\frac{t^5}{5} - \frac{2t^3}{3} + t\right] + C$$

Where $t = \sqrt{1 + \frac{1}{x^4}}$

Example 96 Evaluate $\int \frac{1}{\sqrt[3]{x} + \sqrt[4]{x}}\,dx$.

Sol. Let $\quad I = \int \frac{1}{\sqrt[3]{x} + \sqrt[4]{x}}\,dx$

Put $\quad x^{1/12} = t, \quad \Rightarrow \quad x = t^{12}$ and $dx = 12t^{11}\,dt$

$$\therefore \quad I = \int \frac{1}{t^4 + t^3}\cdot 12\,t^{11}\,dt = 12\int \frac{t^8}{t+1}\,dt$$

Again put $(t + 1) = y$

$$\therefore\ dt = dy = 12\int \frac{(y-1)^8}{y}\,dy$$

$$= 12\int \frac{(y^8 - 8y^7 + 28y^6 - 56y^5 + 70y^4 - 56y^3 + 28y^2 - 8y + 1)}{y}dy$$

[using binomial]

$$= 12\int (y^7 - 8y^6 + 28y^5 - 56y^4 + 70y^3 - 56y^2 + 28y - 8 + 1/y)dy$$

$$= 12\left(\frac{y^8}{8} - \frac{8y^7}{7} + \frac{28y^6}{6} - \frac{56y^5}{5} + \frac{70y^4}{4} - \frac{56y^3}{3} + \frac{28y^2}{2} - 8y + \log|y|\right) + C_1$$

Where $\quad y = x^{1/12} + 1$

Exercise for Session 6

■ Evaluate the following integrals

1. $\int \frac{x^4 - 1}{x^{2(}x^4 + x^2 + 1)^{1/2}}\, dx$

2. $\int \frac{(x+2)\, dx}{(x^2 + 3x + 3)\sqrt{x+1}}$

3. $\int \frac{dx}{(x+1)^{1/3} + (x+1)^{1/2}}$

4. $\int \frac{dx}{(x+a)^{8/7}(x-b)^{6/7}}$

5. $\int \frac{\sec x\, .dx}{\sqrt{\sin(x+2A) + \sin A}}$

6. The value of $\int [\{x\}]\, dx$; (where $[.]$ and $\{.\}$ denotes greatest integer and fractional part of x) is equal to

(a) 0 (b) 1
(c) 2 (d) – 1

7. If $\int f(x)\cos x\, dx = \frac{1}{2} f^2(x) + C$, then $f(x)$ can be

(a) x (b) 1
(c) $\cos x$ (d) $\sin x$

8. The value of, $\int \frac{\sin x + \cos x}{9 + 16\sin 2x}\, dx$ is

(a) $\frac{1}{40}\log\left|\frac{5+4(\sin x - \cos x)}{5-4(\sin x - \cos x)}\right| + C$ (b) $\log\left|\frac{5+4(\sin x - \cos x)}{5-4(\sin x - \cos x)}\right| + C$

(c) $\frac{1}{10}\log\left|\frac{5+4(\sin x + \cos x)}{5-4(\sin x + \cos x)}\right| + C$ (d) None of these

9. The value of $\int \frac{\cos 7x - \cos 8x}{1 + 2\cos 5x}\, dx$, is

(a) $\frac{\sin 2x}{2} + \frac{\cos 3x}{3} + C$ (b) $\sin x - \cos x + C$

(c) $\frac{\sin 2x}{2} - \frac{\cos 3x}{3} + C$ (d) None of these

10. The value of $\int \frac{\cos 5x + \cos 4x}{1 - 2\cos 3x}\, dx$, is

(a) $\sin x + \sin 2x + C$ (b) $\sin x - \frac{\sin 2x}{2} + C$

(c) $-\sin x - \frac{\sin 2x}{2} + C$ (d) None of these

Session 7

Euler's Substitution, Reduction Formula and Integration Using Diffrentiation

Euler's Substitution, Reduction and Integration Using Diffrentiation

Integration Using Euler's Substitutions

Integrals of the form $\int f(x), \sqrt{ax^2+bx+c}\,dx$ are calculated with the aid of one of the three Euler's substitutions

(i) $\sqrt{ax^2+bx+c} = t \pm x\sqrt{a}$, if $a>0$.

(ii) $\sqrt{ax^2+bx+c} = tx+\sqrt{c}$, if $c>0$.

(iii) $\sqrt{ax^2+bx+c} = (x-\alpha)\,t$, if $ax^2+bx+c = a(x-\alpha)(x-\beta)$, i.e. If α is real root of (ax^2+bx+c).

Remark

The Euler's substitutions often lead to rather cumbersome calculations, therefore they should be applied only when it is difficult to find another method for calculating a given integral.

Example 97 *Evaluate* $I = \int \frac{x\,dx}{(\sqrt{7x-10-x^2})^3}$.

Sol. In this case $a<0$ and $c<0$. Therefore, neither (I) nor (II) Euler's Substitution is applicable. But the quadratic $7x-10-x^2$ has real roots $\alpha=2, \beta=5$.

$\therefore$ We use the substitution (III)

i.e. $\sqrt{7x-10-x^2} = \sqrt{(x-2)(5-x)} = (x-2)\,t$

Where $(5-x) = (x-2)\,t^2$

or $5+2t^2 = x(1+t^2)$

$\therefore$ $x = \frac{5+2t^2}{1+t^2}$

$(x-2)\,t = \left(\frac{5+2t^2}{1+t^2}-2\right)t = \frac{3t}{1+t^2}$

$\therefore$ $dx = \frac{-6t}{(1+t^2)^2}\,dt$

Hence, $I = \int \frac{x\,dx}{(\sqrt{7x-10-x^2})^3} = \int \frac{\left(\frac{5+2t^2}{1+t^2}\right)\cdot\frac{-6t}{(1+t^2)^2}\,dt}{\left(\frac{3t}{1+t^2}\right)^3}$

$= \frac{-6}{27}\int \frac{5+2t^2}{t^2}\,dt$

$= \frac{-2}{9}\int\left(\frac{5}{t^2}+2\right)dt = \frac{-2}{9}\left[\frac{-5}{t}+2t\right]+C$

$\therefore$ $\int \frac{x\,dx}{(\sqrt{7x-10-x^2})^3} = \frac{-2}{9}\left(\frac{-5}{t}+2t\right)+C$,

where, $t = \frac{\sqrt{7x-10-x^2}}{x-2}$

Example 98 Evaluate $\int \frac{dx}{x+\sqrt{x^2-x+1}}$.

Sol. Since, here $c=1$, we can apply the second Euler's Substitution.

$\sqrt{x^2-x+1} = tx-1$

Therefore, $(2t-1)\,x = (t^2-1)\,x^2 \Rightarrow x = \frac{2t-1}{t^2-1}$

$\therefore$ $dx = -\frac{2(t^2-t+1)\,dt}{(t^2-1)^2}$ and $x+\sqrt{x^2-x+1} = \frac{t}{t-1}$

$\therefore$ $I = \int \frac{dx}{x+\sqrt{x^2-x+1}} = \int \frac{-2t^2+2t-2}{t(t-1)(t+1)^2}\,dt$

Using partial fractions, we have

$\frac{-2t^2+2t-2}{t(t-1)(t+1)^2} = \frac{A}{t}+\frac{B}{t-1}+\frac{C}{(t+1)}+\frac{D}{(t+1)^2}$

or $(-2t^2+2t-2) = A(t-1)(t+1)^2 + Bt(t+1)^2 + C(t-1)(t+1)t + Dt$

we get $A=2, \quad B=-1/2, \quad C=-3/2, \quad D=-3$

Hence, $I = 2\int\frac{dt}{t} - \frac{1}{2}\int\frac{dt}{t-1} - \frac{3}{2}\int\frac{dt}{(t+1)} - 3\int\frac{dt}{(t+1)^2}$

$= 2\log_e|t| - \frac{1}{2}\log_e|t-1| - \frac{3}{2}\log_e|t+1| + \frac{3}{(t+1)} + C$

$\left[\text{where } t = \frac{\sqrt{x^2-x+1}+1}{x}\right]$

Introduction of Reduction Formulae (a recursive relation) Over Indefinite Integrals

Reduction formulae makes it possible to reduce an integral depending on the index $n > 0$, called the order of the integral, to an integral of the same type with smaller index. (i.e. To reduce the integrals into similar integrals of order less than or greater than given integral).

Application of reduction formula is given with the help of some examples.

Reduction Formula for $\int \sin^n x\,dx$

Let $I_n = \int \sin^n x\,dx = \int \underset{\text{I}}{\sin^{n-1} x} \underset{\text{II}}{\sin x}\,dx$

$= -\sin^{n-1} x \cos x + \int (n-1)\sin^{n-2} x \cos^2 x\,dx$

$= -\sin^{n-1} x \cos x + (n-1)\int \sin^{n-2} x(1-\sin^2 x)\,dx$

$= -\sin^{n-1} x \cos x + (n-1)\int (\sin^{n-2} x - \sin^n x)\,dx$

$= -\sin^{n-1} x \cos x + (n-1) I_{n-2} - (n-1) I_n$

$\therefore n I_n = -\sin^{n-1} x \cos x + (n-1) I_{n-2}$

$\Rightarrow I_n = -\dfrac{\sin^{n-1} x \cos x}{n} + \dfrac{n-1}{n} I_{n-2}$

Thus, $\int \sin^n x\,dx = \dfrac{-\sin^{n-1} x \cos x}{n} + \dfrac{n-1}{n}\int \sin^{n-2} x\,dx$

Reduction Formula for $\int \cos^n x\,dx$

Let $I_n = \int \cos^n x\,dx = \int \underset{\text{I}}{\cos^{n-1} x} \underset{\text{II}}{\cos x}\,dx$

$= \cos^{n-1} x \sin x + \int (n-1)\cos^{n-2} x \sin^2 x\,dx$

$= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x (1-\cos^2 x)\,dx$

$= \cos^{n-1} x \sin x + (n-1) I_{n-2} - (n-1) I_n$

$\therefore \quad nI_n = \cos^{n-1} x \sin x + (n-1) I_{n-2}$

or $\int \cos^n x\,dx = \dfrac{\cos^{n-1} x \sin x}{n} + \dfrac{n-1}{n}\int \cos^{n-2} x\,dx$

Reduction Formula for $\int \tan^n x\,dx$

Let $I_n = \int \tan^n x\,dx$

$\Rightarrow I_n = \int \tan^{n-2} x \tan^2 x\,dx = \int \tan^{n-2} x (\sec^2 x - 1)\,dx$

$= \int \tan^{n-2} x \sec^2 x - I_{n-2} = \int t^{n-2}\,dt - I_{n-2}$

where, $\tan x = t \Rightarrow \sec^2 x\,dx = dt$

$I_n = \dfrac{t^{n-1}}{n-1} - I_{n-2}$

$\therefore \quad I_n = \dfrac{\tan^{n-1} x}{n-1} - I_{n-2}$

$\Rightarrow \quad \int \tan^n x\,dx = \dfrac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x\,dx$

Reduction Formula for $\int \text{cosec}^n x\,dx$

Let $I_n = \int \text{cosec}^n x\,dx = \int \underset{\text{I}}{\text{cosec}^{n-2} x} \underset{\text{II}}{\text{cosec}^2 x}\,dx$

$= \text{cosec}^{n-2} x\,(-\cot x) - \int (n-2)\,\text{cosec}^{n-2} x\,(\text{cosec}^2 x - 1)\,dx$

$= -\text{cosec}^{n-2} x \cot x - (n-2)\int (\text{cosec}^n x - \text{cosec}^{n-2} x)\,dx$

$= -\text{cosec}^{n-2} x \cot x - (n-2) I_n + (n-2) I_{n-2}$

$\therefore \quad (n-1) I_n = -\text{cosec}^{n-2} x \cot x + (n-2) I_{n-2}$

or $I_n = -\dfrac{\text{cosec}^{n-2} x \cot x}{n-1} + \dfrac{n-2}{n-1} I_{n-2}$

$\therefore \int \text{cosec}^n x\,dx = -\dfrac{\text{cosec}^{n-2} x \cot x}{n-1} + \dfrac{n-2}{n-1}\int \text{cosec}^{n-2} x\,dx$

Reduction Formula for $\int \sec^n x\,dx$

Let $I_n = \int \sec^n x\,dx = \int \underset{\text{I}}{\sec^{n-2} x} \underset{\text{II}}{\sec^2 x}\,dx$

$= \sec^{n-2} x \tan x - \int (n-2)\sec^{n-3} x \sec x \tan x \cdot \tan x\,dx$

$= \sec^{n-2} x \tan x - (n-2)\int \sec^{n-2} x (\sec^2 x - 1)\,dx$

$= \sec^{n-2} x \tan x - (n-2) I_n + (n-2) I_{n-2}$

$\Rightarrow (n-1) I_n = \sec^{n-2} x \tan x + (n-2) I_{n-2}$

or $I_n = \dfrac{\sec^{n-2} x \tan x}{(n-1)} + \dfrac{(n-2)}{(n-1)} I_{n-2}$

$\therefore \int \sec^n x\,dx = \dfrac{\sec^{n-2} x \tan x}{(n-1)} + \dfrac{(n-2)}{(n-1)}\int \sec^{n-2} x\,dx$

Reduction Formula for $\int \cot^n x\,dx$

Let $I_n = \int \cot^n x\,dx = \int \cot^{n-2} x \cot^2 x\,dx$

$= \int \cot^{n-2} x\,(\text{cosec}^2 x - 1)\,dx$

$= \int \cot^{n-2} x\,(\text{cosec}^2 x - 1)\,dx = \int \cot^{n-2} x\,dx$

$= \int t^{n-2}\,dt - I_{n-2}$, where $t = \cot x$

$$I_n = -\frac{\cot^{n-1} x}{n-1} - I_{n-2}$$

$$\therefore \quad \int \cot^n x\, dx = -\frac{\cot^{n-1} x}{n-1} - \int \cot^{n-2} x\, dx$$

Reduction Formula for $\int \sin^m x \cos^n x\, dx$

Let $A = \sin^{m-1} x \cos^{n+1} x$

$$\therefore \quad \frac{dA}{dx} = (m-1)\sin^{m-2} x \cos^{n+2} x - (n+1)\sin^m x \cos^n x$$

$$= (m-1)\sin^{m-2} x \cos^n x\,(1-\sin^2 x) - (n+1)\sin^m x \cos^n x$$

$$= (m-1)\sin^{m-2} x \cos^n x - (m-1+n+1)\sin^m x \cos^n x$$

$$\Rightarrow \quad \frac{dA}{dx} = (m-1)\sin^{m-2} x \cos^n x - (m+n)\sin^m x \cos^n x$$

Integrating with respect to x on both the sides, we get

$$A = (m-1)\int \sin^{m-2} x \cos^n x\, dx - (m+n)\int \sin^m x \cos^n x\, dx$$

$$\Rightarrow \quad (m+n)\int \sin^m x \cos^n x\, dx = (m-1)\int \sin^{m-2} x \cos^n x\, dx - P$$

$$\Rightarrow \quad \int \sin^m x \cos^n x\, dx = \frac{(m-1)}{(m+n)}\int \sin^{m-2} x \cos^n x\, dx - \frac{\sin^{m-1} x \cos^{n+1} x}{m+n}$$

or $$I_{m,n} = \frac{(m-1)}{(m+n)} I_{m-2,n} - \frac{\sin^{m-1} x \cos^{n+1} x}{(m+n)}$$

Remarks

Similarly, we can show

1. $\int \sin^m x \cos^n x\, dx = \frac{\sin^{m+1} x \cos^{n+1} x}{m+n} + \frac{n-1}{m+n}\int \sin^m x \cos^{n-2} x\, dx$

2. $\int \sin^m x \cos^n x\, dx = \frac{\sin^{m+1} x \cos^{n+1} x}{m+1} + \frac{m+n+2}{m+1}\int \sin^{m+2} x \cos^n x\, dx$

3. $\int \sin^m x \cos^n x\, dx = \frac{\sin^{m+1} x \cos^{n+1} x}{n+1} + \frac{m+n+2}{n+1}\int \sin^m x \cos^{n+2} x\, dx$

4. $\int \sin^m x \cos^n x\, dx = -\frac{\sin^{m-1} x \cos^{n+1} x}{n+1} + \frac{m-1}{n+1}\int \sin^{m-2} x \cos^{n+2} x\, dx$

5. $\int \sin^m x \cos^n x\, dx = \frac{\sin^{m+1} x \cos^{n-1} x}{m+1} + \frac{n-1}{m+1}\int \sin^{m+2} x \cos^{n-2} x\, dx$

Reduction Formula for $\int \cos^m x \sin nx\, dx$

Let $I_{m,n} = \int \underset{\text{I}}{\cos^m x} \underset{\text{II}}{\sin nx}\, dx$

$$= -\frac{\cos^m x \cos nx}{n} - \frac{m}{n}\int \cos^{m-1} x \sin x \cos nx\, dx$$

$$= -\frac{\cos^m x \cos nx}{n} - \frac{m}{n}\int \cos^{m-1} x \{\sin nx \cos x - \sin(n-1)x\}\, dx$$

[using $\sin(n-1)x = \sin nx \cos x - \cos nx \sin x$

$\Rightarrow \sin x \cos nx = \sin nx \cos x - \sin(n-1)x$]

$$= -\frac{\cos^m x \cos nx}{n} - \frac{m}{n}\int \cos^m x \sin nx\, dx + \frac{m}{n}\int \cos^{m-1} x \sin(n-1)x\, dx$$

$$I_{m,n} = -\frac{\cos^m x \cos nx}{n} - \frac{m}{n} I_{m,n} + \frac{m}{n} I_{m-1,n-1}$$

$$\Rightarrow \quad \frac{m+n}{n} I_{m,n} = -\frac{\cos^m x \cos nx}{n} + \frac{m}{n} I_{m-1,n-1}$$

or $$I_{m,n} = -\frac{\cos^m x \cos nx}{m+n} + \frac{m}{m+n} I_{m-1,n-1}$$

Remarks

Similarly, we can show

1. $\int \cos^m x \cos nx\, dx = \frac{\cos^m x \sin nx}{m+n} + \frac{m}{m+n}\int \cos^{m-1} x \cos(n-1)x\, dx$

2. $\int \sin^m x \sin nx\, dx = \frac{n \sin^m x \cos nx}{m^2-n^2} - \frac{m \sin^{m-1} x \cos x \cos nx}{m^2-n^2} + \frac{m(m-1)}{m^2-n^2}\int \sin^{m-2} x \sin nx\, dx$

3. $\int \sin^m x \cos nx\, dx = \frac{n \sin^m x \sin nx}{m^2-n^2} - \frac{m \sin^{m-1} x \cos x \cos nx}{m^2-n^2} + \frac{m(m-1)}{m^2-n^2}\int \sin^{m-2} x \cos nx\, dx$

Example 99 Evaluate $I_n = \int \frac{dx}{(x^2+a^2)^n}$.

Sol. Here, $I_n = \int \frac{dx}{(x^2+a^2)^n} = \int \frac{1}{(x^2+a^2)^n} \cdot 1\, dx$

Applying Integration by parts, we get

$$= \frac{1}{(x^2+a^2)^n} \cdot x - \int \frac{(2x)}{(x^2+a^2)^{n+1}} \cdot (-n) \cdot (x)\, dx$$

$$= \frac{x}{(x^2+a^2)^n} + 2n\int \frac{x^2}{(x^2+a^2)^{n+1}}\, dx$$

$$= \frac{x}{(x^2+a^2)^n} + 2n\int \frac{x^2+a^2-a^2}{(x^2+a^2)^{n+1}}\, dx$$

$$\therefore \quad I_n = \frac{x}{(x^2+a^2)^n} + 2n\int \frac{1}{(x^2+a^2)^n}\,dx - 2a^2 n\int \frac{dx}{(x^2+a^2)^{n+1}}$$

$$I_n = \frac{x}{(x^2+a^2)^n} + 2n\,I_n - 2n\,a^2\,I_{n+1}$$

$$\therefore \quad 2n\,a^2\,I_{n+1} = \frac{x}{(x^2+a^2)^n} + (2n-1)\,I_n$$

$$\text{or} \qquad I_{n+1} = \frac{1}{2n\,a^2}\cdot\frac{x}{(x^2+a^2)^n} + \frac{(2n-1)}{2n}\cdot\frac{1}{a^2}\,I_n$$

Remark

Above obtained formula reduces the calculations of the integral I_{n+1} to the calculations of the integral I_n and consequently, allows us to calculate completely an integral with natural index, as

$$I_1 = \int \frac{dx}{x^2+a^2} = \frac{1}{a}\tan^{-1}\left(\frac{x}{a}\right) + C$$

$\therefore$ From above formula

Let $n = 1$

$$I_2 = \int \frac{dx}{(x^2+a^2)^2} = \frac{1}{2a^2}\cdot\frac{x}{x^2+a^2} + \frac{1}{2a^2}\cdot I_1$$

$$= \frac{1}{2a^2}\cdot\frac{x}{x^2+a^2} + \frac{1}{2a^2}\cdot\frac{1}{a}\cdot\tan^{-1}\left(\frac{x}{a}\right) + C$$

$$= \frac{1}{2a^2}\cdot\frac{x}{x^2+a^2} + \frac{1}{2a^3}\cdot\tan^{-1}\left(\frac{x}{a}\right) + C$$

Let $n = 2$

$$I_3 = \int \frac{dx}{(x^2+a^2)^3} = \frac{1}{4a^2}\cdot\frac{x}{(x^2+a^2)^2} + \frac{3}{4a^2}\,I_2$$

$$= \frac{1}{4a^2}\cdot\frac{x}{(x^2+a^2)^2} + \frac{3}{8a^4}\cdot\frac{x}{x^2+a^2} + \frac{3}{8a^5}\tan^{-1}\left(\frac{x}{a}\right) + C$$

...and so on.

Example 100 Derive reduction formula for $I_{(n,m)} = \int \frac{\sin^n x}{\cos^m x}\,dx$.

Sol. Using Integration by parts for $I_{(n,m)}$, we get

$$I_{(n,m)} = \int \underset{\text{I}}{\sin^{n-1} x}\;\underset{\text{II}}{\frac{\sin x}{\cos^m x}}\,dx$$

$$= \sin^{n-1} x\cdot\frac{(\cos x)^{-m+1}}{(m-1)} - \int (n-1)\sin^{n-2} x\cdot\cos x\cdot\frac{(\cos x)^{-m+1}}{(m-1)}\,dx$$

$$= \frac{1}{m-1}\cdot\frac{\sin^{n-1} x}{\cos^{m-1} x} - \frac{(n-1)}{(m-1)}\cdot\int\frac{\sin^{n-2} x}{\cos^{m-2} x}\,dx$$

$$I_{n,m} = \frac{1}{(m-1)}\cdot\frac{\sin^{n-1} x}{\cos^{m-1} x} - \frac{(n-1)}{(m-1)}\cdot I_{(n-2,\,m-2)}$$

is required reduction formula.

Integration Using Differentiation

In $\int\frac{dx}{(a+b\cos x)^2}$, $\int\frac{dx}{(a+b\sin x)^2}$, $\int\frac{dx}{(\sin x + a\sec x)^2}$, $\int\frac{a+b\sin x}{(b+a\sin x)^2}\,dx$,... we follow the following method.

1. Let $A = \frac{\sin x}{a+b\cos x}$ or $A = \frac{\cos x}{a+b\sin x}$ according to the integral to evaluated is of the form
$$\int\frac{dx}{(a+b\cos x)^2} \quad \text{or} \quad \int\frac{dx}{(a+b\sin x)^2}$$
2. Find $\frac{dA}{dx}$ and express it in terms of $\frac{1}{a+b\cos x}$ or $\frac{1}{a+b\sin x}$ as the case may be.
3. Integrate both the sides of the expression obtained in step 2 to obtain the value of the required integral.

Example 101 ***Evaluate*** $\int\frac{dx}{(5+4\cos x)^2}$.

Sol. Here, $A = \frac{\sin x}{5+4\cos x}$, then

$$\frac{dA}{dx} = \frac{(5+4\cos x)(\cos x) - \sin x(-4\sin x)}{(5+4\cos x)^2}$$

$$\Rightarrow \quad \frac{dA}{dx} = \frac{5\cos x + 4}{(5+4\cos x)^2} = \frac{\frac{5}{4}(4\cos x + 5) + 4 - \frac{25}{4}}{(5+4\cos x)^2}$$

$$\Rightarrow \quad \frac{dA}{dx} = \frac{5}{4}\cdot\frac{1}{(5+4\cos x)} - \frac{9}{4}\cdot\frac{1}{(5+4\cos x)^2}$$

Integrating both the sides w.r.t. 'x', we get

$$A = \frac{5}{4}\int\frac{dx}{5+4\cos x} - \frac{9}{4}\int\frac{dx}{(5+4\cos x)^2}$$

$$\Rightarrow \quad \frac{9}{4}\int\frac{dx}{(5+4\cos x)^2} = \frac{5}{4}\int\frac{dx}{5+4\cos x} - A$$

$$= \frac{5}{4}\int\frac{dx}{5+4\frac{(1-\tan^2 x/2)}{(1+\tan^2 x/2)}} - \frac{\sin x}{(5+4\cos x)}$$

$$\Rightarrow \int\frac{dx}{(5+4\cos x)^2} = \frac{5}{9}\int\frac{1+\tan^2 x/2}{9+\tan^2 x/2}\,dx - \frac{4}{9}\cdot\frac{\sin x}{5+4\cos x}$$

$$\Rightarrow \int\frac{dx}{(5+4\cos x)^2} = \frac{5}{9}\int\frac{2\,dt}{9+t^2} - \frac{4}{9}\cdot\frac{\sin x}{5+4\cos x}$$

(where $\tan x/2 = t$)

$$\Rightarrow \int \frac{dx}{(5+4\cos x)^2} = \frac{10}{9}\cdot\frac{1}{3}\tan^{-1}\left(\frac{t}{3}\right) - \frac{4}{9}\cdot\frac{\sin x}{5+4\cos x}$$

$$\Rightarrow \int \frac{dx}{(5+4\cos x)^2} = \frac{10}{27}\tan^{-1}\left(\frac{\tan x/2}{3}\right) - \frac{4}{9}\left(\frac{\sin x}{5+4\cos x}\right) + C$$

Example 102 Evaluate $\int \frac{dx}{(16+9\sin x)^2}$.

Sol. Let $A = \frac{\cos x}{16+9\sin x}$ ...(i)

$$\Rightarrow \frac{dA}{dx} = \frac{(16+9\sin x)(-\sin x) - \cos x(9\cos x)}{(16+9\sin x)^2}$$

$$\Rightarrow \frac{dA}{dx} = \frac{-16\sin x - 9}{(16+9\sin x)^2}$$

$$\Rightarrow \frac{dA}{dx} = \frac{-\frac{16}{9}(9\sin x + 16) + \frac{256}{9} - 9}{(16+9\sin x)^2}$$

$$\Rightarrow \frac{dA}{dx} = -\frac{16}{9}\cdot\frac{1}{(16+9\sin x)} + \frac{175}{9(16+9\sin x)^2} \quad ...(ii)$$

Integrating both the sides of Eq. (ii) w.r.t. 'x', we get

$$A = -\frac{16}{9}\int \frac{dx}{16+9\sin x} + \frac{175}{9}\int \frac{dx}{(16+9\sin x)^2}$$

$$\Rightarrow \frac{175}{9}\int \frac{dx}{(16+9\sin x)^2} = A + \frac{16}{9}\int \frac{(1+\tan^2 x/2)\,dx}{16+16\tan^2 x/2 + 18\tan x/2}$$

$$\Rightarrow \frac{175}{9}\int \frac{dx}{(16+9\sin x)^2} = A + \frac{16}{9}\int \frac{2\,dt}{16t^2+18t+16}$$

[where $\tan x/2 = t$]

$$\Rightarrow \frac{175}{9}\int \frac{dx}{(16+9\sin x)^2} = A + \frac{2}{9}\int \frac{dt}{t^2 + \frac{9}{8}t + 1}$$

$$= A + \frac{2}{9}\int \frac{dt}{\left(t+\frac{9}{16}\right)^2 + \left(\frac{\sqrt{175}}{16}\right)^2}$$

$$= A + \frac{2}{9}\times\frac{16}{\sqrt{175}}\tan^{-1}\left(\frac{16t+9}{\sqrt{175}}\right)$$

$$\Rightarrow \int \frac{dx}{(16+9\sin x)^2} = \frac{9}{175}\cdot\frac{\cos x}{(16+9\sin x)} + \frac{2}{(175)^{3/2}}\tan^{-1}\left(\frac{16\tan x/2+9}{\sqrt{175}}\right) + C$$

Example 103 Evaluate $\int \frac{dx}{(\sin x + a\sec x)^2}$ when $|a| > 1/2$.

Sol. Here, $I = \int \frac{dx}{(\sin x + a\sec x)^2}$ or $I = \int \frac{\cos^2 x\,dx}{(\sin x\cos x + a)^2}$

$$= \int \frac{\cos^2 x\,dx}{a^2 + 2a\sin x\cos x + \sin^2 x\cos^2 x}$$

$$= \int \frac{\cos^2 x\,dx}{a^2 + a\sin 2x + \frac{1}{4}\sin^2 2x}$$

$$= \int \frac{4\cos^2 x\,dx}{(4a^2 + 4a\sin 2x + \sin^2 2x)} = 2\int \frac{(1+\cos 2x)\,dx}{(2a+\sin 2x)^2}$$

$$= 2\int \frac{dx}{(2a+\sin 2x)^2} + 2\int \frac{\cos 2x\,dx}{(2a+\sin 2x)^2}$$

$$\Rightarrow I = 2I_1 + \int \frac{dt}{t^2} \quad [\text{where } (2a+\sin 2x) = t, (2\cos 2x)\,dx = dt]$$

$$\Rightarrow I = 2I_1 - \frac{1}{(2a+\sin 2x)} + C$$

where $I_1 = \int \frac{dx}{(2a+\sin 2x)^2}$ ...(i)

Put $A = \frac{\cos 2x}{2a+\sin 2x}$

$$\Rightarrow \frac{dA}{dx} = \frac{(2a+\sin 2x)(-2\sin 2x) - \cos 2x(2\cos 2x)}{(2a+\sin 2x)^2}$$

$$\Rightarrow \frac{dA}{dx} = \frac{-4a\sin 2x - 2}{(2a+\sin 2x)^2}$$

$$\Rightarrow \frac{dA}{dx} = \frac{-4a(\sin 2x + 2a) - 2 + 8a^2}{(2a+\sin 2x)^2}$$

$$\Rightarrow \frac{dA}{dx} = -\frac{4a}{(2a+\sin 2x)} + \frac{(8a^2-2)}{(2a+\sin 2x)^2}$$

Integrating both the sides w.r.t. 'x', we get

$$\Rightarrow A = -4a\int \frac{dx}{(2a+\sin 2x)} + (8a^2-2)\,I_1$$

$$\Rightarrow (8a^2-2)\,I_1 = A + 4a\int \frac{\sec^2 x\,dx}{2a + 2\tan x + 2a\tan^2 x}$$

$$= A + \frac{4a}{2a}\int \frac{dt}{t^2 + \frac{t}{a} + 1}$$

$$= A + 2\int \frac{dt}{\left(t+\frac{1}{2a}\right)^2 + \left(1 - \frac{1}{4a^2}\right)}$$

$$= A + 2\frac{(2a)}{\sqrt{4a^2-1}}\tan^{-1}\left(\frac{(2at+1)}{\sqrt{4a^2-1}}\right)$$

$$\Rightarrow (8a^2-2)\,I_1 = \frac{\cos 2x}{2a+\sin 2x} + \frac{4a}{\sqrt{4a^2-1}}\tan^{-1}\left(\frac{(2a\tan x+1)}{\sqrt{4a^2-1}}\right) \quad ...(ii)$$

From Eqs. (i) and (ii)

$$I = \frac{1}{(4a^2-1)}\cdot\frac{\cos 2x}{(2a+\sin 2x)} + \frac{4a}{(4a^2-1)^{3/2}}\tan^{-1}\left(\frac{2a\tan x+1}{\sqrt{4a^2-1}}\right) - \frac{1}{(2a+\sin 2x)} + C$$

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *The value of* $\int \frac{dx}{\cos^6 x + \sin^6 x}$, *is equal to*

(a) $\tan^{-1}(2\cot 2x) + C$ (b) $\tan^{-1}(\cot 2x) + C$

(c) $\tan^{-1}\left(\frac{1}{2}\cot 2x\right) + C$ (d) $\tan^{-1}(-2\cot 2x) + C$

Sol. Let $I = \int \frac{dx}{\cos^6 x + \sin^6 x} = \int \frac{\sec^6 x\, dx}{1 + \tan^6 x}$

$$= \int \frac{(1 + \tan^2 x)^2 \cdot \sec^2 x}{1 + \tan^6 x}\, dx$$

Put $\tan x = t \Rightarrow \sec^2 x\, dx = dt = \int \frac{(1 + t^2)^2}{1 + t^6}\, dt$

$$= \int \frac{(1 + t^2)^2}{(1 + t^2)(1 - t^2 + t^4)}\, dt$$

$$= \int \frac{1 + t^2}{1 - t^2 + t^4}\, dt = \int \frac{(1 + 1/t^2)\, dt}{(1/t^2 - 1 + t^2)} = \int \frac{\left(1 + \frac{1}{t^2}\right) dt}{(t - 1/t)^2 + 1},$$

Put $t - \frac{1}{t} = z$

$\therefore \left(1 + \frac{1}{t^2}\right) dt = dz = \int \frac{dz}{z^2 + 1} = \tan^{-1}(z) + C$

$$= \tan^{-1}\left(\frac{t^2 - 1}{t}\right) + C = \tan^{-1}\left(\frac{\tan^2 x - 1}{\tan x}\right) + C$$

$$= \tan^{-1}(-2\cot 2x) + C$$

Hence, (d) is the correct answer.

● **Ex. 2** $\int \frac{e^{\tan^{-1} x}}{(1 + x^2)}\left[(\sec^{-1}\sqrt{1 + x^2})^2 + \cos^{-1}\left(\frac{1 - x^2}{1 + x^2}\right)\right] dx,$ *$(x > 0)$ is equal to*

(a) $e^{\tan^{-1} x} \cdot \tan^{-1} x + C$

(b) $\frac{e^{\tan^{-1} x} \cdot (\tan^{-1} x)^2}{2} + C$

(c) $e^{\tan^{-1} x} \cdot (\sec^{-1}(\sqrt{1 + x^2}))^2 + C$

(d) $e^{\tan^{-1} x} \cdot (\operatorname{cosec}^{-1}(\sqrt{1 + x^2}))^2 + C$

Sol. Note that $\sec^{-1}\sqrt{1 + x^2} = \tan^{-1} x$; $\cos^{-1}\left(\frac{1 - x^2}{1 + x^2}\right) = 2\tan^{-1} x$,

For $x > 0$

$$\Rightarrow \quad I = \int \frac{e^{\tan^{-1} x}}{1 + x^2}\{(\tan^{-1} x)^2 + 2\tan^{-1} x\}\, dx,$$

Put $\tan^{-1} x = t$

$$= \int e^t (t^2 + 2t)\, dt = e^t \cdot t^2 = e^{\tan^{-1} x}(\tan^{-1} x)^2 + C$$

Hence, (c) is the correct answer.

● **Ex. 3** *Let* $I = \int \frac{e^x}{e^{4x} + e^{2x} + 1}\, dx$, $J = \int \frac{e^{-x}}{e^{-4x} + e^{-2x} + 1}\, dx.$ *Then, for an arbitrary constant c, the value of* $J - I$ *equals to* **[IIT JEE 2008]**

(a) $\frac{1}{2}\log\left(\frac{e^{4x} - e^{2x} + 1}{e^{4x} + e^{2x} + 1}\right) + C$ (b) $\frac{1}{2}\log\left(\frac{e^{2x} + e^x + 1}{e^{2x} - e^x + 1}\right) + C$

(c) $\frac{1}{2}\log\left(\frac{e^{2x} - e^x + 1}{e^{2x} + e^x + 1}\right) + C$ (d) $\frac{1}{2}\log\left(\frac{e^{4x} + e^{2x} + 1}{e^{4x} - e^{2x} + 1}\right) + C$

Sol. $J = \int \frac{e^{3x}}{1 + e^{2x} + e^{4x}}\, dx$

$$J - I = \int \frac{(e^{3x} - e^x)}{1 + e^{2x} + e^{4x}}\, dx = \int \frac{(u^2 - 1)}{1 + u^2 + u^4}\, du \qquad (u = e^x)$$

$$= \int \frac{\left(1 - \frac{1}{u^2}\right) du}{1 + \frac{1}{u^2} + u^2} = \int \frac{\left(1 - \frac{1}{u^2}\right) du}{\left(u + \frac{1}{u}\right)^2 - 1} = \int \frac{dt}{t^2 - 1} \qquad \left(t = u + \frac{1}{u}\right)$$

$$= \frac{1}{2}\log\left|\frac{t - 1}{t + 1}\right| + C = \frac{1}{2}\log\left|\frac{u^2 - u + 1}{u^2 + u + 1}\right| + C$$

$$= \frac{1}{2}\log\left|\frac{e^{2x} - e^x + 1}{e^{2x} + e^x + 1}\right| + C$$

Hence, (c) is the correct answer.

● **Ex. 4** *Integral of* $\sqrt{1 + 2\cot x(\cot x + \operatorname{cosec} x)}$ *w.r.t. x, is*

(a) $2\ln\cos\frac{x}{2} + C$ (b) $2\ln\sin\frac{x}{2} + C$

(c) $\frac{1}{2}\ln\cos\frac{x}{2} + C$ (d) $\ln\sin x - \ln(\operatorname{cosec} x - \cot x) + C$

Sol. $I = \int \sqrt{1 + 2\operatorname{cosec} x \cot x + 2\cot^2 x}\, dx$

$$= \int \sqrt{\operatorname{cosec}^2 x + 2\operatorname{cosec} x \cot x + \cot^2 x}\, dx$$

$$= \int (\operatorname{cosec} x + \cot x)\, dx$$

$$= \int \frac{1 + \cos x}{\sin x}\, dx = \int \cot\left(\frac{x}{2}\right) dx = 2\log\left|\sin\frac{x}{2}\right| + C$$

Hence, (b) is the correct answer.

● **Ex. 5** *If* $I_n = \int \cot^n x\, dx$, *then* $I_0 + I_1 + 2(I_2 + I_3 + \ldots + I_8) + I_9 + I_{10}$ *equals to (where* $u = \cot x$*)*

(a) $u + \frac{u^2}{2} + \ldots + \frac{u^9}{9}$ (b) $-\left(u + \frac{u^2}{2} + \ldots + \frac{u^9}{9}\right)$

(c) $-\left(u + \frac{u^2}{2!} + \ldots + \frac{u^9}{9!}\right)$ (d) $\frac{u}{2} + \frac{2u^2}{3} + \ldots + \frac{9u^9}{10}$

Sol. $I_n = \int \cot^n x\, dx = \int \cot^{n-2} x \cdot (\operatorname{cosec}^2 x - 1)\, dx$

$$I_n = -\frac{u^{n-1}}{n-1} - I_{n-2} \quad \text{or} \quad I_n + I_{n-2} = -\frac{u^{n-1}}{n-1} \quad [\text{put } n = 2, 3, 4, \ldots, 10]$$

$$I_2 + I_0 = -\frac{u}{1}$$

$$I_3 + I_1 = -\frac{u^2}{2}$$

$$I_4 + I_2 = -\frac{u^3}{3}$$

.....

.....

$$I_{10} + I_9 = -\frac{u^9}{9}$$

Adding, $I_0 + I_1 + 2(I_2 + I_3 + \ldots + I_8) + I_9 + I_{10}$

$$= -\left(u + \frac{u^2}{2} + \ldots + \frac{u^9}{9}\right)$$

Hence, (b) is the correct answer.

● ***Ex. 6*** *Let $f(x) = x + \sin x$. Suppose g denotes the inverse function of f. The value of $g'\left(\frac{\pi}{4} + \frac{1}{\sqrt{2}}\right)$ has the value equal to*

(a) $\sqrt{2} - 1$ (b) $\dfrac{\sqrt{2}+1}{\sqrt{2}}$

(c) $2 - \sqrt{2}$ (d) $\sqrt{2} + 1$

Sol. $f(x) = y = x + \sin x$

$$\Rightarrow \quad \frac{dy}{dx} = 1 + \cos x$$

$$g'(y) = \frac{dx}{dy} = \frac{1}{1 + \cos x}$$

where $y = \dfrac{\pi}{4} + \dfrac{1}{\sqrt{2}} = x + \sin x \;\Rightarrow\; x = \dfrac{\pi}{4}$

$$\therefore \quad g'\left(\frac{\pi}{4} + \frac{1}{\sqrt{2}}\right) = \frac{1}{1 + (1/\sqrt{2})}$$

$$= \frac{\sqrt{2}}{\sqrt{2}+1} = \sqrt{2}(\sqrt{2} - 1) = 2 - \sqrt{2}$$

Hence, (c) is the correct answer.

● ***Ex. 7*** *The value of $\int \dfrac{dx}{\sqrt{(x-a)(b-x)}}$, is*

(a) $2\sin^{-1}\sqrt{\dfrac{x-a}{b-a}} + C$ (b) $2\sin^{-1}\sqrt{\dfrac{x-b}{b-a}} + C$

(c) $\sin^{-1}\sqrt{\dfrac{x-a}{b-a}} + C$ (d) None of these

Sol. Let $x = a\cos^2\theta + b\sin^2\theta$ in the given integral.

So that, $dx = a(2\cos\theta)(-\sin\theta) + b(2\sin\theta)(\cos\theta)\, d\theta$

$$dx = 2(b-a)\sin\theta\cos\theta\, d\theta$$

$$\therefore \quad I = \int \frac{2(b-a)\sin\theta\cos\theta\, d\theta}{\sqrt{(a\cos^2\theta + b\sin^2\theta - a)(b - a\cos^2\theta - b\sin^2\theta)}}$$

$$= 2(b-a)\int \frac{\sin\theta\cos\theta\, d\theta}{\sqrt{(b\sin^2\theta - a\sin^2\theta)(b\cos^2\theta - a\cos^2\theta)}}$$

$$= 2(b-a)\int \frac{\sin\theta\cos\theta\, d\theta}{(b-a)\sin\theta\cos\theta} = 2\int 1\, d\theta$$

$$= 2\theta + C = 2\sin^{-1}\sqrt{\frac{x-a}{b-a}} + C$$

Hence, (a) is the correct answer.

● ***Ex. 8*** *The value of $\int \dfrac{(x-1)}{(x+1)\sqrt{x^3+x^2+x}}\, dx$, is*

(a) $2\tan^{-1}\sqrt{\dfrac{x+1}{x}} + C$ (b) $\tan^{-1}\sqrt{\dfrac{x^2+x+1}{x}} + C$

(c) $2\tan^{-1}\sqrt{\dfrac{x^2+x+1}{x}} + C$ (d) None of these

Sol. Let $I = \int \dfrac{(x-1)}{(x+1)\sqrt{x^3+x^2+x}}\, dx$

$$= \int \frac{(x^2-1)}{(x+1)^2\sqrt{x^3+x^2+x}}\, dx$$

$$= \int \frac{x^2(1 - 1/x^2)}{(x^2+2x+1)\sqrt{x^3+x^2+x}}\, dx$$

$$= \int \frac{x^2(1 - 1/x^2)}{x(x+2+1/x)\cdot x\sqrt{x+1+1/x}}\, dx$$

Put $x + \dfrac{1}{x} = t$,

$\Rightarrow (1 - 1/x^2)\, dx = dt$

$$= \int \frac{dt}{(t+2)\sqrt{t+1}}, \text{ which reduces to } \int \frac{dx}{P\sqrt{Q}}.$$

Let $t + 1 = z^2$

$$\therefore \quad dt = 2z\, dz = \int \frac{2z\, dz}{(z^2+1)\sqrt{z^2}}$$

$$= 2\int \frac{dz}{z^2+1} = 2\tan^{-1}(z) + C$$

$$= 2\tan^{-1}(\sqrt{t+1}) + C = 2\tan^{-1}\sqrt{\frac{x^2+x+1}{x}} + C$$

Hence, (c) is the correct answer.

● ***Ex. 9*** *The value of $\int \dfrac{(1+x^2)\, dx}{(1-x^2)\sqrt{1+x^2+x^4}}$, is*

(a) $-\dfrac{1}{2\sqrt{3}}\log\left|\dfrac{\sqrt{x^4+x^2+1} - \sqrt{3}x}{\sqrt{x^4+x^2+1} + \sqrt{3}x}\right| + C$

(b) $\dfrac{1}{2\sqrt{3}}\log\left|\dfrac{\sqrt{x^4+x^2+1} + \sqrt{2}x}{\sqrt{x^4+x^2+1} - \sqrt{2}x}\right| + C$

(c) $\dfrac{1}{2\sqrt{3}}\log\left|\dfrac{\sqrt{x^4-x^2+1} - \sqrt{3}x}{\sqrt{x^4+x^2+1} + \sqrt{3}x}\right| + C$

(d) None of the above

Sol. Let $I = \int \frac{(1+x^2)\,dx}{(1-x^2)\sqrt{1+x^2+x^4}}$

$$= \int \frac{x^2\left(1+\frac{1}{x^2}\right)dx}{x\left(\frac{1}{x}-x\right)x\sqrt{\frac{1}{x^2}+1+x^2}}$$

$$= -\int \frac{(1+1/x^2)\,dx}{(1-1/x)\sqrt{(x-1/x)^2+3}}$$

Put $x - \frac{1}{x} = t = \left(1+\frac{1}{x^2}\right)dx = dt \Rightarrow -\int \frac{dt}{t\sqrt{t^2+3}}$

Again, put $t^2 + 3 = s^2$

$\Rightarrow \quad 2t\,dt = 2s\,ds = -\int \frac{s\,ds}{s(s^2-3)} = -\int \frac{ds}{s^2-(\sqrt{3})^2}$

$$= -\frac{1}{2\sqrt{3}}\log\left|\frac{s-\sqrt{3}}{s+\sqrt{3}}\right| + C$$

$$= -\frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{t^2+3}-\sqrt{3}}{\sqrt{t^2+3}+\sqrt{3}}\right| + C$$

$$= -\frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{(x-1/x)^2+3}-\sqrt{3}}{\sqrt{(x-1/x)^2+3}+\sqrt{3}}\right| + C$$

$$= -\frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{x^2+\frac{1}{x^2}+1}-\sqrt{3}}{\sqrt{x^2+\frac{1}{x^2}+1}+\sqrt{3}}\right| + C$$

$$= -\frac{1}{2\sqrt{3}}\log\left|\frac{\sqrt{x^4+x^2+1}-\sqrt{3}x}{\sqrt{x^4+x^2+1}+\sqrt{3}x}\right| + C$$

Hence (a) is the correct answer.

● **Ex. 10** *The value of* $I = \int \frac{dx}{(a+bx^2)\sqrt{b-ax^2}}$, *is*

(a) $\frac{1}{\sqrt{a(a^2+b^2)}}\tan^{-1}\left(\frac{x\sqrt{a^2+b^2}}{a\sqrt{b-ax^2}}\right)+C$

(b) $\frac{1}{\sqrt{(a^2+b^2)}}\tan^{-1}\left(\frac{x\sqrt{a^2+b^2}}{a\sqrt{b-ax^2}}\right)+C$

(c) $\frac{1}{\sqrt{a(a^2+b^2)}}\tan^{-1}\left(\frac{x\sqrt{a^2+b^2}}{a}\right)+C$

(d) None of the above

Sol. Substituting $ax^2 = b\sin^2\theta$

$\Rightarrow \quad dx = \sqrt{\frac{b}{a}}\cos\theta\,d\theta$

$$\therefore \quad I = \int \frac{\sqrt{\frac{b}{a}}\cos\theta\,d\theta}{\left(a+\frac{b^2}{a}\sin^2\theta\right)\sqrt{b-b\sin^2\theta}}$$

$$= \sqrt{a}\int \frac{\cos\theta\,d\theta}{(a^2+b^2\sin^2\theta)\cdot\cos\theta}$$

$$= \sqrt{a}\int \frac{d\theta}{a^2+b^2\sin^2\theta},$$

dividing numerator and denominator by $\cos^2\theta$, we get

$$= \sqrt{a}\int \frac{\sec^2\theta\,d\theta}{a^2\sec^2\theta + b^2\tan^2\theta}, \text{ put } \tan\theta = t$$

$$= \sqrt{a}\int \frac{dt}{a^2(1+t^2)+b^2t^2} = \sqrt{a}\int \frac{dt}{(a^2+b^2)t^2+a^2}$$

$$= \frac{\sqrt{a}}{a^2+b^2}\int \frac{dt}{t^2+\frac{a^2}{a^2+b^2}}$$

$$= \frac{\sqrt{a}}{a^2+b^2}\cdot\left(\frac{\sqrt{a^2+b^2}}{a}\right)\tan^{-1}\left(\frac{t\sqrt{a^2+b^2}}{a}\right)+C$$

$$= \frac{1}{\sqrt{a(a^2+b^2)}}\cdot\tan^{-1}\left(\frac{x\sqrt{a^2+b^2}}{a\sqrt{b-ax^2}}\right)+C \qquad \left[\because\ t=\tan\theta=\frac{x}{\sqrt{b-ax^2}}\right]$$

Hence (a) is the correct answer.

● **Ex. 11** *The value of* $I = \int \frac{dx}{2x\sqrt{1-x}\sqrt{(2-x)+\sqrt{1-x}}}$

$$= -\frac{1}{2}\left\{\log\left(z+\frac{3}{2}+\sqrt{z^2+3z+3}\right)\right\}+\frac{1}{2}\left|\log s-\frac{1}{2}+\sqrt{s^2-s+1}\right|+C$$

and $s - z = \frac{k}{x}$, *then value of k, is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. Here, $I = \int \frac{dx}{2x\sqrt{1-x}\sqrt{(2-x)+\sqrt{1-x}}}$,

put $(1-x) = t^2 - dx = 2t\,dt$

$$= -\int \frac{2t\,dt}{2(1-t^2)\cdot t\sqrt{1+t^2+t}}$$

$$= -\int \frac{dt}{(1-t^2)\sqrt{t^2+t+1}}$$

$$= \int \frac{dt}{(t-1)(t+1)\sqrt{t^2+t+1}} = \frac{1}{2}\int\left(\frac{1}{t-1}-\frac{1}{t+1}\right)\cdot\frac{dt}{\sqrt{t^2+t+1}}$$

$\because \ \frac{1}{(t-1)(t+1)} = \frac{1}{2}\left(\frac{1}{t-1}-\frac{1}{t+1}\right)$

$$= \frac{1}{2}\int \frac{1}{(t-1)\sqrt{t^2+t+1}}\,dt - \frac{1}{2}\int \frac{1}{(t+1)\sqrt{t^2+t+1}}\,dt$$

Let $I = \frac{1}{2}I_1 - \frac{1}{2}I_2$ ...(i)

where, $I_1 = \int \frac{dt}{(t-1)\sqrt{t^2+t+1}}$

and $I_2 = \int \frac{dt}{(t+1)\sqrt{t^2+t+1}}$

For I_1, put $(t-1) = \frac{1}{z} \Rightarrow dt = -\frac{1}{z^2}\,dz$

$$I_1 = \int \frac{-1/z^2\,dz}{\frac{1}{z}\sqrt{\left(1+\frac{1}{z}\right)^2+\left(1+\frac{1}{z}\right)+1}} = -\int \frac{dz}{\sqrt{\left(z+\frac{3}{2}\right)^2+\left(\frac{\sqrt{3}}{2}\right)^2}}$$

$$= -\log\left|\left(z+\frac{3}{2}\right)+\sqrt{z^2+3z+3}\right| \quad ...(ii)$$

For I_2, put $(t+1)=\frac{1}{S}$

$\Rightarrow \quad dt = -\frac{1}{s^2}ds$

$$I_2 = -\int \frac{ds}{\sqrt{\left(s-\frac{1}{2}\right)^2+\frac{3}{4}}}$$

$$= -\log\left|\left(s-\frac{1}{2}\right)+\sqrt{s^2-s+1}\right| \quad ...(iii)$$

$$\therefore \quad I = -\frac{1}{2}\left\{\log\left(z+\frac{3}{2}+\sqrt{z^2+3z+3}\right)\right\} + \frac{1}{2}\log\left|\left(s-\frac{1}{2}\right)+\sqrt{s^2-s+1}\right| + C$$

where, $z=\frac{1}{\sqrt{1-x}-1}$ and $s=\frac{1}{\sqrt{1-x}+1}$

$$\therefore \quad s-z=\frac{1}{\sqrt{1-x}+1}-\frac{1}{\sqrt{1-x}-1}=\frac{2}{x}\Rightarrow k=2$$

Hence (b) is the correct answer.

● ***Ex. 12*** *If* $\int \frac{dx}{(x^2+a^2)^2} = \frac{1}{ka^2}\left\{\frac{x}{x^2+a^2}+\frac{1}{a}\tan^{-1}\frac{x}{a}\right\}+C$. *Then the value of k, is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. Here, we know

$$\int \frac{dx}{x^2+a^2} = \frac{1}{a}\tan^{-1}\frac{x}{a}+C \quad ...(i)$$

Also, $$\int \frac{1}{x^2+a^2}\cdot 1\,dx = \frac{1}{x^2+a^2}x - \int \frac{-2x}{(x^2+a^2)^2}x\,dx$$

$$= \frac{x}{x^2+a^2}+2\int \frac{x^2+a^2-a^2}{(x^2+a^2)^2}dx$$

I II

$$\int \frac{dx}{x^2+a^2} = \frac{x}{x^2+a^2}+2\int \frac{dx}{x^2+a^2}-2a^2\int \frac{dx}{(x^2+a^2)^2} \quad ...(ii)$$

From Eqs. (i) and (ii), we get

$$\frac{1}{a}\tan^{-1}\frac{x}{a} = \frac{x}{x^2+a^2}+2\frac{1}{a}\tan^{-1}\frac{x}{a}-2a^2\int \frac{dx}{(x^2+a^2)^2}$$

$$\Rightarrow \quad 2a^2\int \frac{dx}{(x^2+a^2)^2} = \frac{x}{x^2+a^2}+\frac{1}{a}\tan^{-1}\frac{x}{a}$$

or $$\int \frac{dx}{(x^2+a^2)^2} = \frac{1}{2a^2}\left\{\frac{x}{x^2+a^2}+\frac{1}{a}\tan^{-1}\frac{x}{a}\right\}+C$$

$$= \frac{1}{ka^2}\left\{\frac{x}{x^2+a^2}+\frac{1}{a}\tan^{-1}\frac{x}{a}\right\}+C$$

$$\therefore \quad k=2$$

Hence, (b) is the correct answer.

● ***Ex. 13*** *If* $\int \frac{dx}{(x^2+a^2)^3} = \frac{x}{4a^2(x^2+a^2)}+\frac{m}{na^2}\left\{\frac{x}{2a^2(x^2+a^2)}+\frac{1}{2a^3}\tan^{-1}\left(\frac{x}{a}\right)\right\}+C$. *Then* $|m-n|$ *is equal to*

(a) 4 (b) 3 (c) 2 (d) 1

Sol. Let $$I = \int \frac{dx}{(x^2+a^2)^3} \quad ...(i)$$

and $$I_1 = \int \frac{1}{(x^2+a^2)^2}dx \quad ...(ii)$$

$$= \int \frac{1}{(x^2+a^2)^2}\cdot 1\,dx = \frac{1}{(x^2+a^2)^2}\cdot x - \int \frac{-2(2x)}{(x^2+a^2)^3}x\,dx$$

I II

$$= \frac{x}{(x^2+a^2)^2}+4\int \frac{x^2+a^2-a^2}{(x^2+a^2)^3}dx$$

$$= \frac{x}{(x^2+a^2)^2}+4\int \frac{1}{(x^2+a^2)^2}dx - 4a^2\int \frac{dx}{(x^2+a^2)^3}$$

$\Rightarrow \quad I_1 = \frac{x}{(x^2+a^2)^2}+4I_1-4a^2\cdot I$ [using Eqs. (i) and (ii)]

$\Rightarrow 4a^2 I = \frac{x}{(x^2+a^2)^2}+3I_1$

$\Rightarrow \quad I = \frac{x}{4a^2(x^2+a^2)^2}+\frac{3}{4a^2}I_1 \quad ...(iii)$

[using previous example,

$$I_1 = \int \frac{dx}{(x^2+a^2)^2} = \frac{x}{2a^2(x^2+a^2)}+\frac{1}{2a^3}\tan^{-1}\left(\frac{x}{a}\right)+C\Bigg]$$

$$\Rightarrow \quad I = \frac{x}{4a^2(x^2+a^2)^2}+\frac{3}{4a^2}\left\{\frac{x}{2a^2(x^2+a^2)}+\frac{1}{2a^3}\tan^{-1}\left(\frac{x}{a}\right)\right\}+C \quad ...(iv)$$

$m=3$ and $n=4$

$|m-n| = |3-4| = |-1| = 1$

Hence, (d) is the correct answer.

● ***Ex. 14*** *If* $y(x-y)^2 = x$, *then* $\int \frac{dx}{(x-3y)} = \frac{m}{n}\ln[(x-y)^2-1]$. *Then* $(m+2n)$ *is equal to*

(a) 1 (b) 3 (c) 5 (d) 7

Sol. Let $$P = \int \frac{dx}{(x-3y)} = \frac{1}{2}\ln[(x-y)^2-1]$$

$$\therefore \quad \frac{dP}{dx} = \frac{1}{x-3y} = \frac{(x-y)\left\{1-\frac{dy}{dx}\right\}}{\{(x-y)^2-1\}} \quad ...(i)$$

Given, $y(x-y)^2 = x$, on differentiating both the sides, we get

$$\frac{dy}{dx} = \frac{1-2y(x-y)}{(x-y)(x-3y)} \quad ...(ii)$$

$$\therefore \quad \frac{dP}{dx} = \frac{(x-y)\left\{1-\frac{1-2y(x-y)}{(x-y)(x-3y)}\right\}}{\{(x-y)^2-1\}}$$

$$= \frac{(x-y)(x-3y)-1+2y(x-y)}{(x-3y)\{(x-y)^2-1\}} = \frac{(x-y)^2-1}{(x-3y)\{(x-y)^2-1\}}$$

$$\therefore \frac{dP}{dx} = \frac{1}{(x-3y)} \quad \ldots(iii)$$

which is true as given

$$\therefore \int \frac{dx}{(x-3y)} = \frac{1}{2}\log\{(x-y)^2-1\},$$

$$\therefore \quad m = 1, n = 2$$

$$\Rightarrow \quad m + 2n = 5$$

Hence, (c) is the correct answer.

● **Ex. 15** *If* $\int (x+\sqrt{1+x^2})^n\, dx.$

$$= \frac{1}{a(n+1)}\{x+\sqrt{1+x^2}\}^{n+1} + \frac{1}{-b(n-1)}\{x+\sqrt{1+x^2}\}^{n-1} + C$$

Then $(a+b)$ *is equal to*

(a) 2 (b) 3 (c) 4 (d) 5

Sol. Let $I = \int (x+\sqrt{1+x^2})^n\, dx$

Put $$x + \sqrt{1+x^2} = t \quad \ldots(i)$$

$$\Rightarrow \quad \left(1 + \frac{1}{2\sqrt{1+x^2}} \cdot 2x\right) dx = dt$$

$$\Rightarrow \quad \left(\frac{\sqrt{1+x^2}+x}{\sqrt{1+x^2}}\right) dx = dt \quad \ldots(ii)$$

We know, $t = x + \sqrt{1+x^2} = x + \sqrt{1+x^2} \times \dfrac{x-\sqrt{1+x^2}}{x-\sqrt{1+x^2}}$

$$t = \frac{-1}{x-\sqrt{1+x^2}} \Rightarrow t = x + \sqrt{1+x^2}$$

$$-\frac{1}{t} = x - \sqrt{1+x^2}$$

Subtracting, we get

$$2\sqrt{1+x^2} = t + \frac{1}{t} \quad \text{or} \quad \frac{1}{\sqrt{1+x^2}} = \frac{2t}{t^2+1} \quad \ldots(iii)$$

From Eqs. (i), (ii) and (iii), we get

$$dx = \frac{t^2+1}{2t^2}\, dt$$

$$\therefore \quad I = \int t^n \cdot \frac{t^2+1}{(2t^2)}\, dt = \frac{1}{2}\int (t^n + t^{n-2})\, dt$$

$$= \frac{1}{2}\left[\frac{t^{n+1}}{n+1} + \frac{t^{n-1}}{n-1}\right] + C$$

$$\Rightarrow \quad I = \frac{1}{2(n+1)}[x+\sqrt{(1+x^2)}]^{n+1} + \frac{1}{2(n-1)}(x+\sqrt{(1+x^2)})^{n-1} + C \quad \ldots(iv)$$

Then comparing the values of a and b by Eq. (iv) $a = 2, b = 2$

$$\therefore \quad (a+b) = (2+2) = 4$$

Hence, (c) is the correct answer.

● **Ex. 16** *If* $\int \frac{f(x)}{x^3-1}\, dx$, *where* $f(x)$ *is a polynomial of degree 2 in x such that* $f(0) = f(1) = 3f(2) = -3$ *and* $\int \frac{f(x)}{x^3-1}\, dx = -\log|x-1| + \log|x^2+x+1|$

$$+ \frac{m}{\sqrt{n}}\tan^{-1}\left(\frac{2x+1}{\sqrt{3}}\right) + C.$$ *Then* $(2m+n)$ *is*

(a) 3 (b) 5 (c) 7 (d) 9

Sol. Let $f(x) = ax^2 + bx + c$

Given, $f(0) = f(1) = 3f(2) = -3$

$$\therefore \quad f(0) = c = -3$$

$$f(1) = a + b + c = -3$$

$$3f(2) = 3(4a + 2b + c) = -3$$

On solving, we get $a = 1, b = -1, c = -3$

$$\therefore \quad f(x) = x^2 - x - 3$$

$$\Rightarrow \quad I = \int \frac{f(x)}{x^3-1}\, dx = \int \frac{x^2-x-3}{(x-1)(x^2+x+1)}\, dx$$

Using partial fractions, we get

$$\frac{(x^2-x-3)}{(x-1)(x^2+x+1)} = \frac{A}{(x-1)} + \frac{Bx+C}{(x^2+x+1)}$$

we get, $A = -1, \quad B = 2, \quad C = 2$

$$\therefore I = \int -\frac{1}{x-1}\, dx + \int \frac{(2x+2)}{(x^2+x+1)}\, dx$$

$$= -\log|x-1| + \int \frac{(2x+1)\, dx}{x^2+x+1} + \int \frac{1\, dx}{x^2+x+1}$$

$$= -\log|x-1| + \log|x^2+x+1| + \int \frac{dx}{(x+1/2)^2 + (\sqrt{3}/2)^2}$$

$$= -\log|x-1| + \log|x^2+x+1| + \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{2x+1}{\sqrt{3}}\right) + C$$

$\therefore$ On comparing $m = 2, n = 3 \Rightarrow 2m + n = 7.$

Hence, (c) is the correct answer.

● **Ex. 17** *The value of* $\int \frac{(1+x)}{x(1+xe^x)^2}\, dx$, *is equal to*

(a) $\log\left|\dfrac{x}{1+xe^x}\right| + \dfrac{1}{(1+xe^x)} + C$

(b) $\log\left|\dfrac{xe^x}{1+xe^x}\right| + \dfrac{1}{1+xe^x} + C$

(c) $\log\left|\dfrac{xe^x}{1+e^x}\right| + \dfrac{1}{1+xe^x} + C$

$$= \frac{1}{2}\sin^{-1}\left(\frac{x}{a}\right) + \frac{1}{2}\{\log|x + \sqrt{a^2 - x^2}|\} - \frac{1}{2}\log a + C$$

$$= \frac{1}{2}\sin^{-1}\left(\frac{x}{a}\right) + \frac{1}{2}\log|x + \sqrt{a^2 - x^2}| + C_1$$

$$\left[\text{where } C_1 = C - \frac{1}{2}\log a\right]$$

Hence, (a) is the correct answer.

● ***Ex. 19*** *The value of* $\int \frac{x^2 - 1}{(x^2+1)\sqrt{x^4+1}} dx$, *is equal to*

(a) $\frac{1}{\sqrt{2}}\sec^{-1}\left(\frac{x^2+1}{\sqrt{2}x}\right) + C$ (b) $\sqrt{2}\sec^{-1}\left(\frac{x^2+1}{\sqrt{2}x}\right) + C$

(c) $\frac{1}{\sqrt{2}}\operatorname{cosec}^{-1}\left(\frac{x^2+1}{\sqrt{2}x}\right) + C$ (d) $\sqrt{2}\operatorname{cosec}^{-1}\left(\frac{x^2+1}{\sqrt{2}x}\right) + C$

Sol. Let $I = \int \frac{(x^2-1)}{(x^2+1)\sqrt{x^4+1}} dx = \int \frac{x^2(1 - 1/x^2)\, dx}{x^2\left(x + \frac{1}{x}\right)\sqrt{x^2 + \frac{1}{x^2}}}$

$$= \int \frac{(1 - 1/x^2)\, dx}{\left(x + \frac{1}{x}\right)\sqrt{\left(x + \frac{1}{x}\right)^2 - 2}}$$

Put $x + \frac{1}{x} = t \quad \Rightarrow \quad \left(1 - \frac{1}{x^2}\right) dx = dt$

$$= \int \frac{dt}{t\sqrt{t^2 - 2}} = \frac{1}{\sqrt{2}}\sec^{-1}\left(\frac{t}{\sqrt{2}}\right) + C$$

$$= \frac{1}{\sqrt{2}}\sec^{-1}\left(\frac{x^2+1}{\sqrt{2}x}\right) + C$$

Hence, (a) is the correct answer.

JEE Type Solved Examples :
More than One Correct Option Type Questions

● ***Ex. 20*** $\int \frac{\sqrt{4 + x^2}}{x^6} dx = \frac{A(4 + x^2)^{3/2}(Bx^2 - 6)}{x^5} + C$, *then*

(a) $A = \frac{1}{120}$ (b) $B = 1$

(c) $A = -\frac{1}{120}$ (d) $B = -1$

Sol. Here, $I = \int \frac{\sqrt{4 - x^2}}{x^6} dx = \int \frac{\sqrt{1 + \frac{4}{x^2}}}{x^5} dx = \int \frac{\sqrt{1 + \frac{4}{x^2}}}{x^2 \cdot x^3} dx$

Put $\quad t = \sqrt{1 + \frac{4}{x^2}} \Rightarrow t^2 = 1 + \frac{4}{x^2}$

$$\therefore \quad 2t\, dt = -\frac{8}{x^3} dx$$

$$\Rightarrow \quad I = \frac{1}{16}\int (t^2 - t^4)\, dx = \frac{1}{16}\left\{\frac{t^3}{3} - \frac{t^5}{5}\right\} + C$$

$$= \frac{1}{120}\cdot\frac{(4 + x^2)^{3/2}}{x^5}(x^2 - 6) + C$$

$$A = \frac{1}{120},\ B = 1$$

Hence, (a) and (b) are the correct answers.

● **Ex. 21** *The value of the integral* $\int e^{\sin^2 x}(\cos x + \cos^3 x)\sin x\,dx$ *is*

(a) $\frac{1}{2}e^{\sin^2 x}(3 - \sin^2 x) + C$

(b) $e^{\sin^2 x}\left(1 + \frac{1}{2}\cos^2 x\right) + C$

(c) $e^{\sin^2 x}(3\cos^2 x + 2\sin^2 x) + C$

(d) $e^{\sin^2 x}(2\cos^2 x + 3\sin^2 x) + C$

Sol. Put $t = \sin^2 x$

The integral reduces to $I = \frac{1}{2}\int e^t(2 - t)\,dt = \frac{3}{2}e^t - \frac{te^t}{2} + C$

$= \frac{1}{2}e^{\sin^2 x}(3 - \sin^2 x) + C$ [option (a)]

$= e^{\sin^2 x}\left(1 + \frac{1}{2}\cos^2 x\right) + C$ [option (b)]

Hence, (a) and (b) are the correct answers.

● **Ex. 22** *If* $I = \int(\sqrt{\tan x} + \sqrt{\cot x})\,dx = f(x) + c$, *then* $f(x)$ *is equal to*

(a) $\sqrt{2}\sin^{-1}(\sin x - \cos x)$ (b) $\frac{\pi}{\sqrt{2}} - \sqrt{2}\cos^{-1}(\sin x - \cos x)$

(c) $\sqrt{2}\tan^{-1}\left(\frac{\tan x - 1}{\sqrt{2}\sqrt{\tan x}}\right)$ (d) None of these

Sol. $I = \int(\sqrt{\tan x} + \sqrt{\cot x})\,dx = \int\sqrt{2}\cdot\frac{\sin x + \cos x}{\sqrt{2\sin x\cos x}}\,dx$

If $\sin x - \cos x = p$, then $(\cos x + \sin x)\,dx = dp$

$I = \sqrt{2}\int\frac{dp}{\sqrt{1 - p^2}} = \sqrt{2}\sin^{-1}p + c = \sqrt{2}\sin^{-1}(\sin x - \cos x) + c$

$= \frac{\pi}{\sqrt{2}} - \sqrt{2}\cos^{-1}(\sin x - \cos x) = \sqrt{2}\tan^{-1}\frac{\sin x - \cos x}{\sqrt{1 - (\sin x - \cos x)^2}}$

$= \sqrt{2}\tan^{-1}\frac{\sin x - \cos x}{\sqrt{2\sin x\cos x}} = \sqrt{2}\tan^{-1}\left(\frac{\tan x - 1}{\sqrt{2\tan x}}\right)$

Hence, (a), (b) and (c) are the correct answers.

JEE Type Solved Examples : Passage Based Questions

Passage

(Q. Nos. 23 to 25)

For integral $\int f\left(x - \frac{a}{x}\right)\cdot\left(1 + \frac{a}{x^2}\right)dx$, *put* $x - \frac{a}{x} = t$

For integral $\int f\left(x + \frac{a}{x}\right)\cdot\left(1 - \frac{a}{x^2}\right)dx$, *put* $x + \frac{a}{x} = t$

For integral $\int f\left(x^2 - \frac{a}{x^2}\right)\cdot\left(x + \frac{a}{x^3}\right)dx$, *put* $x^2 - \frac{a}{x^2} = t$

For integral $\int f\left(x^2 + \frac{a}{x^2}\right)\cdot\left(x - \frac{a}{x^3}\right)dx$, *put* $x^2 + \frac{a}{x^2} = t$

many integrands can be brought into above forms by suitable reductions or transformations.

● **Ex. 23** $\int\frac{x^4 - 2}{x^2\sqrt{x^4 + x^2 + 2}}\,dx$

(a) $\sqrt{x^2 + 1 + \frac{1}{x^2}} + C$ (b) $\sqrt{x^2 + 1 + \frac{2}{x^2}} + C$

(c) $\sqrt{x^2 + \frac{1}{x^2}} + C$ (d) $\sqrt{x^2 + \frac{2}{x^2}} + C$

Sol. Here, $I = \int\frac{x - \frac{2}{x^3}}{\sqrt{x^2 + 1 + \frac{2}{x^2}}}\,dx$

Put $x^2 + \frac{2}{x^2} + 1 = t \Rightarrow 2\left(x - \frac{2}{x^3}\right)dx = dt$

$= \frac{1}{2}\int\frac{dt}{\sqrt{t}} = \frac{1}{2}\cdot\frac{t^{1/2}}{1/2} + C = \sqrt{t} + C$

$= \sqrt{x^2 + \frac{2}{x^2} + 1} + C$

Hence, (b) is the correct answer.

● **Ex. 24** $\int\frac{(x - 1)}{(x + 1)\sqrt{x^3 + x^2 + x}}\,dx$

(a) $\tan^{-1}\left(x + \frac{1}{x} + 1\right) + C$ (b) $\tan^{-1}\sqrt{x + \frac{1}{x} + 1} + C$

(c) $2\tan^{-1}\sqrt{x + \frac{1}{x} + 1} + C$ (d) None of these

Sol. $\int\frac{x^2 - 1}{(x + 1)^2\sqrt{x^3 + x^2 + x}}\,dx = \int\frac{\left(1 - \frac{1}{x^2}\right)}{\left(x + \frac{1}{x} + 2\right)\sqrt{x + \frac{1}{x} + 1}}\,dx$

Put $x + \frac{1}{x} + 1 = t^2 \Rightarrow \left(1 - \frac{1}{x^2}\right)dx = 2t\,dt$

$= \int\frac{2t\,dt}{(t^2 + 1)t} = 2\int\frac{1}{(t^2 + 1)}\,dt$

$= 2\cdot\tan^{-1}(t) + C = 2\tan^{-1}\left(\sqrt{x + \frac{1}{x} + 1}\right) + C$

Hence, (c) is the correct answer.

● ***Ex. 25*** $\int \frac{5x^4 + 4x^5}{(x^5 + x + 1)^2}\, dx$

(a) $x^5 + x + 1 + C$ (b) $\frac{x^5}{x^5 + x + 1} + C$

(c) $x^{-4} + x^{-5} + C$ (d) $\frac{x^5}{x^5 + x + 1} + C$

Sol. Here, $I = \sqrt{\frac{5x^4 + 4x^5}{(x^5 + x + 1)^2}}$

Divide numerator and denominator by x^{10}, we get

$$I = \int \frac{5x^{-6} + 4x^{-5}}{(1 + x^{-4} + x^{-5})^2}\, dx$$

Put $1 + x^{-4} + x^{-5} = t \Rightarrow (-4x^{-5} - 5x^{-6})\, dx = dt$

$$\therefore \quad I = -\int \frac{dt}{t^2} = \frac{1}{t} + C = \frac{1}{1 + x^{-4} + x^{-5}} + C$$

$$= \frac{x^5}{x^5 + x + 1} + C$$

Hence, (d) is the correct answer.

JEE Type Solved Examples :
Matching Type Questions

● ***Ex. 26*** *If $x \in (0, 1)$ then match the entries of Column I with Column II considering 'c' as an arbitrary constant of integration.*

Column I	Column II
(A) $\int \tan\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-1}{\sqrt{1+\sqrt{x}}+1}}\right) dx$	(p) $\frac{4}{3}x^{3/4} + C$
(B) $\int \cot\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-\sqrt[4]{x}}{\sqrt{1+\sqrt{x}}+\sqrt[4]{x}}}\right) dx$	(q) $\frac{4}{5}x^{5/4} + C$
(C) $\int \left(\frac{1-\tan\left(\frac{1}{2}\sin^{-1}\left(\frac{1-\sqrt{x}}{1+\sqrt{x}}\right)\right)}{1+\tan\left(\frac{1}{2}\sin^{-1}\left(\frac{1-\sqrt{x}}{1+\sqrt{x}}\right)\right)}\right) dx$	(r) $\frac{2}{3}x^{3/4} + C$
(D) $\int \sqrt{x}\tan\left(2\tan^{-1}\left(\frac{\sqrt{\sqrt{1+\sqrt{x}}+1}-\sqrt{\sqrt{1+\sqrt{x}}-1}}{\sqrt{\sqrt{1+\sqrt{x}}+1}+\sqrt{\sqrt{1+\sqrt{x}}-1}}\right)\right) dx$	(s) $\frac{2}{5}x^{5/4} + C$

Sol. Let $\sqrt{x} = \tan^2\theta$

$$x = \tan^4\theta \quad \Rightarrow \quad \tan\theta = x^{1/4}$$

$$\therefore \quad dx = 4\tan^3\theta\sec^2\theta\, d\theta \qquad \begin{bmatrix} \because\ x \in (0, 1) \\ \therefore\ \theta \in (0, \pi/4) \end{bmatrix}$$

$$\therefore \quad \sqrt{1+\sqrt{x}} = \sec\theta$$

(A) $I = \int \tan\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-1}{\sqrt{1+\sqrt{x}}+1}}\right) dx$

$$\Rightarrow \tan\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-1}{\sqrt{1+\sqrt{x}}+1}}\right) = \tan\left(2\tan^{-1}\sqrt{\frac{\sec\theta - 1}{\sec\theta + 1}}\right)$$

$$= \tan\left(2\tan^{-1}\left(\tan\frac{\theta}{2}\right)\right) = \tan\theta$$

$$\therefore \quad I = \int \tan\theta \cdot 4\tan^3\theta\sec^2\theta\, d\theta$$

$$= \frac{4}{5}\tan^5\theta + C = \frac{4}{5}(x^{5/4}) + C$$

(B) $I = \int \cot\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-\sqrt[4]{x}}{\sqrt{1+\sqrt{x}}+\sqrt[4]{x}}}\right) dx$

$$\therefore \quad \cot\left(2\tan^{-1}\sqrt{\frac{\sqrt{1+\sqrt{x}}-\sqrt[4]{x}}{\sqrt{1+\sqrt{x}}+\sqrt[4]{x}}}\right) = \cot\left(2\tan^{-1}\sqrt{\frac{\sec\theta - \tan\theta}{\sec\theta + \tan\theta}}\right)$$

$$= \cot\left(2\tan^{-1}\sqrt{(\sec\theta - \tan\theta)^2}\right)$$

$$= \cot\left(2\tan^{-1}\frac{1-\sin\theta}{\cos\theta}\right)$$

If $\theta \in (0, \pi/4)$, then $\sec\theta - \tan\theta > 0$

$$= \cot\left(2\tan^{-1}\tan\left(\frac{\pi}{4} - \frac{\theta}{2}\right)\right) = \cot\left(\frac{\pi}{2} - \theta\right) = \tan\theta$$

$$\therefore \quad I = \int \tan\theta \cdot 4\tan^3\theta\sec^2\theta\, d\theta$$

$$= \frac{4}{5}\tan^5\theta + C = \frac{4}{5}(x^{5/4}) + C$$

(C) $\frac{1}{2}\sin^{-1}\left(\frac{1-\sqrt{x}}{1+\sqrt{x}}\right) = \frac{1}{2}\sin^{-1}\left(\frac{1-\tan^2\theta}{1+\tan^2\theta}\right)$

$$= \frac{1}{2}\sin^{-1}(\cos 2\theta) = \frac{1}{2}\sin^{-1}\sin\left(\frac{\pi}{2} - 2\theta\right) = \frac{\pi}{4} - \theta$$

$$\therefore \quad \int \left(\frac{1-\tan\left(\frac{1}{2}\sin^{-1}\left(\frac{1-\sqrt{x}}{1+\sqrt{x}}\right)\right)}{1+\tan\left(\frac{1}{2}\sin^{-1}\left(\frac{1-\sqrt{x}}{1+\sqrt{x}}\right)\right)}\right) dx$$

$$= \int \frac{1-\tan\left(\frac{\pi}{4} - \theta\right)}{1+\tan\left(\frac{\pi}{4} - \theta\right)} 4\tan^3\theta\sec^2\theta\, d\theta$$

$$= \int \tan\left(\frac{\pi}{4} - \left(\frac{\pi}{4} - \theta\right)\right) 4\tan^3\theta\sec^2\theta\, d\theta$$

$$= \int 4\tan^4\theta\sec^2\theta\, d\theta$$

$$= \frac{4}{5}\tan^5\theta + C = \frac{4}{5}(x^{5/4}) + C$$

(D) Let $\sqrt{x} = \tan^2\theta \Rightarrow x = \tan^4\theta$

$\therefore \quad dx = 4\tan^3\theta\sec^2\theta\, d\theta \qquad \left[\because\ x \in (0,1)\ \therefore\ \theta \in (0, \pi/4)\right]$

$\therefore \sqrt{1+\sqrt{x}} = \sec\theta$

$$I = \int \sqrt{x}\tan\left(2\tan^{-1}\left(\frac{\sqrt{\sqrt{1+\sqrt{x}}+1} - \sqrt{\sqrt{1+\sqrt{x}}-1}}{\sqrt{\sqrt{1+\sqrt{x}}+1} + \sqrt{\sqrt{1+\sqrt{x}}-1}}\right)\right)dx$$

$$\therefore \sqrt{x}\tan\left(2\tan^{-1}\left(\frac{\sqrt{\sqrt{1+\sqrt{x}}+1} - \sqrt{\sqrt{1+\sqrt{x}}-1}}{\sqrt{\sqrt{1+\sqrt{x}}+1} + \sqrt{\sqrt{1+\sqrt{x}}-1}}\right)\right)$$

$$= \tan^2\theta\cdot\tan\left(2\tan^{-1}\left(\frac{\sqrt{\sec\theta+1} - \sqrt{\sec\theta-1}}{\sqrt{\sec\theta+1} + \sqrt{\sec\theta-1}}\right)\right)$$

$$= \tan^2\theta\cdot\tan\left(2\tan^{-1}\left(\frac{\cos\frac{\theta}{2} - \sin\frac{\theta}{2}}{\cos\frac{\theta}{2} + \sin\frac{\theta}{2}}\right)\right)$$

$$= \tan^2\theta\cdot\tan\left(2\tan^{-1}\tan\left(\frac{\pi}{4} - \frac{\theta}{2}\right)\right)$$

$$= \tan^2\theta\cdot\tan\left(\frac{\pi}{2} - \theta\right) = \tan^2\theta\cdot\cot\theta = \tan\theta$$

$\therefore \quad I = \int \tan\theta\cdot 4\tan^3\theta\sec^2\theta\, d\theta = \frac{4\tan^5\theta}{5} + C = \frac{4}{5}(x^{5/4}) + C$

(A) → (q); (B) → (q); (C) → (q); (D) → (q)

JEE Type Solved Examples :
Single Integer Answer Type Questions

● ***Ex. 27*** *If the primitive of the function* $f(x) = \dfrac{x^{2009}}{(1+x^2)^{1006}}$ *w.r.t. x is equal to* $\dfrac{1}{n}\left(\dfrac{x^2}{1+x^2}\right)^m + C$, *then* $\dfrac{n}{m}$ *is equal to .....*

Sol. $f(x) = \int \dfrac{x^{2009}}{(1+x^2)^{1006}}\,dx$

Put $1 + x^2 = t \ \Rightarrow\ 2x\,dx = dt$

$$\therefore \quad I = \frac{1}{2}\int \frac{(t-1)^{1004}\,dt}{t^{1006}} = \frac{1}{2}\int\left(1-\frac{1}{t}\right)^{1004}\cdot\frac{1}{t^2}\,dt$$

Put $1 - \dfrac{1}{t} = y \ \Rightarrow\ \dfrac{1}{t^2}\,dt = dy$

$$\therefore \quad I = \frac{1}{2}\int y^{1004}dy = \frac{1}{2}\cdot\frac{y^{1005}}{1005} + C$$

$$= \frac{1}{2010}\cdot\left(\frac{t-1}{t}\right)^{1005} + C = \frac{1}{2010}\cdot\left(\frac{x^2}{1+x^2}\right)^{1005} + C$$

$$\Rightarrow \quad m = 1005,\ n = 2010 \ \Rightarrow \frac{n}{m} = \frac{2010}{1005} = 2$$

● ***Ex. 28*** *Suppose* $\begin{vmatrix} f'(x) & f(x) \\ f''(x) & f'(x) \end{vmatrix} = 0$ *where* $f(x)$ *is continuous differentiable function with* $f'(x) \neq 0$ *and satisfies* $f(0) = 1$ *and* $f'(0) = 2$, *then* $f(x) = e^{\lambda x} + k$, *then* $\lambda + k$ *is equal to .....*

Sol. $f'(x)\cdot f'(x) - f(x)\cdot f''(x) = 0$ or $\dfrac{[f'(x)]^2 - f(x)f''(x)}{[f'(x)]^2} = 0$

$$\frac{d}{dx}\left[\frac{f(x)}{f'(x)}\right] = 0$$

Integrating, $\dfrac{f(x)}{f'(x)} + C$ ...(i)

Put $x = 0,\ \dfrac{f(0)}{f'(0)} = C \ \Rightarrow\ C = \dfrac{1}{2}$.

Hence, $\dfrac{f(x)}{f'(x)} = \dfrac{1}{2}$ ...(ii)

From Eq. (i), $2f(x) = f'(x) \ \therefore\ \dfrac{f'(x)}{f(x)} = 2$

Again, integrating, $\ln[f(x)] = 2x + k$

Put $x = 0$ to get, $k = 0$

$$f(x) = e^{2x} \ \Rightarrow\ \lambda + k = 2 + 0 = 2$$

● ***Ex. 29*** $\int\{\sin(101x)\cdot\sin^{99}x\}\,dx = \dfrac{\sin(100x)(\sin x)^{\lambda}}{\mu}$, *then* $\dfrac{\lambda}{\mu}$ *is equal to .....*

Sol. (1) $I = \int\{\sin(100\,x + x)\cdot(\sin x)^{99}\}\,dx$

$$= \int\{\sin(100\,x)\cos x + \cos 100\,x\sin x\}(\sin x)^{99}\,dx$$

$$= \int \underbrace{\sin(100x)}_{\text{I}}\ \underbrace{\cos x\cdot(\sin x)^{99}}_{\text{II}}\,dx + \int\cos(100x)\cdot(\sin x)^{100}\,dx$$

$$= \frac{\sin(100x)(\sin x)^{100}}{100}$$

$$- \frac{100}{100}\int\cos(100x)(\sin x)^{100}\,dx + \int\cos(100x)(\sin x)^{100}\,dx$$

$$= \frac{\sin(100x)(\sin x)^{100}}{100} + C$$

$$\Rightarrow \lambda = 100,\ \mu = 100 \ \Rightarrow\ \frac{\lambda}{\mu} = \frac{100}{100} = 1$$

Subjective Type Questions

● **Ex. 30** *If I_n denotes $\int z^n\, e^{1/z}\, dz$, then show that* $(n+1)!\, I_n = I_0 + e^{1/z}\,(1!\, z^2 + 2!\, z^3 + \ldots + n!\, z^{n+1})$.

Sol. $I_n = \int z^n\, e^{1/z}\, dz$, applying integration by parts taking $e^{1/z}$ as first function and z^n as second function. We get,

$$I_n = \frac{e^{1/z}\cdot z^{n+1}}{(n+1)} - \int e^{1/z}\left(-\frac{1}{z^2}\right)\cdot\frac{z^{n+1}}{n+1}\,dz$$

$$= \frac{e^{1/z}\cdot z^{n+1}}{(n+1)} + \frac{1}{(n+1)}\int e^{1/z}\cdot z^{n-1}\,dz$$

$$I_n = \frac{e^{1/z}\cdot z^{n+1}}{(n+1)} + \frac{I_{n-1}}{(n+1)}$$

$$= \frac{e^{1/z}\cdot z^{n+1}}{(n+1)} + \frac{1}{(n+1)}\left[\frac{e^{1/z}\cdot z^n}{n} + \frac{1}{n}\,I_{n-2}\right]$$

$$= \frac{e^{1/z}\,(z)^{n+1}}{(n+1)} + \frac{e^{1/z}\cdot(z)^n}{(n+1)\,n} + \frac{1}{(n+1)\,n}\,I_{n-2}$$

$$= \frac{e^{1/z}\cdot(z)^{n+1}}{(n+1)} + \frac{e^{1/z}\cdot(z)^n}{(n+1)n} + \frac{e^{1/z}\cdot(z)^{n-1}}{(n+1)n\cdot(n-1)} + \frac{1}{(n+1)n(n-1)}\,I_{n-3}$$

$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$
$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$

$$= \frac{e^{1/z}\cdot(z)^{n+1}}{n+1} + \frac{e^{1/z}\cdot(z)^n}{(n+1)\,n} + \ldots + \frac{e^{1/z}\cdot(z)^1}{(n+1)\,n\ldots 3\cdot 2} + \frac{1}{(n+1)\,n\,(n-1)\ldots 3\cdot 2}\,I_0$$

Multiplying both the sides by $(n+1)!$. We get,

$$(n+1)!\, I_n = (e^{1/z}\cdot z^{n+1}\cdot n! + e^{1/z}\cdot z^n\,(n-1)! + \ldots + \ldots + e^{1/z}\cdot z^3\cdot(2)! + e^{1/z}\cdot z^2\cdot 1!) + I_0$$

$$\Rightarrow \quad I_n\,(n+1)! = I_0 + e^{1/z}\,(1!\, z^2 + 2!\, z^3 + \ldots + n!\, z^{n+1})$$

Hence Proved.

● **Ex. 31** *If $I_n = \int x^n\,\sqrt{a^2 - x^2}\,dx$, prove that* $I_n = -\dfrac{x^{n-1}\,(a^2-x^2)^{3/2}}{(n+2)} + \dfrac{(n-1)}{(n+2)}\,a^2\,I_{n-2}$.

Sol. $I_n = \int x^n\,\sqrt{a^2-x^2}\,dx = \int \underset{\text{I}}{x^{n-1}}\cdot\underset{\text{II}}{\{x\,\sqrt{a^2-x^2}\}}\,dx$

Applying integration by parts, we get

$$= x^{n-1}\cdot\left\{-\frac{(a^2-x^2)^{3/2}}{3}\right\} + \int (n-1)\,x^{n-2}\cdot\left\{-\frac{(a^2-x^2)^{3/2}}{3}\right\}dx$$

$$= -\frac{x^{n-1}\,(a^2-x^2)^{3/2}}{3} + \frac{(n-1)}{3}\int x^{n-2}\cdot(a^2-x^2)\,\sqrt{a^2-x^2}\,dx$$

$$\Rightarrow \quad I_n = -\frac{x^{n-1}\,(a^2-x^2)^{3/2}}{3} + \frac{(n-1)\,a^2}{3}\,I_{n-2} - \frac{(n-1)}{3}\,I_n$$

$$\therefore \quad I_n + \frac{(n-1)}{3}\,I_n = -\frac{x^{n-1}\,(a^2-x^2)^{3/2}}{3} + \frac{(n-1)\,a^2}{3}\,I_{n-2}$$

$$\left(\frac{n+2}{3}\right)I_n = -\frac{x^{n-1}\,(a^2-x^2)^{3/2}}{3} + \frac{(n-1)\,a^2}{3}\,I_{n-2}$$

$$I_n = -\frac{x^{n-1}\,(a^2-x^2)^{3/2}}{(n+2)} + \frac{(n-1)\,a^2}{(n+2)}\,I_{n-2}$$

Hence Proved.

● **Ex. 32** *If $I_m = \int (\sin x + \cos x)^m\,dx$, then show that* $m\,I_m = (\sin x + \cos x)^{m-1}\cdot(\sin x - \cos x) + 2\,(m-1)\,I_{m-2}$

Sol. $\because\ I_m = \int (\sin x + \cos x)^m\,dx$

$$= \int (\sin x + \cos x)^{m-1}\cdot(\sin x + \cos x)\,dx,$$

Applying integration by parts

$$= (\sin x + \cos x)^{m-1}(\cos x + \sin x) - \int (m-1)\,(\sin x + \cos x)^{m-2}\cdot(\cos x - \sin x)\cdot(\sin x - \cos x)\,dx$$

$$= (\sin x + \cos x)^{m-1}(\sin x - \cos x) + (m-1)\int (\sin x + \cos x)^{m-2}\,(\sin x - \cos x)^2\,dx$$

As we know, $(\sin x + \cos x)^2 + (\sin x - \cos x)^2 = 2$,

$$\therefore I_m = (\sin x + \cos x)^{m-1}\,(\sin x - \cos x) + (m-1)\int (\sin x + \cos x)^{m-2}\cdot\{2 - (\sin x + \cos x)^2\}\,dx$$

$$= (\sin x + \cos x)^{m-1}\,(\sin x - \cos x) + (m-1)\int 2\,(\sin x + \cos x)^{m-2}\,dx - (m-1)\int (\sin x + \cos x)^m\,dx$$

$$I_m = (\sin x + \cos x)^{m-1}\,(\sin x - \cos x) + 2\,(m-1)\,I_{m-2} - (m-1)\,I_m$$

or $(m-1)I_m + I_m = (\sin x + \cos x)^{m-1}(\sin x - \cos x) + 2(m-1)I_{m-2}$

or $\quad m\,I_m = (\sin x + \cos x)^{m-1}\,(\sin x - \cos x) + 2\,(m-1)\,I_{m-2}$

Hence Proved.

● **Ex. 33** *If $I_{m,n} = \int \cos^m x\cdot\cos nx\,dx$, show that* $(m+n)\,I_{m,n} = \cos^m x\cdot\sin nx + m\,I_{(m-1,\,n-1)}$

Sol. We have,

$$I_{m,n} = \int \underset{\text{I}}{\cos^m x}\cdot\underset{\text{II}}{\cos n\,x}\,dx$$

$$= (\cos^m x)\left[\frac{\sin nx}{n}\right] - \int m\cos^{m-1}x\,(-\sin x)\cdot\frac{\sin nx}{n}\,dx$$

$$= \frac{1}{n}\cos^m x\cdot\sin nx + \frac{m}{n}\int \cos^{m-1}x\,\{\sin x\cdot\sin nx\}\,dx$$

As we have, $\cos(n-1)\,x = \cos nx\cos x + \sin nx\sin x$

$$\therefore\ I_{m,n} = \frac{1}{n}\cos^m x\cdot\sin x + \frac{m}{n}\int \cos^{m-1}x\,\{\cos(n-1)\,x - \cos nx\cdot\cos x\}\,dx$$

$$= \frac{1}{n}\cos^m x\cdot\sin x + \frac{m}{n}\int \cos^{m-1}x\cdot\cos(n-1)\,x\,dx - \frac{m}{n}\int \cos^m x\cdot\cos n\,x\,dx$$

$$= \frac{1}{n}\cos^m x\cdot\sin nx + \frac{m}{n}\,I_{m-1,\,n-1} - \frac{m}{n}\,I_{m,n}$$

$$I_{m,n} + \frac{m}{n} I_{m,n} = \frac{1}{n} [\cos^m x \cdot \sin nx + m I_{m-1,n-1}]$$

$$\left(\frac{m+n}{n}\right) I_{m,n} = \frac{1}{n} [\cos^m x \cdot \sin nx + m I_{m-1,n-1}]$$

$$(m+n) I_{m,n} = \cos^m x \cdot \sin nx + m I_{m-1,n-1}$$

● **Ex. 34** *Evaluate* $\int \frac{\tan\left(\frac{\pi}{4} - x\right)}{\cos^2 x \sqrt{\tan^3 x + \tan^2 x + \tan x}} dx.$

Sol. $I = \int \frac{\tan\left(\frac{\pi}{4} - x\right) dx}{\cos^2 x \sqrt{\tan^3 x + \tan^2 x + \tan x}}$

$$= \int \frac{(1 - \tan^2 x)\, dx}{(1 + \tan x)^2 \cos^2 x \sqrt{\tan^3 x + \tan^2 x + \tan x}}$$

$$I = \int \frac{-\left(1 - \frac{1}{\tan^2 x}\right) \sec^2 x\, dx}{\left(\tan x + 2 + \frac{1}{\tan x}\right) \sqrt{\tan x + 1 + \frac{1}{\tan x}}}$$

let $\quad y = \sqrt{\tan x + 1 + \frac{1}{\tan x}}$

$$\Rightarrow \quad 2y\, dy = \left(\sec^2 x - \frac{1}{\tan^2 x} \cdot \sec^2 x\right) dx$$

$$\therefore \quad I = \int \frac{-2y\, dy}{(y^2+1) \cdot y} = -2 \int \frac{dy}{1+y^2} = -2 \tan^{-1} y + C$$

$$= -2 \tan^{-1}\left(\sqrt{\tan x + 1 + \frac{1}{\tan x}}\right) + C$$

● **Ex. 35** *Evaluate* $\int \frac{x^2 + n(n-1)}{(x \sin x + n \cos x)^2} dx.$

Sol. Here, $\quad I = \int \frac{x^2 + n(n-1)}{(x \sin x + n \cos x)^2} dx$

Multiplying and dividing by x^{2n-2}, we get

$$I = \int \frac{\{x^2 + n(n-1)\}\, x^{2n-2}}{(x^n \sin x + n x^{n-1} \cos x)^2} dx$$

We know $x^n \sin x + n x^{n-1} \cos x = t$

$$\Rightarrow \{(n x^{n-1} \sin x) + (x^n \cos x) + n(n-1) x^{n-2} \cos x - (n x^{n-1} \sin x)\, dx = dt\}$$

$$\Rightarrow x^{n-2} \cos x \cdot \{x^2 + n(n-1)\}\, dx = dt$$

Keeping this in mind, we put

$$I = \int \frac{\{x^2 + n(n-1)\} \cdot x^{n-2} \cdot \cos x}{(x^n \sin x + n x^{n-1} \cos x)^2} \cdot x^n \cdot \sec x\, dx$$

II I

Applying integration by parts, we get

$$= x^n \sec x \cdot \left(-\frac{1}{(x^n \sin x + n x^{n-1} \cos x)}\right) + \int \frac{(x^n \sec x \tan x + n x^{n-1} \cdot \sec x)}{(x^n \sin x + n x^{n-1} \cos x)} dx$$

$$= -\frac{(x \sec x)}{(x \sin x + n \cos x)} + \int \sec^2 x\, dx$$

$$= -\frac{(x \sec x)}{(x \sin x + n \cos x)} + \tan x + C \qquad \textbf{Hence Proved.}$$

● **Ex. 36** *If* $\cos\theta > \sin\theta > 0$, *then evaluate*

$$\int \left\{ \log\left(\frac{1+\sin 2\theta}{1-\sin 2\theta}\right)^{\cos^2\theta} + \log\left(\frac{\cos 2\theta}{1+\sin 2\theta}\right)\right\} d\theta$$

Sol. Here, $\quad I = \int \left\{ \log\left(\frac{1+\sin 2\theta}{1-\sin 2\theta}\right)^{\cos^2\theta} + \log\left(\frac{\cos 2\theta}{1+\sin 2\theta}\right)\right\} d\theta$

$$= \int \left\{ 2\cos^2\theta \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right) - \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right)\right\} d\theta$$

$$= \int (2\cos^2\theta - 1) \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right) d\theta$$

$$= \int \underset{\text{II}}{\cos 2\theta} \cdot \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right) \underset{\text{I}}{d\theta}, \text{ applying integration by parts}$$

$$= \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right) \cdot \frac{\sin 2\theta}{2} - \int \frac{2}{\cos 2\theta} \cdot \frac{\sin 2\theta}{2} d\theta$$

$$= \frac{\sin 2\theta}{2} \log\left(\frac{\cos\theta + \sin\theta}{\cos\theta - \sin\theta}\right) + \frac{1}{2} \log|\cos 2\theta| + C$$

● **Ex. 37** *Evaluate* $\int \frac{\tan^{-1} x}{x^4} dx.$

Sol. $I = \int \frac{\tan^{-1} x}{x^4} dx = \int \underset{\text{I}}{\tan^{-1} x} \cdot \underset{\text{II}}{\frac{1}{x^4}} dx$

$$= (\tan^{-1} x)\left(-\frac{1}{3x^3}\right) - \int \frac{1}{1+x^2} \cdot \frac{1}{(-3x^3)} dx$$

$$= -\frac{\tan^{-1} x}{3x^3} + \frac{1}{3} \int \frac{dx}{x^3 (1+x^2)},$$

Put $1 + x^2 = t$,

$$2x\, dx = dt = -\frac{\tan^{-1} x}{3x^3} + \frac{1}{6} \int \frac{dt}{(t-1)^2 \cdot t}$$

$$I = -\frac{\tan^{-1} x}{3x^3} + \frac{1}{6} I_1 \qquad \text{...(i)}$$

Where, $I_1 = \int \frac{1}{(t-1)^2 \cdot t} dt = \int \left\{ \frac{A}{t-1} + \frac{B}{(t-1)^2} + \frac{C}{t} \right\} dt$

Comparing coefficients, we get

$$A = -1,\ B = 1,\ C = 1$$

$$\therefore \quad I_1 = \int \left\{ -\frac{1}{(t-1)} + \frac{1}{(t-1)^2} + \frac{1}{t} \right\} dt$$

$$= -\log|t-1| - \frac{1}{(t-1)} + \log|t| \qquad \text{...(ii)}$$

$\therefore$ From Eqs. (i) and (ii), we get

$$I = -\frac{\tan^{-1} x}{3x^3} + \frac{1}{6}\left\{-\log|x^2| - \frac{1}{x^2} + \log|1+x^2|\right\} + C$$

$$= -\frac{\tan^{-1} x}{3x^3} - \frac{1}{6}\log\left|\frac{x^2+1}{x^2}\right| - \frac{1}{6x^2} + C$$

● ***Ex. 38*** *Evaluate* $\int x^2 \log(1-x^2)\,dx$, *and hence prove that* $\frac{1}{1\cdot 5} + \frac{1}{2\cdot 7} + \frac{1}{3\cdot 9} + \ldots = \frac{2}{3}\log 2 - \frac{8}{9}$.

Sol. We know, $\log(1-x) = -\left\{x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \ldots \infty\right\}$

Put x^2 instead of x in the above identity,

$$\Rightarrow \quad \log(1-x^2) = -\left\{x^2 + \frac{x^4}{2} + \frac{x^6}{3} + \frac{x^8}{4} + \ldots \infty\right\}$$

$$\Rightarrow \quad x^2\log(1-x^2) = -\left\{x^4 + \frac{x^6}{2} + \frac{x^8}{3} + \frac{x^{10}}{4} + \ldots \infty\right\}$$

Integrating both the sides, we get

$$\int x^2\log(1-x^2)\,dx = -\left\{\frac{x^5}{1\cdot 5} + \frac{x^7}{2\cdot 7} + \frac{x^9}{3\cdot 9} + \ldots \infty\right\} + C$$

Now, to find constant of integration, put $x = 0$

$$\Rightarrow \quad 0 = 0 + C$$

$$\Rightarrow \quad C = 0$$

$$\therefore \quad \int \underset{\text{II}}{x^2}\ \underset{\text{I}}{\log(1-x^2)}\,dx = -\left\{\frac{x^5}{1\cdot 5} + \frac{x^7}{2\cdot 7} + \frac{x^9}{3\cdot 9} + \ldots \infty\right\}$$

Applying integration by parts, and taking limits 0 to 1 for LHS

$$\Rightarrow \quad \left(\frac{x^3}{3}\log(1-x^2)\right)_0^1 - \int_0^1 \frac{x^3}{3}\cdot\frac{1(-2x)}{1-x^2}\,dx$$

$$\Rightarrow \quad \left(\frac{x^3}{3}\log(1-x^2)\right)_0^1 + \frac{2}{3}\left(-\frac{x^3}{3} - x + \frac{1}{2}\log\left|\frac{1+x}{1-x}\right|\right)_0^1$$

Taking $\log(1-x^2) = \log(1+x) + \log(1-x)$

and $\quad \log\left(\frac{1+x}{1-x}\right) = \log(1+x) - \log(1-x)$

$$\Rightarrow \quad \frac{1}{3}\log 2 + \frac{1}{3}\log 2 - \frac{2}{3} - \frac{2}{9} + \lim_{x\to 1}\left(\frac{x^3}{3} - \frac{1}{3}\right)\log(1-x)$$

$$\left[\because \lim_{x\to 1}(x^3-1)\log(1-x) = 0\right]$$

$$\Rightarrow \quad \frac{2}{3}\log 2 - \frac{8}{9} = \text{RHS}$$

$$\therefore \quad \frac{1}{1\cdot 5} + \frac{1}{2\cdot 7} + \frac{1}{3\cdot 9} + \ldots = \frac{2}{3}\log(2) - \frac{8}{9}$$

● ***Ex. 39*** *Evaluate* $\int \frac{a + b\sin x}{(b + a\sin x)^2}\,dx$

Sol. Here, $I = \int \frac{a + b\sin x}{(b + a\sin x)^2}\,dx = \frac{b}{a}\int \frac{\frac{a^2}{b} - b + (b + a\sin x)}{(b + a\sin x)^2}\,dx$

$$I = \frac{a^2 - b^2}{a}\int \frac{dx}{(b + a\sin x)^2} + \frac{b}{a}\int \frac{dx}{(b + a\sin x)} \qquad \ldots(\text{i})$$

Now, let $A = \frac{\cos x}{b + a\sin x} \Rightarrow \frac{dA}{dx} = \frac{-b\sin x - a}{(b + a\sin x)^2}$

$$\Rightarrow \quad \frac{dA}{dx} = -\frac{b}{a}\left\{\frac{a\sin x + b + \frac{a^2}{b} - b}{(b + a\sin x)^2}\right\}$$

$$\Rightarrow \quad \frac{dA}{dx} = -\frac{b}{a}\left\{\frac{1}{b + a\sin x} + \frac{a^2 - b^2}{b(b + a\sin x)^2}\right\}$$

Integrating both the sides w.r.t. 'x', we get

$$A = -\frac{b}{a}\int \frac{dx}{b + a\sin x} - \frac{(a^2 - b^2)}{a}\int \frac{dx}{(b + a\sin x)^2}$$

$$\Rightarrow \quad \frac{a^2 - b^2}{a}\int \frac{dx}{(b + a\sin x)^2} = -\frac{b}{a}\int \frac{dx}{b + a\sin x} - A \qquad \ldots(\text{ii})$$

From Eqs. (i) and (ii), we get

$$I = -\frac{b}{a}\int \frac{dx}{(b + a\sin x)} - A + \frac{b}{a}\int \frac{dx}{(b + a\sin x)}$$

$$\Rightarrow \quad I = -A + C \quad \Rightarrow \quad I = -\left(\frac{\cos x}{b + a\sin x}\right) + C$$

● ***Ex. 40*** *Evaluate* $\int \frac{dx}{(x-1)^{3/4}(x+2)^{5/4}}$.

Sol. Let $I = \int \frac{dx}{(x-1)^{3/4}(x+2)^{5/4}} = \int \frac{dx}{(x+2)^2\left(\frac{(x-1)}{(x+2)}\right)^{3/4}}$

Let $\quad \frac{x-1}{x+2} = t$

So that, $\quad \frac{3}{(x+2)^2}\,dx = dt$

$$\therefore \quad I = \int \frac{dt}{3\,t^{3/4}} = \frac{1}{3}\int t^{-3/4}\,dt$$

$$= \frac{1}{3}\cdot\frac{t^{1/4}}{1/4} + C = \frac{4}{3}\left(\frac{x-1}{x+2}\right)^{1/4} + C$$

Indefinite Integral Exercise 1 :
Single Option Correct Type Questions

1. Let $f(x) = \int \frac{x^2}{(1+x^2)(1+\sqrt{1+x^2})}\,dx$ and $f(0) = 0$. Then $f(1)$ is equal to

(a) $\log_e(1+\sqrt{2})$ (b) $\log_e(1+\sqrt{2}) - \frac{\pi}{4}$

(c) $\log_e(1+\sqrt{2}) + \frac{\pi}{4}$ (d) None of these

2. If $\int f(x)\,dx = f(x)$, then $\int \{f(x)\}^2\,dx$ is equal to

(a) $\frac{1}{2}\{f(x)\}^2$ (b) $\{f(x)\}^3$

(c) $\frac{\{f(x)\}^3}{3}$ (d) $\{f(x)\}^2$

3. If $\int f(x)\,dx = F(x)$, then $\int x^3 f(x^2)\,dx$ is equal to

(a) $\frac{1}{2}[x^2\{F(x)\}^2 - \int \{F(x)\}^2\,dx]$

(b) $\frac{1}{2}[x^2F(x^2) - \int F(x^2)\,d(x^2)]$

(c) $\frac{1}{2}[x^2F(x) - \frac{1}{2}\int \{F(x)\}^2\,dx]$

(d) None of the above

4. If n is an odd positive integer, then $\int |x^n|\,dx$ is equal to

(a) $\left|\frac{x^{n+1}}{n+1}\right| + C$ (b) $\frac{x^{n+1}}{n+1} + C$

(c) $\frac{|x|^n x}{n+1} + C$ (d) None of these

5. Let $F(x)$ be the primitive of $\frac{3x+2}{\sqrt{x-9}}$ w.r.t. x. If $F(10) = 60$, then the value of $F(13)$ is

(a) 66 (b) 132

(c) 248 (d) 264

6. $\int (x^x)^x\,(2x\log_e x + x)\,dx$ is equal to

(a) $x^{(x^x)} + C$ (b) $(x^x)^x + C$

(c) $x^2 \cdot \log_e x + C$ (d) None of these

7. The value of $\int x\log x(\log x - 1)\,dx$ is equal to

(a) $2(x\log x - x)^2 + C$

(b) $\frac{1}{2}(x\log x - x)^2 + C$

(c) $(x\log x)^2 + C$

(d) $\frac{1}{2}(x\log x)^3 + C$

8. $\int \frac{x^2-1}{x^3\sqrt{2x^4-2x^2+1}}\,dx$ is equal to

(a) $\frac{\sqrt{2x^4-2x^5+1}}{x^2} + C$ (b) $\frac{\sqrt{2x^4-2x^2+1}}{x^3} + C$

(c) $\frac{\sqrt{2x^4+2x^2+1}}{x} + C$ (d) $\frac{\sqrt{2x^4-2x^2+1}}{2x^2} + C$

9. Let $f(x)$ be a polynomial satisfying $f(0) = 2$, $f'(0) = 3$ and $f''(x) = f(x)$. Then $f(4)$ is equal to

(a) $\frac{5(e^8+1)}{2e^4}$ (b) $\frac{5(e^8-1)}{2e^4}$

(c) $\frac{2e^4}{5(e^8-1)}$ (d) $\frac{2e^4}{5(e^8+1)}$

10. $\int \frac{e^{(x^2+4\ln x)} - x^3 e^{x^2}}{x-1}\,dx$ is equal to

(a) $\left(\frac{e^{3\ln x} - e^{\ln x}}{2x}\right)e^{x^2} + C$ (b) $\frac{(x-1)xe^{x^2}}{2} + C$

(c) $\frac{(x^2-1)}{2x} - e^{x^2} + C$ (d) None of these

11. $\int \tan^4 x\,dx = A\tan^3 x + B\tan x + f(x)$, then

(a) $A = \frac{1}{3}$, $B = -1$, $f(x) = x + C$

(b) $A = \frac{2}{3}$, $B = -1$, $f(x) = x + C$

(c) $A = \frac{1}{3}$, $B = 1$, $f(x) = x + C$

(d) $A = \frac{2}{3}$, $B = 1$, $f(x) = -x + C$

12. If the anti-derivative of $\int \frac{\sin^4 x}{x}\,dx$ is $f(x)$, then $\int \frac{\sin^4\{(p+q)x\}}{x}\,dx$ in terms of $f(x)$ is

(a) $f\{(p+q)x\}$ (b) $\frac{f\{(p+q)x\}}{p+q}$

(c) $f\{(p+q)x\}(p+q)$ (d) None of these

13. $\int\left(\frac{\sin\theta}{\cos 3\theta} + \frac{\sin 3\theta}{\cos 9\theta} + \frac{\sin 9\theta}{\cos 27\theta}\right)d\theta$ is equal to

(a) $\frac{1}{2}\log\left|\frac{\sec 27\theta}{\sec\theta}\right| + C$ (b) $\frac{1}{2}\log\left|\frac{\sec\theta}{\sec 27\theta}\right| + C$

(c) $\frac{1}{2}\log\left|\frac{\sqrt[27]{\sec 27\theta}}{\sec\theta}\right| + C$ (d) None of these

14. Let $x^2 \neq n\pi - 1, n \in N$. Then, the value of $\int x\sqrt{\frac{2\sin(x^2+1)-\sin 2(x^2+1)}{2\sin(x^2+1)+\sin 2(x^2+1)}}\,dx$ is equal to

(a) $\log\left|\frac{1}{2}\sec(x^2+1)\right|+C$ (b) $\log\left|\sec\left(\frac{x^2+1}{2}\right)\right|+C$

(c) $\frac{1}{2}\log|\sec(x^2+1)|+C$ (d) None of these

15. $\int \frac{dx}{\cos(2x)\cos(4x)}$ is equal to

(a) $\frac{1}{2\sqrt{2}}\log\left|\frac{1+\sqrt{2}\sin 2x}{1-\sqrt{2}\sin 2x}\right|-\frac{1}{2}(\log|\sec 2x-\tan 2x|)+C$

(b) $\frac{1}{2\sqrt{2}}\log\left|\frac{1+\sqrt{2}\sin 2x}{1+\sqrt{2}\sin x}\right|-\frac{1}{2}(\log|\sec 2x-\tan 2x|)+C$

(c) $\frac{1}{\sqrt{2}}\log\left|\frac{1+\sqrt{2}\sin 2x}{1-\sqrt{2}\sin 2x}\right|-\frac{1}{2}(\log|\sec 2x-\tan 2x|)+C$

(d) None of the above

16. $\int \frac{1-7\cos^2 x}{\sin^7 x\cos^2 x}\,dx=\frac{f(x)}{(\sin x)^7}+C$, then $f(x)$ is equal to

(a) $\sin x$ (b) $\cos x$ (c) $\tan x$ (d) $\cot x$

17. $\int \frac{\sin^3 x}{(\cos^4 x+3\cos^2 x+1)\tan^{-1}(\sec x+\cos x)}\,dx$ is equal to

(a) $\tan^{-1}(\sec x+\cos x)+C$ (b) $\log_e|\tan^{-1}(\sec x+\cos x)|+C$

(c) $\frac{1}{(\sec x+\cos x)^2}+C$ (d) None of these

18. The primitive of the function $f(x)=x|\cos x|$, when $\frac{\pi}{2}<x<\pi$ is given by

(a) $\cos x+x\sin x+C$

(b) $-\cos x-x\sin x+C$

(c) $x\sin x-\cos x+C$

(d) None of the above

19. The primitive of the function $f(x)=(2x+1)|\sin x|$, when $\pi<x<2\pi$ is

(a) $-(2x+1)\cos x+2\sin x+C$

(b) $(2x+1)\cos x-2\sin x+C$

(c) $(x^2+x)\cos x+C$

(d) None of the above

20. Given, $f(x)=\begin{vmatrix} 0 & x^2-\sin x & \cos x-2 \\ \sin x-x^2 & 0 & 1-2x \\ 2-\cos x & 2x-1 & 0 \end{vmatrix}$, then $\int f(x)\,dx$ is equal to

(a) $\frac{x^3}{3}-x^2\sin x+\sin 2x+C$

(b) $\frac{x^3}{3}-x^2\sin x-\cos 2x+C$

(c) $\frac{x^3}{3}-x^2\cos x-\cos 2x+C$

(d) None of the above

Indefinite Integral Exercise 2 :
More than One Option Correct Type Questions

21. $\int \frac{dx}{(x+1)(x-2)}=A\log(x+1)+B\log(x-2)+C$, where

(a) $A+B=0$ (b) $AB=0$

(c) $A/B=-1$ (d) None of these

22. If $\int \frac{dx}{(x^2+1)(x^2+4)}=k\tan^{-1}x+l\tan^{-1}\frac{x}{2}+C$, then

(a) $k=\frac{1}{3}$ (b) $l=\frac{2}{3}$ (c) $k=-\frac{1}{3}$ (d) $l=-\frac{1}{6}$

23. If $\int x\log(1+x^2)\,dx=\phi(x)\log(1+x^2)+x(\psi)+C$, then

(a) $\phi(x)=\frac{1+x^2}{2}$ (b) $\psi(x)=\frac{1+x^2}{2}$

(c) $\psi(x)=-\frac{1+x^2}{2}$ (d) $\phi(x)=-\frac{1+x^2}{2}$

24. If $\int \frac{4e^x+6e^{-x}}{9e^x-4e^{-x}}\,dx=Ax+B\log_e(9e^{2x}-4)+C$, then

(a) $A=\frac{3}{2}$ (b) $B=\frac{35}{36}$

(c) C is indefinite (d) $A+B=-\frac{19}{36}$

25. If $\int \tan^5 x\,dx=A\tan^4 x+B\tan^2 x+g(x)+C$, then

(a) $A=\frac{1}{4}, B=-\frac{1}{2}$

(b) $g(x)=\ln|\sec x|$

(c) $g(x)=\ln|\cos x|$

(d) $A=-\frac{1}{4}, B=\frac{1}{3}$

Indefinite Integral Exercise 3 :
Statement I and II Type Questions

■ **Directions** (Q. Nos. 26 to 30) For the following questions, choose the correct answers from the codes (a), (b), (c) and (d) defined as follows :

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I.

(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I.

(c) Statement I is true, Statement II is false.

(d) Statement I is false, Statement II is true.

26. **Statement I** If y is a function of x such that $y(x-y)^2 = x$, then $\int \frac{dx}{x-3y} = \frac{1}{2}[\log(x-y)^2 - 1]$

Statement II $\int \frac{dx}{x-3y} = \log(x-3y) + C$

27. **Statement I** Integral of an even function is not always an odd function.

Statement II Integral of an odd function is an even function.

28. **Statement I** If $a>0$ and $b^2 - 4ac < 0$, then the value of the integral $\int \frac{dx}{ax^2+bx+c}$ will be of the type $\mu \tan^{-1}\frac{x+A}{B} + C$, where A, B, C, μ are constants.

Statement II If $a>0, b^2 - 4ac < 0$, then $ax^2 + bx + C$ can be written as sum of two squares.

29. **Statement I** $\int \left(\frac{1}{1+x^4}\right) dx = \tan^{-1}(x^2) + C$

Statement II $\int \frac{1}{1+x^2} dx = \tan^{-1} x + C$

30. **Statement I** $\int 2^{\tan^{-1} x} d(\cot^{-1} x) = \frac{2^{\tan^{-1} x}}{\ln 2} + C$

Statement II $\frac{d}{dx}(a^x + C) = a^x \ln a$

Indefinite Integral Exercise 4 :
Passage Based Questions

Passage I

(Q. Nos. 31 to 33)

Let us consider the integral of the following forms

$$f(x_1, \sqrt{mx^2 + nx + p})^{1/2}$$

Case I *If* $m>0$, *then put* $\sqrt{mx^2 + nx + C} = u \pm x\sqrt{m}$

Case II *If* $p>0$, *then put* $\sqrt{mx^2 + nx + C} = ux \pm \sqrt{p}$

Case III *If quadratic equation* $mx^2 + nx + p = 0$ *has real roots* α *and* β *there put* $\sqrt{mx^2 + nx + p} = (x-\alpha)u$ or $(x-\beta)u$

31. If $I = \int \frac{dx}{x - \sqrt{9x^2 + 4x + 6}}$ to evaluate I, one of the most proper substitution could be

(a) $\sqrt{9x^2 + 4x + 6} = u \pm 3x$

(b) $\sqrt{9x^2 + 4x + 6} = 3u \pm x$

(c) $x = \frac{1}{t}$

(d) $9x^2 + 4x + 6 = \frac{1}{t}$

32. $\int \frac{(x + \sqrt{1+x^2})^{15}}{\sqrt{1+x^2}} dx$ is equal to

(a) $\frac{(x + \sqrt{1+x^2})^{16}}{10} + C$

(b) $\frac{1}{15(\sqrt{1+x^2} + x)} + C$

(c) $\frac{15}{(\sqrt{1+x^2} - x)} + C$

(d) $\frac{(x + \sqrt{1+x^2})^{15}}{15} + C$

33. To evaluate $\int \frac{dx}{(x-1)\sqrt{-x^2 + 3x - 2}}$ one of the most suitable substitution could be

(a) $\sqrt{-x^2 + 3x - 2} = u$

(b) $\sqrt{-x^2 + 3x - 2} = (ux\sqrt{2})$

(c) $\sqrt{-x^2 + 3x - 2} = u(1-x)$

(d) $\sqrt{-x^2 + 3x - 2} = u(x+2)$

Passage II

(Q. Nos. 34 to 36)

Let $I_{n,m} = \int \sin^n x \cos^m x\, dx$. *Then, we can relate* $I_{n,m}$ *with each of the following* :

(i) $I_{n-2,m}$ (ii) $I_{n+2,m}$

(iii) $I_{n,m-2}$ (iv) $I_{n,m+2}$

(v) $I_{n-2,m+2}$ (vi) $I_{n+2,m-2}$

Suppose we want to establish a relation between $I_{n,m}$ *and* $I_{n,m-2}$ *, then we get*

$$P(x) = \sin^{n+1} x \cos^{m-1} x \qquad \ldots(i)$$

In $I_{n,m}$ *and* $I_{n,m-2}$ *the exponent of* $\cos x$ *is* m *and* $m-2$ *respectively, the minimum of the two is* $m-2$, *adding* 1 *to the minimum we get* $m-2+1=m-1$. *Now, choose the exponent* $m-1$ *of* $\cos x$ *in* $P(x)$. *Similarly, choose the exponent of* $\sin x$ *for* $P(x) = (nH)\sin^n x \cos^m x - (m-1)\sin^{n+2} x \cos^{m-2} x$.

Now, differentiating both the sides of Eq. (i), *we get*

$$= (n+1)\sin^n x \cos^m x - (m-1)\sin^n x (1-\cos^2 x)\cos^{m-2} x$$

$$= (n+1)\sin^n x \cos^m x - (m-1)\sin^n x \cos^{m-2} x + (m-1)\sin^n x \cos^n x$$

$$= (n+m)\sin^n x \cos^m x - (m-1)\sin^n x \cos^{m-2} x$$

Now, integrating both the sides, we get

$$\sin^{n+1} x \cos^{m-1} x = (n+m) I_{n,m} - (m-1) I_{n,m-2}$$

Similarly, we can establish the other relations.

34. The relation between $I_{4,2}$ and $I_{2,2}$ is

(a) $I_{4,2} = \frac{1}{6}(-\sin^3 x \cos^3 x + 3 I_{2,2})$

(b) $I_{4,2} = \frac{1}{6}(\sin^3 x \cos^3 x + 3 I_{2,2})$

(c) $I_{4,2} = \frac{1}{6}(\sin^3 x \cos^3 x - 3 I_{2,2})$

(d) $I_{4,2} = \frac{1}{4}(-\sin^3 x \cos^3 x + 2 I_{2,2})$

35. The relation between $I_{4,2}$ and $I_{6,2}$ is

(a) $I_{4,2} = \frac{1}{5}(\sin^5 x \cos^3 x + 8 I_{6,2})$

(b) $I_{4,2} = \frac{1}{5}(-\sin^5 x \cos^3 x + 8 I_{6,2})$

(c) $I_{4,2} = \frac{1}{5}(\sin^5 x \cos^3 x - 8 I_{6,2})$

(d) $I_{4,2} = \frac{1}{6}(\sin^5 x \cos^3 x + 8 I_{6,2})$

36. The relation between $I_{4,2}$ and $I_{4,4}$ is

(a) $I_{4,2} = \frac{1}{3}(\sin^5 x \cos^3 x + 8 I_{4,4})$

(b) $I_{4,2} = \frac{1}{3}(-\sin^5 x \cos^3 x + 8 I_{4,4})$

(c) $I_{4,2} = \frac{1}{3}(\sin^5 x \cos^3 x - 8 I_{4,4})$

(d) $I_{4,2} = \frac{1}{3}(\sin^5 x \cos^3 x + 6 I_{4,4})$

Passage III

(Q. Nos. 37 to 38)

If $f : R \to (0, \infty)$ be a differentiable function $f(x)$ satisfying $f(x+y) - f(x-y) = f(x)\cdot\{f(y) - f(y) - y\}$, $\forall\, x, y \in R$, $(f(y) \neq f(-y)$ for all $y \in R)$ and $f'(0) = 2010$.

Now, answer the following questions.

37. Which of the following is true for $f(x)$

(a) $f(x)$ is one-one and into

(b) $\{f(x)\}$ is non-periodic, where $\{\cdot\}$ denotes fractional part of x.

(c) $f(x) = 4$ has only two solutions.

(d) $f(x) = f^{-1}(x)$ has only one solution.

38. let $g(x) = \log_e(\sin x)$, and $\int f(g(x)) \cos x\, dx = h(x) + c$, (where c is constant of integration), then $h\left(\frac{\pi}{2}\right)$ is equal to

(a) 0 (b) $\frac{1}{2010}$

(c) 1 (d) $\frac{1}{2011}$

Passage IV

(Q. Nos. 39 to 41)

Let $f : R \to R$ *be a function as* $f(x) = (x-1)(x+2)(x-3)(x-6) - 100$. *If* $g(x)$ *is a polynomial of degree* ≤ 3 *such that* $\int \frac{g(x)}{f(x)}\, dx$ *does not contain any logarithm function and* $g(-2) = 10$. *Then*

39. The equation $f(x) = 0$ has

(a) all four distinct roots

(b) three distinct real roots

(c) two real and two imaginary

(d) all four imaginary roots

40. The minimum value of $f(x)$ is

(a) -136 (b) -100

(c) -84 (d) -68

41. $\int \frac{g(x)}{f(x)}\, dx$, equals

(a) $\tan^{-1}\left(\frac{x-2}{2}\right) + c$ (b) $\tan^{-1}\left(\frac{x-1}{1}\right) + c$

(c) $\tan^{-1}(x) + c$ (d) None of these

Indefinite Integral Exercise 5 :
Matching Type Questions

42. Match the following :

	Column I		Column II
(A)	If $I = \int \frac{\sin x - \cos x}{\lvert \sin x - \cos x \rvert}\, dx$, where $\frac{\pi}{4} < x < \frac{3\pi}{8}$, then I is equal to	(p)	$\sin x$
(B)	If $\int \frac{x^2}{(x^3+1)(x^3+2)}\, dx = \frac{1}{3} f\left(\frac{x^3+1}{x^3+2}\right) + C$, then $f(x)$ is equal to	(q)	$x + C$
(C)	If $\int \sin^{-1} x \cdot \cos^{-1} x\, dx = f^{-1}(x)\left[\frac{\pi}{2} x - x f^{-1}(x) - 2\sqrt{1-x^2}\right] + 2x + C$, then $f(x)$ is equal to	(r)	$\ln \lvert x \rvert$
(D)	If $\int \frac{dx}{x f(x)} = f(f(x)) + C$, then $f(x)$ is equal to	(s)	$\sin^{-1} x$

43. Match the following :

	Column I		Column II
(A)	If $\int \left(\frac{x^2 + \cos^2 x}{1+x^2}\right) \operatorname{cosec}^2 x\, dx = A \cot^{-1} x + B \frac{\operatorname{cosec} x}{\sec x}$, then	(p)	$A = 1$
(B)	If $\int \sqrt{x + \sqrt{x^2+2}}\, dx = \frac{A}{3}(x + \sqrt{x^2+2})^{3/2} - \frac{B}{(x + \sqrt{x^2+2})}$, then	(q)	$B = -1$
(C)	If $\int \frac{\sqrt{2-x-x^2}}{x^2}\, dx = A\sqrt{\frac{2-x-x^2}{x}} + \frac{B}{4\sqrt{2}} \log\left(\frac{4 - x + 4\sqrt{2-x-x^2}}{x}\right) - \sin^{-1}\left(\frac{2x+1}{3}\right)$, then	(r)	$B = 2$
(D)	If $\int \frac{\sin 2x}{\sin^4 x + \cos^4 x}\, dx = B \cot^{-1}(\tan^2 x)$, then	(s)	$A = -1$

Indefinite Integral Exercise 6 :
Single Integer Answer Type Questions

44. If $\int \frac{(2x+3)\, dx}{x(x+1)(x+2)(x+3)+1} = C - \frac{1}{f(x)}$, where $f(x)$ is of the form of $ax^2 + bx + c$, then $(a+b+c)$ equals to ..... .

45. Let $F(x)$ be the primitive of $\frac{3x+2}{\sqrt{x-9}}$ w.r.t. x. If $F(10) = 60$, then the sum of digits of the value of $F(13)$, is ..... .

46. Let $u(x)$ and $v(x)$ are differentiable function such that $\frac{u(x)}{v(x)} = 7$. If $\frac{u'(x)}{v'(x)} = p$ and $\left(\frac{u(x)}{v(x)}\right)' = q$, then $\frac{p+q}{p-q}$ has the value equal to ..... .

47. If $\int \frac{1}{(x^2-1)} \ln\left(\frac{x-1}{x+1}\right) dx = 6A\left[\ln\left(\frac{x-1}{x+1}\right)\right]^2 + C$, then find $24A$.

48. If $\int \frac{e^x (2-x^2)}{(1-x)\sqrt{1-x^2}}\, dx = \mu e^x \left(\frac{1+x}{1-x}\right)^{\lambda} + C$, then $2(\lambda + \mu)$ is equal to ..... .

49. If $\int \frac{\cos x - \sin x + 1 - x}{e^x + \sin x + x}\,dx = \ln\{f(x)\} + g(x) + C$, where C is the constant of integrating and $f(x)$ is positive, then $\frac{f(x)+g(x)}{e^x + \sin x}$ is equal to ..... .

50. Suppose $A = \int \frac{dx}{x^2 + 6x + 25}$ and $B = \int \frac{dx}{x^2 - 6x - 27}$.

If $12(A+B) = \lambda \cdot \tan^{-1}\left(\frac{x+3}{4}\right) + \mu \cdot \ln\left|\frac{x-9}{x+3}\right| + C$, then the value of $(\lambda + \mu)$ is ... .

51. If $\int \frac{\cos 6x + \cos 9x}{1 - 2\cos 5x}\,dx = -\frac{\sin 4x}{k} - \sin x + C$, then the value of k is ..... .

52. The value of $\int \frac{\tan x}{1 + \tan x + \tan^2 x}\,dx = x - \frac{1}{\sqrt{A}}\tan^{-1}\left(\frac{2\tan x + 1}{\sqrt{A}}\right) + C$, then the value of A is..... .

53. $\int \sin^{5/2} x \cos^3 x\,dx = 2\sin^{A/2} x\left[\frac{1}{B} - \frac{1}{C}\sin^2 x\right] + C$, then the value of $(A+B) - C$ is equal to ..... .

54. If $\int (x^{2010} + x^{804} + x^{402})(2x^{1608} + 5x^{402} + 10)^{1/402}\,dx = \frac{1}{10a}(2x^{2010} + 5x^{804} + 10x^{402})^{a/402}$. Then $(a - 400)$ is equal to .....

55. If $\int e^{x^3 + x^2 - 1}(3x^4 + 2x^3 + 2x)\,dx = h(x) + c$ Then the value of $h(1)\cdot h(-1)$, is .....

Indefinite Integral Exercise 7 :
Subjective Type Questions

56. Evaluate $e^{(x\sin x + \cos x)}dx\left[\frac{x^4\cos^3 x - x\sin x + \cos x}{x^2\cos^2 x}\right]$

57. Evaluate $\int \sqrt{x + \sqrt{x^2 + 2}}\,dx$.

58. Evaluate $\int \frac{dx}{(\sqrt{(x-\alpha)^2 - \beta^2})(ax+b)}$.

59. Evaluate $\int \frac{\sqrt{1 + \sqrt[3]{x}}}{\sqrt[3]{x^2}}\,dx$.

60. Evaluate $\int \frac{\sin^3(\theta/2)\,d\theta}{\cos\theta/2\sqrt{\cos^3\theta + \cos^2\theta + \cos\theta}}$.

61. Evaluate $\int \frac{(2\sin\theta + \sin 2\theta)\,d\theta}{(\cos\theta - 1)\sqrt{\cos\theta + \cos^2\theta + \cos^3\theta}}$.

62. Connect $\int x^{m-1}(a + bx^n)^p\,dx$ with $\int x^{m-n-1}(a+bx^n)^p\,dx$ and evaluate $\int \frac{x^8\,dx}{(1-x^3)^{1/3}}$.

63. Evaluate $\int \operatorname{cosec}^2 x \ln(\cos x + \sqrt{\cos 2x})\,dx$.

64. Evaluate $\int \frac{dx}{(\sin x + a\sec x)^2}$, $a \in N$.

65. Evaluate $\int \frac{dx}{x - \sqrt{x^2 + 2x + 4}}$.

66. Evaluate $\int \frac{dx}{1 + \sqrt{x^2 + 2x + 2}}$.

67. Evaluate $\int \frac{x^4 + 1}{x^6 + 1}\,dx$.

68. Evaluate $\int \frac{dx}{(1-x^3)^{1/3}}\,dx$.

69. Evaluate $\int \frac{(x + \sqrt{1+x^2})^{15}}{\sqrt{1+x^2}}\,dx$.

70. If $y^2 = ax^2 + 2bx + c$, and $u_n = \int \frac{x^n}{y}\,dx$, prove that $(n+1)\,a\,u_{n+1} + (2n+1)\,bu_n + {}^nc\,y_{n-1} = x^n y$ and deduce that $au_1 = y - b\,u_0$; $2a^2u_2 = y(ax - 3b) - (ac - 3b^2)\,u_0$.

Indefinite Integrals Exercise 8 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

71. $\int \frac{\sec^2 x}{(\sec x + \tan x)^{9/2}}\,dx$ equals to (for some arbitrary constant K) **[Only One Correct Option 2012]**

(a) $\frac{-1}{(\sec x + \tan x)^{11/2}}\left\{\frac{1}{11} - \frac{1}{7}(\sec x + \tan x)^2\right\} + K$

(b) $\frac{1}{(\sec x + \tan x)^{11/2}}\left\{\frac{1}{11} - \frac{1}{7}(\sec x + \tan x)^2\right\} + K$

(c) $\frac{-1}{(\sec x + \tan x)^{11/2}}\left\{\frac{1}{11} + \frac{1}{7}(\sec x + \tan x)^2\right\} + K$

(d) $\frac{1}{(\sec x + \tan x)^{11/2}}\left\{\frac{1}{11} + \frac{1}{7}(\sec x + \tan x)^2\right\} + K$

72. If $I = \int \frac{e^x}{e^{4x} + e^{2x} + 1}\,dx$, $J = \int \frac{e^{-x}}{e^{-4x} + e^{-2x} + 1}\,dx$. Then, for an arbitrary constant c, the value of $J - I$ equals **[Only One Correct Option 2008]**

(a) $\frac{1}{2}\log\left|\frac{e^{4x} - e^{2x} + 1}{e^{4x} + e^{2x} + 1}\right| + C$ (b) $\frac{1}{2}\log\left|\frac{e^{2x} + e^x + 1}{e^{2x} - e^x + 1}\right| + C$

(c) $\frac{1}{2}\log\left|\frac{e^{2x} - e^x + 1}{e^{2x} + e^x + 1}\right| + C$ (d) $\frac{1}{2}\log\left|\frac{e^{4x} + e^{2x} + 1}{e^{4x} - e^{2x} + 1}\right| + C$

(ii) JEE Main & AIEEE

73. The integral $\int \frac{2x^{12} + 5x^9}{(x^5 + x^3 + 1)^3}\,dx$ is equal to **[2016 JEE Main]**

(a) $\frac{-x^5}{(x^5 + x^3 + 1)^2} + C$ (b) $\frac{x^{10}}{2(x^5 + x^3 + 1)^2} + C$

(c) $\frac{x^5}{2(x^5 + x^3 + 1)^2} + C$ (d) $\frac{-x^{10}}{2(x^5 + x^3 + 1)^2} + C$

where, C is an arbitrary constant.

74. The integral $\int \frac{dx}{x^2(x^4 + 1)^{\frac{3}{4}}}$ equals **[2015 JEE Main]**

(a) $\left(\frac{x^4 + 1}{x^4}\right)^{\frac{1}{4}} + C$ (b) $(x^4 + 1)^{\frac{1}{4}} + C$

(c) $-(x^4 + 1)^{\frac{1}{4}} + C$ (d) $-\left(\frac{x^4 + 1}{x^4}\right)^{\frac{1}{4}} + C$

75. The integral $\int \left(1 + x - \frac{1}{x}\right) e^{x + \frac{1}{x}}\,dx$ is equal to **[2014 JEE Main]**

(a) $(x - 1)\,e^{x + \frac{1}{x}} + C$ (b) $x e^{x + \frac{1}{x}} + C$

(c) $(x + 1)\,e^{x + \frac{1}{x}} + C$ (d) $-x e^{x + \frac{1}{x}} + C$

76. If $\int f(x)\,dx = \psi(x)$, then $\int x^5 f(x^3)\,dx$ is equal to **[2013 JEE Main]**

(a) $\frac{1}{3}[x^3\psi(x^3) - \int x^2\psi(x^3)dx] + C$

(b) $\frac{1}{3}x^3\psi(x^3) - 3\int x^3\psi(x^3)\,dx + C$

(c) $\frac{1}{3}x^3\psi(x^3) - \int x^2\psi(x^3)\,dx + C$

(d) $\frac{1}{3}[x^3\psi(x^3) - \int x^3\psi(x^3)\,dx] + C$

77. If the integral $\int \frac{5\tan x}{\tan x - 2}\,dx = x + a\log|\sin x - 2\cos x| + k$, then a is equal to **[2012 AIEEE]**

(a) -1 (b) -2

(c) 1 (d) 2

78. The value of $\sqrt{2}\int \frac{\sin x\,dx}{\sin\left(x - \frac{\pi}{4}\right)}$ is **[2012 AIEEE]**

(a) $x + \log\left|\cos\left(x - \frac{\pi}{4}\right)\right| + C$ (b) $x + \log\left|\sin\left(x - \frac{\pi}{4}\right)\right| + C$

(c) $x - \log\left|\sin\left(x - \frac{\pi}{4}\right)\right| + C$ (d) $x - \log\left|\cos\left(x - \frac{\pi}{4}\right)\right| + C$

Solutions

1. Let $I = \sqrt{\dfrac{x^2}{(1+x^2)1+(1+x^2)}}\,dx$

Put $x = \tan\theta \Rightarrow dx = \sec^2 d\theta$

Putting, $x = \tan\theta$, $I = \int \dfrac{\tan^2\theta}{1+\sec\theta}\,d\theta$

$= \int (\sec\theta - 1)\,d\theta$

$= \log(\sec\theta + \tan\theta) - \theta + C$

$f(x) = \log_e(x + \sqrt{x^2+1}) - \tan^{-1} x + C$

$f(0) = 0 \Rightarrow C = 0$

$\Rightarrow \quad f(1) = \log_e(1+\sqrt{2}) - \tan^{-1} 1$

$= \log_e(1+\sqrt{2}) - \dfrac{\pi}{4}$

2. We have, $\int f(x)\,dx = f(x)$

$\Rightarrow \quad \dfrac{d}{dx}\{f(x)\} = f(x) \quad \Rightarrow \quad \dfrac{1}{f(x)}\,d\{f(x)\} = dx$

$\Rightarrow \quad \log\{f(x)\} = x + \log C \quad \Rightarrow \quad f(x) = Ce^x$

$\Rightarrow \quad \{f(x)\}^2 = C^2e^{2x}$

$\Rightarrow \quad \int \{f(x)\}^2\,dx = \int C^2e^{2x}\,dx = \dfrac{C^2e^{2x}}{2} = \dfrac{1}{2}\{f(x)\}^2$

3. We have, $\int f(x)\,dx = F(x)$

$\therefore \quad \int x^3 f(x^2)\,dx = \dfrac{1}{2}\int \underbrace{x^2}_{\text{I}}\ \underbrace{f(x^2)\,d(x^2)}_{\text{II}}$

$= \dfrac{1}{2}[x^2F(x^2) - \int F(x^2)\,d(x^2)]$

4. We have the following cases :

***Case* I** When $x \geq 0$

In this case, we have

$\int |x^n|\,dx = \int |x|^n\,dx = \int x^n\,dx \qquad [\because |x| = x]$

$= \dfrac{x^{n+1}}{n+1} + C = \dfrac{|x|^n x}{n+1} + C \qquad [\because x \geq 0 \Rightarrow |x| = x]$

***Case* II** When $x \leq 0$

In this case, we have $|x| = -x$

$\therefore \quad \int |x^n|\,dx = \int |x|^n\,dx$

$= \int (-x)^n\,dx = -\int x^n\,dx \qquad [\because n \text{ in odd}]$

$= -\dfrac{x^{n+1}}{n+1} + C = \dfrac{(-x)^n x}{n+1} + C = \dfrac{|x|^n x}{n+1} + C$

Hence, $\int |x^n|\,dx = \dfrac{|x|^n x}{n+1} + C$

5. $F(x) = \int \dfrac{3x+2}{\sqrt{x-9}}\,dx$. Let $x - 9 = t^2$

$\Rightarrow \quad dx = 2t\,dt$

$\therefore \quad F(x) = \int \left(\dfrac{3(t^2+9)+2}{t}\cdot 2t\right) dt$

$= 2\int (29 + 3t^2)\,dt = 2[29t + t^3]$

$F(x) = 2[29\sqrt{x-9} + (x-9)^{3/2}] + C$

Given, $F(10) = 60 = 2[29+1] + C \Rightarrow C = 0$

$\therefore \quad F(x) = 2[29\sqrt{x-9} + (x-9)^{3/2}]$

$F(13) = 2[29\times 2 + 4\times 2] = 132$

6. We have, $\int (x^x)^x\,(2x\log_e x + x)\,dx$

$= \int x^{x^2}(2x\log_e x + x)\,dx$

$= \int 1\cdot d(x^{x^2}) = x^{x^2} + C = (x^x)^x + C$

7. We have, $\int x\log x(\log x - 1)\,dx$

$= \int \log x\,(x\log x - x)\,dx$

$= \int (x\log x - x)\,d(x\log x - x)$

$= \dfrac{(x\log x - x)^2}{2} + C$

8. $\int \dfrac{\left(\dfrac{1}{x^3} - \dfrac{1}{x^5}\right)dx}{\sqrt{2 - \dfrac{2}{x^2} + \dfrac{1}{x^4}}}$

Let $2 - \dfrac{2}{x^2} + \dfrac{1}{x^4} = z \Rightarrow \dfrac{1}{4}\int \dfrac{dz}{\sqrt{z}}$

$\Rightarrow \quad \dfrac{1}{2}\sqrt{z} + C \Rightarrow \dfrac{1}{2}\sqrt{2 - \dfrac{2}{x^2} + \dfrac{1}{x^4}} + C$

or $\sqrt{\dfrac{2x^4 - 2x^2 + 1}{2x^2}} + C$

9. We have, $f''(x) = f(x)$

$\Rightarrow \quad 2f'(x)\,f''(x) = 2f(x)\,f'(x)$

$\Rightarrow \quad \dfrac{d}{dx}\{f'(x)\}^2 = \dfrac{d}{dx}\{f(x)\}^2$

$\Rightarrow \quad \{f'(x)\}^2 = \{f(x)\}^2 + C \qquad \ldots(i)$

Now, $f(0) = 2$ and $f'(0) = 3$. Therefore, from Eq. (i), we get

$\{f'(0)\}^2 = \{f(0)\}^2 + C$

$\Rightarrow \quad 9 = 4 + C \Rightarrow C = 5$

$\therefore \quad \{f'(x)\}^2 = \{f(x)\}^2 + 5$

$\Rightarrow \quad f'(x) = \sqrt{5 + \{f(x)\}^2}$

$\Rightarrow \quad \int \dfrac{1}{\sqrt{(\sqrt{5})^2 + \{f(x)\}^2}}\,d\{f(x)\} = \int dx$

$\Rightarrow \quad \log\left|f(x) + \sqrt{5 + \{f(x)\}^2}\right| = x + C_1$

$\therefore \quad f(0)=2 \Rightarrow \log|2+3|=C_1$

$\Rightarrow \quad C_1=\log 5$

$\therefore \quad \log|f(x)+\sqrt{5+\{f(x)\}^2}|=x+\log 5$

$\Rightarrow \log\left\{\frac{f(x)+\sqrt{5+\{f(x)\}^2}}{5}\right\}=x$

$\Rightarrow f(x)+\sqrt{5+\{f(x)\}^2}=5e^x$

$\Rightarrow \sqrt{5+\{f(x)\}^2}+f(x)=5e^x$ and $\sqrt{5+\{f(x)\}^2}-f(x)=5e^{-x}$

$\Rightarrow \quad 2f(x)=5(e^x-e^{-x})$

$\Rightarrow \quad f(x)=\frac{5}{2}(e^x-e^{-x})$

$\Rightarrow \quad f(4)=\frac{5}{2}(e^4-e^{-4}) \Rightarrow f(4)=\frac{5(e^8-1)}{2e^4}$

10. We have, $\int \frac{e^{x^2+4\ln x}-x^3e^{x^2}}{x-1}dx=\int \frac{e^{x^2}\cdot x^4-x^3e^{x^2}}{x-1}dx$

$=\int x^3e^{x^2}dx=\frac{1}{2}\int te^t dt$, [where $t=x^2$]

$=\frac{1}{2}(t-1)e^t+C=\frac{1}{2}(x^2-1)e^{x^2}+C$

11. $\int \tan^4 x\,dx=\int(\tan^2 x\sec^2 x-\sec^2 x+1)\,dx$

$=\frac{\tan^3 x}{3}-\tan x+x+C$

$\Rightarrow \quad A=\frac{1}{3}, B=-1$ and $f(x)=x+C$

12. $\int \frac{\sin^4 x}{x}dx=f(x) \Rightarrow \int \frac{\sin^4(p+q)x}{(p+q)x}dx=\frac{f\{(p+q)x\}}{p+q}$

$\int \frac{\sin^4(p+q)x}{x}dx=f\{(p+q)x\}$

13. On solving, $\frac{\sin\theta}{\cos 3\theta}=\frac{1}{2}[\tan 3\theta-\tan\theta]$

$\frac{\sin 3\theta}{\cos 9\theta}=\frac{1}{2}[\tan 9\theta-\tan 3\theta]$

$\frac{\sin 9\theta}{\cos 27\theta}=\frac{1}{2}[\tan 27\theta-\tan 9\theta]$

$\therefore \int\left(\frac{\sin\theta}{\cos 3\theta}+\frac{\sin 3\theta}{\cos 9\theta}+\frac{\sin 9\theta}{\cos 27\theta}\right)d\theta=\frac{1}{2}\int(\tan 27\theta-\tan\theta)\,d\theta$

$=\frac{1}{2}\left\{\frac{1}{27}\log(\sec 127\theta)-\log(\sec\theta)\right\}+C$

$=\frac{1}{2}\log\frac{\sqrt[27]{\sec 27\theta}}{\sec\theta}+C$

14. We have, $\int x\sqrt{\frac{2\sin(x^2+1)-\sin 2(x^2+1)}{2\sin(x^2+1)+\sin 2(x^2+1)}}dx$

$=\int x\sqrt{\frac{2\sin(x^2+1)-2\sin(x^2+1)\cos(x^2+1)}{2\sin(x^2+1)+2\sin(x^2+1)\cos(x^2+1)}}dx$

$=\int x\sqrt{\frac{1-\cos(x^2+1)}{1+\cos(x^2+1)}}dx=\int x\tan\left(\frac{x^2+1}{2}\right)dx$

$=\int \tan\left(\frac{x^2+1}{2}\right)d\left(\frac{x^2+1}{2}\right)=\log\left|\sec\left(\frac{x^2+1}{2}\right)\right|+C$

15. $\int \frac{\sin(4x-2x)\,dx}{\sin(2x)\cos(2x)\cos(4x)}=\int \frac{\sin(4x)\,dx}{\sin(2x)\cos(4x)}-\int \sec 2x\,dx$

$=2\int \frac{\cos 2x\,dx}{\cos 4x}-\frac{1}{2}(\log|\sec 2x-\tan 2x|)$

$=2\int \frac{\cos 2x}{(1-2\sin^2 2x)}dx-\frac{1}{2}(\log|\sec 2x-\tan 2x|)$

$=\frac{2}{2\sqrt{2}}\left[\frac{1}{2\times 1}\log\left|\frac{1+\sqrt{2}\sin 2x}{1-\sqrt{2}\sin 2x}\right|\right]-\frac{1}{2}\log|\sec 2x-\tan 2x|+C$

$=\frac{1}{2\sqrt{2}}\left[\log\left|\frac{1+\sqrt{2}\sin 2x}{1-\sqrt{2}\sin 2x}\right|\right]-\frac{1}{2}\log|\sec 2x-\tan 2x|+C$

16. $\int \frac{1-7\cos^2 x}{\sin^7 x\cos^2 x}dx=\int\left(\frac{\sec^2 x}{\sin^7 x}-\frac{7}{\sin^7 x}\right)dx$

$=\int \frac{\sec^2 x}{\sin^7 x}dx-\int \frac{7}{\sin^7 x}dx=I_1+I_2$

Now, $I_1=\int \frac{\sec^2 x}{\sin^7 x}dx=\frac{\tan x}{\sin^7 x}+7\int \frac{\tan x\cdot\cos x}{\sin^8 x}dx$

$=\frac{\tan x}{\sin^7 x}+I_2$

$\therefore \quad I_1+I_2=\frac{\tan x}{\sin^2 x}+C \Rightarrow f(x)=\tan x$

17. We have, $\int \frac{\sin^3 x}{(\cos^4 x+3\cos^2 x+1)\tan^{-1}(\sec x+\cos x)}dx$

$=\int \frac{\frac{\sin^3 x}{\cos^2 x}}{(\cos^2 x+3+\sec^2 x)\tan^{-1}(\sec x+\tan x)}dx$

$=\int \frac{1}{1+(\sec x+\cos x)^2}\times\frac{\sin x(1-\cos^2 x)}{\cos^2 x}$

$\times\frac{1}{\tan^{-1}(\sec x+\tan x)}dx$

$=\int \frac{1}{\tan^{-1}(\sec x+\cos x)}\times\frac{1}{1+(\sec x+\cos x)^2}$

$(\tan x\sec x-\sin x)\,dx$

$=\int \frac{1}{\tan^{-1}(\sec x+\cos x)}d|\tan^{-1}(\sec x+\cos x)|$

$=\log_e|\tan^{-1}(\sec x+\cos x)|+C$

18. We have, $f(x)=x|\cos x|, \frac{\pi}{2}<x<\pi$

$\Rightarrow \quad f(x)=-x\cos x$ [$\because \cos x<0$ for $x\in(\pi/2,\pi)$]

Hence, required primitive is given by

$\int f(x)\,dx=-\int x\cos x\,dx+C=-x\sin x-\cos x+C$

19. We have, $f(x) = (2x+1)\,|\sin x|,\ \pi < x < 2\pi$

$\Rightarrow \quad f(x) = -(2x+1)\sin x$

Hence, required primitive is given by

$$-\int \underset{\text{I}}{(2x+1)}\ \underset{\text{II}}{\sin x}\,dx = -[-(2x+1)\cos x + 2\sin x] + C$$

$$= (2x+1)\cos x - 2\sin x + C$$

20. We have, $f(x) = \begin{vmatrix} 0 & x^2-\sin x & \cos x - 2 \\ \sin x - x^2 & 0 & 1-2x \\ 2-\cos x & 2x-1 & 0 \end{vmatrix}$

$$\Rightarrow \quad f(x) = \begin{vmatrix} 0 & \sin x - x^2 & 2-\cos x \\ x^2-\sin x & 0 & 2x-1 \\ \cos x - 2 & 1-2x & 0 \end{vmatrix}$$

[Interchanging rows and columns]

$$\Rightarrow \quad f(x) = (-1)^3 \begin{vmatrix} 0 & x^2-\sin x & \cos x - 2 \\ \sin x - x^2 & 0 & 1-2x \\ 2-\cos x & 2x-1 & 0 \end{vmatrix}$$

[Taking (-1) common from each column]

$\Rightarrow \quad f(x) = -f(x)$

$\Rightarrow \quad f(x) = 0$

$\Rightarrow \quad \int f(x)\,dx = 0$

21. $$\int \frac{dx}{(x+1)(x-2)} = \int \left(-\frac{1}{3(x+1)} + \frac{1}{3(x-2)}\right) dx$$

$$= -\frac{1}{3}\log(x+1) + \frac{1}{3}\log(x-2) + C$$

$\therefore \quad A = -\frac{1}{3},\ B = \frac{1}{3}$

$\therefore \quad A + B = 0 \ \Rightarrow \ \frac{A}{B} = \frac{-\frac{1}{3}}{\frac{1}{3}} = -1$

22. $$\frac{1}{3}\int \left(\frac{1}{x^2+1} - \frac{1}{x^2+4}\right) dx$$

$$\Rightarrow \ \frac{1}{3}\tan^{-1}x - \frac{1}{6}\tan^{-1}\frac{x}{2} = k\tan^{-1}x + l\tan^{-1}\frac{x}{2}$$

$\therefore \quad k = \frac{1}{3} \quad \text{and} \quad l = -\frac{1}{6}$

23. $$I = \int \underset{\text{I}}{x}\ \underbrace{\log(1+x^2)}_{\text{II}}\,dx = \log(1+x^2)\cdot\frac{x^2}{2} - \int \frac{1}{1+x^2}\cdot 2x\cdot\frac{x^2}{2}\,dx$$

$$= \frac{x^2}{2}\log(1+x^2) - \int \frac{x^3}{x^2+1}\,dx$$

$$I = \left(\frac{x^2+1}{2}\right)\log(1+x^2) - \left(\frac{x^2+1}{2}\right) + C$$

$\therefore \quad \phi(x) = \frac{x^2+1}{2},\ \psi(x) = -\left(\frac{1+x^2}{2}\right)$

24. $$I = \int \frac{4e^2 + 6^{-x}}{9e^x - 4e^{-x}}\,dx$$

$$I = \int \frac{4e^{2x} + 6}{9e^{2x} - 4}\,dx, \text{ put } 9e^{2x} - 4 = z \ \Rightarrow \ 18e^{2x}dx = dz$$

Then, $$I = \int \frac{1}{z}\left\{4\cdot\frac{z+4}{9} + 6\right\}\frac{1}{18}\,\frac{dz}{\frac{z+4}{9}}$$

$$= \int \frac{1}{z(z+4)}\left\{\frac{2z+8}{9} + 3\right\} dz$$

$$= \frac{1}{9}\int \frac{2z+35}{z(z+4)}\,dz = \frac{1}{9}\int \frac{2(z+4)+27}{z(z+4)}\,dz$$

$$= \frac{2}{9}\int \frac{dz}{z} + \frac{3}{4}\int\left(\frac{1}{z} - \frac{1}{z+4}\right) dz$$

$$= \left(\frac{2}{9} + \frac{3}{4}\right)\log z - \frac{3}{4}\log(z+4) + C$$

$$= \frac{35}{36}\log(9e^{2x} - 4) = \frac{3}{4}\log(e^{2x}) + C$$

$$= -\frac{3}{2}x + \frac{35}{36}\log(9e^{2x} - 4) - \frac{3}{2}\log 3 + C$$

25. $$\int \tan^3 x\,(\sec^2 x - 1)\,dx = \int \tan^3 x\sec^2 x\,dx - \int \tan^3 x\,dx$$

$$I_1 = \int \tan^3 x\sec^2 x\,dx = \frac{\tan^4 x}{4} + C_1$$

$$I_2 = \int \tan x\,(\sec^2 x - 1)\,dx$$

$$= \frac{\tan^2 x}{2} - \ln|\sec x| + C_2$$

26. The Statement II is false since while writing

$$\int \frac{dx}{x-3y} = \log(x-3y) + C,$$

we are assuming that y is a constant. We will know prove the Statement I. From the given relation $(x-y)^2 = \frac{x}{y}$ and

$$2\log(x-y) = \log x - \log y.$$

Also, $\frac{dy}{dx} = \left(-\frac{y}{x}\right)\cdot\frac{x+y}{x-3y}$. To prove the integral relation it is sufficient to show that $\frac{d}{dx}\text{RHS} = \frac{1}{x-3y}$.

Now, $\text{RHS} = \frac{1}{2}\log\left[\frac{x}{y} - 1\right] \qquad \left[\because (x-y)^2 = \frac{x}{y}\right]$

$$= \frac{1}{2}[\log(x-y) - \log y]$$

$$= \frac{1}{2}\left[\frac{\log x - \log y}{2} - \log y\right] = \frac{1}{4}[\log x - 3\log y]$$

$$\Rightarrow \ \frac{d}{dx}\text{RHS} = \frac{1}{4}\left[\frac{1}{x} - \frac{3}{y}\frac{dy}{dx}\right]$$

$$= \frac{1}{4}\left[\frac{1}{x} - \frac{3}{y}\left(-\frac{y}{x}\right)\frac{x+y}{x-3y}\right] = \frac{1}{x-3y}$$

Thus, Statement I is true. Hence, choice (c) is correct.

27. Let $g(x) = f(x) + f(-x)$

Assuming, $\int f(x)\,dx = F(x) + C$

$$\int g(x)\,dx = \int \{f(x) + f(-x)\}\,dx$$
$$= \int f(x)\,dx + \int f(-x)\,dx$$
$$= F(x) + C + \{-F(-x) + C'\}$$
$$= F(x) - F(-x) + C + C'$$

which may be an odd function, if $C + C' = 0$.

Similarly, integral of an odd function is not always an even function.

Hence, Statement I is true and Statement II is false.

28. If $a > 0$ and $b^2 - 4ac < 0$, then

$$ax^2 + bx + c = a\left(x + \frac{b}{2a}\right)^2 + \frac{4ac - b^2}{4a}$$

$$\Rightarrow \quad \int \frac{dx}{ax^2 + bx + c} = \int \frac{dx}{a\left(x + \frac{b}{2a}\right)^2 + k^2}$$

where $k^2 = \dfrac{4ac - b^2}{4a} > 0$. which will have an answer of the type

$$\frac{1}{a} \cdot \frac{1}{k/\sqrt{a}} \tan^{-1} \frac{x + \frac{b}{2a}}{k/\sqrt{a}} + C \quad \text{or} \quad \mu \tan^{-1} \frac{x + A}{B} + C$$

Thus, choice (a) is correct.

29. $I = \int \dfrac{dx}{x^4 + 1} \Rightarrow I = \dfrac{1}{2} \int \dfrac{\frac{2}{x^2}}{x^2 + \frac{1}{x^2}}\,dx$

$$= \frac{1}{2} \int \frac{\left(1 + \frac{1}{x^2}\right)}{\left(x - \frac{1}{x}\right)^2 + 2}\,dx - \frac{1}{2} \int \frac{\left(1 - \frac{1}{x^2}\right)}{\left(x + \frac{1}{x}\right)^2 - 2}\,dx$$

$$I = \frac{1}{2} \cdot \frac{1}{\sqrt{2}} \tan^{-1}\left(\frac{x - \frac{1}{x}}{2}\right) + \frac{1}{2} \cdot \frac{1}{2} \log\left(\frac{x + \frac{1}{x} - 1}{x + \frac{1}{x} + 1}\right) + C$$

$\therefore$ Statement I is false.

30. Since, $\cot^{-1} x = \dfrac{\pi}{2} - \tan^{-1} x,$

$\therefore \quad d(\cot^{-1} x) = -\,d\,(\tan^{-1} x)$

Thus, $\int 2^{\tan^{-1} x}\,d(\cot^{-1} x) = -\int 2^{\tan^{-1} x}\,d(\tan^{-1} x)$

$$= -\frac{2^{\tan^{-1} x}}{\ln 2} + C$$

$\therefore$ Statement I is false. Statement II is true.

31. As $m = 9 > 0$, hence, we can substitute

$$\sqrt{9x^2 + 4x + 6} = u \pm 3x$$

32. Here, as per notations given, we can substitute

$$\sqrt{1 + x^2} = (u - x)$$

As $m = 1 > 0$ and $p = 1 > 0$

$$\Rightarrow \quad I = \int \frac{u^{15}}{u}\,du = \int u^{14} du = \frac{1}{15} u^{15} + C$$
$$= \frac{1}{15}(x + \sqrt{1 + x^2})^{15} + C$$

33. Here, $m = -1 < 0$

$p = -2 < 0$

Also, $-x^2 + 3x - 2 = -(x - 1)(x - 2)$

We can use case III

$\Rightarrow$ Putting, $\sqrt{-x^2 + 3x - 2} = u(x - 2)$

or $\quad (x - 1)\,u \quad$ or $\quad u(1 - x)$

34. Let $P = \sin^3 x \cos^3 x$

$$\frac{dP}{dx} = 3\sin^2 x \cos^4 x - 3\sin^4 x \cos^2 x$$
$$= 3\sin^2 x (1 - \sin^2 x)\cos^2 x - 3\sin^4 x \cos^2 x$$
$$= 3\sin^2 x \cos^2 x - 6\sin^4 x \cos^2 x$$

$\therefore \quad P = 3I_{2,2} - 6I_{4,2}$

$\therefore \quad I_{4,2} = \dfrac{1}{6}(-P + 3I_{2,2})$

35. Let $P = \sin^5 x \cos^3 x$

$\therefore \quad \dfrac{dP}{dx} = 5\sin^4 x \cos^4 x - 3\sin^6 x \cos^2 x$

$$= 5\sin^4 x (1 - \sin^2 x)\cos^2 x - 3\sin^6 x \cos^2 x$$
$$= 5\sin^4 x \cos^2 x - 8\sin^6 x \cos^2 x$$

$\therefore \quad P = 5I_{4,2} - 8I_{6,2}$

$\therefore \quad I_{4,2} = \dfrac{1}{5}(P + 8I_{6,2})$

36. Let $P = \sin^5 x \cos^3 x$

$\therefore \quad \dfrac{dP}{dx} = 5\sin^4 x \cos^4 x - 3\sin^6 x \cos^2 x$

$$= 5\sin^4 x \cos^4 x - 3\sin^4 x (1 - \cos^2 x)\cos^2 x$$
$$= 8\sin^4 x \cos^4 x - 3\sin^4 x \cos^2 x$$

$\therefore \quad P = 8I_{4,4} - 3I_{4,2}$

$\therefore \quad I_{4,2} = \dfrac{1}{3}(-P + 8I_{4,4})$

37. Here, $2f'(x) = \lim\limits_{h \to 0}\left(\dfrac{f(x + h) - f(x)}{h} + \dfrac{f(x\,x - h) - f(x)}{-h}\right)$

$$= \lim_{h \to 0}\left(\frac{f(x + h) - f(x - h)}{h}\right) \qquad \ldots(i)$$

$\therefore \quad 2f'(0) \lim\limits_{h \to 0}\left(\dfrac{f(h) - f(0)}{h} + \dfrac{f(-h) - f(0)}{-h}\right)$

$$= \lim_{h \to 0} \frac{f(h) - f(-h)}{h} \ldots(ii)$$

Now by given relation, we have

$f(h) - f(-h) = \dfrac{f(x + h) - f(x - h)}{-h}$ and $f(0) = 1$

From Eqs. (i) and (ii), we have $\frac{f'(x)}{f(x)} = 2010$

$\Rightarrow \quad f(x) = e^{2010e}, f(0) = 1$

$\therefore$ $\{f(x)\}$ is non-periodic.

38. Here, $\int f(g(x)) \cos x\, dx = \int f(\log(\sin x)) . \cos x\, dx$

$$= \int e^{2010 \log (\sin x)} . \cos x\, dx$$

$$= \int (\sin x)^{2010} . \cos x\, dx$$

$$= \int (\sin x)^{2010} . \cos x\, dx$$

$$= \frac{(\sin x)^{2011}}{2011} + C$$

$\therefore \quad h(x) = \frac{(\sin x)^{2011}}{2011}$

$\Rightarrow \quad h\left(\frac{\pi}{2}\right) = \frac{1}{2011}$

Sol. (Q.Nos. 39 to 41)

Here, $f(x) = (x-1)(x+2)(x-3)(x-6) - 100$

$$= (x^2 - 4x + 3)(x^2 - 4x - 12) - 100$$

$$= (x^2 - 4x)^2 - 9(x^2 - 4x) - 136$$

$$= (x^2 - 4x + 8)(x^2 - 4x - 17)$$

39. $\therefore f(x) = 0 \Rightarrow \underbrace{(x^2 - 4x + 8)}_{D > 0} \underbrace{(x^2 - 4x + 17}_{D < 0} = 0$

$\therefore$ Equation has two distinct and two imaginary roots.

40. $f(x) = (x^2 - 4x - 17)(x^2 - 4x + 8)$

$$= \{((x-2)^2 - 21\}\{(x-2)^2 + 4\}$$

$\because \quad (f(x))_{\min} = (-21)(4) = -84$

which occurs at $x = 2$

41. $\because \quad \int \frac{g(x)}{f(x)} = \frac{g(x)}{(x^2 - 4x - 17)(x^2 - 4x + 8)}$

$$= \frac{Ax + B}{x^2 - 4x - 17} + \frac{Cx + D}{x^2 - 4x + 8}$$

Clearly, A, B and C must be zero.

$\therefore \quad \frac{g(x)}{(x^2 - 4x - 17)(x^2 - 4x + 8)} = \frac{D}{x^2 - 4x + 8}$

$\therefore \quad g(x) = D(x^2 - 4x - 17)$

$g(-2) = D(4 + 8 - 17) = -10$ [given]

$\Rightarrow \quad \frac{g(x)}{f(x)} = \frac{2(x^2 - 4x - 17)}{(x^2 - 4x - 17)(x^2 - 4x + 8)} = \frac{2}{x^2 - 4x + 8}$

$\therefore \quad \int \frac{g(x)}{f(x)}\, dx = \int \frac{2}{x^2 - 4x + 8}\, dx = 2\int \frac{dx}{(x-2)^2 + (2)^2}$

$$= 2 \cdot \frac{1}{2} \tan^{-1}\left(\frac{x-2}{2}\right) + C = \tan^{-1}\left(\frac{x-2}{2}\right) + C$$

42. (A) If $\frac{\pi}{4} < x < \frac{3\pi}{8}$, then $\sin x > \cos x$

$\therefore \quad \int \frac{\sin x - \cos x}{|\sin x - \cos x|}\, dx = \int 1\, dx = x + C$

(B) $\int \frac{x^2 dx}{(x^3 + 1)(x^3 + 2)} = \frac{1}{3}\int 3x^2 \left(\frac{1}{x^3 + 1} - \frac{1}{x^3 + 2}\right) dx$

$$= \frac{1}{3} \ln \left|\frac{x^3 + 1}{x^3 + 2}\right| + C$$

(C) $\int \sin^{-1} x \cos^{-1} x\, dx = \int \left[\frac{\pi}{2} \sin^{-1} x - (\sin^{-1} x)^2\right] dx$

$\Rightarrow \frac{\pi}{2}(x \sin^{-1} x + \sqrt{1 - x^2}) - \{x(\sin^{-1} x)^2$

$$+ \sin^{-1} x \sqrt{1 - x^2} - x\} + C \text{ (by parts)}$$

$\Rightarrow \sin^{-1} x \left[\frac{\pi}{2} x - x \sin^{-1} x - 2\sqrt{1 - x^2}\right] + \frac{\pi}{2}\sqrt{1 - x^2} + 2x + C$

$\therefore \quad f^{-1}(x) = \sin^{-1} x,\ f(x) = \sin x$

(D) $\int \frac{dx}{x \ln |x|} = \ln |\ln |x|| + C$

$\therefore \quad f(x) = \ln |x|$

43. (A) $I = \int \left(\frac{x^2 + \cos^2 x}{1 + x^2}\right) \cdot \operatorname{cosec}^2 x\, dx$

$$= \int \left(\frac{x^2 + 1 - \sin^2 x}{1 + x^2}\right) \cdot \operatorname{cosec}^2 x\, dx$$

$$= \int \left(\operatorname{cosec}^2 x - \frac{1}{1 + x^2}\right) dx = -\cot x + \cot^{-1} x + k$$

$\Rightarrow \quad A = 1,\ B = -1$

(B) $I = \int \sqrt{x + \sqrt{x^2 + 2}}\, dx$

Put $\sqrt{x^2 + 2} + x = t \quad \Rightarrow \quad \sqrt{x^2 + 2} - x = \frac{2}{t}$

$\therefore \quad 2x = t - \frac{2}{t} \quad \Rightarrow \quad 2\, dx = \left(1 + \frac{2}{t^2}\right) dt$

$$= \frac{1}{2}\int \left(\sqrt{t} + \frac{2}{t^{3/2}}\right) dt$$

$\Rightarrow \quad I = \frac{1}{2} \cdot \frac{t^{3/2}}{\frac{3}{2}} + \frac{1}{-\frac{1}{2} t^{1/2}} + k$

$$= \frac{1}{3}(x + \sqrt{x^2 + 2})^{3/2} - \frac{2}{\sqrt{x + \sqrt{x^2 + 2}}} + k$$

$\Rightarrow \quad A = 1$ and $B = 2$

(C) $I = \int \frac{2 - x - x^2}{x^2 \sqrt{2 - x - x^2}}\, dx$

$$= -\int \frac{dx}{\sqrt{2 - x - x^2}} + 2\int \frac{dx}{x^2 \sqrt{2 - x - x^2}} - \int \frac{dx}{x\sqrt{2 - x - x^2}}$$

$$= -\int \frac{dx}{\sqrt{\frac{9}{4} - \left(x + \frac{1}{2}\right)^2}} + 2\int -\frac{dt}{\sqrt{2 - \frac{1}{t} - \frac{1}{t^2}}} + \int \frac{\frac{1}{t}dt}{\sqrt{2 - \frac{1}{t} - \frac{1}{t^2}}} \quad \left(\text{put } x = \frac{1}{t}\right)$$

$$= -\sin^{-1}\left(\frac{2x+1}{3}\right) - \frac{1}{2}\int \frac{(4t-1)dt}{\sqrt{2t^2 - t - 1}} + \frac{1}{2}\int \frac{dt}{\sqrt{2t^2 - t - 1}}$$

$$= -\sin^{-1}\left(\frac{2x+1}{3}\right) - \frac{1}{2}\frac{\sqrt{2t^2 - t - 1}}{\frac{1}{2}} + \frac{1}{2\sqrt{2}}\int \frac{dt}{\sqrt{t^2 - \frac{t}{2} - \frac{1}{2} + \frac{1}{16} - \frac{1}{16}}}$$

$$= -\sin^{-1}\left(\frac{2x+1}{3}\right) - \frac{\sqrt{2 - x - x^2}}{x} + \frac{1}{2\sqrt{2}}\log\left|\left(t - \frac{1}{4}\right) + \sqrt{2t^2 - t - 1}\right| + K$$

$$= -\frac{\sqrt{2 - x - x^2}}{x} + \frac{1}{2\sqrt{2}}\log\left|\frac{(4-x) + \sqrt{2 - x - x^2}}{4x}\right| - \sin^{-1}\left(\frac{2x+1}{3}\right) + K$$

(D) $\int \frac{\sin 2x}{\sin^4 x + \cos^4 x}\,dx$, dividing N^r and D^r by $\cos^4 x$

$$I = \int \frac{2\tan x \cdot \sec^2 x}{\tan^4 x + 1}dx, \text{ put } \tan^2 x = t$$

$\Rightarrow 2\tan x \cdot \sec^2 x\,dx = dt = \int \frac{dt}{t^2+1} = -\cot^{-1}(t) + C$

$\Rightarrow -\cot^{-1}(\tan^2 x) + C \quad \therefore B = -1$

44. $\int \frac{2x+3}{(x^2+3x)(x^2+3x+2)+1}\,dx$

Put $x^2 + 3x = t \Rightarrow (2x+3)\,dx = dt$

$$\int \frac{dt}{t(t+2)+1} = \int \frac{dt}{(t+1)^2} = C - \frac{1}{t+1} = C - \frac{1}{x^2+3x+1}$$

$\Rightarrow \quad a = 1, b = 3, c = 1 \Rightarrow a + b + c = 5$

45. $F(x) = \int \frac{3x+2}{\sqrt{x-9}}\,dx.$

Let $x - 9 = t^2 \Rightarrow dx = 2t\,dt$

$\therefore \quad F(x) = \int \left(\frac{3(t^2+9)+2}{t} \cdot 2t\right) dt$

$$= 2\int (29 + 3t^2)\,dt = 2[29t + t^3]$$

$$F(x) = 2[29\sqrt{x-9} + (x-9)^{3/2}] + C$$

Given, $F(10) = 60 = 2[29 + 1] + C$

$\Rightarrow \quad C = 0$

$\therefore \quad F(x) = 2[29\sqrt{x-9} + (x-9)^{3/2}]$

$$F(13) = 2[29 \times 2 + 4 \times 2]$$

$$= 4 \times 33 = 132$$

Hence, sum of digits $= 1 + 3 + 2 = 6$

46. $u(x) = 7v(x) \Rightarrow u'(x) = 7v'(x)$

$\Rightarrow \quad p = 7$ (given)

Again, $\frac{u(x)}{v(x)} = 7 \Rightarrow \left(\frac{u(x)}{v(x)}\right)' = 0$

$\Rightarrow \quad q = 0$

Now, $\frac{p+q}{p-q} = \frac{7+0}{7-0} = 1$

47. Let $t = \ln\left(\frac{x-1}{x+1}\right) \Rightarrow \frac{dt}{dx} = \frac{2}{x^2-1}$

$$I = \int \frac{1}{2}t\,dt = \frac{1}{4}t^2 + C$$

$$I = \frac{1}{4}\left[\ln\left(\frac{x-1}{x+1}\right)\right]^2 + C$$

$\Rightarrow \quad 6A = \frac{1}{4} \Rightarrow 24A = 1$

48. $I = \int e^x \left(\frac{1}{(1-x)\sqrt{1-x^2}} + \sqrt{\frac{1+x}{1-x}}\right) dx$

As $\frac{d}{dx}\left(\sqrt{\frac{1+x}{1-x}}\right) = \frac{1}{(1-x)\sqrt{1-x^2}}$

$\therefore \quad I = e^x\sqrt{\frac{1+x}{1-x}} + C \Rightarrow I = e^x\left(\frac{1+x}{1-x}\right)^{1/2} + C$

$\Rightarrow \quad \mu = 1, \lambda = \frac{1}{2}$

$\Rightarrow \quad 2(\mu + \lambda) = 2\left(1 + \frac{1}{2}\right) = 2 \times \frac{3}{2} = 3$

49. $I = \int \frac{(e^x + \cos x + 1) - (e^x + \sin x + x)}{e^x + \sin x + x}\,dx$

$$= \ln(e^x + \sin x + x) - x + C$$

$\therefore \quad f(x) = e^x + \sin x + x$ and $g(x) = -x$

$\Rightarrow \quad f(x) + g(x) = e^x + \sin x$

$\Rightarrow \quad \frac{f(x) + g(x)}{e^x + \sin x} = 1$

50. $12\left[\frac{1}{4}\tan^{-1}\frac{x+3}{4} + \frac{1}{2\cdot 6}\ln\left|\frac{x-9}{x+3}\right|\right] = 3\tan^{-1}\left(\frac{x+3}{4}\right) + \ln\left|\frac{x-9}{x+3}\right|$

$\Rightarrow \quad \lambda = 3, \mu = 1$

$\Rightarrow \quad \lambda + \mu = 4$

51. $\frac{2\cos\frac{15}{2}x\cos\frac{3}{2}x}{1 - 2\left(2\cos^2\frac{5x}{2} - 1\right)} = \frac{2\left(4\cos^3\frac{5x}{2} - 3\cos\frac{5x}{2}\right)\cos\frac{3x}{2}}{3 - 4\cos^2\frac{5x}{2}}$

$$= -2\cos\frac{5x}{2}\cos\frac{3x}{2}$$

$$= -(\cos 4x + \cos x)$$

$$I = -\frac{\sin 4x}{4} - \sin x + C$$

52. $I=\int \frac{\tan x}{1+\tan x+\tan^2 x}\,dx=\int \frac{\frac{\sin x}{\cos x}}{\frac{1}{\cos^2 x}+\frac{\sin x}{\cos x}}\,dx$

$=\int \frac{\sin 2x}{2+\sin 2x}\,dx=\int dx-2\int \frac{dx}{2+\sin 2x}$

$=x-2\int \frac{\sec^2 x}{2\sec^2 x+2\tan x}\,dx$

Let $t=\tan x, dt=\sec^2 x\,dx$

$=x-\frac{2}{2}\int \frac{dx}{t^2+t+1}=x-\int \frac{dt}{\left(t+\frac{1}{2}\right)^2+\left(\frac{\sqrt{3}}{2}\right)^2}$

$I=x-\frac{1}{\sqrt{3}}\tan^{-1}\left(\frac{2\tan x+1}{\sqrt{3}}\right)+C$

53. $\int \sin^{5/2}x\cos^3 x\,dx=\int \sin^2 x\sin^{1/2}x\cos^2 x\cos x\,dx$

$=\int \sin^2 x\sin^{1/2}x(1-\sin^2 x)\cos x\,dx$

$=\int t^2 t^{1/2}(1-t^2)\,dt=\int [t^{5/2}-t^{9/2}]dt$

$=\int t^{5/2}dt-\int t^{9/2}dt=\frac{t^{7/2}}{7/2}-\frac{t^{11/2}}{11/2}+C$

$=\frac{2}{7}t^{7/2}-\frac{2}{11}t^{11/2}+C=\frac{2}{7}\sin^{7/2}x-\frac{2}{11}\sin^{11/2}x+C$

$=2\sin^{7/2}x\left[\frac{1}{7}-\frac{1}{11}\sin^2 x\right]+C$

$\Rightarrow \quad A=7, B=7, C=11$

$\Rightarrow \quad (A+B)-C=(7+7)-11=3$

54. Let $I=\int (x^{2010}+x^{804}+x^{402})(2x^{1608}+5x^{402}+10)^{1/402}dx$

$=\int x(x^{2009}+x^{508}+x^{401})\cdot(2x^{1608}+5x^{402}+10)^{1/402}dx$

$=\int (x^{2009}+x^{803}+x^{401})\cdot(2x^{2010}+5x^{804}+10^{402})^{1/402}dx$

Put $2x^{2010}+5x^{804}+10^{x^{402}}=t$

$\Rightarrow \quad 4020(x^{2009}+x^{803}+x^{401})\,dx=dt$

$\therefore \quad I=\int \frac{1}{4020}\cdot(t)^{1/402}dt=\frac{1}{4020}\cdot\frac{t^{1/420+1}}{1/402+1}$

$=\frac{1}{4020}\cdot\frac{t^{403/402}}{403/402}$

$=\frac{1}{4030}(2x^{2010}+5x^{804}+10^{402})^{403/402}$

$\therefore \; a-400=3$

55. Let $e^{x^3+x^2-1}(3x^4+2x^3+2x)\,dx$

$=\int x^2\cdot e^{x^3+x^2-1}\cdot(3x^2+2x)\,dx+\int e^{x^3+x^2-1}\cdot(2x)\,dx$

I II

Applying by parts in first internal, we get

$I=x\cdot e^{x^3+x^2-1}-\int 2x\cdot e^{x^3+x^2-1}dx+\int e^{x^3-x^2-1}(2x)\,dx$

$=x^2\cdot e^{x^3+x^2-1}+C=h(x)+C$

$\therefore \quad h(x)=x^2\cdot e^{x^3+x^2-1}$

$\Rightarrow \quad h(1)\cdot h(-1)=e^1\cdot e^{-1}=1$

56. $I=\int e^{(x\sin x+\cos x)}\left\{\frac{x^4\cos^3 x-x\sin x+\cos x}{x^2\cos^2 x}\right\}dx$

$=\int e^{(x\sin x+\cos x)}\cdot(x^2\cos x)\,dx$

$-\int e^{(x\sin x+\cos x)}\cdot\frac{d}{dx}\left(\frac{1}{x\cos x}\right)dx$

$=e^{(x\sin x+\cos x)}\cdot\left(x-\frac{1}{x\cos x}\right)+C$

57. $I=\int \sqrt{x+\sqrt{x^2+2}}\,dx$

Let $x+\sqrt{x^2+2}=p$ or $x^2+2=p^2+x^2-2px$

$\Rightarrow \quad x=\frac{p^2-2}{2p}$ or $dx=\frac{(p^2+2)\,dp}{2p^2}$

$I=\int \frac{p^{1/2}(p^2+2)}{2p^2}\,dp=\frac{1}{2}\int p^{1/2}\,dp+\int p^{-3/2}\,dp$

$=\frac{1}{3}(x+\sqrt{x^2+2})^{3/2}-2\frac{1}{\sqrt{x+\sqrt{x^2+2}}}+C$

58. $I=\int \frac{dx}{(ax+b)\sqrt{(x-\alpha)^2-\beta^2}}$

Put $(x-\alpha)=\beta\sec\theta \Rightarrow dx=\beta\sec\theta\tan\theta\,d\theta$

$\therefore \quad I=\int \frac{d\theta}{a(\alpha\cos\theta+\beta)+b\cos\theta}$

$=\int \frac{d\theta}{(a\alpha+b)\cos\theta+a\beta}$

$=\frac{1}{(a\alpha+b)}\int \frac{d\theta}{\cos\theta+\left(\frac{a\beta}{a\alpha+b}\right)}$

if $\left|\frac{a\beta}{a\alpha+b}\right|<1$ ...(i)

Then, $I=\frac{1}{(a\alpha+b)}\cdot\operatorname{cosec}\alpha^1\log\left|\frac{\cot\frac{\alpha^1}{2}+1}{\cot\frac{\alpha^1}{2}-1}\right|+C$

where $\frac{a\beta}{a\alpha+b}=\cos\alpha^1,\ \tan\frac{\theta}{2}=t$

Again, if $\left|\frac{a\beta}{a\alpha+b}\right|>1$

$I=\frac{1}{a\alpha+b}\cot\alpha^1\tan^{-1}\left(t\tan\frac{\alpha^1}{2}\right)$

where $\sec\alpha^1=\frac{a\beta}{a\alpha+b} \Rightarrow \tan\frac{\theta}{2}=t$

59. $I=\int \frac{\sqrt{1+\sqrt[3]{x}}}{\sqrt[3]{x^2}}\,dx=\int x^{-2/3}(1+x^{1/3})^{1/2}\,dx,$

$m=-\frac{2}{3}, n=\frac{1}{3}, p=\frac{1}{2}$

$\therefore \quad \dfrac{m+1}{n} = 1$ ie, integer

$\therefore$ Let us make the substitution,

$$1 + x^{1/3} = t^2 \quad \therefore \quad \frac{1}{3} x^{-2/3}\, dx = 2t\, dt$$

Hence, $$I = 6 \int t^2\, dt = 2t^3 + C = 2(1 + x^{1/3})^{3/2} + C$$

60. $$I = \int \frac{\sin^3(\theta/2)}{\cos\theta/2 \sqrt{\cos^3\theta + \cos^2\theta + \cos\theta}}\, d\theta$$

$$= \frac{1}{2} \int \frac{2 \sin\theta/2 \cdot \cos\theta/2 \cdot 2\sin^2\theta/2}{2\cos^2\theta/2 \sqrt{\cos^3\theta + \cos^2\theta + \cos\theta}}\, d\theta$$

$$= \frac{1}{2} \int \frac{\sin\theta(1 - \cos\theta)}{(1 + \cos\theta)\sqrt{\cos^3\theta + \cos^2\theta + \cos\theta}}\, d\theta$$

Put $\cos\theta = t \Rightarrow -\sin\theta\, d\theta = dt$

$\therefore$ $$I = \frac{1}{2} \int \frac{(t-1)}{(t+1)\sqrt{t^3 + t^2 + t}}\, dt$$

$$= \frac{1}{2} \int \frac{t^2 - 1}{(t+1)^2 \sqrt{t^3 + t^2 + t}}\, dt$$

$$= \frac{1}{2} \int \frac{(1 - 1/t^2)}{(t + \frac{1}{t} + 2)\sqrt{t + 1 + \frac{1}{t}}}\, dt$$

Put $t + 1 + \dfrac{1}{t} = u^2 \Rightarrow \left(1 - \dfrac{1}{t^2}\right) dt = 2u\, du$

$$I = \frac{1}{2} \int \frac{2u\, du}{(u^2 + 1) \cdot u} = \int \frac{du}{u^2 + 1} = \tan^{-1}(u) + C$$

$$= \tan^{-1}\left(t + 1 + \frac{1}{t}\right)^{1/2} + C$$

$$= \tan^{-1}(\cos\theta + \sec\theta + 1)^{1/2} + C$$

61. $$I = \int \frac{(2\sin\theta + \sin 2\theta)\, d\theta}{(\cos\theta - 1)\sqrt{\cos\theta + \cos^2\theta + \cos^3\theta}}$$

Put $\cos\theta = x^2$

$\Rightarrow \quad -\sin\theta\, d\theta = 2x\, dx$

$$= 2 \int \frac{(1 + x^2)}{(1 - x^2)} \cdot \frac{2x\, dx}{\sqrt{x^2 + x^4 + x^6}}$$

$$= 4 \int \frac{(1 + 1/x^2)\, dx}{(1/x - x)\sqrt{(1/x - x)^2 + 3}},$$

Put $\dfrac{1}{x} - x = t$

$\Rightarrow \left(-\dfrac{1}{x^2} - 1\right) dx = dt$

$$= -4 \int \frac{dt}{t\sqrt{t^2 + 3}}$$

Again, put $t^2 + 3 = u^2$

$\Rightarrow \quad 2t\, dt = 2u\, du$

$\therefore$ $$I = 4 \int \frac{-u\, du}{u(u^2 - 3)} = -4 \int \frac{du}{u^2 - 3}$$

$$= -\frac{2}{\sqrt{3}} \log\left|\frac{u - \sqrt{3}}{u + \sqrt{3}}\right| + C$$

$$= -\frac{2}{\sqrt{3}} \log\left|\frac{\sqrt{t^2 + 3} - \sqrt{3}}{\sqrt{t^2 + 3} + \sqrt{3}}\right| + C$$

$$= -\frac{2}{\sqrt{3}} \log\left|\frac{\sqrt{x^2 + 1/x^2 + 1} - \sqrt{3}}{\sqrt{x^2 + 1/x^2 + 1} + \sqrt{3}}\right| + C$$

$$= -\frac{2}{3} \log\left|\frac{\sqrt{\cos\theta + \sec\theta + 1} - \sqrt{3}}{\sqrt{\cos\theta + \sec\theta + 1} + \sqrt{3}}\right| + C$$

62. Let $$I_{m-1} = \int x^{m-1}(a + bx^n)^p\, dx$$

and $$I_{m-n-1} = \int x^{m-n-1}(a + bx^n)^p\, dx$$

Let $$p = x^{\lambda+1}(a + bx^n)^{\mu+1}$$

where λ and μ are the smaller indices of x and $(a + bx^n)$.

Here, $\lambda = m - n - 1, \mu = p$

$\therefore$ $$p = x^{m-n}(a + bx^n)^{p+1}$$

Differentiating w.r.t. x, we have

$$\frac{dp}{dx} = x^{m-n}(p+1)(a + bx^n)^p (n\, bx^{n-1}) + (a + bx^n)^{p+1}(m - n)\, x^{m-n-1}$$

$$= nb(p+1)\, x^{m-1}(a + bx^n)^p + (m - n)\, x^{m-n-1}(a + bx^n)^p \{a + bx^n\}$$

$$= nb(p+1)\, x^{m-1}(a + bx^n)^p + a(m - n)\, x^{m-n-1}(a + bx^n)^p + b(m - n)\, x^{m-1}(a + bx^n)^p$$

$= b(np + m)\, x^{m-1}(a + bx^n)^p + a(m - n)\, x^{m-n-1}(a + bx^n)^p$Integrating both the sides w.r.t. x, we get

$$p = b(np + m)\, I_{m-1} + a(m - n)\, I_{m-n-1}$$

$\therefore\ x^{m-n}(a + bx^n)^{p+1} = b(np + m)\, I_{m-1} + a(m - n)\, I_{m-n-1}$

or $$I_{m-1} = \frac{x^{m-n}(a + bx^n)^{p+1}}{b(np + m)} - \frac{a(m - n)}{b(np + m)} \cdot I_{m-n-1}$$

Hence Proved.

Again, $$\int \frac{x^8}{(1 - x^3)^{1/3}}\, dx = \int x^{9-1}(1 - x^3)^{-1/3}\, dx$$

Here, $m = 9, \quad b = -1, \quad n = 3, \quad p = -1/3, \quad a = 1$

$\therefore$ $$I_8 = \frac{(x^6(1 - x^3)^{2/3})}{-8} + \frac{6}{8} I_5 \qquad \text{...(i)}$$

$\Rightarrow$ $$I_5 = \frac{x^3(1 - x^3)^{2/3}}{-5} + \frac{3}{5} I_2 \qquad (\text{here } m = 6)$$

$\Rightarrow$ $$I_2 = \frac{(1 - x^3)^{2/3}}{2}$$

Hence, $$I_8 = -\frac{1}{8}x^6(1 - x^3)^{2/3} - \frac{3}{20}x^3(1 - x^3)^{2/3} - \frac{9}{40}(1 - x^3)^{2/3} + C$$

63. Let $$I = \int \operatorname{cosec}^2 x \ln(\cos x + \sqrt{\cos 2x})\, dx$$

$$= \int \operatorname{cosec}^2 x \cdot \ln\{\sin x(\cot x + \sqrt{\cot^2 x - 1})\}\, dx$$

$$= \int \text{cosec}^2 x \ln(\sin x)\, dx + \int \text{cosec}^2 x \cdot \ln(\cot x + \sqrt{\cot^2 x - 1})\, dx$$

In second integral put $\cot x = 1$

$\therefore \quad \text{cosec}^2 x\, dx = dt$

$\therefore \quad I = \int \text{cosec}^2 x \cdot \ln(\sin x)\, dx - \int \ln(t + \sqrt{t^2 - 1})\, dt$

In first integral (integrating by parts taking $\text{cosec}^2 x$ as second integral) and in second integral (integration by parts taking unity as second function).

We have, $(\ln \sin x)(-\cot x) - \int \cot x (-\cot x)\, dx$

$$- \ln(t + \sqrt{t^2 - 1})\, t + \int \frac{t\, dt}{\sqrt{t^2 - 1}}$$

$$= -\cot x (\ln \sin x) - \cot x - x - t \ln(t + \sqrt{t^2 - 1}) + \sqrt{t^2 - 1} + C$$

$$= -\cot x (\ln \sin x) - \cot x - x - \cot x \{\ln(\cot x + \sqrt{\cot^2 x - 1})\} + \sqrt{\cot^2 x - 1} + C$$

$$= -\cot x \cdot \ln(\cos x + \sqrt{\cos 2x}) - \cot x - x + \sqrt{\cot^2 x - 1} + C$$

64. $I = \int \frac{dx}{(\sin x + a \sec x)^2}\ a \in N = \int \frac{\cos^2 x\, dx}{(a + \sin x \cos x)^2}$

$$= \int \frac{\cos^2 x\, dx}{(a^2 + \sin^2 x \cdot \cos^2 x + 2a \sin x \cdot \cos x)}$$

$$= \int \frac{4 \cos^2 x\, dx}{4a^2 + \sin^2 2x + 4a \sin 2x} = 2 \int \frac{1 + \cos 2x}{(2a + \sin 2x)^2}\, dx$$

$$= 2 \int \frac{1}{(2a + \sin 2x)^2}\, dx + 2 \int \frac{\cos 2x}{(2a + \sin 2x)^2}\, dx$$

$$= 2I_1 - \frac{1}{(2a + \sin 2x)} \qquad \ldots(\text{i})$$

$$I_1 = \int \frac{dx}{(2a + \sin 2x)^2},$$

we know

$$\therefore \quad I_1 = \int \frac{du}{(4a^2 - 1)\frac{\sqrt{4a^2 - 1}\sqrt{1 - u^2}}{(2a - u)}}$$

$$u = 2a \frac{\sin 2x + 1}{2a + \sin 2x} = \frac{1}{(4a^2 - 1)^{3/2}} \int \frac{(2a - u)}{\sqrt{1 - u^2}}\, du$$

$$\Rightarrow \frac{du}{dx} = \frac{(4a^2 - 1)\cos 2x}{(2a + \sin 2x)^2}$$

$$\Rightarrow \frac{1}{(4a^2 - 1)^{3/2}} [2a \sin^{-1} u + \sqrt{1 - u^2}] = I_1 \text{ and } \sin 2x = \frac{2au - 1}{2a - u}$$

$$\therefore \quad I = \frac{1}{(4a^2 - 1)^{3/2}} \left[2a \sin^{-1} \left(\frac{2a \sin 2x + 1}{2a + \sin 2x} \right) + \sqrt{1 - \left(\frac{2a \sin 2x + 1}{2a + \sin 2x} \right)} \right] - \frac{1}{(2a + \sin 2x)} + C$$

65. $I = \int \frac{dx}{x - \sqrt{x^2 + 2x + 4}}$

Put $\sqrt{x^2 + 2x + 4} = t + x$

$$\Rightarrow \quad x^2 + 2x + 4 = t^2 + x^2 + 2tx$$

$$\Rightarrow \quad 2x - 2tx = t^2 - 4$$

$$\Rightarrow \quad x = \frac{t^2 - 4}{2 - 2t} = \frac{1}{2} \frac{(t^2 - 4)}{(1 - t)}$$

$$\Rightarrow \quad dx = -\frac{1}{2} \left[\frac{t^2 - 2t + 4}{(1 - t)^2} \right]$$

$$\therefore \quad I = -\frac{1}{2} \int \frac{t^2 - 2t + 4}{-t(1 - t)^2}\, dt$$

$$= \frac{1}{2} \int \left[\frac{4}{t} + \frac{3}{(1 - t)} + \frac{3}{(1 - t)^2} \right] dt$$

$$= \frac{1}{2} \left[4 \log |t| - 3 \log |1 - t| + \frac{3}{(1 - t)} \right]$$

$$= 2 \log |\sqrt{x^2 + 2x + 4} - x| - \frac{3}{2} \log |1 - \sqrt{x^2 + 2x + 4} + x| + \frac{3}{2(1 - \sqrt{x^2 + 2x + 4} + x)}$$

$$= 2 \log |\sqrt{x^2 + 2x + 4} - x| - \frac{3}{2} \log |\sqrt{x^2 + 2x + 4} - 1 - x| - \frac{3}{2(\sqrt{x^2 + 2x + 4} - x - 1)}$$

66. $I = \int \frac{dx}{1 + \sqrt{x^2 + 2x + 2}}$

$\sqrt{x^2 + 2x + 2} = t - x$, squaring both the sides, we get

$$x^2 + 2x + 2 = t^2 + x^2 - 2tx$$

$$2x + 2tx = t^2 - 2$$

$$x = \frac{t^2 - 2}{2(1 + t)}$$

$$\Rightarrow \quad dx = \frac{t^2 + 2t + 2}{2(1 + t)^2}\, dt$$

$$\therefore \quad 1 + \sqrt{x^2 + 2x + 2} = 1 + t - \frac{t^2 - 2}{2(1 + t)} = \frac{t^2 + 4t + 4}{2(1 + t)}$$

$$\Rightarrow \quad I = \int \frac{2(1 + t)(t^2 + 2t + 2)}{(t^2 + 4t + 4) \cdot 2 \cdot (1 + t)^2}\, dt = \int \frac{(t^2 + 2t + 2)}{(1 + t)(t + 2)^2}\, dt$$

Using partial fractions, we get

$$I = \int \frac{dt}{t + 1} - 2 \int \frac{dt}{(t + 2)^2}$$

$$= \ln |t + 1| + \frac{2}{(t + 2)} + C$$

$$I = \ln(x + 1 + \sqrt{x^2 + 2x + 2}) + \frac{2}{(x + 2) + \sqrt{x^2 + 2x + 2}} + C$$

67. $$I=\int \frac{x^4+1}{x^6+1}\,dx=\int \frac{(x^2+1)^2-2x^2}{(x^2+1)(x^4-x^2+1)}\,dx$$

$$=\int \frac{(1+1/x^2)\,dx}{(x^2+1/x^2-1)}-2\int \frac{x^2\,dx}{(x^3)^2+1}$$

$$=\int \frac{(1+1/x^2)\,dx}{(x-1/x)^2+1}-2\int \frac{x^2\,dx}{(x^3)^2+1}$$

In first integral put $x-1/x=t$ and in second integral put $x^3=u$

$$=\int \frac{dt}{t^2+1}-\frac{2}{3}\int \frac{du}{u^2+1}$$

$$=\tan^{-1}(t)-\frac{2}{3}\tan^{-1}(u)+C$$

$$=\tan^{-1}(x-1/x)-\frac{2}{3}\tan^{-1}(x^3)+C$$

68. $I=\int \frac{dx}{(1-x^3)^{1/3}}$

Put $x=1/t,\ dx=-1/t^2\,dt$

$$\therefore \quad I=-\int \frac{dt}{t^2(1-1/t^3)^{1/3}}=-\int \frac{dt}{t(t^3-1)^{1/3}}$$

Again, put $t^3-1=u^3 \Rightarrow 3t^2\,dt=3u^2\,du$

$$=-\int \frac{u^2\,du}{(1+u^3)\cdot u}=-\int \frac{u\,du}{(1+u)(1-u+u^2)}$$

$$=\frac{1}{3}\int \frac{du}{1+u}-\frac{1}{3}\int \frac{u+1}{u^2-u+1}\,du$$

(using partial fractions)

$$=\frac{1}{3}\int \frac{du}{u+1}-\frac{1}{3}\int \frac{1/2(2u-1)+3/2}{(u^2-u+1)}\,du$$

$$=\frac{1}{3}\int \frac{du}{u+1}-\frac{1}{6}\int \frac{2u-1}{u^2-u+1}\,du-\frac{1}{2}\int \frac{du}{(u-1/2)^2+3/4}$$

$$=\frac{1}{3}\log|u+1|-\frac{1}{6}\log|u^2-u+1|-\frac{1}{2}\cdot\frac{1}{\sqrt{3}/2}\tan^{-1}\left\{\frac{2u-1}{\sqrt{3}}\right\}+C$$

$$=\frac{1}{3}\log|(t^3-1)^{1/3}+1|-\frac{1}{6}\log|(t^3-1)^{2/3}-(t^3-1)^{1/3}+1|-\frac{1}{\sqrt{3}}\tan^{-1}\left\{\frac{2(t^3-1)^{1/3}-1}{\sqrt{3}}\right\}+C$$

$$=\frac{1}{3}\log\left|\frac{(1-x^3)^{1/3}+x}{x}\right|-\frac{1}{6}\log\left|\frac{(1-x^3)^{2/3}-(1-x^3)^{1/3}+x^2}{x^2}\right|-\frac{1}{\sqrt{3}}\tan^{-1}\left\{\frac{2(1-x^3)^{1/3}-x}{\sqrt{3}x}\right\}+C$$

69. $I=\int \frac{(x+\sqrt{1+x^2})^{15}}{\sqrt{1+x^2}}\,dx$

Put $(x+\sqrt{1+x^2})=t$

$$\therefore \left(1+\frac{x}{\sqrt{1+x^2}}\right)dx=dt \quad \text{or} \quad \frac{t\,dx}{\sqrt{1+x^2}}=dt$$

$$\therefore \ I=\int t^{15}\cdot\frac{dt}{t}=\int t^{14}\,dt=\frac{t^{15}}{15}+C=\frac{(x+\sqrt{1+x^2})^{15}}{15}+C$$

70. $\because u_{n+1}=\int \frac{x^{n+1}}{y}\,dx=\int \frac{x^{n+1}}{\sqrt{ax^2+2bx+c}}\,dx$

$$=\frac{1}{2a}\int \frac{x^n(2ax+2b)-2bx^n}{\sqrt{ax^2+2bx+c}}\,dx$$

$$=\frac{1}{2a}\int x^n\frac{(2ax+2b)\,dx}{\sqrt{ax^2+2bx+c}}-\frac{b}{a}\int \frac{x^n}{\sqrt{ax^2+2bx+c}}\,dx$$

$$u_{n+1}=\frac{1}{2a}\int x^n\frac{(2ax+2b)}{\sqrt{ax^2+2bx+c}}-\frac{b}{a}u_n$$

I II

$$u_{n+1}=\frac{1}{2a}\left[x^n\cdot 2\sqrt{ax^2+2bx+c}-\int nx^{n-1}\cdot 2\sqrt{(ax^2+bx+c)}\,dx\right]-\frac{b}{a}u_n$$

$$=\frac{1}{a}x^n y-\frac{n}{a}\int x^{n-1}\cdot\sqrt{ax^2+2bx+c}\,dx-\frac{b}{a}u_n$$

$$au_{n+1}=x^n y-n\int \frac{x^{n-1}(ax^2+2bx+c)}{\sqrt{ax^2+2bx+c}}\,dx-\frac{b}{a}u_n$$

$$au_{n+1}=x^n y-n[au_{n+1}+2bu_n+cu_{n-1}]-bu_n$$

$$\Rightarrow (n+1)a\,u_{n+1}+(2n+1)bu_n+nc\cdot u_{n-1}=x^n y \qquad \ldots(i)$$

Now, putting, $n=0$ in both the sides, we get

$$au_1+bu_0=x^0 y$$

$$au_1=y-bu_0 \qquad \ldots(ii)$$

Putting $n=1$ in Eq. (i), we get

$$2au_2+3bu_1+cu_0=xy$$

$$2au_2+3b\left(\frac{y-bu_0}{a}\right)+cu_0=xy \qquad \text{[from Eq. (ii)]}$$

$$\Rightarrow 2a^2u_2+3by-3b^2u_0+acu_0=axy$$

$$\Rightarrow 2a^2u_2=y(ax-3b)+(3b^2-ac)u_0$$

71. **Plan** Integration by Substitution

i.e. $$I=\int f\{g(x)\}\cdot g'(x)\,dx$$

Put $$g(x)=t \ \Rightarrow g'(x)\,dx=dt$$

$$\therefore \quad I=\int f(t)\,dt$$

Description of Situation Generally, students gets confused after substitution, i.e. $\sec x+\tan x=t$.

Now, for $\sec x$, we should use

$$\sec^2 x-\tan^2 x=1$$

$$\Rightarrow \quad (\sec x-\tan x)(\sec x+\tan x)=1$$

$$\Rightarrow \quad \sec x-\tan x=\frac{1}{t}$$

Here, $I=\int \frac{\sec^2 dx}{(\sec x+\tan x)^{9/2}}$

Put $\sec x+\tan x=t$

$\Rightarrow \quad (\sec x\tan x+\sec^2 x)dx=dt$

$\Rightarrow \quad \sec x\cdot t\,dx=dt$

$\Rightarrow \quad \sec x\,dx=\frac{dt}{t}$

$\therefore \quad \sec x-\tan x=\frac{1}{t} \Rightarrow \sec x=\frac{1}{2}\left(t+\frac{1}{t}\right)$

$\therefore \quad I=\int \frac{\sec x\cdot\sec x\,dx}{(\sec x+\tan x)^{9/2}}$

$\Rightarrow \quad I=\int \frac{\frac{1}{2}\left(t+\frac{1}{t}\right)\cdot\frac{dt}{t}}{t^{9/2}}=\frac{1}{2}\int\left(\frac{1}{t^{9/2}}+\frac{1}{t^{13/2}}\right)dt$

$$=-\frac{1}{2}\left\{\frac{2}{7t^{7/2}}+\frac{2}{11t^{11/2}}\right\}+K$$

$$=-\left[\frac{1}{7(\sec x+\tan x)^{7/2}}+\frac{1}{11(\sec x+\tan x)^{11/2}}\right]+K$$

$$=\frac{-1}{(\sec x+\tan x)^{11/2}}\left\{\frac{1}{11}+\frac{1}{7}(\sec x+\tan x)^2\right\}+K$$

72. Since, $I=\int \frac{e^x}{e^{4x}+e^{2x}+1}dx$ and $J=\int \frac{e^{3x}}{1+e^{2x}+e^{4x}}dx$

$\therefore \quad J-I=\int \frac{(e^{3x}-e^x)}{1+e^{2x}+e^{4x}}dx$

Put $e^x=u \Rightarrow e^x dx=du$

$\therefore \quad J-I=\int \frac{(u^2-1)}{1+u^2+u^4}du=\int \frac{\left(1-\frac{1}{u^2}\right)}{1+\frac{1}{u^2}+u^2}du$

$$=\int \frac{\left(1-\frac{1}{u^2}\right)}{\left(u+\frac{1}{u}\right)^2-1}\,du$$

Put $u+\frac{1}{u}=t \Rightarrow \left(1-\frac{1}{u^2}\right)du=dt$

$$=\int \frac{dt}{t^2-1}=\frac{1}{2}\log\left|\frac{t-1}{t+1}\right|+C$$

$$=\frac{1}{2}\log\left|\frac{u^2-u+1}{u^2+u+1}\right|+C=\frac{1}{2}\log\left|\frac{e^{2x}-e^x+1}{e^{2x}+e^x+1}\right|+C$$

73. Let $I=\int \frac{2x^{12}+5x^9}{(x^5+x^3+1)^3}dx=\int \frac{2x^{12}+5x^9}{x^{15}(1+x^{-2}+x^{-5})^3}dx$

$$=\int \frac{2x^{-3}+5x^{-6}}{(1+x^{-2}+x^{-5})^3}dx$$

Now, put $1+x^{-2}+x^{-5}=t$

$\Rightarrow \quad (-2x^{-3}-5x^{-6})\,dx=dt$

$\Rightarrow \quad (2x^{-3}+5x^{-6})\,dx=-dt$

$\therefore \quad I=-\int \frac{dt}{t^3}=-\int t^{-3}\,dt$

$$=-\frac{t^{-3+1}}{-3+1}+C=\frac{1}{2t^2}+C=\frac{x^{10}}{2(x^5+x^3+1)^2}+C$$

74. $\int \frac{dx}{x^2(x^4+1)^{\frac{3}{4}}}=\int \frac{dx}{x^5\left(1+\frac{1}{x^4}\right)^{\frac{3}{4}}}$

Put $1+\frac{1}{x^4}=t^4 \Rightarrow -\frac{4}{x^5}dx=4t^3dt$

$\Rightarrow \quad \frac{dx}{x^5}=-t^3dt$

$\therefore \quad I=\int \frac{-t^3dt}{t^3}=-\int dt=-t+C=-\left(1+\frac{1}{x^4}\right)^{\frac{1}{4}}+C$

75. $\int\left(1+x-\frac{1}{x}\right)e^{x+\frac{1}{x}}dx=\int e^{x+\frac{1}{x}}dx+\int x\left(1-\frac{1}{x^2}\right)e^{x+\frac{1}{x}}dx$

$$=\int e^{x+\frac{1}{x}}dx+xe^{x+\frac{1}{x}}-\int \frac{d}{dx}(x)e^{x+\frac{1}{x}}dx$$

$$=\int e^{x+\frac{1}{x}}dx+xe^{x+\frac{1}{x}}-\int e^{x+\frac{1}{x}}dx$$

$$\left[\because \int\left(1-\frac{1}{x^2}\right)e^{x+\frac{1}{x}}dx=e^{x+\frac{1}{x}}\right]$$

$$=\int e^{x+\frac{1}{x}}dx+xe^{x+\frac{1}{x}}-\int ex^{x+\frac{1}{x}}dx$$

$$=xe^{x+\frac{1}{x}}+C$$

76. Given, $\int f(x)\,dx=\psi(x)$

Let $I=\int x^5 f(x^3)\,dx$

Put $x^3=t$

$\Rightarrow \quad x^2dx=\frac{dt}{3}$ ...(i)

$\therefore \quad I=\frac{1}{3}\int t\,f(t)\,dt$

$$=\frac{1}{3}\left[t\int f(t)\,dt-\int\left\{\frac{d}{dtt}(t)\,dt\right\}dt\right]$$

[Integration by parts]

$$=\frac{1}{3}[t\,\psi(t)-\int \psi(t)\,dt]$$

$$=\frac{1}{3}[x^3\psi(x^3)-3\int x^2\psi(x^3)\,dx]+C \quad \text{[from Eq. (i)]}$$

$$=\frac{1}{3}x^3\psi(x^3)-\int x^2\psi(x^3)\,dx+C$$

77. **Given** Integral is $\int \frac{5 \tan x}{\tan x - 2}\, dx$

To find The value of a, if

$\int \frac{5 \tan x}{\tan x - 2}\, dx = x + a \log |\sin x - 2 \cos x| + k$...(i)

Now, let us assume that $I = \int \frac{5 \tan x}{\tan x - 2}\, dx$

Multiplying by $\cos x$ in numerator and denominator, we get

$$I = \int \frac{5 \sin x}{\sin x - 2 \cos x}\, dx$$

This special integration requires special substitution of type

$$N^r = A(D^r) + B\left(\frac{dD^r}{dx}\right)$$

$\Rightarrow$ Let $5 \sin x = A(\sin x - 2 \cos x) + B(\cos x + 2 \sin x)$

$\Rightarrow 0 \cos x + 5 \sin x = (A + 2B) \sin x + (B - 2A) \cos x$

Comparing the coefficients of $\sin x$ and $\cos x$, we get

$$A + 2B = 5 \quad \text{and} \quad B - 2A = 0$$

Solving the above two equations in A and B, we get

$$A = 1 \quad \text{and} \quad B = 2$$

$\Rightarrow 5 \sin x = (\sin x - 2 \cos x) + 2(\cos x + 2 \sin x)$

$\Rightarrow I = \int \frac{5 \sin x}{\sin x - 2 \cos x}\, dx$

$$= \int \frac{(\sin x - 2 \cos x) + 2(\cos x + 2 \sin x)}{(\sin x - 2 \cos x)}\, dx$$

$\Rightarrow I = \int \frac{\sin x - 2 \cos x}{\sin x - 2 \cos x}\, dx + 2 \int \frac{(\cos x + 2 \sin x)}{(\sin x - 2 \cos x)}\, dx$

$\Rightarrow I = \int 1\, dx + 2 \int \frac{d(\sin x - 2 \cos x)}{(\sin x - 2 \cos x)}$

$\Rightarrow I = x + 2 \log |(\sin x - 2 \cos x)| + k$ ...(ii)

where, k is the constant of integration.

Now, by comparing the value of I in Eqs. (i) and (ii), we get $a = 2$.

78. Let $I = \sqrt{2} \int \frac{\sin x}{\sin\left(x - \frac{\pi}{4}\right)}\, dx$

Put $x - \frac{\pi}{4} = t \quad \Rightarrow \quad dx = dt$

$\therefore$ $$I = \sqrt{2} \int \frac{\sin\left(\frac{\pi}{4} + t\right) dt}{\sin t}$$

$$= \sqrt{2} \int \left[\frac{1}{\sqrt{2}} \cot t + \frac{1}{\sqrt{2}}\right] dt$$

$$= 1 + \log |\sin t| + C$$

$$= x + \log \left|\sin\left(x - \frac{\pi}{4}\right)\right| + C$$

Session 1

Integration Basics, Geometrical Interpretation of Definite Integral, Evaluation of Definite Integrals by Substitution

Integration Basics

What is Definite Integral ?

Let f be a function of x defined in the closed interval $[a, b]$ and ϕ be another function, such that $\phi'(x) = f(x)$ for all x in the domain of f, then

$$\int_a^b f(x)\,dx = [\phi(x) + c]_a^b = \phi(b) - \phi(a)$$

is called the definite integral of the function $f(x)$ over the interval $[a, b]$, a and b are called the limits of integration, a being the lower limit and b be the upper limit.

Remark

In definite integrals constant of integration is never present.

Working Rules

To evaluate definite integral $\int_a^b f(x)\,dx$.

1. First evaluate the indefinite integral $\int f(x)\,dx$ and suppose the result is $g(x)$.
2. Next find $g(b)$ and $g(a)$.
3. Finally, the value of the definite integral is obtained by subtracting $g(a)$ from $g(b)$.

   Thus, $\int_a^b f(x)\,dx = [g(x)]_a^b = g(b) - g(a)$

Example 1 Evaluate

(i) $\int_0^1 \frac{1}{3+4x}\,dx$ (ii) $\int_0^{\pi/2} \sin^4 x\,dx$

Sol. (i) Here, $I = \int_0^1 \frac{1}{3+4x}\,dx = \left[\frac{\ln(3+4x)}{4}\right]_0^1$

$$= \frac{1}{4}[\ln 7 - \ln 3] = \frac{1}{4}\ln\left(\frac{7}{3}\right)$$

(ii) Let $I = \int_0^{\pi/2} \sin^4 x\,dx$

$$= \frac{1}{4}\int_0^{\pi/2} (2\sin^2 x)^2\,dx = \frac{1}{4}\int_0^{\pi/2} (1-\cos 2x)^2\,dx$$

$$= \frac{1}{4}\int_0^{\pi/2} (1 - 2\cos 2x + \cos^2 2x)\,dx$$

$$= \frac{1}{4}\int_0^{\pi/2} \left(1 - 2\cos 2x + \frac{1+\cos 4x}{2}\right)dx$$

$$= \frac{1}{4}\int_0^{\pi/2} \left(\frac{3 - 4\cos 2x + \cos 4x}{2}\right)dx$$

$$= \frac{1}{8}\left[3x - \frac{4}{2}\sin 2x + \frac{\sin 4x}{4}\right]_0^{\pi/2}$$

$$= \frac{1}{8}\left[\left(\frac{3\pi}{2} - 2\sin\pi + \frac{1}{4}\sin 2\pi\right) - 0\right]$$

$$= \frac{1}{8}\left(\frac{3\pi}{2} - 0 + 0\right) = \frac{3\pi}{16}$$

Example 2 The value of $\int_{-1}^1 \left[\frac{d}{dx}\left(\tan^{-1}\frac{1}{x}\right)\right]dx$ is

(a) $\pi/2$ (b) $\pi/4$ (c) $-\pi/2$ (d) None of these

Sol. Let $I = \int_{-1}^1 \left[\frac{d}{dx}\left(\tan^{-1}\frac{1}{x}\right)\right]dx$

Here, $\frac{d}{dx}\left(\tan^{-1}\frac{1}{x}\right) = \frac{d}{dx}(\cot^{-1}x) = \frac{-1}{1+x^2}$

$\therefore \quad I = \int_{-1}^1 -\frac{1}{1+x^2}\,dx = -\int_{-1}^1 \frac{1}{1+x^2}\,dx$

$$= -(\tan^{-1}x)_{-1}^1 = -[\tan^{-1}(1) - \tan^{-1}(-1)]$$

$$= -\left(\frac{\pi}{4} + \frac{\pi}{4}\right) = -\frac{\pi}{2}$$

Hence, (c) is the correct answer.

Remark

Note that $\int_{-1}^1 \left(\frac{d}{dx}\tan^{-1}\frac{1}{x}\right)dx = \left(\tan^{-1}\frac{1}{x}\right)_{-1}^1 = \tan^{-1}(1) - \tan^{-1}(-1)$

$$= \frac{\pi}{4} - \left(-\frac{\pi}{4}\right) = \frac{\pi}{2}$$

is incorrect, because $\tan^{-1}\left(\frac{1}{x}\right)$ is not a anti-derivative (primitive) of $\frac{d}{dx}\left(\tan^{-1}\frac{1}{x}\right)$ on the interval $[-1, 1]$.

Example 3 *If* $I_n = \int_1^e (\log x)^n\, dx$, *then* $I_n + nI_{n-1}$ *is equal to*

(a) $\frac{1}{e}$ (b) e (c) $e-1$ (d) None of these

Sol. We have, $I_n = \int_1^e (\log x)^n\, dx = \int_1^e \underbrace{(\log x)^n}_{\text{I}} \cdot \underbrace{1}_{\text{II}}\, dx$

$$\therefore \quad I_n = [x\cdot(\log x)^n]_1^e - \int_1^e n\cdot(\log x)^{n-1}\cdot\frac{1}{x}\cdot x\,dx$$

$$= (e-0) - n\int_1^e (\log_e x)^{n-1}dx = e - n\cdot I_{n-1}$$

$\therefore\ I_n + n\cdot I_{n-1} = e$

Hence, (b) is the correct answer.

Example 4 All the values of 'a' for which $\int_1^2 \{a^2 + (4-4a)x + 4x^3\}dx \le 12$ are given by

(a) $a = 3$ (b) $a \le 4$

(c) $0 \le a < 3$ (d) None of these

Sol. We have, $\int_1^2 \{a^2 + (4-4a)x + 4x^3\}dx \le 12$

$$\Rightarrow \quad [a^2x + (2-2a)x^2 + x^4]_1^2 \le 12$$

$$\Rightarrow a^2(2-1) + (2-2a)(4-1) + (2^4 - 1^4) \le 12$$

$$\Rightarrow \quad a^2 + 3(2-2a) + 15 \le 12$$

$$\Rightarrow \quad a^2 - 6a + 9 \le 0$$

$$\Rightarrow \quad (a-3)^2 \le 0$$

$$\therefore \quad a = 3$$

Hence, (a) is the correct answer.

Geometrical Interpretation of Definite Integral

If $f(x) > 0$ for all $x \in [a, b]$, then $\int_a^b f(x)\, dx$ is numerically equal to the area bounded by the curve $y = f(x)$, the X-axis and the straight lines $x = a$ and $x = b$ i.e. $\int_a^b f(x)\, dx$

In general, $\int_a^b f(x)\, dx$ represents the algebraic sum of the areas of the figures bounded by the curve $y = f(x)$, the X-axis and the straight lines $x = a$ and $x = b$. The areas above X-axis are taken with plus sign and the areas below X-axis are taken with minus sign,

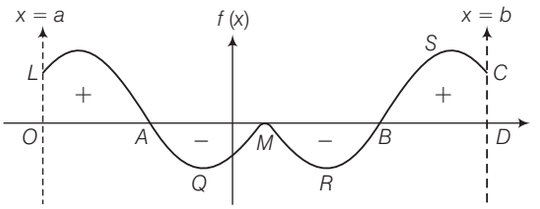

Figure 2.1

i.e. $\int_a^b f(x)\, dx$ = Area (OLA) − Area (AQM) − Area (MRB) + Area $(BSCD)$

Remark

$\int_a^b f(x)\, dx$, represents algebraic sum of areas means that area of function $y = f(x)$ is asked between a to b.

$\Rightarrow$ Area bounded $= \int_a^b |f(x)|\, dx$ and not been represented by $\int_a^b f(x)\, dx$. e.g. If someone asks for the area of $y = x^3$ between -1 to 1, then $y = x^3$ could be plotted as

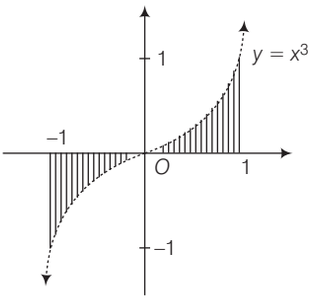

Figure 2.2

$$\therefore \quad \text{Area} = \int_{-1}^0 -x^3\, dx + \int_0^1 x^3\, dx = \frac{1}{2}$$

or using above definition, area $= \int_{-1}^1 |x^3|\, dx = 2\int_0^1 x^3\, dx$

$$= 2\left[\frac{x^4}{4}\right]_0^1 = \frac{1}{2}$$

But, if we integrate x^3 between -1 to 1.

$\Rightarrow \quad \int_{-1}^1 x^3\, dx = 0$ which does not represent the area.

Thus, students are adviced to make difference between area and definite integral.

Example 5 Evaluate $\int_0^3 |(x-1)(x-2)|\, dx$.

Sol. Let $I = \int_0^3 |(x-1)(x-2)|\, dx$

We know,

$$|(x-1)(x-2)| = \begin{cases} (x-1)(x-2), & x < 1 \text{ or } x > 2 \\ -(x-1)(x-2), & 1 < x < 2 \end{cases}$$

Using number line rule,

$$I = \int_0^3 |(x-1)(x-2)|\, dx$$

$$= \int_0^1 (x-1)(x-2)\,dx - \int_1^2 (x-1)(x-2)\,dx + \int_2^3 (x-1)(x-2)\,dx$$

$$= \int_0^1 (x^2-3x+2)\,dx - \int_1^2 (x^2-3x+2)\,dx + \int_2^3 (x^2-3x+2)\,dx$$

$$= \left[\frac{x^3}{3} - \frac{3x^2}{2} + 2x\right]_0^1 - \left[\frac{x^3}{3} - \frac{3x^2}{2} + 2x\right]_1^2 + \left[\frac{x^3}{3} - \frac{3x^2}{2} + 2x\right]_2^3$$

$$= \left(\frac{1}{3} - \frac{3}{2} + 2\right) - \left(\frac{8}{3} - \frac{12}{2} + 4 - \frac{1}{3} + \frac{3}{2} - 2\right) + \left(\frac{27}{3} - \frac{27}{2} + 6 - \frac{8}{3} + \frac{12}{2} - 4\right) = \frac{11}{6}$$

Evaluation of Definite Integrals by Substitution

Sometimes, the indefinite integral may need substitution, say $x = \phi(t)$. Then, in that case don't forget to change the limits of integration a and b corresponding to the new variable t. The substitution $x = \phi(t)$ is not valid, if it is not continuous in the interval $[a, b]$.

Example 6 Show that

$$\int_0^{\pi/2} \frac{dx}{a^2\cos^2 x + b^2 \sin^2 x} = \frac{\pi}{2ab};\ a, b > 0.$$

Sol. Let $$I = \int_{x=0}^{x=\pi/2} \frac{dx}{a^2\cos^2 x + b^2 \sin^2 x}$$

$$= \int_{x=0}^{x=\pi/2} \frac{\sec^2 x\,dx}{a^2 + b^2\tan^2 x}$$

(divide numerator and denominator by $\cos^2 x$)

Put $\tan x = t \Rightarrow \sec^2 x\,dx = dt$

$$\therefore \quad I = \int_{t=0}^{t=\infty} \frac{dt}{a^2 + b^2 t^2}$$

We find the new limits of integration $t = \tan x \Rightarrow t = 0$ when $x = 0$ and $t = \infty$ when $x = \pi/2$.

$$\Rightarrow \quad I = \frac{1}{b^2}\int_0^\infty \frac{dt}{\left(\frac{a}{b}\right)^2 + t^2} = \frac{1}{b^2}\cdot\frac{1}{a/b}\left[\tan^{-1}\frac{bt}{a}\right]_0^\infty$$

$$= \frac{1}{ab}\left[\frac{\pi}{2} - 0\right] = \frac{\pi}{2ab}$$

Example 7 Evaluate $\int_{-2}^{2} \frac{dx}{4+x^2}$ directly as well as by the substitution $x = 1/t$. Examine as to why the answer don't valid?

Sol. Let $$I = \int_{-2}^{2} \frac{dx}{4+x^2}$$

$$= \left[\frac{1}{2}\tan^{-1}\left(\frac{x}{2}\right)\right]_{-2}^{2} = \frac{1}{2}\left[\tan^{-1}(1) - \tan^{-1}(-1)\right]$$

$$= \frac{1}{2}\left[\frac{\pi}{4} - \left(-\frac{\pi}{4}\right)\right] = \frac{\pi}{4}$$

$$\Rightarrow \quad I = \frac{\pi}{4}$$

On the other hand; if $x = 1/t$, then

$$I = \int_{-2}^{2} \frac{dx}{4+x^2} = -\int_{-1/2}^{1/2} \frac{dt}{t^2(4 + 1/t^2)} = -\int_{-1/2}^{1/2} \frac{dt}{4t^2+1}$$

$$= -\left[\frac{1}{2}\tan^{-1}(2t)\right]_{-1/2}^{1/2}$$

$$= -\frac{1}{2}\tan^{-1}(1) - \left(-\frac{1}{2}\tan^{-1}(-1)\right)$$

$$= -\frac{\pi}{8} - \frac{\pi}{8} = -\frac{\pi}{4}$$

$\therefore\ I = -\frac{\pi}{4}$, when $x = \frac{1}{t}$

In above two results, $I = -\pi/4$ is wrong. Since, the integrand $\frac{1}{4+x^2} > 0$ and therefore the definite integral of this function cannot be negative.

Since, $x = 1/t$ is discontinuous at $t = 0$, then substitution is not valid. ($\because I = \pi/4$)

Remark

It is important that the substitution must be continuous in the interval of integration.

Example 8 Evaluate $\int_0^{1/2} x \cdot \frac{\sin^{-1} x}{\sqrt{1-x^2}}\,dx$.

Sol. Let $I = \int_0^{1/2} x \cdot \frac{\sin^{-1} x}{\sqrt{1-x^2}}\,dx$

Put $\sin^{-1} x = \theta$, then $x = \sin\theta \Rightarrow dx = \cos\theta\,d\theta$

Also when $x = 0$, then $\theta = 0$ and when $x = \frac{1}{2}$,

then $\theta = \sin^{-1}\left(\frac{1}{2}\right) = \frac{\pi}{6}$

$$\therefore \quad I = \int_0^{\pi/6} \sin\theta \cdot \frac{\theta}{\sqrt{1-\sin^2\theta}} \cdot \cos\theta\,d\theta = \int_0^{\pi/6} \theta \cdot \sin\theta\,d\theta$$

$$= (-\theta\cdot\cos\theta)_0^{\pi/6} + \int_0^{\pi/6} \cos\theta\,d\theta,$$

using integeration by parts.

$$= (-\theta\cos\theta)_0^{\pi/6} + (\sin\theta)_0^{\pi/6}$$

$$= -\frac{\pi}{6}\cos\frac{\pi}{6} + 0 + \sin\frac{\pi}{6} - 0 = \frac{-\sqrt{3}\pi}{12} + \frac{1}{2}$$

Example 9 For any $n > 1$, evaluate the integral $\int_0^{\infty} \frac{1}{(x+\sqrt{x^2+1})^n}\,dx$.

Sol. Let $I = \int_0^{\infty} \frac{1}{(x+\sqrt{1+x^2})^n}\,dx$

Put $x+\sqrt{1+x^2} = t \quad \Rightarrow \sqrt{1+x^2} = t - x$

$\Rightarrow 1+x^2 = (t-x)^2 \quad \Rightarrow x = \frac{t^2-1}{2t}$ or $x = \frac{1}{2}\left(t - \frac{1}{t}\right)$

$\therefore \quad dx = \frac{1}{2}\left(1+\frac{1}{t^2}\right)dt$

$\therefore \quad I = \int_{t=1}^{\infty} \frac{1}{t^n}\cdot\frac{1}{2}\left(1+\frac{1}{t^2}\right)dt = \frac{1}{2}\int_1^{\infty}(t^{-n}+t^{-n-2})dt$

$$= \frac{1}{2}\left[\frac{t^{1-n}}{1-n} + \frac{t^{-n-1}}{-(n+1)}\right]_1^{\infty} = \frac{1}{2}\left[0-\left(\frac{1}{1-n}-\frac{1}{n+1}\right)\right]$$

$$= \frac{1}{2}\left[\frac{-2n}{1-n^2}\right] = \frac{n}{n^2-1}$$

Example 10 The value of $\int_0^{e-1} \frac{e^{\frac{x^2+2x-1}{2}}}{(x+1)}\,dx + \int_1^{e} x\log x \cdot e^{\frac{x^2-2}{2}}\,dx$ is equal to

(a) $(\sqrt{e})^{(e^2+1)}$ (b) $(\sqrt{e})^{e^2-1}$ (c) 0 (d) $(\sqrt{e})^{e^2-2}$

Sol. Let $I = \int_0^{e-1} \frac{e^{\frac{x^2+2x-1}{2}}}{(x+1)}\,dx + \int_1^{e} x\log x \cdot e^{\frac{x^2-2}{2}}\,dx$

Put $x+1 = t$ in first integral

$$\therefore \quad I = \int_1^{e} \frac{e^{\frac{t^2-2}{2}}}{t}\,dt + \int_1^{e} x\log x \cdot e^{\frac{x^2-2}{2}}\,dx$$

$$= \int_1^{e} e^{\frac{t^2-2}{2}}\left\{\frac{1}{t} + t\cdot\log t\right\}dt = \left(\log t \cdot e^{\frac{t^2-2}{2}}\right)_1^{e}$$

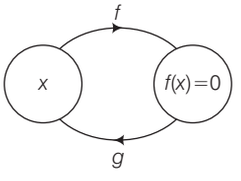
$$= (\sqrt{e})^{e^2-2}$$

Hence, (d) is the correct answer.

Example 11 Let $f(x) = \int_2^x \frac{dt}{\sqrt{1+t^4}}$ and g be the inverse of f. Then, the value of $g'(0)$ is

(a) 1 (b) 17 (c) $\sqrt{17}$ (d) None of these

Sol. Here, $f'(x) = \frac{1}{\sqrt{1+x^4}} = \frac{dy}{dx}$



Now, $g'(x) = \frac{dx}{dy} = \sqrt{1+x^4}$

When $y = 0$ i.e. $\int_2^x \frac{dt}{\sqrt{1+t^4}} = 0$, then $x = 2$

Therefore, $g'(0) = \sqrt{1+16} = \sqrt{17}$

Hence, (c) is the correct answer.

Example 12 Let $a_n = \int_0^{\pi/2} (1-\sin t)^n \sin 2t$, then $\lim_{n\to\infty} \sum_{n=1}^{n} \frac{a_n}{n}$ is equal to

(a) 1/2 (b) 1
(c) 4/3 (d) 3/2

Sol. We have, $a_n = \int_0^{\pi/2} (1-\sin t)^n \sin 2t\,dt$

Let $1-\sin t = u \Rightarrow -\cos t\,dt = du$

$$\therefore \quad a_n = 2\int_0^1 u^n(1-u)du = 2\left(\int_0^1 u^n du - \int_0^1 u^{n+1}du\right)$$

$$= 2\left(\frac{1}{n+1} - \frac{1}{n+2}\right)$$

Therefore, $\frac{a_n}{n} = 2\left(\frac{1}{n(n+1)} - \frac{1}{n(n+2)}\right)$

$$\therefore \lim_{n\to\infty} \sum_{n=1}^{n} \frac{a_n}{n} = 2\left[\sum\left(\frac{1}{n}-\frac{1}{n+1}\right) - \frac{1}{2}\sum\left(\frac{1}{n}-\frac{1}{n+2}\right)\right]$$

$$= 2\sum_{n=1}^{n}\left(\frac{1}{n}-\frac{1}{n+1}\right) - \sum_{n=1}^{n}\left(\frac{1}{n}-\frac{1}{n+2}\right)$$

$$= 2(1) - \left[\left(1-\frac{1}{3}\right)+\left(\frac{1}{2}-\frac{1}{4}\right)+\left(\frac{1}{3}-\frac{1}{5}\right)+\ldots\right] = 2-\frac{3}{2} = \frac{1}{2}$$

Hence, (a) is the correct answer.

Example 13 The value of $x > 1$ satisfying the equation $\int_1^x t\ln t\,dt = \frac{1}{4}$ is

(a) $\sqrt{e}$ (b) e (c) e^2 (d) $e-1$

Sol. Let $I = \int_1^x t\ln t\,dt = \left[\ln t \cdot \frac{t^2}{2}\right]_1^x$

$$-\frac{1}{2}\int_1^x \frac{1}{t}\cdot t^2\,dt = \frac{x^2}{2}\ln x - \frac{1}{2}\left[\frac{t^2}{2}\right]_1^x$$

$$= \frac{x^2\ln x}{2} - \frac{1}{4}[x^2-1] = \frac{1}{4}$$

$$\therefore \frac{x^2\ln x}{2} - \frac{1}{4}x^2 = 0 \Rightarrow [2\ln x - 1] = 0 \qquad (\text{as } x > 1)$$

$$\Rightarrow \quad \ln x = \frac{1}{2} \Rightarrow x = \sqrt{e}$$

Hence, (a) is the correct answer.

Example 14 If $\lim_{a\to\infty}\frac{1}{a}\int_0^{\infty}\frac{x^2+ax+1}{1+x^4}\cdot\tan^{-1}\left(\frac{1}{x}\right)dx$ is equal to $\frac{\pi^2}{k}$, where $k\in N$, then k equals to

(a) 4 (b) 8 (c) 16 (d) 32

Sol. Let $I=\int_0^{\infty}\frac{x^2+ax+1}{1+x^4}\cdot\tan^{-1}\left(\frac{1}{x}\right)dx$

Put $x=1/t$ and adding, we get

[using $\tan^{-1}(1/x)+\cot^{-1}x=\pi/2$]

$$I=\frac{\pi}{4}\int_0^{\infty}\frac{(x^2+1)+ax}{1+x^4}dx$$

$$=\frac{\pi}{4}\left[\int_0^{\infty}\frac{(x^2+1)}{1+x^4}dx+a\int_0^{\infty}\frac{x\,dx}{1+x^4}\right]$$

$$=\frac{\pi}{4}\left[\frac{\pi}{2\sqrt{2}}+\frac{a\pi}{4}\right]=\left[\frac{\pi^2}{8\sqrt{2}}+\frac{\pi^2 a}{16}\right]$$

$$\therefore\quad l=\lim_{a\to\infty}\frac{1}{a}\left[\frac{\pi^2}{8\sqrt{2}}+\frac{\pi^2 a}{16}\right]=\lim_{a\to\infty}\left[\frac{\pi^2}{(8\sqrt{2})a}+\frac{\pi^2}{16}\right]=\frac{\pi^2}{16}$$

$$\Rightarrow\quad k=16$$

Hence, (c) is the correct answer.

Example 15 If the value of definite integral $\int_1^a x\cdot a^{-[\log_a x]}\,dx$, where $a>1$ and $[x]$ denotes the greatest integer, is $\frac{e-1}{2}$, then the value of 'a' equals to

(a) $\sqrt{e}$ (b) e (c) $\sqrt{e+1}$ (d) $e-1$

Sol. Let $I=\int_1^a x\cdot a^{-[\log_a x]}\,dx$

Put $\log_a x=t\quad\Rightarrow\quad a^t=x$

$$\therefore\quad I=\ln a\cdot\int_0^1(a^t\cdot a^{-[t]}\cdot a^t)\,dt=\ln a\cdot\int_0^1(a^{t-[t]}\cdot a^t)dt$$

$$=\ln a\cdot\int_0^1(a^{\{t\}}\cdot a^t)dt=\ln a\cdot\int_0^1 a^{2t}\,dt$$

$$=\left[\frac{\ln a}{2}\cdot\frac{a^{2t}}{\ln a}\right]_0^1=\frac{1}{2}(a^2-1)\qquad[\text{as }\{t\}=t,\text{ if }t\in(0,1)]$$

$$\therefore\quad\frac{1}{2}(a^2-1)=\frac{e-1}{2}\ \Rightarrow\ a=\sqrt{e}$$

Aliter $\quad x\in(1,a)$

$$\Rightarrow\quad\log_a x\in(0,1)\ \Rightarrow\ [\log_a x]=0$$

$$\therefore\quad I=\int_1^a x\,dx=\frac{1}{2}(a^2-1)=\frac{e-1}{2}\ \Rightarrow\ a=\sqrt{e}$$

Hence, (a) is the correct answer.

Exercise for Session 1

1. $\int_0^{\pi/4}\cos^2 x\,dx$
2. $\int_0^{\pi/2}\frac{dx}{1+\cos x}$
3. $\int_0^{\pi/2}\sqrt{1+\cos x}\,dx$
4. $\int_0^{\pi/6}\sin 2x\cdot\cos x\,dx$
5. $\int_1^2\frac{dx}{\sqrt{x}-\sqrt{x-1}}$
6. $\int_0^1\log x\,dx$
7. $\int_0^{\pi/4}\frac{(\sin x+\cos x)}{9+16\sin 2x}dx$
8. $\int_a^b\frac{1}{\sqrt{(x-a)(b-x)}}dx, b>a$
9. $\int_a^b\sqrt{\frac{x-a}{b-x}}dx$
10. $\int_0^{\pi/4}\sqrt{\tan x}\,dx$
11. $\int_0^{\pi}\cos 2x.\log(\sin x)dx$
12. $\int_0^{\pi/4}e^{\sin x}\left(\frac{x\cos^3 x-\sin x}{\cos^2 x}\right)dx$
13. If $f(x)$ is a function satisfying $f\left(\frac{1}{x}\right)+x^2f(x)=0$ for all non-zero x, then $\int_{\sin\theta}^{\operatorname{cosec}\theta}f(x)dx$ is equal to
14. The value of $\int_0^1\left(\prod_{r=1}^{n}(n+r)\right)\left(\sum_{k=1}^{n}\frac{1}{x+k}\right)dx$ equals to

    (a) n (b) $n!$ (c) $(n+1)!$ (d) $n\cdot n!$
15. The true set of values of 'a' for which the inequality $\int_x^0(3^{-2x}-2\cdot 3^{-x})\,dx\ge 0$ is true, is

    (a) $[0, 1]$ (b) $[-\infty, -1]$ (c) $[0, \infty]$ (d) $[-\infty, -1]\cup[1, \infty]$

Session 2

Properties of Definite Integral

Properties of Definite Integrals

Property I. $\int_a^b f(x)\,dx = \int_a^b f(t)\,dt$

i.e. The integration is independent of the change of variable.

Proof Let $\phi(x)$ be a primitive of $f(x)$, then

$$\frac{d}{dx}[\phi(x)] = f(x) \Rightarrow \frac{d}{dt}[\phi(t)] = f(t)$$

Therefore, $\int_a^b f(x)\,dx = [\phi(x)]_a^b = \phi(b) - \phi(a)$ ...(i)

and $\int_a^b f(t)\,dt = [\phi(t)]_a^b = \phi(b) - \phi(a)$ ...(ii)

From Eqs. (i) and (ii), we have

$$\int_a^b f(x)\,dx = \int_a^b f(t)\,dt$$

Property II. $\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx$

i.e. if the limits of definite integral are interchanged, then its value changes by minus sign only.

Proof Let $\phi(x)$ be a primitive of $f(x)$, then

$$\int_a^b f(x)\,dx = \phi(b) - \phi(a)$$

and $-\int_b^a f(x)\,dx = -[\phi(a) - \phi(b)] = \phi(b) - \phi(a)$

$\therefore$ $\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx$

Property III. $\int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx$ (King's property)

Proof On RHS put $(a - x) = t$, so that $dx = -dt$

Also, when $x = 0$, then $t = a$ and when $x = a$, then $t = 0$

$\therefore$ $\int_0^a f(a-x)\,dx = -\int_a^0 f(t)\,dt = \int_0^a f(t)\,dt = \int_0^a f(x)\,dx$

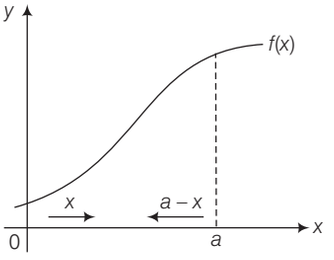
$\therefore$ $\int_0^a f(a-x)\,dx = \int_0^a f(x)\,dx$

Remark

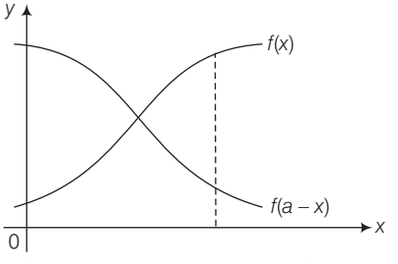
This property is useful to evaluate a definite integral without first finding the corresponding indefinite integrals which may be difficult or sometimes impossible to find.

Geometrically $\int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx$

This property says that when integrating from 0 to a, we will get the same result whether we use the function $f(x)$ or $f(a - x)$. The justification for this property will become clear from the figures below :



As x progresses from 0 to a, the variable $a - x$ progresses from a to 0. Thus, whether we use x or $a - x$, the entire interval $[0, a]$ is still covered.



The function $f(a - x)$ can be obtained from the function $f(x)$ by first flipping $f(x)$ along the y-axis and then shifting it right by a units. Notice that in the interval $[0, a]$, $f(x)$ and $f(a - x)$ describe precisely the same area.

There are two ways to look at the justification of this property, as described in the figures on the left and right respectively.

Example 16 Show that

(i) $\int_0^{\pi/2} f(\sin x)\,dx = \int_0^{\pi/2} f(\cos x)\,dx$

(ii) $\int_0^{\pi/2} f(\tan x)\,dx = \int_0^{\pi/2} f(\cot x)\,dx$

(iii) $\int_0^{\pi/2} f(\sin 2x)\sin x\,dx = \int_0^{\pi/2} \sqrt{2}\, f(\cos 2x)\cdot\cos x\,dx$

$= \int_0^{\pi/2} f(\sin 2x)\cdot\cos x\,dx$

(iv) $\int_0^{\pi} x f(\sin x)\,dx = \frac{\pi}{2}\int_0^{\pi} f(\sin x)\,dx$

[IIT JEE 1982]

Sol. (i) We know,

$$\int_0^{\pi/2} f(\sin x)\,dx = \int_0^{\pi/2} f\left[\sin\left(\frac{\pi}{2}-x\right)\right]dx$$

$$\left[\text{using } \int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx\right]$$

$$= \int_0^{\pi/2} f(\cos x)\,dx$$

$$\therefore \int_0^{\pi/2} f(\sin x)\,dx = \int_0^{\pi/2} f(\cos x)\,dx$$

(ii) $\int_0^{\pi/2} f(\tan x)\,dx = \int_0^{\pi/2} f\left(\tan\left(\frac{\pi}{2}-x\right)\right)dx$

$$\left[\text{using } \int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx\right]$$

$$= \int_0^{\pi/2} f(\cot x)\,dx$$

$$\therefore \int_0^{\pi/2} f(\tan x)\,dx = \int_0^{\pi/2} f(\cot x)\,dx$$

(iii) We know, $I = \int_0^{\pi/2} f(\sin 2x)\sin x\,dx$ ...(i)

$$= \int_0^{\pi/2} f\left[\sin 2\left(\frac{\pi}{2}-x\right)\right]\cdot\sin\left(\frac{\pi}{2}-x\right)dx$$

$$\left[\text{using } \int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx\right]$$

$$= \int_0^{\pi/2} f(\sin(\pi-2x))\cos x\,dx$$

$$I = \int_0^{\pi/2} f(\sin 2x)\cos x\,dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_0^{\pi/2} f(\sin 2x)(\sin x + \cos x)\,dx$$

$$= \sqrt{2}\int_0^{\pi/2} f(\sin 2x)\sin\left(x+\frac{\pi}{4}\right)dx$$

Put $x + \frac{\pi}{4} = \left(\frac{\pi}{2} - \theta\right)$ $\left(\text{i.e. } x = \frac{\pi}{4} - \theta\right)$

$$\Rightarrow \quad 2I = -\sqrt{2}\int_{\pi/4}^{-\pi/4} f(\cos 2\theta)\cos\theta\,d\theta$$

$$= \sqrt{2}\int_{-\pi/4}^{\pi/4} f(\cos 2\theta)\cos\theta\,d\theta$$

$$= 2\sqrt{2}\int_0^{\pi/4} f(\cos 2\theta)\cos\theta\,d\theta \text{ (since it is even)}$$

$$\therefore \quad I = \sqrt{2}\int_0^{\pi/4} f(\cos 2\theta)\cos\theta\,d\theta$$

(iv) Let $I = \int_0^{\pi} x\,f(\sin x)\,dx$ ...(i)

Replacing x by $(\pi - x)$, we get

$$I = \int_0^{\pi} (\pi - x)\,f(\sin(\pi - x))\,dx$$

$$\Rightarrow \quad I = \int_0^{\pi} (\pi - x)\,f(\sin x)\,dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_0^{\pi} \pi\,f(\sin x)\,dx \Rightarrow I = \frac{\pi}{2}\int_0^{\pi} f(\sin x)\,dx$$

$$\therefore \int_0^{\pi} x\,f(\sin x)\,dx = \frac{\pi}{2}\int_0^{\pi} f(\sin x)\,dx$$

Example 17 If f and g are continuous functions satisfying $f(x) = f(a-x)$ and $g(x) + g(a-x) = 2$, then show that $\int_0^a f(x)\,g(x)\,dx = \int_0^a f(x)\,dx$.

Sol. Let $I = \int_0^a f(x)\,g(x)\,dx = \int_0^a f(a-x)\,g(a-x)\,dx$

$$= \int_0^a f(x)\cdot[2 - g(x)]\,dx$$

$$\left[\text{using } \int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx\right]$$

$\because \quad f(x) = f(a-x)$ and $g(a-x) + g(x) = 2$ (given)

$$\therefore \quad \int_0^a f(x)\cdot g(x)\,dx = 2\int_0^a f(x)\,dx - \int_0^a f(x)\cdot g(x)\,dx$$

or $2\int_0^a f(x)\cdot g(x)\,dx = 2\int_0^a f(x)\,dx$

$$\Rightarrow \quad \int_0^a f(x)\,g(x)\,dx = \int_0^a f(x)\,dx$$

Example 18 Evaluate

(i) $\int_0^{\pi/2} \frac{dx}{1+\sqrt{\tan x}}$ (ii) $\int_0^{\pi/2} \log(\tan x)\,dx$

(iii) $\int_0^{\pi/4} \log(1+\tan x)\,dx$ (iv) $\int_0^{\pi/2} \frac{\sin x - \cos x}{1+\sin x\cos x}\,dx$

Sol. (i) Let $I = \int_0^{\pi/2} \frac{dx}{1+\sqrt{\tan x}} = \int_0^{\pi/2} \frac{\sqrt{\cos x}}{\sqrt{\cos x}+\sqrt{\sin x}}\,dx$ ...(i)

Then, $I = \int_0^{\pi/2} \frac{\sqrt{\cos(\pi/2 - x)}}{\sqrt{\cos(\pi/2-x)}+\sqrt{\sin(\pi/2-x)}}\,dx$

$$= \int_0^{\pi/2} \frac{\sqrt{\sin x}}{\sqrt{\sin x}+\sqrt{\cos x}}\,dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_0^{\pi/2} \frac{\sqrt{\sin x}}{\sqrt{\sin x}+\sqrt{\cos x}}\,dx + \int_0^{\pi/2} \frac{\sqrt{\cos x}}{\sqrt{\sin x}+\sqrt{\cos x}}\,dx$$

$$= \int_0^{\pi/2} \frac{\sqrt{\sin x}+\sqrt{\cos x}}{\sqrt{\sin x}+\sqrt{\cos x}}\,dx = \int_0^{\pi/2} 1\,dx$$

$$= [x]_0^{\pi/2} = \frac{\pi}{2} - 0 \Rightarrow 2I = \frac{\pi}{2} \Rightarrow I = \frac{\pi}{4}$$

(ii) Let $I = \int_0^{\pi/2} \log(\tan x)\,dx$ ...(i)

Then, $I = \int_0^{\pi/2} \log\left\{\tan\left(\frac{\pi}{2}-x\right)\right\}dx$

$$\Rightarrow \quad I = \int_0^{\pi/2} \log(\cot x)\,dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_0^{\pi/2} \log(\tan x)\,dx + \int_0^{\pi/2} \log(\cot x)\,dx$$

$$= \int_0^{\pi/2} (\log\tan x + \log\cot x)\,dx$$

$$= \int_0^{\pi/2} \log(\tan x\cdot\cot x)\,dx = \int_0^{\pi/2} \log(1)\,dx$$

$$\Rightarrow \quad 2I = 0 \Rightarrow I = 0$$

(iii) Let $I = \int_0^{\pi/4} \log(1+\tan x)\,dx$ ...(i)

$$= \int_0^{\pi/4} \log[1+\tan(\pi/4 - x)]\,dx$$

$$= \int_0^{\pi/4} \log\left(1+\frac{\tan\pi/4 - \tan x}{1+\tan(\pi/4)\cdot\tan x}\right)dx$$

$$= \int_0^{\pi/4} \log\left(\frac{1+\tan x+1-\tan x}{1+\tan x}\right)dx$$

$$= \int_0^{\pi/4} \log\left(\frac{2}{1+\tan x}\right)dx$$

$$= \int_0^{\pi/4} \log(2)\,dx - \int_0^{\pi/4} \log(1+\tan x)\,dx$$

$\Rightarrow I = (\log 2)(x)_0^{\pi/4} - I$ [using Eq. (i)]

$\Rightarrow 2I = \frac{\pi}{4}\log 2 \Rightarrow I = \frac{\pi}{8}\log 2$

(iv) Let $I = \int_0^{\pi/2} \frac{\sin x - \cos x}{1+\sin x\cos x}\,dx$ ...(i)

Then, $I = \int_0^{\pi/2} \frac{\sin\left(\frac{\pi}{2}-x\right) - \cos\left(\frac{\pi}{2}-x\right)}{1+\sin\left(\frac{\pi}{2}-x\right)\cos\left(\frac{\pi}{2}-x\right)}\,dx$

$\Rightarrow I = \int_0^{\pi/2} \frac{\cos x - \sin x}{1+\cos x\cdot\sin x}\,dx$ ...(ii)

Adding Eqs. (i) and (ii), we get

$2I = \int_0^{\pi/2} \frac{\sin x - \cos x}{1+\sin x\cos x}\,dx + \int_0^{\pi/2} \frac{\cos x - \sin x}{1+\sin x\cos x}\,dx \Rightarrow$

$2I = 0 \Rightarrow I = 0$

Example 19 The value of $\int_0^a \log(\cot a + \tan x)\,dx$, where $a \in (0, \pi/2)$ is equal to

(a) $a\log(\sin a)$ (b) $-a\log(\sin a)$

(c) $-a\log(\cos a)$ (d) None of these

Sol. Let $I = \int_0^a \log(\cot a + \tan x)\,dx$

$$= \int_0^a \log\left(\frac{\cos a}{\sin a} + \frac{\sin x}{\cos x}\right)dx$$

$$= \int_0^a \log\left(\frac{\cos(a-x)}{\sin a\cos x}\right)dx$$

$$= \int_0^a \log[\cos(a-x)]\,dx - \int_0^a \log(\sin a)\,dx - \int_0^a \log(\cos x)\,dx$$

$$= \int_0^a \log\cos(x)\,dx - \int_0^a \log(\sin a)\,dx - \int_0^a \log(\cos x)\,dx$$

$\left[\text{using } \int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx \text{ to first integral}\right]$

$$= -\log(\sin a)\int_0^a dx = -a\log(\sin a)$$

Hence, (b) is the correct answer.

Property IV. $\int_a^b f(x)\,dx = \int_a^b f(a+b-x)\,dx$ (King's property)

Proof Put $x = a+b-t \Rightarrow dx = -dt$

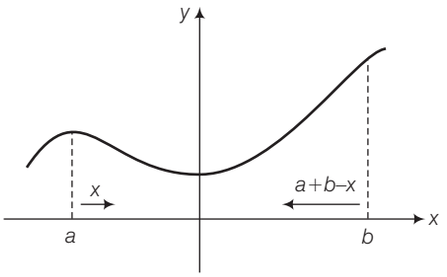
Also, when $x = a$, then $t = b$, and when $x = b$

$$\therefore \int_a^b f(x)\,dx = \int_b^a f(a+b-t)(-dt) = -\int_b^a f(a+b-t)\,dt$$

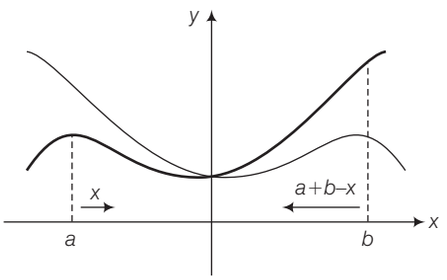
$$= \int_a^b f(a+b-t)\,dt = \int_a^b f(a+b-x)\,dx$$

$$\therefore \int_a^b f(x)\,dx = \int_a^b f(a+b-x)\,dx$$

Geometrically $\int_0^a f(x)dx = \int^{a^b} f(a+b-x)\,dx$



As the variable x varies from a to b, the variable $a+b-x$ varies from b to a. Thus, whether we use x or $a+b-x$, the entire interval $[a, b]$ is covered in both the cases and the areas will be the same.



The graph of $f(a+b-x)$ can be obtained from the graph of $f(x)$ by first flipping the graph of $f(x)$ along the y-axis and then shifting it $(a+b)$ units towards the right; the areas described by $f(x)$ and $f(a+b-x)$ in the interval $[a, b]$ are precisely the same.

Example 20 ***Evaluate*** $\int_{\pi/6}^{\pi/3} \frac{dx}{1+\sqrt{\tan x}}$.

Sol. Let $I = \int_{\pi/6}^{\pi/3} \frac{dx}{1+\sqrt{\tan x}} = \int_{\pi/6}^{\pi/3} \frac{\sqrt{\cos x}\cdot dx}{\sqrt{\cos x}+\sqrt{\sin x}}$ ... (i)

then, $I = \int_{\pi/6}^{\pi/3} \frac{\sqrt{\cos(\pi/2-x)}}{\sqrt{\cos(\pi/2-x)}+\sqrt{\sin(\pi/2-x)}}\,dx$

$(\because a+b = \pi/2)$

$\Rightarrow I = \int_{\pi/6}^{\pi/3} \frac{\sqrt{\sin x}}{\sqrt{\sin x}+\sqrt{\cos x}}\,dx$ ...(ii)

Adding Eqs. (i) and (ii), we get

$$2I = \int_{\pi/6}^{\pi/3} 1\,dx = \frac{\pi}{3} - \frac{\pi}{6} = \frac{\pi}{6} \Rightarrow I = \frac{\pi}{12}$$

Example 21 Prove that

$$\int_a^b \frac{f(x)}{f(x)+f(a+b-x)}\,dx = \frac{b-a}{2}.$$

Sol. Let $$I = \int_a^b \frac{f(x)}{f(x)+f(a+b-x)}\,dx \quad \text{...(i)}$$

then, $$I = \int_a^b \frac{f(a+b-x)}{f(a+b-x)+f(a+b-(a+b-x))}\,dx$$

$$\Rightarrow \quad I = \int_a^b \frac{f(a+b-x)}{f(a+b-x)+f(x)}\,dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_a^b \frac{f(a+b-x)+f(x)}{f(a+b-x)+f(x)}\,dx$$

$$\Rightarrow \quad 2I = \int_a^b 1\,dx = (b-a) \Rightarrow I = \frac{b-a}{2}$$

Example 22 Solve

$$I = \int_{\cos^4 t}^{-\sin^4 t} \frac{\sqrt{f(z)}\,dz}{\sqrt{f(\cos 2t - z)}+\sqrt{f(z)}}.$$

Sol. We have, $$I = \int_{\cos^4 t}^{-\sin^4 t} \frac{\sqrt{f(z)}\,dz}{\sqrt{f(\cos 2t - z)}+\sqrt{f(z)}} \quad \text{...(i)}$$

$$\therefore \quad I = \int_{\cos^4 t}^{-\sin^4 t} \frac{\sqrt{f(\cos 2t - z)}\,dz}{\sqrt{f(\cos 2t - z)}+\sqrt{f(z)}} \quad \text{..(ii)}$$

$$\left[\text{using } \int_a^b f(x)\,dx = \int_a^b f(a+b-x)\,dx\right]$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_{\cos^4 t}^{-\sin^4 t} dz \Rightarrow 2I = (z)_{\cos^4 t}^{-\sin^4 t}$$

$$\therefore \quad I = -\frac{1}{2}(\sin^4 t + \cos^4 t) = -\frac{1}{2}(1 - 2\sin^2 t \cos^2 t)$$

$$= -\frac{1}{2}\left(1 - \frac{1}{2}\sin^2 2t\right) = -\frac{1}{2} + \frac{1}{4}\sin^2 2t$$

Directions (Ex 23-25) *Let the function f satisfies*

$$f(x)\cdot f'(-x) = f(-x)\cdot f'(x) \text{ for all } x \text{ and } f(0) = 3.$$

Example 23 The value of $f(x)\cdot f(-x)$ for all x is

(a) 4 (b) 9
(c) 12 (d) 16

Sol. Given, $$f(x)\cdot f'(-x) = f(-x)\cdot f'(x)$$

$$\Rightarrow \quad \frac{f'(x)}{f(x)} = \frac{f'(-x)}{f(-x)}$$

Integrating both sides, we get

$$\ln f(x) = -f(-x) + C$$

$$\ln[f(x)\cdot f(-x)] = C$$

$$f(x)\cdot f(-x) = C$$

But $$f(0) = 3$$

$$\Rightarrow \quad f^2(0) = C \therefore C = 9$$

$$\therefore \quad f(x)\cdot f(-x) = 9$$

Aliter $$f(x)\cdot f'(x) - f(-x)\cdot f'(x) = 0$$

$$\Rightarrow \quad \frac{d}{dx}[f(-x)\cdot f(x)] = 0$$

Integrating both sides, we get $f(x)\cdot f(-x) = \text{Constant}$

Hence, (b) is the correct answer.

Example 24 $\int_{-51}^{51} \frac{dx}{3+f(x)}$ has the value equal to

(a) 17 (b) 34
(c) 102 (d) 0

Sol. Let $$I = \int_{-51}^{51} \frac{dx}{3+f(x)} = \int_{-51}^{51} \frac{dx}{3+f(-x)}$$

$$\left[\text{using } \int_a^b f(x)dx = \int_a^b f(a+b-x)dx\right]$$

$$2I = \int_{-51}^{51} \frac{6+f(x)+f(-x)}{[3+f(x)][3+f(-x)]}dx$$

$$= \int_{-51}^{51} \frac{6+f(x)+f(-x)}{9+3[f(x)+f(-x)]+f(x)\cdot f(-x)}\,dx$$

$$= \int_{-51}^{51} \frac{6+f(x)+f(-x)}{18+3[f(x)+f(-x)]}\,dx$$

$$= \frac{1}{3}\int_{-51}^{51} dx = \frac{2\cdot 51}{3}$$

$$\Rightarrow \quad I = \frac{51}{3} = 17$$

Hence, (a) is the correct answer.

Example 25 Number of roots of $f(x) = 0$ in $[-2, 2]$ is

(a) 0 (b) 1
(c) 2 (d) 4

Sol. Let $x = \alpha$ be the root of $f(x) = 0$.

$$\therefore \quad f(\alpha) = 0$$

$$f(x)\cdot f(-x) = 9$$

Put $x = \alpha$, then $0 = 9$ (impossible)

Therefore, $f(x)$ has no root but $f(0) = 3$.

$\therefore f(x) > 0, \forall\ x \in R$ as f is continuous possible function $f(x) = 3e^{-x}$.

Hence, (a) is the correct answer.

Exercise for Session 2

1. The value of $\int_0^{\pi/4} \log(1+\tan\theta)\,d\theta$ is equal to

(a) $\frac{\pi}{2}\log 2$ (b) $-\frac{\pi}{4}\log 2$ (c) $\frac{\pi}{8}\log 2$ (d) None of these

2. For any integer n, the value of $\int_0^{\pi} e^{\cos^2 x}\cdot\cos^3(2n+1)x\cdot dx$ is equal to

(a) 0 (b) 1 (c) –1 (d) None of these

3. The value of $\int_2^3 \frac{\sqrt{x}}{\sqrt{5-x}+\sqrt{x}}\,dx$ is equal to

(a) 1/2 (b) 1/3 (c) 1/4 (d) None of these

4. The value of $\int_0^2 \frac{dx}{(17+8x-4x^2)(e^{6(1-x)}+1)}$ is equal to

(a) $-\frac{1}{8\sqrt{21}}\log\left|\frac{2-\sqrt{21}}{2+\sqrt{21}}\right|$ (b) $-\frac{1}{8\sqrt{21}}\log\left|\frac{2+\sqrt{21}}{\sqrt{21}-2}\right|$

(c) $-\frac{1}{8\sqrt{21}}\left\{\log\left|\frac{2-\sqrt{21}}{2+\sqrt{21}}\right|-\log\left|\frac{2+\sqrt{21}}{\sqrt{21}-2}\right|\right\}$ (d) None of these

5. If f is an odd function, then the value of $\int_{-a}^{a} \frac{f(\sin x)}{f(\cos x)+f(\sin^2 x)}\,dx$ is equal to

(a) 0 (b) $f(\cos x)+f(\sin x)$ (c) 1 (d) None of these

6. If $[x]$ stands for the greatest integar function, then $\int_4^{10} \frac{[x^2]\,dx}{[x^2-28x+196]+[x^2]}$ is

(a) 1 (b) 2 (c) 3 (d) 4

7. The value of $\int_0^{\pi} \frac{x\,dx}{1+\cos\alpha\cdot\sin\alpha}(0<\alpha<\pi)$ is

(a) $\frac{\pi}{\sin\alpha}$ (b) $\frac{\pi\alpha}{\sin\alpha}$ (c) $\frac{\alpha}{\sin\alpha}$ (d) $\frac{\sin\alpha}{\alpha}$

8. If f, g, h be continuous functions on $[0, a]$ such that $f(a-x)=f(x)$, $g(a-x)=-g(x)$ and $3h(x)=5+4h(a-x)$, then the value of $\int_0^a f(x)\cdot g(x)\cdot h(x)dx$ is

(a) 0 (b) 1 (c) a (d) $2a$

9. If $2f(x)+f(-x)=\frac{1}{x}\sin\left(x-\frac{1}{x}\right)$, then the value of $\int_{1/e}^{e} f(x)dx$ is

(a) 0 (b) e (c) $1/e$ (d) $e+1/e$

10. Prove that $\int_0^{\pi} xf(\sin x)dx=\frac{\pi}{2}\int_0^{\pi} f(\sin x)dx$.

11. Evaluate $\int_0^{\pi} \frac{x^2\sin 2x\cdot\sin\left(\frac{\pi}{2}\cos x\right)dx}{(2x-\pi)}$.

12. Number of positive continuous function $f(x)$ defined on $[0, 1]$ for which $\int_0^1 f(x)dx=1$, $\int_0^1 xf(x)dx=2$ and $\int_0^1 x^2 f(x)dx=4$.

13. Let $I_1=\int_0^1 \frac{e^x}{1+x}dx$ and $I_2=\int_0^1 \frac{x^2}{e^{x^3}(2-x^3)}dx$. Then $\frac{I_1}{I_2}$ is equal to

(a) $\frac{3}{e}$ (b) $\frac{3}{e}$ (c) $3e$ (d) $\frac{1}{3e}$

14. If $f(x)=\frac{e^x}{1+e^x}$, $I_1=\int_{f(-a)}^{f(x)} x\cdot g\{x(1-x)\}dx$ and $I_2=\int_{f(-a)}^{f(a)} g\{x(1-x)\}dx$, then the value of $\frac{I_2}{I_1}$ is

(a) 1 (b) –3 (c) –1 (d) 2

Session 3

Applications of Piecewise Function Property

Applications of Piecewise Function Property

Property V (a). $\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx,$

where $c \leftrightarrow R$

Proof Let $\phi(x)$ be primitive of $f(x)$, then

$$\int_a^b f(x)\,dx = \phi(b) - \phi(a) \qquad \ldots(i)$$

and $\int_a^c f(x)dx + \int_c^b f(x)dx = [\phi(c) - \phi(a)] + [\phi(b) - \phi(c)]$

$$= \phi(b) - \phi(a) \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx$$

Generalisation Property V(a) can be generalised into the following form

$$\int_a^b f(x)dx = \int_a^{c_1} f(x)dx + \int_{c_1}^{c_2} f(x)\,dx + \ldots + \int_{c_n}^b f(x)dx$$

where, $a < c_1 < c_2 < \ldots < c_{n-1} < c_n < b$

Property V (b).

$$\int_0^a f(x)\,dx = \int_0^{a/2} f(x)\,dx + \int_0^{a/2} f(a-x)\,dx$$

Proof As we know,

$$\int_0^a f(x)\,dx = \int_0^{a/2} f(x)\,dx + \int_{a/2}^a f(x)\,dx$$

Put $x = a - t \Rightarrow dx = -dt$ in the second integral also, when $x = a/2$, then $t = a/2$ and when $x = a$, then $t = 0$.

$$\therefore \quad \int_0^a f(x)\,dx = \int_0^{a/2} f(x)\,dx + \int_{a/2}^0 f(a-t)\,(-dt)$$

$$= \int_0^{a/2} f(x)\,dx + \int_0^{a/2} f(a-t)\,dt$$

$$\int_0^a f(x)\,dx = \int_0^{a/2} f(x)\,dx + \int_0^{a/2} f(a-x)\,dx$$

Property V (c).

$$\int_a^b f(x)\,dx = \begin{cases} 0, & \text{if } f(a+x) = -f(b-x) \\ 2\int_a^{\frac{a+b}{2}} f(x)\,dx, & \text{if } f(a+x) = f(b-x) \end{cases}$$

Proof Let us consider the function $f(x)$ on $[a, b]$ when $f(a+x) = f(b-x)$, then f is even symmetric about the mid-point $x = \dfrac{a+b}{2}$ on the interval $[a, b]$ when $f(a+x) = -f(b-x)$, then f is odd symmetric about the mid-point $x = \dfrac{a+b}{2}$ of the interval $[a, b]$.

$$\therefore \text{Using } \int_{-a}^a f(x)\,dx = \begin{cases} 0, & \text{if } f \text{ is an odd function} \\ 2f(x)dx, & \text{if } f \text{ is an even function} \end{cases}$$

$$\Rightarrow \int_a^b f(x)dx = \begin{cases} 0, & \text{if } f(a+x) = -f(b-x) \\ 2\int_a^{\frac{a+b}{2}} f(x)\,dx, & \text{if } f(a+x) = f(b-x) \end{cases}$$

Example 26 ***Given function,*** $f(x) = \begin{cases} x^2, \text{ for } 0 \le x < 1 \\ \sqrt{x}, \text{ for } 1 \le x \le 2 \end{cases}$.

Evaluate $\int_0^2 f(x)\,dx$.

Sol. Here, $\int_0^2 f(x)\,dx = \int_0^1 f(x)\,dx + \int_1^2 f(x)\,dx$

$$\therefore \quad \int_0^2 f(x)\,dx = \int_0^1 x^2\,dx + \int_1^2 \sqrt{x}\,dx$$

$$= \left[\frac{x^3}{3}\right]_0^1 + \left[\frac{x^{3/2}}{3/2}\right]_1^2$$

$$= \left[\frac{x^3}{3}\right]_0^1 + \left[\frac{2}{3}x\sqrt{x}\right]_1^2$$

$$= \left[\frac{1}{3} - 0\right] + \frac{2}{3}[2\sqrt{2} - 1]$$

$$= \frac{1}{3} + \frac{4\sqrt{2}}{3} - \frac{2}{3} = \frac{4\sqrt{2}}{3} - \frac{1}{3} = \frac{1}{3}(4\sqrt{2} - 1)$$

Example 27 Evaluate the integral $I = \int_0^2 |1 - x|\,dx$.

Sol. By definition, $|a-b| = \begin{cases} b-a, & \text{if } a < b \\ a-b, & \text{if } a > b \end{cases}$

Then, $|1-x| = \begin{cases} (1-x), & 0 \le x \le 1 \\ (x-1), & 1 \le x \le 2 \end{cases}$

$$\therefore \int_0^2 |1-x|\,dx = \int_0^1 (1-x)\,dx + \int_1^2 (x-1)\,dx$$

$$= \left[x - \frac{x^2}{2}\right]_0^1 + \left[\frac{x^2}{2} - x\right]_1^2$$

$$= \left\{\left(1-\frac{1}{2}\right) - (0-0)\right\} + \left\{\left(\frac{4}{2}-2\right) - \left(\frac{1}{2}-1\right)\right\}$$

$$= \frac{1}{2} + \left\{0 + \frac{1}{2}\right\} = 1$$

Example 28 Evaluate

(i) $\int_0^{\pi} |\cos x|\,dx$ (ii) $\int_0^2 |x^2+2x-3|\,dx$

Sol. (i) $\int_0^{\pi} |\cos x|\,dx = \int_0^{\pi/2} |\cos x|\,dx + \int_{\pi/2}^{\pi} |\cos x|\,dx$

$$= \int_0^{\pi/2} (\cos x)\,dx - \int_{\pi/2}^{\pi} (\cos x)\,dx$$

$$= [\sin x]_0^{\pi/2} - [\sin x]_{\pi/2}^{\pi}$$

$$= (1-0) - (0-1) = 2$$

(ii) $\int_0^2 |x^2+2x-3|\,dx$

$$= \int_0^1 |x^2+2x-3|\,dx + \int_1^2 |x^2+2x-3|\,dx \quad \ldots(i)$$

We have, $x^2+2x-3 = (x+3)(x-1)$

$\therefore \quad x^2+2x-3 > 0$ for $x < -3$ or $x > 1$

and $x^2+2x-3 < 0$ for $-3 < x < 1$

So, $|x^2+2x-3|$

$$= \begin{cases} (x^2+2x-3), & \text{for } x < -3 \text{ or } x > 1 \\ -(x^2+2x-3), & \text{for } -3 < x < 1 \end{cases}$$

$\therefore$ Eq. (i) becomes

$$I = \int_0^1 -(x^2+2x-3)\,dx + \int_1^2 (x^2+2x-3)\,dx$$

$$= -\left[\frac{x^3}{3} + x^2 - 3x\right]_0^1 + \left[\frac{x^3}{3} + x^2 - 3x\right]_1^2$$

$$= 4$$

Example 29 Evaluate $\int_{-1}^1 (x - [x])\,dx$, where [.] denotes the greatest integral part of x.

Sol. Let $I = \int_{-1}^1 (x-[x])\,dx = \int_{-1}^1 x \cdot dx - \int_{-1}^1 [x]\,dx$

$$= \left(\frac{x^2}{2}\right)_{-1}^1 - \left(\int_{-1}^0 [x]\,dx + \int_0^1 [x]\,dx\right)$$

$$= \frac{1}{2}(1-1) - \left(\int_{-1}^0 -1\,dx + \int_0^1 0\,dx\right)$$

$$= 0 + (x)_{-1}^1 - 0 = 1$$

Example 30 Evaluate $\int_0^2 \{x\}\,dx$, where $\{x\}$ denotes the fractional part of x.

Sol. $\int_0^2 \{x\}\,dx = \int_0^2 (x-[x])\,dx = \int_0^2 x\,dx - \int_0^2 [x]\,dx$

$$= \left(\frac{x^2}{2}\right)_0^2 - \left(\int_0^1 [x]\,dx + \int_1^2 [x]\,dx\right)$$

$$= \frac{1}{2}(4-0) - \left(\int_0^1 0\,dx + \int_1^2 1\,dx\right)$$

$$= 2 - (x)_1^2 = 2 - (1) = 1$$

Remark

In above example, for greatest integer less than or equal to x, it is compulsory to break it at integral limits.

Example 31 Evaluate $\int_0^9 \{\sqrt{x}\}\,dx$, where $\{x\}$ denotes the fractional part of x.

Sol. $\int_0^9 \{\sqrt{x}\}\,dx = \int_0^9 \left(\sqrt{x} - [\sqrt{x}]\right)dx$

$$= \int_0^9 (x^{1/2})\,dx - \int_0^9 [\sqrt{x}]\,dx$$

$$= \frac{2}{3}(x^{3/2})_0^9 - \int_0^9 [\sqrt{x}]\,dx$$

$$= \frac{2}{3}[27] - \int_0^9 [\sqrt{x}]\,dx$$

As $\int_0^9 [\sqrt{x}]\,dx \Rightarrow 0 \le x \le 9$ and $0 \le \sqrt{x} \le 3$

Thus, it should be divided into three parts

$$0 \le \sqrt{x} \le 1, 1 \le \sqrt{x} \le 2, 2 \le \sqrt{x} \le 3$$

i.e. $I = 2(9) - \int_0^9 [\sqrt{x}]\,dx$

$$= 18 - \left[\int_0^1 [\sqrt{x}]\,dx + \int_1^4 [\sqrt{x}]\,dx + \int_4^9 [\sqrt{x}]\,dx\right]$$

$$= 18 - \left(\int_0^1 0\,dx + \int_1^4 1\,dx + \int_4^9 2\,dx\right)$$

$$= 18 - \left(0 + (x)_1^4 + (2x)_4^9\right) = 18 - (3+10) = 5$$

Example 32 If for a real number y, $[y]$ is the greatest integer less than or equal to y, then find the value of the integral $\int_{\pi/2}^{3\pi/2} [2\sin x]\,dx$.

Sol. We know, $-1 \le \sin x \le 1$ as $x \in [\pi/2, 3\pi/2]$

$\Rightarrow \quad -2 \le 2\sin x \le 2$

$\therefore$ $2\sin x$ must be divided (or broken) at $x = 5\pi/6, \pi, 7\pi/6$.

As $2\sin x = +1, 0, -1$ at these points.

$$\therefore \int_{\pi/2}^{3\pi/2} [2\sin x]\,dx = \int_{\pi/2}^{5\pi/6} [2\sin x]\,dx + \int_{5\pi/6}^{\pi} [2\sin x]\,dx$$

$$+ \int_{\pi}^{7\pi/6} [2\sin x]\,dx + \int_{7\pi/6}^{3\pi/2} [2\sin x]\,dx$$

$$= \int_{\pi/2}^{5\pi/6} 1\,dx + \int_{5\pi/6}^{\pi} 0\,dx + \int_{\pi}^{7\pi/6} (-1)\,dx + \int_{7\pi/6}^{3\pi/2} (-2)\,dx$$

$$= \left(\frac{5\pi}{6} - \frac{\pi}{2}\right) + 0 - \left(\frac{7\pi}{6} - \pi\right) - 2\left(\frac{3\pi}{2} - \frac{7\pi}{6}\right) = -\frac{\pi}{2}$$

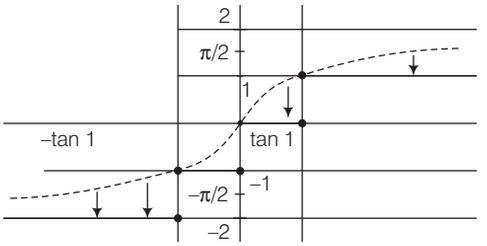
Example 33 The value of $\int_0^{100} [\tan^{-1} x]\,dx$ is equal to (where [.] denotes the greatest integer function)

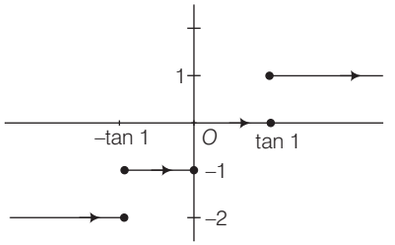
(a) tan 1 – 100 (b) $\pi/2 - \tan 1$

(c) 100 – tan 1 (d) None of these

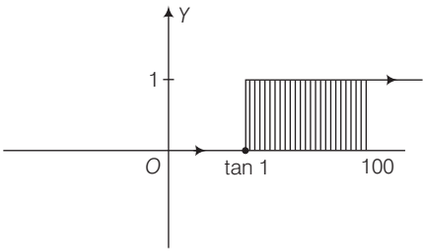
Sol. Let $I = \int_0^{100} [\tan^{-1} x]\,dx$

where $[\tan^{-1} x]$ is shown as





$\therefore \int_0^{100} [\tan^{-1} x]\,dx$ is shown as



$$= 1 \times (100 - \tan 1)$$

Hence, (c) is the correct answer.

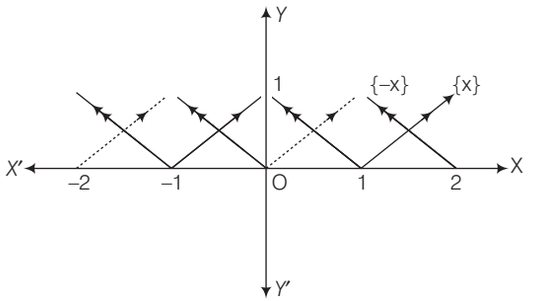
Example 34 The value of $\int_{-2}^{2} \min\{x - [x], -x - [-x]\}\,dx$ is equal to (where [.] denotes the greatest integer function)

(a) 1/2 (b) 1

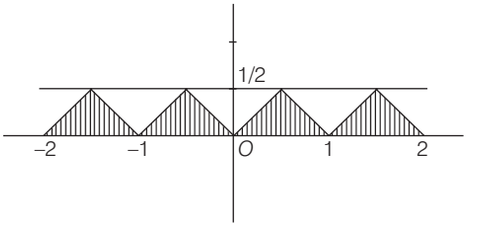
(c) 3/2 (d) 2

Sol. Let $f(x) = \min(x - [x], -x - [-x]) = \min(\{x\}, \{-x\})$

Graphically, $\{x\}$ and $\{-x\}$ could be plotted as;



From the above graph, we need $\int_{-2}^{2} \min(\{x\}, \{-x\})$ shown as



$$\therefore \quad \int_{-2}^{2} f(x)\,dx = 4\int_0^1 f(x)\,dx = 4 \times \frac{1}{2} \times 1 \times \frac{1}{2} = 1$$

Hence, (b) is the correct answer.

Example 35 ***The value of*** $\int_1^2 (x^{[x^2]} + [x^2]^x)\,dx$ ***is equal to where [.] denotes the greatest integer function***

(a) $\frac{5}{4} + \sqrt{3} + (2^{\sqrt{3}} - 2^{\sqrt{2}}) + \frac{1}{\log 3}(9 - 3^{\sqrt{3}})$

(b) $\frac{5}{4} + \sqrt{3} + \frac{\sqrt{2}}{3} + \frac{1}{\log 2}(2^{\sqrt{3}} - 2^{\sqrt{2}}) + \frac{1}{\log 3}(9 - 3^{\sqrt{3}})$

(c) $\frac{5}{4} + \frac{\sqrt{2}}{3} + \frac{1}{\log 2}(2^{\sqrt{3}} - 2^{\sqrt{2}}) + \frac{1}{\log 3}(9 - 3^{\sqrt{3}})$

(d) None of the above

Sol. Let $I = \int_1^2 (x^{[x^2]} + [x^2]^x)\,dx$

$$= \int_1^{\sqrt{2}} (x+1)\,dx + \int_{\sqrt{2}}^{\sqrt{3}} (x^2 + 2^x)\,dx + \int_{\sqrt{3}}^{2} (x^3 + 3^x)\,dx$$

$$= \left[\frac{x^2}{2} + x\right]_1^{\sqrt{2}} + \left[\frac{x^3}{3} + \frac{2^x}{\log 2}\right]_{\sqrt{2}}^{\sqrt{3}} + \left[\frac{x^4}{4} + \frac{3^x}{\log 3}\right]_{\sqrt{3}}^{2}$$

$$= \frac{5}{4} + \sqrt{3} + \frac{\sqrt{2}}{3} + \frac{1}{\log 2}(2^{\sqrt{3}} - 2^{\sqrt{2}}) + \frac{1}{\log 3}(3^2 - 3^{\sqrt{3}})$$

Hence, (b) is the correct answer.

Example 36 The value of $\int_0^{2\pi} [|\sin x| + |\cos x|]\,dx$ is equal to

(a) $\frac{\pi}{2}$ (b) π (c) $\frac{3\pi}{2}$ (d) 2π

Sol. Let $f(x) = [|\sin x| + |\cos x|]$

As, $|\sin x| \geq \sin^2 x$ and $|\cos x| \geq \cos^2 x$

$\therefore$ $|\sin x| + |\cos x| \geq 1$

and $|\sin x| + |\cos x| \leq \sqrt{1^2 + 1^2}$

$\Rightarrow$ $1 \leq |\sin x| + |\cos x| \leq \sqrt{2}$

Thus, $[|\sin x| + |\cos x|] = 1$

$\therefore$ $\int_0^{2\pi} [|\sin x| + |\cos x|]\, dx = \int_0^{2\pi} 1\, dx = 2\pi$

Hence, (d) is the correct answer.

Example 37 The value of the definite integral $\int_0^{\pi/2} \sin|2x - \alpha|\, dx$, where $\alpha \in [0, \pi]$, is

(a) 1 (b) $\cos\alpha$ (c) $\frac{1+\cos\alpha}{2}$ (d) $\frac{1-\cos\alpha}{2}$

Sol. Let $I = \int_{-\alpha}^{(\pi-\alpha)} \sin|t|\, dt$, where $2x - \alpha = t \Rightarrow dx = \frac{dt}{2}$

$$= \frac{1}{2}\int_{-\alpha}^{0} -\sin t\, dt + \frac{1}{2}\int_0^{\pi-\alpha} \sin t\, dt$$

$$= \left[\frac{1}{2}\cos t\right]_{-\alpha}^{0} - \left[\frac{1}{2}\cos t\right]_0^{\pi-\alpha}$$

$$= \frac{1}{2}[1 - \cos\alpha] - \frac{1}{2}[-\cos\alpha - 1]$$

$$= \frac{1}{2}(1 - \cos\alpha) + \frac{1}{2}(1 + \cos\alpha) = 1$$

$$= \frac{1}{2}(1 - \cos\alpha) + \frac{1}{2}(1 + \cos\alpha) = 1$$

Hence, (a) is the correct answer.

Example 38 Let f be a continuous functions satisfying

$$f'(\ln x) = \begin{cases} 1 & \text{for} \quad 0 < x \leq 1 \\ e^x - 1 & \text{for} \quad x > 1 \end{cases}$$

and $f(0) = 0$, then $f(x)$ can be defined as

(a) $f(x) = \begin{cases} 1, & \text{if} \quad x \leq 0 \\ 1 - e^x, & \text{if} \quad x > 0 \end{cases}$ (b) $f(x) = \begin{cases} 1, & \text{if} \quad x \leq 0 \\ e^x - 1, & \text{if} \quad x > 0 \end{cases}$

(c) $f(x) = \begin{cases} x, & \text{if} \quad x < 0 \\ e^x, & \text{if} \quad x > 0 \end{cases}$ (d) $f(x) = \begin{cases} x, & \text{if} \quad x \leq 0 \\ e^x - 1, & \text{if} \quad x > 0 \end{cases}$

Sol. $f'(\ln x) = \begin{cases} 1, & \text{for} \quad 0 < x \leq 1 \\ x, & \text{for} \quad x > 1 \end{cases}$

Put $\ln x = t \Rightarrow x = e^t$

For $x > 1$; $f'(t) = e^t$ for $t > 0$

Integrating $f(t) = e^t + C$; $f(0) = e^0 + C \Rightarrow C = -1$ [given, $f(0) = 0$]

$\therefore$ $f(t) = e^t - 1$, for $t > 0$ (corresponding to $x > 1$)

Therefore, $f(x) = e^x - 1$, for $x > 0$ ...(i)

Again, for $0 < x \leq 1$,

$$f'(\ln x) = 1 \qquad (\because x = e^t)$$

$f'(t) = 1$, for $t \leq 0$

$f(t) = t + C$

$f(0) = 0 + C \Rightarrow C = 0 \Rightarrow f(t) = t$, for $t \leq 0$

$\Rightarrow$ $f(x) = x$, for $x \leq 0$

Hence, (d) is the correct answer.

Example 39 The integral $\int_{\pi/4}^{5\pi/4} (|\cos t| \sin t + |\sin t| \cos t)\, dt$ has the value equal to

(a) 0 (b) 1/2

(c) $1/\sqrt{2}$ (d) 1

Sol. Let

$$I = \int_{\pi/4}^{\pi/2} 2\sin t \cos t\, dt + \underbrace{\int_{\pi/2}^{\pi} [(-\sin t \cos t) + (\sin t \cos t)]\, dt}_{\text{zero}} + \int_{\pi}^{5\pi/4} (-2\sin t \cos t)\, dt$$

$$= \int_{\pi/4}^{\pi/2} \sin 2t\, dt - \int_{\pi}^{5\pi/4} \sin 2t\, dt$$

These two integrals cancels

$\Rightarrow$ Zero.

Hence, (a) is the correct answer.

Example 40 The value of $\int_0^2 f(x)\, dx$, where

$f(x) = \begin{cases} 0, \text{when } x = \frac{n}{n+1}, & n = 1, 2, 3 \ldots \\ 1, \text{elsewhere} \end{cases}$ 3 is equal to

(a) 1 (b) 2

(c) 3 (d) None of these

Sol. Here, $\int_0^2 f(x)\, dx = \int_0^{1/2} 1\, dx + \int_{1/2}^{2/3} 1\, dx + \int_{2/3}^{3/4} 1\, dx + \ldots + \int_{\frac{n}{n+1}}^{\frac{n}{n-1}} 1\, dx + \ldots + \int_1^2 1\, dx$

$$= \left(\frac{1}{2}\right) + \left(\frac{2}{3} - \frac{1}{2}\right) + \left(\frac{3}{4} - \frac{2}{3}\right) + \ldots + \left(\frac{n}{n+1} - \frac{n-1}{n}\right) + \ldots + 1$$

$$= \frac{n}{n+1} + \ldots + 1, \text{ as } n \to \infty$$

We take, limit $n \to \infty$

We have, $\int_0^2 f(x)\, dx = 1 + 1 = 2$

Hence, (b) is the correct answer.

Exercise for Session 3

1. The value of $\int_{-1}^{3} \{|x-2|+[x]\}\,dx$, where [.] denotes the greatest integer function, is equal to

(a) 5 (b) 6 (c) 7 (d) None of these

2. The value of $\int_{-1}^{3} (|x|+|x-1|)\,dx$ is equal to

(a) 9 (b) 6 (c) 3 (d) None of these

3. Let $f(x)=x-[x]$, for every real number x (where, $[x]$ is integral part of x). Then, the value of $\int_{-1}^{1} f(x)\,dx$ is equal to

(a) 0 (b) 1 (c) 2 (d) None of these

4. The value of $\int_{0}^{2} [x+[x+[x]]]\,dx$ (where, [.] denotes the greatest integer function) is equal to

(a) 2 (b) 3 (c) –3 (d) None of these

5. The value of $\int_{0}^{[x]} \frac{2^x}{2^{[x]}}\,dx$ is equal to (where, [.] denotes the greatest integer function)

(a) $\frac{[x]}{\log 2}$ (b) $\frac{[x]}{2\log 2}$ (c) $\frac{[x]}{4\log 2}$ (d) None of these

6. The value of $\int_{0}^{4} \{x\}\,dx$ (where, {.} denotes fractional part of x) is equal to

(a) $\frac{4}{3}$ (b) $\frac{5}{3}$ (c) $\frac{7}{3}$ (d) None of these

7. The value of $\int_{1}^{4} \{x\}^{[x]}\,dx$ (where, [.] and {.} denote the greatest integer and fractional part of x) is equal to

(a) $\frac{11}{12}$ (b) $\frac{13}{12}$

(c) $\frac{7}{12}$ (d) $\frac{19}{12}$

8. The value of $\int_{0}^{x} [t+1]^3\,dt$ (where, [.] denotes the greatest integer function of x) is equal to

(a) $\left(\frac{[x]([x]+1)}{2}\right)^2 + ([x]+1)^3\{x\}$ (b) $\left(\frac{[x]([x]+1)}{2}\right)^3 + ([x]+1)^3\{x\}$

(c) $\left(\frac{[x]([x]+1)}{2}\right)^3 + ([x]+1)^2\{x\}$ (d) None of these

9. The value of $\int_{0}^{10\pi} [\tan^{-1}x]\,dx$ (where, $[\cdot]$ denotes the greatest integer function of x) is equal to

(a) $\tan 1$ (b) 10π

(c) $10\pi - \tan 1$ (d) None of these

10. If $f(x)=\min\{|x-1|,|x|,|x+1|$, then the value of $\int_{-1}^{1} f(x)\,dx$ is equal to

(a) 1 (b) $\frac{1}{2}$

(c) $\frac{1}{4}$ (d) $\frac{1}{8}$

11. The value of $\int_{0}^{\infty} [2e^{-x}]\,dx$ (where, $[\cdot]$ denotes the greatest integer function of x) is equal to

(a) 1 (b) $\log_e 2$

(c) 0 (d) $\frac{1}{e}$

12. The value of $\int_1^{10\pi}([\sec^{-1}x]+[\cot^{-1}x])dx$ (where, $[\cdot]$ denotes the greatest integer function) is equal to

(a) $(\sec 1)-10\pi$ (b) $10\pi-\sec 1$
(c) $\pi-\sec 1$ (d) None of these

13. The value of $\int_{-\pi/2}^{\pi/2}[\cot^{-1}x]dx$ (where, $[\cdot]$ denotes greatest integer function) is equal to

(a) $\pi+\cot 1$ (b) $\pi+\cot 2$
(c) $\pi+\cot 1+\cot 2$ (d) $\cot 1+\cot 2$

14. The value of $\int_0^{\pi/4}(\tan^n(x-[x])+\tan^{n-2}(x-[x]))dx$ (where, $[\cdot]$ denotes greatest integer function) is equal to

(a) $\frac{1}{n}$ (b) $\frac{1}{n-1}$ (c) $\frac{1}{n(n-1)}$ (d) $\frac{1}{n(n+1)}$

15. The value of $\int_0^2[x^2-x+1]dx$ (where, $[\cdot]$ denotes the greatest integer function) is equal to

(a) $\frac{5+\sqrt{5}}{2}$ b) $\frac{1+\sqrt{5}}{2}$ (c) $\frac{1-\sqrt{5}}{2}$ (d) $\frac{5-\sqrt{5}}{2}$

16. Evaluate $\int_0^a[x^n]dx$, (where, $[\cdot]$ denotes the greatest integer function).

17. Prove that $\int_0^x[x]dx=x[x]-\frac{1}{2}[x]([x]+1)$, where $[\cdot]$ denotes the greatest integer function.

18. If $f(n)=\frac{\int_0^n[x]dx}{\int_0^n\{x\}dx}$ (where, $[\cdot]$ and $\{\}$ denotes greatest integer and fractional part of x and $n\in N$). Then, the value of $f(4)$ is ...

19. If $f(n)=\int_0^x[\cos t]dt$, where $x\in\left(2n\pi,2n\pi+\frac{\pi}{2}\right);n\in N$ and $[\cdot]$ denotes the greatest integer function. Then, the value of $\left|f\left(\frac{1}{\pi}\right)\right|$ is ...

20. If $\int_0^x[x]dx=\int_0^{[x]}xdx, x\notin$ integer (where, $[\cdot]$ and $\{\}$ denotes the greatest integer and fractional parts respectively, then the value of $4\{x\}$ is equal to ...

Session 4

Applications of Even-Odd Property and Half the Integral Limit Property

Applications of Even-Odd Property and Half the Integral Limit Property

Property VI.

$$\int_{-a}^{a} f(x)\,dx = \begin{cases} 2\int_0^a f(x)\,dx, & \text{if } f(x) \text{ is an even function} \\ 0, & \text{if } f(x) \text{ is an odd function} \end{cases}$$

Proof We know,

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx, \text{ if } a < c < b$$

$$\therefore \quad \int_{-a}^{a} f(x)\,dx = \int_{-a}^{0} f(x)\,dx + \int_0^a f(x)\,dx \qquad \ldots(i)$$

Now, $\int_{-a}^{0} f(x)\,dx = \int_a^0 f(-t)(-dt)$, where $t = -x$

$$= -\int_a^0 f(-t)\,dt = \int_0^a f(-t)\,dt$$

$$= \int_0^a f(-x)\,dx \text{ (using properties I and II)}$$

$$= \begin{cases} \int_0^a f(x)\,dx, & \text{if } f(x) \text{ is even} \\ -\int_0^a f(x)\,dx, & \text{if } f(x) \text{ is odd} \end{cases} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$\int_{-a}^{a} f(x)\,dx = \begin{cases} 2\int_0^a f(x)\,dx, & f(x) \text{ is even} \\ 0, & \text{if } f(x) \text{ is odd} \end{cases}$$

Example 41 Evaluate $\int_{-1}^{1} (x^3 + 5x + \sin x)dx$.

Sol. Let, $f(x) = x^3 + 5x + \sin x$

$\therefore \quad f(-x) = -x^3 - 5x - \sin x = -f(x)$

So, $f(x)$ is an odd function).

Hence, $\int_{-1}^{1} (x^3 + 5x + \sin x)dx = 0$

$$\left[\text{using } \int_{-a}^{a} f(x)\,dx = \begin{cases} 2\int_0^a f(x)dx, f(x) \text{ is even} \\ 0, f(x) \text{ is odd} \end{cases}\right]$$

Example 42 Evaluate $\int_{-\pi/4}^{\pi/4} x^3 \sin^4 x\,dx$.

Sol. Let $f(x) = x^3 \sin^4 x$, then

$$f(-x) = (-x)^3 \sin^4(-x) = -x^3 [\sin(-x)]^4$$

$$= -x^3 (-\sin x)^4 = -x^3 \sin^4 x = -f(x)$$

So, $f(x)$ is an odd function.

Hence, $\int_{-\pi/4}^{\pi/4} f(x)\,dx = 0$

i.e. $\int_{-\pi/4}^{\pi/4} x^3 \sin^4 x\,dx = 0$

Example 43 Evaluate $\int_{-\pi/2}^{\pi/2} \sin^2 x\,dx$.

Sol. Let $f(x) = \sin^2 x$, then

$$f(-x) = \sin^2(-x) = [\sin(-x)]^2 = (-\sin x)^2$$

$$= \sin^2 x = f(x)$$

So, $f(x)$ is an even function, hence

$$\int_{-\pi/2}^{\pi/2} (\sin^2 x)\,dx = 2\int_0^{\pi/2} (\sin^2 x)\,dx$$

$$= 2\int_0^{\pi/2} \frac{1 - \cos 2x}{2}\,dx$$

$$= \left(x - \frac{\sin 2x}{2}\right)_0^{\pi/2} = \frac{\pi}{2}$$

$$\therefore \int_{-\pi/2}^{\pi/2} \sin^2 x\,dx = \frac{\pi}{2}$$

Example 44 ***The value of*** $\int_{-1}^{1} \log\left(\frac{2-x}{2+x}\right)dx$ ***is equal to***

(a) $\frac{1}{2}$ (b) 1 (c) –1 (d) 0

Sol. Let $f(x) = \log\left(\frac{2-x}{2+x}\right)$

Now, $f(-x) = \log\left(\frac{2+x}{2-x}\right) = \log\left(\frac{2-x}{2+x}\right)^{-1}$

$$= -\log\left(\frac{2-x}{2+x}\right)$$

$$\therefore \quad f(-x) = -\log\left(\frac{2-x}{2+x}\right) = -f(x)$$

i.e. $f(x)$ is an odd function.

So, $\int_{-1}^{1} f(x)\,dx = \int_{-1}^{1} \log\left(\frac{2-x}{2+x}\right)dx = 0$

$$\left[\because \int_{-a}^{a} f(x)\,dx = \begin{cases} 0, & \text{if } f(x) \text{ is odd} \\ 2\int_0^a f(x)\,dx, & \text{if } f(x) \text{ is even} \end{cases}\right]$$

Hence, (d) is the correct answer.

Example 45 The value of

$\int_0^{\pi} \frac{x\sin(2x)\cdot\sin\left(\frac{\pi}{2}\cos x\right)}{(2x-\pi)}dx$ is equal to

(a) $\frac{8}{\pi}$ (b) $\frac{\pi}{8}$ (c) $\frac{8}{\pi^2}$ (d) $\frac{\pi^2}{8}$

Sol. Let $I = \int_0^{\pi} \frac{x\sin(2x)\cdot\sin\left(\frac{\pi}{2}\cos x\right)}{(2x-\pi)}dx$ ...(i)

$$I = \int_0^{\pi} \frac{(\pi-x)\cdot\sin 2(\pi-x)\cdot\sin\left(\frac{\pi}{2}\cos(\pi-x)\right)}{2(\pi-x)-\pi}dx$$

$$I = \int_0^{\pi} \frac{(\pi-x)\cdot\sin(2x)\cdot\sin\left(\frac{\pi}{2}\cos x\right)}{-(2x-\pi)}dx \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$2I = \int_0^{\pi} \frac{(2x-\pi)\sin 2x\cdot\sin\left(\frac{\pi}{2}\cos x\right)}{(2x-\pi)}dx$$

$$\therefore\ I = \frac{1}{2}\int_0^{\pi} 2\sin x\cos x\cdot\sin\left(\frac{\pi}{2}\cos x\right)dx$$

(put $\cos x = t$, then $-\sin x\,dx = dt$)

$$= -\int_1^{-1} t\sin\left(\frac{\pi}{2}t\right)dt$$

$$= 2\int_0^1 t\cdot\sin\left(\frac{\pi}{2}t\right)dt \quad \text{(using by parts)}$$

$$= 2\left\{\left(t\cdot\frac{\cos\left(\frac{\pi}{2}t\right)}{-\frac{\pi}{2}}\right)_0^1 - \int_0^1 1\cdot\frac{\cos\left(\frac{\pi}{2}t\right)}{-\frac{\pi}{2}}dt\right\}$$

$$= 2\left\{0+\frac{2}{\pi}\cdot\left(\frac{\sin\left(\frac{\pi}{2}t\right)}{\frac{\pi}{2}}\right)_0^1\right\} = \frac{8}{\pi^2}$$

Hence, (c) is the correct answer.

Example 46 ***If*** $f(x) = \begin{vmatrix} \cos x & e^{x^2} & 2x\cos^2 x/2 \\ x^2 & \sec x & \sin x + x^3 \\ 1 & 2 & x+\tan x \end{vmatrix}$, ***then value of*** $\int_{-\pi/2}^{\pi/2} (x^2+1)[f(x)+f''(x)]\,dx$ ***is equal to***

(a) 1 (b) –1 (c) 2 (d) None of these

Sol. As, $f(x) = \begin{vmatrix} \cos x & e^{x^2} & 2x\cos^2 x/2 \\ x^2 & \sec x & \sin x + x^3 \\ 1 & 2 & x+\tan x \end{vmatrix}$

$\Rightarrow f(-x) = -f(x)$

$\Rightarrow f(x)$ is odd. $\Rightarrow f'(x)$ is even.

$\Rightarrow f''(x)$ is odd.

Thus, $f(x)+f''(x)$ is odd function, let

$$\phi(x) = (x^2+1)\cdot\{f(x)+f''(x)\}$$

$$\Rightarrow \quad \phi(-x) = -\phi(x)$$

i.e. $\phi(x)$ is odd.

$$\therefore \quad \int_{-\pi/2}^{\pi/2} \phi(x)\,dx = 0$$

Hence, (d) is the correct answer.

Example 47 The value of

$\int_{-1}^{1} \frac{x}{\sqrt{1-x^2}}\cdot\sin^{-1}(2x\sqrt{1-x^2})\,dx$ is equal to

(a) $4\sqrt{2}$ (b) $4(\sqrt{2}-1)$ (c) $4(\sqrt{2}+1)$ (d) None of these

Sol. Let $I = \int_{-1}^{1} \frac{x}{\sqrt{1-x^2}}\cdot\sin^{-1}(2x\sqrt{1-x^2})\,dx$

$$= 2\int_0^1 \frac{x}{\sqrt{1-x^2}}\cdot\sin^{-1}(2x\sqrt{1-x^2})\,dx$$

$$\left[\text{using } \int_{-a}^{a} f(x)\,dx = 2\int_0^a f(x)\,dx, \text{if } f(-x) = f(x)\right]$$

Put $x = \sin\theta \Rightarrow dx = \cos\theta\,d\theta$

$$\therefore \quad I = 2\int_0^{\pi/2} \frac{\sin\theta}{\sqrt{1-\sin^2\theta}}\cdot\sin^{-1}(2\sin\theta\cos\theta)\cdot\cos\theta\,d\theta$$

$$= 2\int_0^{\pi/4} \sin\theta\cdot 2\theta\,d\theta + 2\int_{\pi/4}^{\pi/2} (\pi-2\theta)\sin\theta\,d\theta$$

$$\left[\text{using } \sin^{-1}(\sin 2\theta) = \begin{cases} 2\theta, & 0<\theta<\pi/4 \\ \pi-2\theta, & \pi/4<\theta<\pi/2 \end{cases}\right]$$

$$= 4\int_0^{\pi/4} \theta\cdot\sin\theta\,d\theta + 2\pi\int_{\pi/4}^{\pi/2} \sin\theta\,d\theta - 4\int_{\pi/4}^{\pi/2} \theta\cdot\sin\theta\,d\theta$$

$$= 4\{\theta(-\cos\theta)\}_0^{\pi/4} - 4\int_0^{\pi/4} 1\cdot(-\cos\theta)d\theta + 2\pi(-\cos\theta)_{\pi/4}^{\pi/2}$$

$$- 4\{\theta(-\cos\theta)\}_{\pi/4}^{\pi/2} + 4\int_{\pi/4}^{\pi/2} (-\cos\theta)\,d\theta$$

$$= -\frac{\pi}{\sqrt{2}} + 2\sqrt{2} + \sqrt{2}\pi - \frac{\pi}{\sqrt{2}} - 4 + 2\sqrt{2} = 4\sqrt{2} - 4$$

$$= 4(\sqrt{2}-1)$$

Hence, (b) is the correct answer.

Example 48 Suppose the function $g_n(x) = x^{2n+1} + a_n x + b_n (n \in N)$ satisfies the equation $\int_{-1}^{1} (px+q) g_n(x)\,dx = 0$ for all linear functions $(px+q)$, then

(a) $a_n = b_n = 0$ (b) $b_n = 0\,; a_n = -\frac{3}{2n+3}$

(c) $a_n = 0\,; b_n = -\frac{3}{2n+3}$ (d) $a_n = \frac{3}{2n+3}; b_n = -\frac{3}{2n+3}$

Sol. We have, $\int_{-1}^{1} (px+q)(x^{2n+1} + a_n x + b_n)\,dx = 0$

Equating the odd component to be zero and integrating, we get

$$\frac{2p}{2n+3} + \frac{2a_n p}{3} + 2b_n q = 0 \text{ for all } p, q$$

Therefore, $b_n = 0$ and $a_n = -\frac{3}{2n+3}$

Hence, (b) is the correct answer.

Property VII (a).

$$\int_0^{2a} f(x)\,dx = \begin{cases} 2\int_0^a f(x)\,dx, & \text{if } f(2a-x) = f(x) \\ 0, & \text{if } f(2a-x) = -f(x) \end{cases}$$

Proof We know,

$$\int_0^{2a} f(x)\,dx = \int_0^a f(x)\,dx + \int_a^{2a} f(x)\,dx \qquad \ldots(\text{i})$$

Consider the integral $\int_0^{2a} f(x)\,dx$; putting $x = 2a - t$, so that $dx = -dt$

Also, when $x = a$, then $t = a$ and when $x = 2a$, then $t = 0$.

$$\therefore \int_a^{2a} f(x)\,dx = \int_a^0 f(2a-t)(-dt) = -\int_a^0 f(2a-t)\,dt$$

$$= \int_0^a f(2a-t)\,dt = \int_0^a f(2a-x)\,dx$$

$$= \begin{cases} \int_0^a f(x)\,dx, & \text{if } f(2a-x) = f(x) \\ -\int_0^a f(x)\,dx, & \text{if } f(2a-x) = -f(x) \end{cases} \ldots(\text{ii})$$

From Eqs. (i) and (ii), we have

$$\int_0^{2a} f(x)\,dx = \begin{cases} 2\int_0^a f(x)\,dx, & \text{if } f(2a-x) = f(x) \\ 0, & \text{if } f(2a-x) = -f(x) \end{cases}$$

Example 49 Evaluate $\int_0^{\pi} \frac{x}{1+\cos^2 x}\,dx$.

Sol. Let $I = \int_0^{\pi} \frac{x}{1+\cos^2 x}\,dx$

$$= \int_0^{\pi} \frac{(\pi - x)\,dx}{1+\cos^2(\pi - x)} = \int_0^{\pi} \frac{\pi\,dx}{1+\cos^2 x} - \int_0^{\pi} \frac{x\,dx}{1+\cos^2 x}$$

$$\therefore \quad I = \pi \int_0^{\pi} \frac{dx}{1+\cos^2 x} - I$$

$$\Rightarrow \quad 2I = \pi \int_0^{\pi} \frac{dx}{1+\cos^2 x} = 2\pi \int_0^{\pi/2} \frac{dx}{1+\cos^2 x}$$

$$\left[\text{using} \int_0^{2a} f(x)\,dx = \begin{cases} 0, & f(2a-x) = -f(x) \\ 2\int_0^a f(x)\,dx, & f(2a-x) = f(x) \end{cases}\right]$$

$$\Rightarrow \quad I = \pi \int_0^{\pi/2} \frac{\sec^2 x}{\sec^2 x + 1}\,dx$$

(dividing numerator and denominator by $\cos^2 x$)

$$I = \pi \int_0^{\pi/2} \frac{\sec^2 x}{2 + \tan^2 x}\,dx$$

Put $\tan x = t \Rightarrow \sec^2 x\,dx = dt$

Also, when $x = 0$, then $t = 0$ and when $x = \pi/2$, then $t = \infty$

Hence, $$I = \pi \int_0^{\infty} \frac{dt}{2+t^2} = \frac{\pi}{\sqrt{2}} \left(\tan^{-1} \frac{t}{\sqrt{2}} \right)_0^{\infty}$$

$$= \frac{\pi}{\sqrt{2}} \left(\frac{\pi}{2} - 0 \right) = \frac{\pi^2}{2\sqrt{2}}$$

Example 50 Prove that $\int_0^{\pi/2} \log(\sin x)\,dx = \int_0^{\pi/2} \log(\cos x)\,dx = -\frac{\pi}{2}\log 2$.

Sol. Let $I = \int_0^{\pi/2} \log(\sin x)\,dx$ ...(i)

Then, $I = \int_0^{\pi/2} \log\sin(\pi/2 - x)\,dx$

$$= \int_0^{\pi/2} \log(\cos x)\,dx \quad \ldots(\text{ii})$$

Adding eqs. (i) and (ii), we get

$$2I = \int_0^{\pi/2} \log\sin x\,dx + \int_0^{\pi/2} \log\cos x\,dx$$

$$= \int_0^{\pi/2} (\log\sin x + \log\cos x)\,dx$$

$$= \int_0^{\pi/2} \log(\sin x \cos x)\,dx = \int_0^{\pi/2} \log\left(\frac{2\sin x \cos x}{2}\right) dx$$

$$= \int_0^{\pi/2} \log\left(\frac{\sin 2x}{2}\right) dx$$

$$= \int_0^{\pi/2} \log(\sin 2x)\,dx - \int_0^{\pi/2} (\log 2)\,dx$$

$$= \int_0^{\pi/2} \log\sin 2x\,dx - (\log 2)(x)_0^{\pi/2}$$

$$\Rightarrow \quad 2I = \int_0^{\pi/2} \log(\sin 2x)\,dx - \frac{\pi}{2}\log 2 \qquad \ldots(\text{iii})$$

Let $I_1 = \int_0^{\pi/2} \log(\sin 2x)\,dx$

$$I_1 = \int_0^{\pi} \log \sin t \, \frac{dt}{2} = \frac{1}{2}\int_0^{\pi} \log \sin t \, dt \text{ (putting } 2x = t)$$

$$= \frac{1}{2} \cdot 2 \int_0^{\pi/2} \log (\sin t)\, dt$$

$$\left[\text{using } \int_0^{2a} f(x)\, dx = \begin{cases} 0, & f(2a - x) = -f(x) \\ 2\int_0^a f(x)\, dx, & f(2a - x) = f(x), \end{cases}\right.$$

$$= \int_0^{\pi/2} \log (\sin x)\, dx$$

$\therefore$ Eq. (iii) becomes $2I = I - \frac{\pi}{2}\log 2$

Hence, $\int_0^{\pi/2} \log \sin x \, dx = -\frac{\pi}{2}\log 2.$

Remark

Students are advised to learn

$\int_0^{\pi/2} \log(\sin x)\, dx = \int_0^{\pi/2} \log(\cos x)\, dx = -\frac{\pi}{2}\log 2.$

Example 51 If $f(x) = -\int_0^x \log(\cos t)\, dt$, then the value of $f(x) - 2f\left(\frac{\pi}{4} + \frac{x}{2}\right) + 2f\left(\frac{\pi}{4} - \frac{x}{2}\right)$ is equal to

(a) $-x\log 2$ (b) $\frac{x}{2}\log 2$

(c) $\frac{x}{3}\log 2$ (d) None of these

Sol. Here, $f\left(\frac{\pi}{4} + \frac{x}{2}\right) = -\int_0^{\pi/4 + x/2} \log(\cos t)\, dt$

$$= -\int_0^{\pi/4} \log(\cos t)\, dt - \int_{\pi/4}^{\pi/4 + x/2} \log(\cos t)\, dt \quad \text{...(i)}$$

$$f\left(\frac{\pi}{4} - \frac{x}{2}\right) = -\int_0^{\pi/4 - x/2} \log(\cos t)\, dt$$

$$= -\int_0^{\pi/4} \log(\cos t)\, dt - \int_{\pi/4}^{\pi/4 - x/2} \log(\cos t)\, dt \quad \text{...(ii)}$$

$\therefore$ $2f\left(\frac{\pi}{4} + \frac{x}{2}\right) - 2f\left(\frac{\pi}{4} - \frac{x}{2}\right)$

$$= 2\int_{\pi/4}^{\pi/4 - x/2} \log(\cos t)\, dt - 2\int_{\pi/4}^{\pi/4 + x/2} \log(\cos t)\, dt$$

Put $t = \frac{\pi}{4} - z$ in first integral and $t = \frac{\pi}{4} + z$ in second integral, we get

$$= -2\int_0^{x/2} \log\cos\left(\frac{\pi}{4} - z\right) dz - 2\int_0^{x/2} \log\cos\left(z + \frac{\pi}{4}\right) dz$$

$$= -2\int_0^{x/2} \log\left(\frac{1}{2}(\cos^2 z - \sin^2 z)\right) dz$$

$$= 2\int_0^{x/2} (\log 2)\, dx - 2\int_0^{x/2} \log(\cos 2z)\, dz$$

$$= x\log 2 - 2\int_0^{x/2} \log(\cos 2z)\, dz$$

$\therefore$ $2f\left(\frac{\pi}{4} + \frac{x}{2}\right) - 2f\left(\frac{\pi}{4} - \frac{x}{2}\right) = x(\log 2) - 2\int_0^{x/2} \log(\cos 2z)\, dz$

$\Rightarrow$ $2f\left(\frac{\pi}{4} + \frac{x}{2}\right) - 2f\left(\frac{\pi}{4} - \frac{x}{2}\right) = x(\log 2) + f(x)$

or $f(x) - 2f\left(\frac{\pi}{4} + \frac{x}{2}\right) + 2f\left(\frac{\pi}{4} - \frac{x}{2}\right) = -x\log 2$

Hence, (a) is the correct answer.

Example 52 If $\int_0^{\pi} \left(\frac{x}{1 + \sin x}\right)^2 dx = A$, then the value for $\int_0^{\pi} \frac{2x^2 \cdot \cos^2 x/2}{(1 + \sin x)^2} dx$ is equal to

(a) $A + 2\pi - \pi^2$ (b) $A - 2\pi + \pi^2$

(c) $2\pi - A - \pi^2$ (d) None of these

Sol. Let $B = \int_0^{\pi} \frac{2x^2 \cos^2 x/2}{(1 + \sin x)^2} dx$

$$\therefore \quad B - A = \int_0^{\pi} \frac{x^2 (2\cos^2 x/2 - 1)}{(1 + \sin x)^2} dx$$

$$= \int_0^{\pi} \frac{x^2 \cdot \cos x}{(1 + \sin x)^2} dx$$

Using by parts,

$$B - A = \left\{ -\frac{x^2}{1 + \sin x} \right\}_0^{\pi} + 2\int_0^{\pi} \frac{x}{(1 + \sin x)} dx$$

$$B - A = -\pi^2 + 2K \quad \text{...(i)}$$

where, $K = \int_0^{\pi} \frac{x\, dx}{1 + \sin x} = \int_0^{\pi} \frac{(\pi - x)\, dx}{1 + \sin x}$

$$\therefore \quad K = \pi\int_0^{\pi} \frac{dx}{1 + \sin x} - K,$$

$$\left[\text{using } \int_0^{2a} f(x)\, dx = \begin{cases} 0, & f(2a - x) = -f(x) \\ 2\int_0^a f(x)\, dx, & f(2a - x) = f(x), \end{cases}\right.$$

$$\Rightarrow 2K = 2\pi\int_0^{\pi/2} \frac{dx}{1 + \sin x} = 2\pi\int_0^{\pi/2} \frac{dx}{1 + \cos x}$$

$$= 2\pi\int_0^{\pi/2} \frac{1}{2}\sec^2\frac{x}{2}\, dx = 2\pi\left\{\tan\frac{x}{2}\right\}_0^{\pi/2} = 2\pi$$

$\therefore$ $K = \pi$

Thus, $B - A = -\pi^2 + 2K$

$\Rightarrow$ $B = A - \pi^2 + 2\pi$

Hence, (a) is the correct answer.

Example 53 ***The value of*** $\int_{-a}^{a} (\cos^{-1} x - \sin^{-1}\sqrt{1-x^2})\,dx\ (a>0)$ ***(where,*** $\int_0^a \cos^{-1} x\,dx = A$***) is***

(a) $\pi a - A$ (b) $\pi a + 2A$

(c) $\pi a - 2A$ (d) $\pi a + A$

Sol. Let $I = \int_{-a}^{a} (\cos^{-1} x - \sin^{-1}\sqrt{1-x^2})\,dx$ (as $a>0$)

$$= \int_{-a}^{0} (\cos^{-1} x - \sin^{-1}\sqrt{1-x^2})\,dx + \int_0^a (\cos^{-1} x - \sin^{-1}\sqrt{1-x^2})\,dx$$

$$= \int_{-a}^{0} \cos^{-1} x\,dx + A - 2\int_0^a \sin^{-1}\sqrt{1-x^2}\,dx$$

$$= -\int_a^0 (\pi - \cos^{-1} x)\,dx + A - 2A$$

$$= \pi a - \int_0^a \cos^{-1} x\,dx - A$$

$$= \pi a - A - A = \pi a - 2A$$

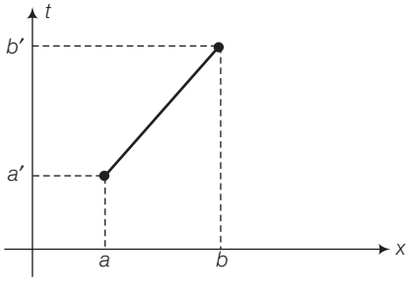
Hence, (c) is the correct answer.

Property VII (b)

$$\int_a^b f(x)\,dx = (b-a)\int_0^1 f[(b-a)\,x + a]\,dx$$

Sometimes, it is convenient to change the limits of integration into some other limits. For example, suppose we have to add two definite integrals I_1 and I_2; the limits of integration of these integrals are different. if we could somehow change the limits of I_2 into those of I_1 or vice-versa, or infact change the limits of both I_1 and I_2 into a third (common) set of limits, the addition could be accomplished easily.

Suppose that $I = \int_a^b f(x)\,dx$. We need to change the limits (a to b) to (a' to b'). As x varies from a to b, we need a new variable t (in terms of x) which varies from a' to b'.



As x varies from a to b, t varies from a to b, t varies from a' to b'.

Thus, $$\frac{t-a'}{x-a} = \frac{b'-a'}{b-a}$$

As described in the figure above, the new variable t is given by,

$$t = a' + \left(\frac{b'-a'}{b-a}\right)(x-a).$$

Thus, $$dt = \frac{b'-a'}{b-a}dx$$

$$\Rightarrow \quad I = \int_0^b f(x)\,dx = \int_{a'}^{b'} f\left(a + \left(\frac{b-a}{b'-a'}\right)(t-a')\right)\left(\frac{b-a}{b'-a'}\right)dt$$

The modified integral has the limits (a' to b'). A particular case of this property is modifying the arbitrary integration limits (a to b) to (0 to 1) i.e. $a' = 0$ and $b' = 1$. For this case,

$$I = \int_a^b f(x)\,dx = (b-a)\int_0^1 f(a + (b-a)t)\,dt$$

Example 54 Evaluate

$$\int_{-4}^{-5} e^{(x+5)^2}\,dx + 3\int_{1/3}^{2/3} e^{9\left(x-\frac{2}{3}\right)^2}\,dx.$$

Sol. Here, we know $\int e^{x^2}\,dx$ cannot be evaluated by indefinite integral.

Let $I_1 = \int_{-4}^{-5} e^{(x+5)^2}\,dx = (-5+4)\int_0^1 e^{[(-5+4)x - 4 + 5]^2}\,dx$

$$\therefore \quad I_1 = -\int_0^1 e^{(x-1)^2}\,dx \qquad \ldots(i)$$

Again, let $I_2 = \int_{1/3}^{2/3} e^{9(x-2/3)^2}dx$

$$= \left(\frac{2}{3} - \frac{1}{3}\right)\int_0^1 e^{9\left[\left(\frac{2}{3}-\frac{1}{2}\right)x + \frac{1}{3} - \frac{2}{3}\right]^2}dx$$

$$= \frac{1}{3}\int_0^1 e^{(x-1)^2}dx = \frac{1}{3}(-I_1) \qquad \ldots(ii)$$

where, $I = I_1 + 3I_2 = I_1 + 3\left(-\frac{I_1}{3}\right) = I_1 - I_1 = 0$

$$\therefore \quad \int_{-4}^{-5} e^{(x+5)^2}\,dx + 3\int_{1/3}^{2/3} e^{9(x-2/3)^2}\,dx = 0$$

Property VII (c) If $f(t)$ is an odd function, then $\phi(x) = \int_a^x f(t)\,dt$ is an even function.

Proof We have, $\phi(-x) = \int_a^{-x} f(t)\,dt$

$$\Rightarrow \quad \phi(-x) = \int_a^{-a} f(t)\,dt + \int_{-a}^{-x} f(t)\,dt$$

$$\Rightarrow \quad \phi(-x) = 0 + \int_{-a}^{-x} f(t)\,dt$$

$$\left[\because f(t) \text{ is an odd function, then } \int_{-a}^{a} f(t)\,dt = 0\right]$$

$\Rightarrow \quad \phi(-x) = -\int_a^x f(-y)\,dy$, where $t = -y$

$\Rightarrow \quad \phi(-x) = \int_a^x f(y)\,dy$

[$\because f$ is an odd function, then $f(-y) = -f(y)$]

$\Rightarrow \quad \phi(-x) = \int_a^x f(t)\,dt$

$\Rightarrow \quad \phi(-x) = \phi(x)$

Hence, $\phi(x) = \int_a^x f(t)\,dt$ is an even function, if $f(t)$ is odd.

Example 55 ***If*** $f(x) = \int_0^x \log\left(\frac{1-t}{1+t}\right)dt$, ***then discuss whether even or odd?***

Sol. Let $\phi(t) = \log\left(\frac{1-t}{1+t}\right)$

$\therefore \quad \phi(-t) = \log\left(\frac{1+t}{1-t}\right) = -\log\left(\frac{1-t}{1+t}\right) = -\phi(t)$

$\Rightarrow \quad \phi(-t) = -\phi(t)$, i.e. $\phi(t)$ is odd function

$\therefore \quad \phi(x) = \int_0^x \log\left(\frac{1-t}{1+t}\right)dt$ is an even function.

Property VII (d) If $f(t)$ is an even function, then $\phi(x) = \int_0^x f(t)\,dt$ is an odd function.

Proof We have, $\phi(-x) = \int_0^{-x} f(t)\,dt = -\int_0^x f(-y)\,dy$, where $t = -y$

$\Rightarrow \quad \phi(-x) = -\int_0^x f(y)\,dy$

[$\because f$ is even function $\Rightarrow f(-y) = f(y)$]

$\Rightarrow \quad \phi(-x) = -\int_0^x f(t)\,dt$

$\Rightarrow \quad \phi(-x) = -\phi(x)$

Hence, $\phi(x)$ is an odd function.

Remark

If $f(t)$ is an even function, then for non-zero 'a', $\int_a^x f(t)\,dt$ is not necessarily an odd function. It will be an odd function, if $\int_0^a f(t)\,dt = 0$, because, if $\phi(x) = \int_a^x f(t)\,dt$, it is an odd function.

$\Rightarrow \quad \phi(-x) = -\phi(x)$

$\Rightarrow \quad \int_a^{-x} f(t)\,dt = -\int_a^x f(t)\,dt$

$\Rightarrow \quad \int_a^0 f(t)\,dt + \int_0^{-x} f(t)\,dt = -\int_a^0 f(t)\,dt - \int_0^x f(t)\,dt$

$\Rightarrow \quad \int_a^0 f(t)\,dt - \int_0^x f(-y)\,dy = -\int_0^a f(t)\,dt - \int_0^x f(t)\,dt$

[where, $y = -t$ in second integral of LHS $\Rightarrow f(-y) = f(y)$]

$\Rightarrow \quad 2\int_a^0 f(t)\,dt = \int_0^x f(y)\,dy - \int_0^x f(t)\,dt$

$\Rightarrow \quad 2\int_a^0 f(t)\,dt = 0$

$\Rightarrow \quad -\int_0^a f(t)\,dt = 0 \Rightarrow \int_0^a f(t)\,dt = 0$

or $\phi(x) = \int_a^x f(t)\,dt$ is an odd function, [when $f(t)$ is even.]

Only, if $\int_0^a f(t)\,dt = 0$

Exercise for Session 4

1. Let $f : R \to R$ and $g : R \to R$ be continous functions, then the value of $\int_{-\pi/2}^{\pi/2} [f(x) + f(-x)][g(x) - g(-x)]\,dx$ is equal to

(a) -1 (b) 0 (c) 1 (d) None of these

2. The value of $\int_{-1}^{1} (x|x|)\,dx$ is equal to

(a) 1 (b) $\frac{1}{2}$ (c) 0 (d) None of these

3. The value of $\int_{-1}^{1} \left(\frac{x^2 + \sin x}{1 + x^2}\right) dx$ is equal to

(a) $2 - \pi$ (b) $\pi - 2$ (c) $2 - \frac{\pi}{2}$ (d) None of these

4. If $f(x)$ is an odd function, then the value of $\int_{-a}^{a} \frac{f(\sin x)}{f(\cos x) + f(\sin^2 x)} dx$ is equal to

(a) 0 (b) $f(\cos x) + f(\sin x)$ (c) 1 (d) None of these

5. The value of $\int_{-1/\sqrt{3}}^{1/\sqrt{3}} \frac{\cos^{-1}\left(\frac{2x}{1+x^2}\right) + \tan^{-1}\left(\frac{2x}{1-x^2}\right) dx}{1 + e^x}$ is equal to

(a) $\frac{\pi}{2}$ (b) $\frac{\pi}{\sqrt{3}}$ (c) $\frac{\pi}{2\sqrt{3}}$ (d) $\frac{\pi}{3\sqrt{3}}$

6. The value of $\int_{-\pi}^{\pi} \frac{\cos^2 x}{1 + a^x} dx$, where $a > 0$, is *[IITJEE 2001]*

(a) π (b) $a\pi$ (c) 2π (d) $\frac{\pi}{2}$

7. The integral $\int_{-1/2}^{1/2} \left\{[x] + \log_e\left(\frac{1+x}{1-x}\right)\right\} dx$ is equal to (where, $[\cdot]$ denotes greatest integer function)

(a) $-\frac{1}{2}$ (b) 0 (c) 1 (d) $2 \log\left(\frac{1}{2}\right)$

8. The value of $\int_{-\pi/2}^{\pi/2} \frac{1}{e^{\sin x} + 1} dx$ is equal to

(a) 0 (b) 1 (c) $\frac{\pi}{2}$ (d) $-\frac{\pi}{2}$

9. If $[\cdot]$ denotes greatest integer function, then the value of $\int_{-\pi/2}^{\pi/2} \left(\left[\frac{\pi}{2}\right] + 0.5\right) dx$ is

(a) π (b) $\frac{\pi}{2}$ (c) 0 (d) $-\frac{\pi}{2}$

10. The equation $\int_{-\pi/4}^{\pi/4} \left\{a|\sin x| + \frac{b \sin x}{1 + \cos^2 x} + c\right\} dx = 0$, where a, b, c are constants gives a relation between

(a) a, b and c (b) a and c (c) a and b (d) b and c

11. The value of $\int_{-2}^{2} \frac{\sin^2 x}{\left[\frac{x}{\pi}\right] + \frac{1}{2}} dx$, where $[\cdot]$ denotes greatest integer function, is

(a) 1 (b) 0 (c) $4 - \sin 4$ (d) None of these

12. Let $f(x)$ be a continuous function such that $\int_{m}^{n+1} f(x)dx = n^3, n \in Z$. Then, the value of $\int_{-3}^{3} f(x)dx$ is

(a) 9 (b) -27 (c) -9 (d) 27

13. Let $f(x)=\dfrac{e^x+1}{e^x-1}$ and $\int_0^1 x^3\cdot\dfrac{e^x+1}{e^x-1}dx=\alpha$. Then, $\int_{-1}^{1} t^3 f(t)\,dt$ is equal to

(a) 0 (b) α (c) 2α (d) None of these

14. Let $f:R\to R$ be a continuous function given by $f(x+y)=f(x)+f(y)$ for all $x, y\in R$. if $\int_0^2 f(x)\,dx=\alpha$, then $\int_{-2}^{2} f(x)\,dx$ is equal to

(a) 2α (b) α (c) 0 (d) None of these

15. The value of $\int_{-2}^{2} |[x]|\,dx$ is equal to

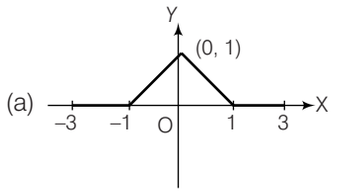
(a) 1 (b) 2 (c) 3 (d) 4

■ **Directions** (Q. Nos. 16 to 17)

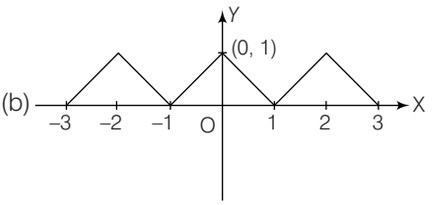
Let $f(x)=\begin{cases}1-|x|, & |x|\le 1\\ 0, & |x|>1\end{cases}$ and $g(x)=f(x+1)+f(x-1)$ for all $x\in R$.

16. The graph for $g(x)$ is given by

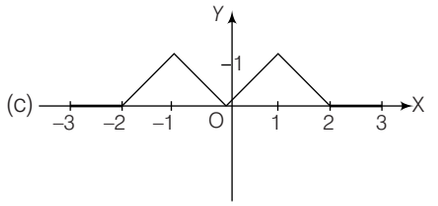
(a)



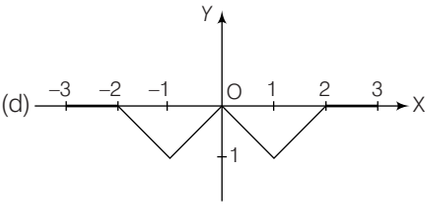
(b)



(c)



(d)



17. The value of $\int_{-3}^{3} g(x)dx$ is

(a) 2 (b) 3 (c) 4 (d) 5

■ **Direction** (Q. Nos. 18 to 20)

Let $I_n=\int_{-\pi}^{\pi}\dfrac{\sin x}{(1+\pi^x)\sin x}\,dx;\ n=0, 1, 2, \ldots$

18. The value of $I_{n+2}-I_n$ is equal to

(a) $n\pi$ (b) π (c) $-\pi$ (d) 0

19. The value of $\sum_{m=1}^{10} I_{2m+1}$ is equal to

(a) 0 (b) 5π
(c) 10π (d) None of these

20. The value of $\sum_{m=1}^{10} I_{2m}$ is equal to

(a) 0 (b) 5π
(c) 10π (d) None of these

Session 5

Applications of Periodic Functions and Newton- Leibnitz's Formula

Applications of Periodic Functions and Newton-Leibnitz's Formula

If $f(x)$ is a periodic function with period T, then the area under $f(x)$ for n periods would be n times the area under $f(x)$ for one period, i.e.

$$\int_0^{nT} f(x)\,dx = n\int_0^{T} f(x)\,dx$$

Now, consider the periodic function $f(x) = \sin x$ as an example. The period of $\sin x$ is 2π.

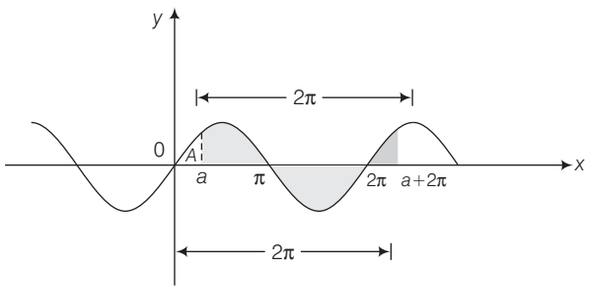


Figure 2.6

Suppose we intend to calculate $\int_a^{a+2\pi} \sin x\,dx$ as depicted above. Notice that the darkly shaded area in the interval $[2\pi, a+2\pi]$ can precisely cover the area marked as

Thus, $$\int_a^{a+2\pi} \sin x\,dx = \int_0^{2\pi} \sin x\,dx$$

This will hold true for every periodic function, i.e.

$$\int_a^{a+T} f(x)\,dx = \int_0^{T} f(x)\,dx$$

(where T is the period of $f(x)$)

This also implies that

$$\int_a^{a+nT} f(x)\,dx = \int_0^{nT} f(x)dx = n\int_0^{T} f(x)\,dx$$

and $$\int_{a+nT}^{b+nT} f(x)\,dx = \int_a^b f(x)\,dx$$

and $$\int_a^{b+nT} f(x)\,dx = \int_a^b f(x)dx + n\int_0^{T} f(x)\,dx$$

Example 56 Evaluate $\int_0^{4\pi} |\cos x|\,dx$.

Sol. Note that $|\cos x|$ is a periodic with period π.

Let $$I = 4\int_0^{\pi} |\cos x|\,dx$$

$$\left[\text{using property, } \int_0^{nT} f(x)\,dx = n\int_0^{T} f(x)\,dx\right]$$

$$= 4\left\{\int_0^{\pi/2} \cos x\,dx - \int_{\pi/2}^{\pi} \cos x\,dx\right\}$$

$$= 4\left\{\left(\sin x\right)_0^{\pi/2} - \left(\sin x\right)_{\pi/2}^{\pi}\right\} = 4\{1+1\} = 8$$

Example 57 Prove that $\int_0^{25} e^{x-[x]}\,dx = 25(e-1)$.

Sol. Since, $x - [x]$ is a periodic function with period one.

Therefore, $e^{x-[x]}$ has period one

$$\therefore \quad I = \int_0^{25\times 1} e^{x-[x]}\,dx = 25\int_0^{1} e^{x-[x]}\,dx$$

$$\left[\text{using property, } \int_0^{nT} f(x)\,dx = n\int_0^{T} f(x)\,dx\right]$$

$$= 25\int_0^{1} e^{x-0}\,dx = 25\left(e^x\right)_0^1 = 25\left(e^1 - e^0\right)$$

$$= 25(e-1)$$

Example 58 ***The value of*** $\int_0^{2n\pi} [\sin x + \cos x]\,dx$ ***is equal to***

(a) $-n\pi$ (b) $n\pi$ (c) $-2n\pi$ (d) None of these

(where [.] denotes the greatest integer function)

Sol. Let $I = \int_0^{2n\pi} [\sin x + \cos x]\,dx$

We know, $\sin x + \cos x = \sqrt{2}\sin\left(x + \frac{\pi}{4}\right)$ ...(i)

$$\therefore \quad \sin x + \cos x = \begin{cases} 1, & 0 \le x \le \pi/2 \\ 0, & \pi/2 < x \le 3\pi/4 \\ -1, & 3\pi/4 < x \le \pi \\ -2, & \pi < x < 3\pi/2 \\ -1, & 3\pi/2 \le x < 7\pi/4 \\ 0, & 7\pi/4 \le x \le 2\pi \end{cases}$$

$$\therefore \int_0^{2\pi} [\sin x + \cos x]\,dx = \int_0^{\pi/2} (1)\,dx + \int_{\pi/2}^{3\pi/4} (0)\,dx$$

$$+\int_{3\pi/4}^{\pi}(-1)dx+\int_{\pi}^{3\pi/2}(-2)\,dx+\int_{3\pi/2}^{7\pi/4}(-1)\,dx+\int_{7\pi/4}^{2\pi}(0)\,dx$$

$$=\left(\frac{\pi}{2}\right)+(0)-\left(\pi-\frac{3\pi}{4}\right)-2\left(\frac{3\pi}{2}-\pi\right)-1\left(\frac{7\pi}{4}-\frac{3\pi}{2}\right)+0$$

$$=-\pi$$

Since, $\sin x+\cos x$ has the period 2π.

So, $I=\int_0^{2n\pi}[\sin x+\cos x]\,dx=n\int_0^{2\pi}[\sin x+\cos x]\,dx$

$=-n\pi$

Hence, (a) is the correct answer.

Example 59 The value of $\int_{-5}^{5} f(x)\,dx$; where $f(x)=$ *minimum* $(\{x+1\},\{x-1\}),\forall\ x\in R$ and $\{.\}$ denotes fractional part of x, is equal to

(a) 3 (b) 4 (c) 5 (d) 6

Sol. We know, $\{x+1\}=\{x-1\}=\{x\}$

Thus, $f(x)=\text{minimum}\,(\{x+1\},\{x-1\})=\{x\}$

$$\Rightarrow\quad \int_{-5}^{5} f(x)\,dx=\int_{-5}^{5}\{x\}\,dx=(5-(-5))\int_0^1\{x\}\,dx$$

[as $\{x\}$ is periodic with period '1']

$$=10\int_0^1(x-[x])\,dx=10\int_0^1 x\,dx$$

$$=10\left(\frac{x^2}{2}\right)_0^1=5$$

Hence, (c) is the correct answer.

Example 60 Show $\int_0^{n\pi+V}|\sin x|\,dx=(2n+1)-\cos V$, where n is a positive integer and $0\le V<\pi$.

[IIT JEE 1994, 2004]

Sol. $\int_0^{n\pi+V}|\sin x|\,dx=\int_0^{V}|\sin x|\,dx+\int_V^{n\pi+V}|\sin x|\,dx$

$$=\int_0^V\sin x\,dx+n\int_0^{\pi}|\sin x|\,dx$$

$$\left[\text{using property, }\int_a^{a+nT}f(x)dx=n\int_0^T f(x)dx\ \text{ i.e. }\int_V^{n\pi V}|\sin x|dx=n\int_V^{\pi}|\sin x|dx\right]$$

$$=\left(-\cos x\right)_0^V+n\int_0^{\pi}\sin x\,dx$$

$$=(-\cos V+1)+n\left(-\cos x\right)_0^{\pi}$$

$$=-(\cos V)+1+n\,(1+1)=(2n+1)-\cos V$$

$\therefore\ \int_0^{n\pi+V}|\sin x|\,dx=(2n+1)-\cos V$, where n is a positive integer and $0\le V<\pi$.

Example 61 The value of $\int_{-2\pi}^{5\pi}\cot^{-1}(\tan x)\,dx$ is equal to

(a) $\frac{7\pi}{2}$ (b) $\frac{7\pi^2}{2}$

(c) $\frac{3\pi}{2}$ (d) π^2

Sol. Let $I=\int_{-2\pi}^{5\pi}\cot^{-1}(\tan x)\,dx$

$$\Rightarrow\quad I=7\int_0^{\pi}\cot^{-1}\left(\cot\left(\frac{\pi}{2}-x\right)\right)dx \qquad ...(i)$$

$$\left[\because\ \int_{nT}^{mT}f(x)\,dx=(m-n)\int_0^T f(x)\,dx\right]$$

As we know, $\cot^{-1}(\cot x)=\begin{cases}x, & 0<x<\pi/2\\ \pi+x, & \pi/2<x<\pi\end{cases}$

$$\therefore\quad I=7\left\{\int_0^{\pi/2}\left(\frac{\pi}{2}-x\right)dx+\int_{\pi/2}^{\pi}\left(\pi+\frac{\pi}{2}-x\right)dx\right\}$$

$$=7\left\{\left(\frac{\pi}{2}x-\frac{x^2}{2}\right)_0^{\pi/2}+\left(\frac{3\pi}{2}x-\frac{x^2}{2}\right)_{\pi/2}^{\pi}\right\}$$

$$=7\left\{\left(\frac{\pi^2}{4}-\frac{\pi^2}{8}\right)+\left(\frac{3\pi^2}{2}-\frac{\pi^2}{2}-\frac{3\pi^2}{4}+\frac{\pi^2}{8}\right)\right\}=\frac{7\pi^2}{2}$$

Hence, (b) is the correct answer.

Example 62 Let $g(x)$ be a continuous and differentiable function such that $\int_0^2\left\{\int_{\sqrt{2}}^{\sqrt{5/2}}[2x^2-3]\,dx\right\}\cdot g(x)\,dx=0$, then $g(x)=0$ when $x\in(0,2)$ has (where, [.] denotes the greatest integer function)

(a) exactly one real root (b) atleast one real root

(c) no real root (d) None of these

Sol. As, $1<2x^2-3<2,\ \forall\ x\in(\sqrt{2},\sqrt{5/2})$

$$\Rightarrow\quad \int_{\sqrt{2}}^{\sqrt{5/2}}[2x^2-3]\,dx>0,\forall\ x\in(0,2)$$

$\Rightarrow\ g(x)=0$ should have atleast one root in (0, 2).

$[\because\ g'(x)\ne 0]$

Hence, (b) is the correct answer.

Example 63 The value of x satisfying $\int_0^{2[x+14]}\left\{\frac{x}{2}\right\}dx=\int_0^{\{x\}}[x+14]\,dx$ is equal to (where, [.] and {.} denotes the greatest integer and fractional part of x)

(a) $[-14,-13)$ (b) (0, 1)

(c) $(-15,-14]$ (d) None of these

Sol. Given, $\int_0^{2[x+14]} \left\{\frac{x}{2}\right\} dx = \int_0^{\{x\}} [x+14]\, dx$

$\Rightarrow \quad \int_0^{28+2[x]} \left\{\frac{x}{2}\right\} dx = \int_0^{\{x\}} (14+[x])\, dx$

$\Rightarrow \quad \int_0^{28} \left\{\frac{x}{2}\right\} dx + \int_{28}^{28+2[x]} \left\{\frac{x}{2}\right\} dx = (14+[x])\{x\}$

$\Rightarrow \quad 14\int_0^{2} \left\{\frac{x}{2}\right\} dx + \int_0^{2[x]} \left\{\frac{x}{2}\right\} dx = (14+[x])\{x\}$

$\left[\text{using } \int_0^{nT} f(x)\,dx = n\int_0^{T} f(x)\,dx \quad \text{and} \right.$
$\left. \int_a^{a+nT} f(x)\,dx = \int_0^{nT} f(x)\,dx; \text{ where } T \text{ is period of } f(x)\right]$

$\Rightarrow \quad 14 + [x] = (14+[x])\{x\}$

$\Rightarrow \quad (14+[x])(1-\{x\}) = 0$

$\Rightarrow \quad [x] = -14$

$\Rightarrow \quad x \in [-14, -13)$

Hence, (a) is the correct answer.

Property IX. Leibnitz's Rule for the Differentiation under the Integral Sign

(i) If the functions $\phi(x)$ and $\psi(x)$ are defined on $[a, b]$ and are differentiable at a point $x \in (a, b)$ and $f(x, t)$ is continuous, then

$$\frac{d}{dx}\left[\int_{\phi(x)}^{\psi(x)} f(x,t)\,dt\right] = \int_{\phi(x)}^{\psi(x)} \frac{\partial}{\partial x} f(x,t)\,dt + \left\{\frac{d^{\psi(x)}}{dx}\right\} f^{(x,\,\psi(x))} - \left\{\frac{d^{\phi(x)}}{dx}\right\} f^{(x, f(x))}$$

(ii) If the functions $\phi(x)$ and $\psi(x)$ are defined on $[a, b]$ and differentiable at a point $x \in (a, b)$ and $f(t)$ is continuous on $[\phi(a), \phi(b)]$, then

$$\frac{d}{dx}\left(\int_{\phi(x)}^{\psi(x)} f(t)\,dt\right) = \frac{d}{dx}\{\psi(x)\}\, f(\psi(x)) - \frac{d}{dx}\{\phi(x)\}\, f(\phi(x))$$

Example 64 Find the derivative of the following with respect to x.

(i) $\int_0^x \cos t\, dt$ (ii) $\int_0^{x^2} \cos t^2 dt$

Sol. (i) Let $f(x) = \int_0^x \cos t\, dt$

$\therefore \frac{d}{dx}(f(x)) = \cos(x)\left\{\frac{d}{dx}(x)\right\} - \cos 0 \cdot \left\{\frac{d}{dx}(0)\right\} = \cos x$

$\left[\text{using Leibnitiz's rule, } \frac{d}{dx}\int_{\phi(x)}^{\psi(x)} f(t)dt = \frac{d}{dx}\{\psi(x)\}f(\psi(x)) - \frac{d}{dx}\{\phi(x)\} + f(\phi(x))\right]$

$\Rightarrow \quad \frac{d}{dx}\left\{\int_0^x \cos t\, dt\right\} = \cos x$

(ii) Let $f(x) = \int_0^{x^2} \cos t^2\, dt$

$\therefore \frac{d}{dx}(f(x)) = \cos(x^2)^2 \cdot \left\{\frac{d}{dx}(x^2)\right\} - \cos(0)^2\left\{\frac{d}{dx}(0)\right\}$

$= 2x \cdot \cos x^4$

$\Rightarrow \quad \frac{d}{dx}\left(\int_0^{x^2} (\cos t^2)\, dt\right) = 2x \cos x^4$

Example 65 Evaluate $\frac{d}{dx}\left(\int_{1/x}^{\sqrt{x}} \cos t^2\, dt\right)$.

Sol. Let $f(x) = \int_{1/x}^{\sqrt{x}} \cos t^2\, dt$

$\therefore \frac{d}{dx}(f(x)) = \cos(\sqrt{x})^2 \cdot \left\{\frac{d}{dx}(\sqrt{x})\right\} - \cos\left(\frac{1}{x}\right)^2\left\{\frac{d}{dx}\left(\frac{1}{x}\right)\right\}$

$= \frac{1}{2\sqrt{x}} \cos x + \frac{1}{x^2} \cdot \cos\left(\frac{1}{x^2}\right)$

$\Rightarrow \quad \frac{d}{dx}\left(\int_{1/x}^{\sqrt{x}} \cos t^2\, dt\right) = \frac{1}{2\sqrt{x}} \cos x + \frac{1}{x^2} \cos\left(\frac{1}{x^2}\right)$

Example 66 *If* $\frac{d}{dx}\left(\int_0^y e^{-t^2}\, dt + \int_0^{x^2} \sin^2 t\, dt\right) = 0$, *find* $\frac{dy}{dx}$.

Sol. We know, $\frac{d}{dx}\left(\int_0^y e^{-t^2}\, dt + \int_0^{x^2} \sin^2 t\, dt\right) = 0$

$\Rightarrow \quad e^{-y^2} \cdot \left\{\frac{d}{dx}(y)\right\} - e^{-0}\left\{\frac{d}{dx}(0)\right\} + \sin^2(x^2)\left\{\frac{d}{dx}(x^2)\right\} - \sin^2 0\left\{\frac{d}{dx}(0)\right\} = 0$

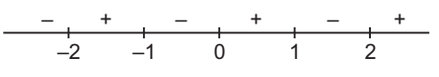
$\Rightarrow \quad e^{-y^2}\frac{dy}{dx} + 2x \sin^2 x^2 = 0 \quad \Rightarrow \quad \frac{dy}{dx} = -2x\, e^{y^2} \sin^2 x^2$

Example 67 Find the points of maxima/minima of $\int_0^{x^2} \frac{t^2 - 5t + 4}{2 + e^t}\, dt$.

Sol. Let $f(x) = \int_0^{x^2} \frac{t^2 - 5t + 4}{2 + e^t}\, dt$

$\therefore f'(x) = \frac{x^4 - 5x^2 + 4}{2 + e^{x^2}} \cdot 2x - 0$

$= \frac{(x-1)(x+1)(x-2)(x+2)\cdot 2x}{2 + e^{x^2}}$



From the wavy curve, it is clear that $f'(x)$ changes its sign at $x = \pm 2, \pm 1, 0$ and hence the points of maxima are $-1, 1$ (as sign changes from + ve to − ve) and of the minima are $-2, 0, 2$ (as sign changes from − ve to + ve).

Example 68 *Find* $\frac{d}{dx}\left(\int_{x^2}^{x^3} \frac{1}{\log t}\,dt\right)$.

Sol. $\frac{d}{dx}\left(\int_{x^2}^{x^3} \frac{1}{\log t}\,dt\right) = \frac{1}{\log x^3}\cdot\frac{d}{dx}(x^3) - \frac{1}{\log x^2}\cdot\frac{d}{dx}(x^2)$

$$= \frac{3x^2}{3\log x} - \frac{2x}{2\log x}$$

$$\therefore \quad \frac{d}{dx}\left(\int_{x^2}^{x^3} \frac{1}{\log t}\,dt\right) = \frac{1}{\log x}(x^2 - x)$$

Example 69 If $y = \int_0^x f(t)\sin\{K(x-t)\}\,dt$, then prove that $\frac{d^2y}{dx^2} + K^2y = Kf(x)$.

Sol. We have, $y = \int_0^x f(t)\sin\{K(x-t)\}\,dt$

Differentiating w.r.t. x, we get

$$\frac{dy}{dx} = \int_0^x \frac{\partial}{\partial x}\{f(t)\sin K(x-t)\}\,dt + \frac{d}{dx}(x)$$

$$\cdot\{f(x)\sin K(x-x)\} - \frac{d}{dx}(0)\{f(0)\sin K(x-0)\}$$

$$= K\int_0^x f(t)\cos K(x-t)\,dt + 0 - 0$$

$$\Rightarrow \frac{dy}{dx} = K\int_0^x f(t)\cos K(x-t)\,dt$$

Again, differentiating both the sides w.r.t. x, we get

$$\frac{d^2y}{dx^2} = K\left\{\int_0^x \frac{\partial}{\partial x}\{f(t)\cos K(x-t)\}\,dt\right.$$

$$\left.+\left\{f(x)\cdot\cos K(x-x)\cdot\frac{d}{dx}(x)\right\} - \{f(0)\cos K(x-0)\cdot\frac{d}{dx}(0)\}\right\}$$

$$= K\left[-K\int_0^x f(t)\sin K(x-t)\,dt + f(x) - 0\right]$$

$$= -K^2\int_0^x f(t)\sin K(x-t)\,dt + Kf(x)$$

$$\Rightarrow \frac{d^2y}{dx^2} = -K^2y + Kf(x) \;\Rightarrow\; \frac{d^2y}{dx^2} + K^2y = Kf(x)$$

Example 70 *If* $\int_{\pi/3}^x \sqrt{3-\sin^2 t}\,dt + \int_0^y \cos t\,dt = 0$, *then evaluate* $\frac{dy}{dx}$.

Sol. Differentiating w.r.t. x, we have

$$\frac{d}{dx}\left(\int_{\pi/3}^x \sqrt{3-\sin^2 t}\,dt\right) + \frac{d}{dx}\int_0^y (\cos t)\,dt = 0$$

$$\Rightarrow \sqrt{3-\sin^2 x}\cdot\frac{d}{dx}(x) - \sqrt{3-\sin^2\frac{\pi}{3}}\cdot\frac{d}{dx}\left(\frac{\pi}{3}\right) + \cos y\cdot\frac{dy}{dx}$$

$$-\cos(0)\frac{d}{dx}(0) = 0$$

$$\Rightarrow \quad \sqrt{3-\sin^2 x} + \cos y\frac{dy}{dx} = 0$$

$$\Rightarrow \quad \frac{dy}{dx} = -\frac{\sqrt{3-\sin^2 x}}{\cos y}$$

Example 71 Let $\frac{d}{dx}(F(x)) = \frac{e^{\sin x}}{x}$, $x > 0$. If $\int_1^4 \frac{2e^{\sin x^2}}{x}\,dx = F(K) - F(1)$, then the possible value of K is

(a) 10 (b) 14 (c) 16 (d) 18

Sol. We have, $\frac{d}{dx}(F(x)) = \frac{e^{\sin x}}{x}$

$$\Rightarrow \quad \int \frac{e^{\sin x}}{x}\,dx = F(x) \qquad \ldots(i)$$

Now, $\int_1^4 \frac{2e^{\sin x^2}}{x}\,dx = \int_1^4 \frac{e^{\sin(x^2)}}{x^2}\,d(x^2) = \int_1^{16} \frac{e^{\sin t}}{t}\,dt$

$(\because x^2 = t)$

$$= [F(t)]_1^{16} = F(16) - F(1)$$

$$\Rightarrow \quad K = 16$$

Hence, (c) is the correct answer.

Example 72 The function $f(x) = \int_0^x \log_{|\sin t|}\left(\sin t + \frac{1}{2}\right)dt$, where $x \in (0, 2\pi)$, then $f(x)$ strictly increases in the interval

(a) $\left(\frac{\pi}{6}, \frac{5\pi}{6}\right)$ (b) $\left(\frac{5\pi}{6}, 2\pi\right)$

(c) $\left(\frac{\pi}{6}, \frac{7\pi}{6}\right)$ (d) $\left(\frac{5\pi}{6}, \frac{7\pi}{6}\right)$

Sol. Here, $f'(x) = \log_{|\sin x|}\left(\sin x + \frac{1}{2}\right) > 0$

$$\Rightarrow \quad \sin x + \frac{1}{2} < 1 \quad \text{and} \quad \left(\sin x + \frac{1}{2}\right) > 0$$

$$\Rightarrow \quad 0 < \sin x + \frac{1}{2} < 1$$

$$\Rightarrow \quad -1/2 < \sin x < 1/2$$

$$\Rightarrow \quad x \in \left(\frac{5\pi}{6}, \frac{7\pi}{6}\right) \text{ as } x \in (0, 2\pi)$$

Hence, (d) is the correct answer.

Example 73 Let $f:(0,\infty)\to R$ and $F(x)=\int_0^x t\,f(t)\,dt$. If $F(x^2)=x^4+x^5$, then $\sum_{r=1}^{12} f(r^2)$ is equal to

(a) 216 (b) 219 (c) 221 (d) 223

Sol. Here, $F(x^2)=x^4+x^5=\int_0^{x^2} t\,f(t)\,dt$

Differentiating w.r.t. x, we get

$$x^2\,f(x^2)\cdot 2x=4x^3+5x^4$$

$$\Rightarrow \quad f(x^2)=2+\frac{5}{2}x \;\Rightarrow\; f(r^2)=2+\frac{5}{2}r$$

$$\therefore \quad \sum_{r=1}^{n} f(r^2)=2n+\frac{5}{2}n(n+1)=\frac{n(5n+13)}{4}$$

$$\Rightarrow \quad \sum_{r=1}^{12} f(r^2)=\frac{12(60+13)}{4}=219$$

Hence, (b) is the correct answer.

Example 74 A function $f(x)$ satisfies $f(x)=\sin x+\int_0^x f'(t)(2\sin t-\sin^2 t)\,dt$, then $f(x)$ is

(a) $\frac{x}{1-\sin x}$ (b) $\frac{\sin x}{1-\sin x}$ (c) $\frac{1-\cos x}{\cos x}$ (d) $\frac{\tan x}{1-\sin x}$

Sol. Differentiating both the sides w.r.t. x, we get

$$f'(x)=\cos x+f'(x)(2\sin x-\sin^2 x)$$

$$\Rightarrow (1+\sin^2 x-2\sin x)f'(x)=\cos x$$

$$\Rightarrow \quad f'(x)=\frac{\cos x}{1+\sin^2 x-2\sin x}=\frac{\cos x}{(1-\sin x)^2}$$

Integrating, we get $f(x)=\int\frac{\cos x}{(1-\sin x)^2}\,dx$

Put $1-\sin x=t$, $f(x)=-\int\frac{dt}{t^2}=\frac{1}{t}=\frac{1}{1-\sin x}+C$

Also, $f(0)=0$, hence $C=-1$

$$f(x)=\frac{1}{1-\sin x}-1=\frac{1-1+\sin x}{1-\sin x}=\frac{\sin x}{1-\sin x}$$

Hence, (b) is the correct answer.

Example 75 If $F(x)=\int_1^x f(t)\,dt$, where $f(t)=\int_1^{t^2}\frac{\sqrt{1+u^4}}{u}\,du$, then the value of $F''(2)$ equals to

(a) $\frac{7}{4\sqrt{17}}$ (b) $\frac{15}{\sqrt{17}}$ (c) $\sqrt{257}$ (d) $\frac{15\sqrt{17}}{68}$

Sol. Here, $f'(t)=\frac{\sqrt{1+t^8}\cdot 2t}{t^2}=\frac{2\sqrt{1+t^8}}{t}$ ...(i)

Now, $F(x)=\int_1^x f(t)dt \;\Rightarrow\; F'(x)=f(x)$

$$F''(x)=f'(x) \;\Rightarrow\; F''(2)=f'(2)$$

From Eq. (i), $f'(2)=\sqrt{256+1}=\sqrt{257}$

Hence, (c) is the correct answer.

Property X. Let a function $f(x,\alpha)$ be continuous for $a\le x\le b$ and $c\le\alpha\le d$, then for any $\alpha\in[c,d]$, if $I(\alpha)=\int_a^b f(x,\alpha)\,dx$, then $\frac{dI(\alpha)}{d\alpha}=\int_a^b\frac{\partial f(x,\alpha)}{\partial\alpha}\,dx$

Example 76 Evaluate $I(b)=\int_0^1\frac{x^b-1}{\ln x}\,dx; b\ge 0$.

Sol. We have, $I(b)=\int_0^1\frac{x^b-1}{\ln x}\,dx$

$$\Rightarrow \quad \frac{d}{db}(I(b))=\int_0^1\frac{\partial}{\partial b}\left(\frac{x^b-1}{\ln x}\right)dx+0-0$$

$$=\int_0^1\frac{x^b\ln x}{\ln x}\,dx=\int_0^1(x^b)\,dx=\left(\frac{x^{b+1}}{b+1}\right)_0^1$$

$$=\frac{1}{b+1}[1-0]=\frac{1}{b+1}$$

$$\therefore \quad \frac{d}{dx}(I(b))=\frac{1}{b+1}$$

Integrating both the sides w.r.t. b, we get

$$I(b)=\log(b+1)+C \qquad ...(i)$$

Given, $I(b)=\int_0^1\frac{x^b-1}{\ln x}\,dx$

$$\therefore \quad I(0)=0 \qquad (\text{when } b=0) \quad ...(ii)$$

Also, from Eq. (i), $I(0)=\log(1)+C$

$$\therefore \quad I(0)=C \qquad ...(iii)$$

From Eqs. (ii) and (iii), $C=0$

$$\Rightarrow \quad I(b)=\log(b+1)$$

Example 77 Prove that $\int_0^{\pi/2}\frac{dx}{(a^2\sin^2 x+b^2\cos^2 x)^2}=\frac{\pi(a^2+b^2)}{4a^3b^3}$.

Sol. Let $I=\int_0^{\pi/2}\frac{1\,dx}{a^2\sin^2 x+b^2\cos^2 x}$

Then, $I=\int_0^{\pi/2}\frac{\sec^2 x}{a^2\tan^2 x+b^2}\,dx=\int_0^{\infty}\frac{dt}{a^2t^2+b^2}$

(where, $t=\tan x$)

$$\Rightarrow \quad I=\frac{1}{ab}\left[\tan^{-1}\left(\frac{at}{b}\right)\right]_0^{\infty}=\frac{1}{ab}\left(\frac{\pi}{2}-0\right)=\frac{\pi}{2ab}$$

Thus, $\int_0^{\pi/2}\frac{1}{a^2\sin^2 x+b^2\cos^2 x}\,dx=\frac{\pi}{2ab}=f(a,b)$ ...(i)

Differentiating both the sides w.r.t. 'a', we get

$$\int_0^{\pi/2} \frac{-2a\sin^2 x}{(a^2\sin^2 x + b^2\cos^2 x)^2}\,dx = -\frac{\pi}{2a^2b}$$

$$\Rightarrow \quad \int_0^{\pi/2} \frac{\sin^2 x}{(a^2\sin^2 x + b^2\cos^2 x)^2}\,dx = \frac{\pi}{4a^3b} \qquad \ldots(ii)$$

Similarly, by differentiating Eq. (i) w.r.t. 'b', we get

$$\int_0^{\pi/2} \frac{\cos^2 x}{(a^2\sin^2 x + b^2\cos^2 x)^2}\,dx = \frac{\pi}{4ab^3} \qquad \ldots(iii)$$

Adding Eqs. (ii) and (iii), we get

$$\int_0^{\pi/2} \frac{(\sin^2 x + \cos^2 x)\,dx}{(a^2\sin^2 x + b^2\cos^2 x)^2} = \frac{\pi}{4a^3b} + \frac{\pi}{4ab^3}$$

$$\Rightarrow \quad \int_0^{\pi/2} \frac{dx}{(a^2\sin^2 x + b^2\cos^2 x)^2} = \frac{\pi}{4a^3b^3}(a^2 + b^2)$$

Example 78 The value of $\int_0^{\pi/2} \frac{\log(1+x\sin^2\theta)}{\sin^2\theta}\,d\theta\,;\, x \geq 0$ is equal to

(a) $\pi(\sqrt{1+x}-1)$ (b) $\pi(\sqrt{1+x}-2)$

(c) $\sqrt{\pi}(\sqrt{1+x}-1)$ (d) None of these

Sol. Given, $f(x) = \int_0^{\pi/2} \frac{\log(1+x\sin^2\theta)}{\sin^2\theta}\,d\theta;\ x \geq 0$

As above integral is function of x. Thus, differentiating both the sides w.r.t. 'x', we get

$$f'(x) = \int_0^{\pi/2} \frac{1}{1+x\sin^2\theta}\cdot\frac{\sin^2\theta}{\sin^2\theta}\,d\theta + 0 - 0$$

(using Newton-Leibnitz's formula)

$$= \int_0^{\pi/2} \frac{d\theta}{1+x\sin^2\theta} = \int_0^{\pi/2} \frac{\operatorname{cosec}^2\theta\,d\theta}{\cot^2\theta + (1+x)}$$

$$= \left(-\frac{1}{\sqrt{1+x}}\cdot\tan^{-1}\frac{\cot\theta}{\sqrt{1+x}}\right)_0^{\pi/2} = \frac{\pi}{2\sqrt{1+x}}$$

$$\therefore \quad f'(x) = \frac{\pi}{2\sqrt{1+x}}$$

$$\Rightarrow \quad f(x) = \pi\sqrt{1+x} + C$$

where, $f(0) = 0 \Rightarrow C = -\pi$

$$\Rightarrow \quad f(x) = \pi\sqrt{1+x} - \pi = \pi(\sqrt{1+x} - 1)$$

Hence, (a) is the correct answer.

Example 79 Let $f(x)$ be a continuous functions for all x, such that $(f(x))^2 = \int_0^x f(t)\cdot\frac{2\sec^2 t}{4+\tan t}\,dt$ and $f(0) = 0$, then

(a) $f\left(\frac{\pi}{4}\right) = \log\frac{5}{4}$ (b) $f\left(\frac{\pi}{4}\right) = \frac{3}{4}$

(c) $f\left(\frac{\pi}{2}\right) = 2$ (d) None of these

Sol. Here, $(f(x))^2 = \int_0^x f(t)\cdot\frac{2\sec^2 t}{4+\tan t}\,dt,$

On differentiating both the sides w.r.t. x, we get

$$2f(x)\cdot f'(x) = f(x)\cdot\frac{2\sec^2 x}{4+\tan x}$$

$$\Rightarrow \quad f'(x) = \frac{\sec^2 x}{4+\tan x}$$

Integrating both the sides, we get

$$f(x) = \int \frac{\sec^2 x}{4+\tan x}\,dx = \log(4+\tan x) + C$$

Since, $f(0) = 0$

$$\Rightarrow \quad 0 = \log(4) + C$$

$$\Rightarrow \quad C = -\log 4$$

$$\therefore \quad f(x) = \log(4+\tan x) - \log(4)$$

$$\Rightarrow \quad f\left(\frac{\pi}{4}\right) = \log(4+1) - \log(4) = \log\frac{5}{4}$$

Hence, (a) is the correct answer.

Exercise for Session 5

1. The value of $\int_{-1}^{10} \text{sgn}(x-[x])dx$ is equal to (where, $[\cdot]$ denotes the greatest integer function)

(a) 9 (b) 10 (c) 11 (d) 12

2. The value of $\int_{0}^{[x]} (x-[x])dx$ (where, $[\cdot]$ denotes the greatest integer function)

(a) $[x]$ (b) $\frac{[x]}{2}$ (c) $x[x]$ (d) None of these

3. The value of $\int_{-\pi/4}^{n\pi-\pi/4} |\sin x + \cos x| dx$ is equal to

(a) $2\sqrt{2}n$ (b) $\sqrt{2}n$ (c) $\frac{1}{2\sqrt{2}}n$ (d) None of these

4. Let $f(x) = x-[x]$ for every real number x (where, $[\cdot]$ denotes greatest integer function), then $\int_{-1}^{1} f(x)dx$ is equal to

(a) 1 (b) 2 (c) 0 (d) $\frac{1}{2}$

5. If $\int_{0}^{x} f(t)dt = x + f\int_{x}^{1} tf(t)\,dt$, then the value of $f(1)$ is

(a) $\frac{1}{2}$ (b) 0 (c) 1 (d) $-\frac{1}{2}$

6. The least value of the function $\phi(x) = \int_{5\pi/4}^{x} (3\sin t + 4\cos t)dt$ on the interval $\left[\frac{5\pi}{4}, \frac{4\pi}{3}\right]$ is

(a) $\sqrt{3} + \frac{3}{2}$ (b) $-2\sqrt{3} + \frac{3}{2} + \frac{1}{\sqrt{2}}$

(c) $\frac{3}{2} + \frac{1}{\sqrt{2}}$ (d) None of these

7. The points of extremum of $\phi(x) = \int_{1}^{x} e^{-t^2/2}(1-t^2)dt$ are

(a) $x = 1, -1$ (b) $x = -1, 2$ (c) $x = 2, 1$ (d) $x = -2, 1$

8. If $f(x)$ is periodic function, with period T, then

(a) $\int_{a}^{b} f(x)dx = \int_{a}^{b+T} f(x)dx$ (b) $\int_{a}^{b} f(x)dx = \int_{a+T}^{b+T} f(x)dx$

(c) $\int_{a}^{b} f(x)dx = \int_{a+T}^{b} f(x)dx$ (d) $\int_{a}^{b} f(x)dx = \int_{a+T}^{b+2T} f(x)dx$

9. Let $\frac{d}{dx}(F(x)) = \frac{e^{\sin x}}{x}$, $x > 0$. If $\int_{1}^{4} \frac{2e^{\sin x^2}}{x} dx = F(k) - F(1)$, then one of the possible value of k is

(a) 4 (b) 8 (c) 16 (d) 32

10. Let $f:(0,\infty) \to R$ and $F(x) = \int_{0}^{x} f(t)dt$. If $F(x^2) = x^2(1+x)$, then $f(4)$ is equal to

(a) $\frac{5}{4}$ (b) 7 (c) 4 (d) 2

11. Let $T > 0$ be a fixed real number. Suppose f is continuous function such that $f(x+T) = f(x)$ for all $x \in R$. If $I = \int_{0}^{T} f(x)\,dx$, then the value of $\int_{3}^{3+3T} f(2x)\,dx$ is

(a) $\frac{3}{2}I$ (b) $2I$ (c) $3I$ (d) $6I$

12. Let $f(x) = \int_{1}^{x} \sqrt{2-t^2}dt$, then the real roots of the equation $x^2 - f'(x) = 0$ are

(a) ± 1 (b) $\pm\frac{1}{\sqrt{2}}$ (c) $\pm\frac{1}{2}$ (d) $\pm\sqrt{2}$

13. Let $f(x)$ be an odd continuous function which is periodic with period 2. If $g(x) = \int_0^x f(t)\,dt$, then

(a) $g(x)$ is an odd function
(b) $g(n) = 0$ for all $n \in N$
(c) $g(2n) = 0$ for all $n \in N$
(d) $g(x)$ is non-periodic

14. Let $f(x)$ be a function defined by $f(x) = \int_1^x t(t^2 - 3t + 2)dt,\ 1 \le x \le 3$. Then, the range of $f(x)$ is

(a) [0, 2] (b) $\left[-\frac{1}{4}, 4\right]$ (c) $\left[-\frac{1}{4}, 2\right]$ (d) None of these

15. The value of $\lim_{x \to 0} \frac{2\int_0^{\cos x} \cos^{-1}(t)}{2x - \sin 2x} dt$ is

(a) 0 (b) $\frac{1}{2}$ (c) $-\frac{1}{2}$ (d) $\frac{2}{3}$

16. If $\int_0^x \frac{bt\cos 4t - a\sin 4t}{t^2} dt = \frac{a\sin 4x}{x}$ for all $x \neq 0$, then a and b are given by

(a) $a = \frac{1}{4}, b = 1$
(b) $a = 2, b = 2$
(c) $a = -1, b = 4$
(d) $a = 2, b = 4$

17. If $f(x) = \int_0^x \{f(t)\}^{-1} dt$ and $\int_0^1 \{f(t)\}^{-1} = \sqrt{2}$, then

(a) $f(x) = \sqrt{2x}$
(b) $f(x) = \sqrt{2\log_e x}$
(c) $f(x) = \sqrt{3x - 1}$
(d) None of these

18. Let f be a real valued function defined on the interval $(-1, 1)$ such that $e^{-x} f(x) = 2 + \int_0^x \sqrt{t^4 + 1}\,dt$, for all $x \in (-1, 1)$ and let f^{-1} be the inverse of f. Then, $(f^{-1})'(2)$ is equal to *[IIT JEE 2010]*

(a) 1
(b) 1/3
(c) 1/2
(d) $1/e$

■ **Directions** (Q. Nos. 19 to 20) *Consider the function defined on* $[0, 1] \to R$

$$f(x) = \frac{\sin x - x\cos x}{x^2},\ \textit{if } x \neq 0 \textit{ and } f(0) = 0.$$

[IIT JEE 2012]

19. $\int_0^1 f(x)\,dx$ is equal to

(a) $1 - \sin(1)$ (b) $\sin(1) - 1$ (c) $\sin(1)$ (d) $-\sin(1)$

20. $\lim_{t \to 0} \frac{1}{t^2} \int_0^t f(x)\,dx$ is equal to

(a) 1/3 (b) 1/6 (c) 1/12 (d) 1/24

Session 6

Integration as Limit of a Sum, Applications of Inequality Gamma Function, Beta Function, Walli's Formula

Integration as Limit of a Sum

Applications of Inequality and Gamma Integrals

An alternative way of describing $\int_a^b f(x)\,dx$ is that the definite integral $\int_a^b f(x)\,dx$ is a limiting case of summation of an infinite series, provided $f(x)$ is continuous on $[a, b]$, i.e. $\int_a^b f(x)\,dx = \lim_{n\to\infty} h \sum_{r=1}^{n-1}$ $f(a + rh)$, where $h = \dfrac{b-a}{n}\cdot$ The converse is also true, *ie*, if we have an infinite series of the above form, it can be expressed as definite integral.

Method to Express the Infinite Series as Definite Integral

(i) Express the given series in the form $\sum \frac{1}{n} f\left(\frac{r}{n}\right)\cdot$

(ii) Then, the limit is its sum when $n \to \infty$, i.e. $\lim_{n\to\infty} \sum \frac{1}{n} f\left(\frac{r}{n}\right)\cdot$

(iii) Replace $\frac{r}{n}$ by x and $\frac{1}{n}$ by (dx) and $\lim_{n\to\infty} \sum$ by the sign of $\int$.

(iv) The lower and the upper limit of integration are limiting values of $\frac{r}{n}$ for the first and the last term of r respectively.

Some particular cases of the above are

(a) $\lim_{n\to\infty} \sum_{r=1}^{n} \frac{1}{n} f\left(\frac{r}{n}\right)$

or $\lim_{n\to\infty} \sum_{r=1}^{n-1} \frac{1}{n} f\left(\frac{r}{n}\right) = \int_0^1 f(x)\,dx$

(b) $\lim_{n\to\infty} \sum_{r=1}^{Pn} \frac{1}{n} f\left(\frac{r}{n}\right) = \int_\alpha^\beta f(x)\,dx$

where, $\alpha = \lim_{n\to\infty} \frac{r}{n} = 0\,(\text{as } r = 1)$

and $\beta = \lim_{n\to\infty} \frac{r}{n} = p\,(\text{as } r = pn)$

Some Important Results to Remember

(i) $\sum_{r=1}^{n} r = \dfrac{n(n+1)}{2}$

(ii) $\sum_{r=1}^{n} r^2 = \dfrac{n(n+1)(2n+1)}{6}$

(iii) $\sum_{r=1}^{n} r^3 = \dfrac{n^2(n+1)^2}{4}$

(iv) In GP, sum of n terms, $S_n = \begin{cases} \dfrac{a(r^n-1)}{(r-1)}, & |r|>1 \\ an, & r=1 \\ \dfrac{a(1-r^n)}{(1-r)}, & |r|<1 \end{cases}$

(v) $\sin\alpha + \sin(\alpha+\beta) + \sin(\alpha+2\beta) + \ldots + \sin[\alpha + (\overline{n-1})\beta]$
$= \dfrac{\sin n\beta/2}{\sin\beta/2}\cdot\sin[\alpha + (n-1)\beta/2]$

(vi) $\cos\alpha + \cos(\alpha+\beta) + \cos(\alpha+2\beta) + \ldots + \cos[\alpha + (\overline{n-1})\beta]$
$= \dfrac{\sin n\beta/2}{\sin\beta/2}\cdot\cos[\alpha + (n-1)\beta/2]$

(vii) $1 - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \frac{1}{5^2} - \frac{1}{6^2} + \ldots\infty = \frac{\pi^2}{12}$

(viii) $1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} + \ldots\infty = \frac{\pi^2}{6}$

(ix) $1 + \frac{1}{3^2} + \frac{1}{5^2} + \ldots\infty = \frac{\pi^2}{8}$

(x) $\frac{1}{2^2} + \frac{1}{4^2} + \frac{1}{6^2} + \ldots\infty = \frac{\pi^2}{24}$

(xi) $\cos\theta = \dfrac{e^{i\theta} + e^{-i\theta}}{2}$, and $\sin\theta = \dfrac{e^{i\theta} - e^{-i\theta}}{2i}$

(xii) $\cos h\theta = \dfrac{e^{\theta} + e^{-\theta}}{2}$ and $\sin h\theta = \dfrac{e^{\theta} - e^{-\theta}}{2}$

Remark

The method of evaluate the integral, as limit of the sum of an infinite series is known as integration by first principles.

Example 80 Evaluate the following :

(i) $\lim_{n\to\infty}\left(\frac{1}{n^2}+\frac{2}{n^2}+\frac{3}{n^2}+\ldots+\frac{n-1}{n^2}\right)$

(ii) $\lim_{n\to\infty}\left(\frac{1}{n+1}+\frac{1}{n+2}+\ldots+\frac{1}{2n}\right)$

(iii) $\lim_{n\to\infty}\left(\frac{n}{n^2+1^2}+\frac{n}{n^2+2^2}+\ldots+\frac{n}{2n^2}\right)$

(iv) $\lim_{n\to\infty}\frac{(1^P+2^P+\ldots+n^P)}{n^{P+1}}, P>0$

Sol. Let

(i) $S_n=\frac{1}{n^2}+\frac{2}{n^2}+\frac{3}{n^2}+\ldots+\frac{n-1}{n^2}$

$=\sum_{r=2}^{n}\frac{r-1}{n^2}=\sum_{r=2}^{n}\frac{1}{n}\left(\frac{r-1}{n}\right)$

$\Rightarrow\quad S=\lim_{n\to\infty}\sum_{r=2}^{n}\frac{1}{n}\left(\frac{r}{n}\right)\qquad\left(\text{as } n\to\infty\Rightarrow\frac{1}{n}\to 0\right)$

$=\int_0^1 x\,dx=\frac{1}{2}$

(ii) Let $S_n=\frac{1}{n+1}+\frac{1}{n+2}+\ldots+\frac{1}{2n}=\sum_{r=1}^{n}\frac{1}{n+r}$

$=\sum_{r=1}^{n}\frac{1}{n\left(1+\frac{r}{n}\right)}$

Hence, $S=\lim_{n\to\infty}S_n=\lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{n}\frac{1}{1+\frac{r}{n}}$

$=\int_0^1\frac{dx}{1+x}=\left[\log(1+x)\right]_0^1=\log 2$

(iii) Let $S_n=\frac{n}{n^2+1^2}+\frac{n}{n^2+2^2}+\ldots+\frac{n}{2n^2}$

$=\sum_{r=1}^{n}\frac{n}{n^2+r^2}=\sum_{r=1}^{n}\frac{1}{n(1+r^2/n^2)}$

Hence, $S=\lim_{n\to\infty}S_n=\lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{n}\frac{1}{1+\frac{r^2}{n^2}}$

$=\int_0^1\frac{dx}{1+x^2}=\left[\tan^{-1}x\right]_0^1=\frac{\pi}{4}$

(iv) Let $S_n=\frac{1^P+2^P+\ldots+n^P}{n^{P+1}}=\sum_{r=1}^{n}\frac{r^P}{n^{P+1}}=\sum_{r=1}^{n}\frac{1}{n}\left(\frac{r}{n}\right)^P$

$\therefore\quad S=\lim_{n\to\infty}S_n=\lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{n}\left(\frac{r}{n}\right)^P$

$=\int_0^1 x^P\,dx=\left[\frac{x^{P+1}}{P+1}\right]_0^1=\frac{1}{P+1}$

Example 81 ***Evaluate*** $S=\sum_{r=0}^{n-1}\frac{1}{\sqrt{4n^2-r^2}}$ ***as*** $n\to\infty$.

Sol. Let $S_n=\sum_{r=0}^{n-1}\frac{1}{\sqrt{4n^2-r^2}}=\sum_{r=0}^{n-1}\frac{1}{n\sqrt{4-(r/n)^2}}$

$=\frac{1}{n}\sum_{r=0}^{n-1}\frac{1}{\sqrt{4-(r/n)^2}}$

Hence, $S=\lim_{n\to\infty}S_n=\lim_{n\to\infty}\frac{1}{n}\sum_{r=0}^{n-1}\frac{1}{\sqrt{4-(r/n)^2}}$

$=\int_0^1\frac{dx}{\sqrt{4-x^2}}=\left[\sin^{-1}\frac{x}{2}\right]_0^1$

$\Rightarrow\qquad S=\sin^{-1}\left(\frac{1}{2}\right)=\frac{\pi}{6}\qquad\therefore\ S=\frac{\pi}{6}$

Example 82 Evaluate

$$\lim_{n\to\infty}\left(\frac{1}{2n+1}+\frac{1}{2n+2}+\ldots+\frac{1}{6n}\right).$$

Sol. Let $S_n=\left(\frac{1}{2n+1}+\frac{1}{2n+2}+\ldots+\frac{1}{6n}\right)$

$=\sum_{r=1}^{4n}\frac{1}{2n+r}=\sum_{r=1}^{4n}\frac{1}{n}\cdot\frac{1}{2+(r/n)}$

$\Rightarrow\quad S=\lim_{n\to\infty}S_n=\int_0^4\frac{dx}{2+x}=\left[\ln|2+x|\right]_0^4$

$=\log 6-\log 2=\log 3$

$\therefore\quad S=\ln 3$

Example 83 Evaluate $\int_1^4(ax^2+bx+c)\,dx$ from the first principle.

Sol. Let $x=1+rh$, where $h=\frac{4-1}{n}=\frac{3}{n}$

As $x\to 1, r\to 0$ and $x\to 4,\ r\to n$

$\therefore\quad\int_1^4(ax^2+bx+c)\,dx=\lim_{n\to\infty}\sum_{r=0}^{n}h\,f(1+rh)$

$=\lim_{n\to\infty}\sum_{r=0}^{n}h\left[a(1+rh)^2+b(1+rh)+c\right]$

$=\lim_{n\to\infty}\sum_{r=0}^{n}\frac{3}{n}\left[a\left(1+\frac{3r}{n}\right)^2+b\left(1+\frac{3r}{n}\right)+c\right]$

$=3\lim_{n\to\infty}\sum_{r=0}^{n}\frac{1}{n}\left[a\left(1+\frac{9r^2}{n^2}+\frac{6r}{n}\right)+b\left(1+\frac{3r}{n}\right)+c\right]$

$=3\lim_{n\to\infty}\frac{1}{n}\left[a\left(n+\frac{9n(n+1)(2n+1)}{6n^2}+\frac{6n(n+1)}{2n}\right)+b\left(n+\frac{3n(n+1)}{2n}\right)+cn\right]$

$=3\left[a(1+3+3)+b(1+3/2)+c\right]=21a+\frac{15}{2}b+3c$

Example 84 ***The value of*** $\lim_{n\to\infty}\left(\sin\frac{\pi}{2n}\cdot\sin\frac{2\pi}{2n}\cdot\sin\frac{3\pi}{2n}\ldots\sin\frac{(n-1)\pi}{n}\right)^{1/n}$ is equal to

(a) $\frac{1}{2}$ (b) $\frac{1}{3}$ (c) $\frac{1}{4}$ (d) None of these

Sol. Let $A=\left\{\lim_{n\to\infty}\sin\frac{\pi}{2n}\cdot\sin\frac{2\pi}{2n}\cdot\sin\frac{3\pi}{2n}\ldots\sin\frac{2(n-1)\pi}{2n}\right\}^{1/n}$

$$\therefore \log A=\lim_{n\to\infty}\frac{1}{n}\log\left(\sin\frac{\pi}{2n}\cdot\sin\frac{2\pi}{2n}\ldots\sin\frac{2(n-1)\pi}{2n}\right)$$

$$=\lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{2(n-1)}\log\sin\frac{r\pi}{2n}$$

$$=\int_0^2\log\sin\left(\frac{\pi x}{2}\right)dx$$

$$\left[\text{using }\lim_{n\to\infty}\Sigma\frac{1}{n}f\left(\frac{r}{n}\right)=\int_a^b f(x)\,dx\right]$$

$$=\int_0^{\pi}\log(\sin t)\cdot\frac{2}{\pi}\,dt \qquad \left[\text{putting }\frac{\pi x}{2}=t\right]$$

$$=\frac{2\cdot2}{\pi}\int_0^{\pi/2}\log(\sin t)\,dt$$

$$\left[\text{using }\int_0^{2a}f(x)\,dx=2\int_0^a f(x)\,dx,\text{ if } f(2a-x)=f(x)\right]$$

$$=\frac{4}{\pi}\left\{-\frac{\pi}{2}\log 2\right\}\left[\text{using}\int_0^{\pi/2}\log(\sin x)dx=-\frac{\pi}{2}\log 2\right]$$

$$=-2\log 2$$

$$\therefore \log A=\log(1/4)\ \Rightarrow\ A=1/4$$

Hence, (c) is the correct answer.

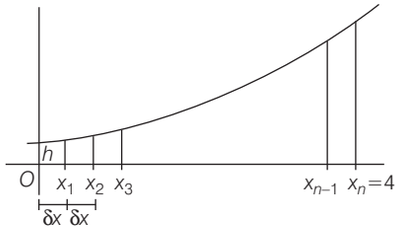
Example 85 ***The interval [0, 4] is divided into n equal sub-intervals by the points*** $x_0, x_1, x_2, \ldots, x_{n-1}, x_n$ ***where*** $0=x_0<x_1<x_2<x_3<\ldots<x_n=4$ **.**

If $\delta x=x_i-x_{i-1}$ for $i=1, 2, 3, \ldots, n$, then $\lim_{\delta x\to0}\sum_{i=1}^{n}x_i\delta x$ is equal to

(a) 4 (b) 8 (c) $\frac{32}{3}$ (d) 16

Sol. $\lim_{\delta x\to0}\delta x(x_1+x_2+x_3+\ldots+x_n)$

$$=\lim_{n\to\infty}\frac{4}{n}\left[\frac{4}{n}+\frac{8}{n}+\frac{12}{n}+\ldots\ldots+4\cdot\frac{n}{n}\right]\qquad\left(\because\delta x=\frac{4}{n}\right)$$



$$=\lim_{n\to\infty}\frac{16}{n^2}(1+2+3+\ldots+n)=\lim_{n\to\infty}\frac{16}{n^2}\cdot\frac{n(n+1)}{2}=8$$

Hence, (b) is the correct answer.

Example 86 The value of $\lim_{n\to\infty}\frac{1}{n}\cdot\sum_{r=1}^{2n}\frac{r}{\sqrt{n^2+r^2}}$ is equal to

(a) $1+\sqrt{5}$ (b) $-1+\sqrt{5}$ (c) $-1+\sqrt{2}$ (d) $1+\sqrt{2}$

Sol. We have, $\lim_{n\to\infty}\frac{1}{n}\cdot\sum_{r=1}^{2n}\frac{r}{\sqrt{n^2+r^2}}$

$$=\lim_{n\to\infty}\frac{1}{n}\cdot\sum_{r=1}^{2n}\frac{\frac{r}{n}}{\sqrt{1+\frac{r^2}{n^2}}}=\int_0^2\frac{x}{\sqrt{1+x^2}}dx=(\sqrt{x^2+1})_0^2=\sqrt{5}-1$$

Hence, (b) is the correct answer.

Applications of Inequality

Sometimes you are asked to prove inequalities involving definite integrals or to estimate the upper and lower boundary values of definite integral, where the exact value of the definite integral is difficult to find. Under these circumstances, we use the following types

Type I. If $f(x)$ is defined on $[a, b]$, then

$$\left|\int_a^b f(x)\,dx\right|\le\int_a^b|f(x)|\,dx.$$

Equality sign holds, where $f(x)$ is entirely of the same sign on $[a, b]$.

Example 87 ***Estimate the absolute value of the integral*** $\int_{10}^{19}\frac{\sin x}{1+x^8}dx$**.**

Sol. To find, $I=\left|\int_{10}^{19}\frac{\sin x}{1+x^8}dx\right|\le\int_{10}^{19}\left|\frac{\sin x}{1+x^8}\right|dx$ ...(i)

(using type I)

Since, $|\sin x|\le1$ for $x\ge10$

The inequality $\left|\frac{\sin x}{1+x^8}\right|\le\frac{1}{|1+x^8|}$ ...(ii)

Also, $10\le x\le19\ \Rightarrow\ 1+x^8>10^8$

$$\Rightarrow\quad\frac{1}{1+x^8}<\frac{1}{10^8}\ \text{ or }\ \frac{1}{|1+x^8|}<10^{-8}\qquad\text{...(iii)}$$

From Eqs. (ii) and (iii), $\left|\frac{\sin x}{1+x^8}\right|<10^{-8}$ is fulfilled.

$$\left|\int_{10}^{19}\frac{\sin x}{1+x^8}dx\right|<\int_{10}^{19}10^{-8}\,dx$$

$$\therefore\quad\left|\int_{10}^{19}\frac{\sin x}{1+x^8}dx\right|<(19-10).10^{-8}<10^{-7}$$

($\because$ the true value of integral $\approx10^{-8}$)

Example 88 The minimum odd value of 'a' ($a > 1$) for which $\int_{10}^{19} \frac{\sin x}{1+x^a}\,dx < \frac{1}{9}$, is equal to

(a) 1 (b) 3 (c) 5 (d) 9

Sol. Let $I = \int_{10}^{19} \frac{\sin x\,dx}{1+x^a} < \int_{10}^{19} \frac{dx}{1+x^a}$

$$\left(\because \sin x < 1 \Rightarrow \frac{\sin x}{1+x^a} < \frac{1}{1+x^a}\right)$$

$$\therefore \quad I < \int_{10}^{19} \frac{dx}{1+x^a} < \int_{10}^{19} \frac{dx}{1+10^a}$$

$$(\because\ 10 < x < 19 \Rightarrow 10^a + 1 < 1 + x^a < 19^a + 1)$$

$$\Rightarrow \quad I < \frac{9}{1+10^a}$$

$$\therefore \frac{9}{1+10^a} < \frac{1}{9} \Rightarrow 1 + 10^a > 81 \quad \text{or } 10^a > 80 \text{ i.e. } a = 2, 3, 4, 5, \ldots$$

$\therefore$ Minimum odd value of 'a' is 3.

Hence, (b) is the correct answer.

Type II.

$$\left|\int_a^b f(x)\,g(x)\,dx\right| \le \sqrt{\left(\int_a^b f^2(x)\,dx\right)\left(\int_a^b g^2(x)\,dx\right)},$$

where $f^2(x)$ and $g^2(x)$ are integrable on $[a, b]$.

Example 89 Prove that $\int_0^1 \sqrt{(1+x)(1+x^3)}\,dx$ cannot exceed $\sqrt{15/8}$.

Sol. $\int_0^1 \sqrt{(1+x)(1+x^3)}dx \le \sqrt{\left(\int_0^1 (1+x)dx\right)\left(\int_0^1 (1+x^3)\,dx\right)}$

$$\le \sqrt{\left(x + \frac{x^2}{2}\right)_0^1 \left(x + \frac{x^4}{4}\right)_0^1}$$

$$\le \sqrt{\frac{3}{2}\cdot\frac{5}{4}} \le \sqrt{\frac{15}{8}}$$

Type III. If $f(x) \mid g(x)$ on $[a, b]$, then $\int_a^b f(x)\,dx \ge \int_a^b g(x)\,dx$. In particular, if $f(x) \ge 0$, then $\int_a^b f(x)\,dx \mid 0$.

Example 90 If $f(x)$ is a continuous function such that $f(x) \mid 0, \forall\ x \in [2, 10]$ and $\int_4^8 f(x)\,dx = 0$, then find $f(6)$.

Sol. $f(x)$ is above the X-axis or on the X-axis for all $x \in [2, 10]$.

If $f(x)$ is greater than zero at any sub-interval of [4, 8], then $\int_4^8 f(x)\,dx$ must be greater than zero. But $\int_4^8 f(x)\,dx = 0$, which shows $f(x)$ can't have any value greater than zero in the sub-interval [4, 8].

$\Rightarrow f(x)$ is constant in the sub-interval [4, 8] and has to be zero at all points, $x \in [4, 8]$.

$$\Rightarrow \quad f(x) = 0, \quad \forall\ x \in [4, 8]$$

$$\Rightarrow \quad f(6) = 0$$

Type IV. For a given function $f(x)$ continuous on $[a, b]$, if you are able to find two continuous functions $f_1(x)$ and $f_2(x)$ on $[a, b]$ such that $f_1(x) \le f(x) \le f_2(x), \forall\ x \in [a, b]$, then

$$\int_a^b f_1(x)\,dx \le \int_a^b f(x)\,dx \le \int_a^b f_2(x)\,dx.$$

Example 91 Prove that $\frac{\pi}{6} \le \int_0^1 \frac{dx}{\sqrt{4 - x^2 - x^3}} \le \frac{\pi}{4\sqrt{2}}$.

Sol. Since, $4 - x^2 \mid 4 - x^2 - x^3 \mid 4 - 2x^2 > 1, \forall\ x \in [0, 1]$

$$\sqrt{4 - x^2} \mid \sqrt{4 - x^2 - x^3} \mid \sqrt{4 - 2x^2} > 1, \forall\ x \in [0, 1]$$

$$\Rightarrow \frac{1}{\sqrt{4 - x^2}} \le \frac{1}{\sqrt{4 - x^2 - x^3}} \le \frac{1}{\sqrt{4 - 2x^2}}, \forall\ x \in [0, 1]$$

$$\Rightarrow \quad \int_0^1 \frac{dx}{\sqrt{4 - x^2}} \le \int_0^1 \frac{dx}{\sqrt{4 - x^2 - x^3}} \le \int_0^1 \frac{1}{\sqrt{4 - 2x^2}}\,dx, \forall\ x \in [0, 1]$$

$$\Rightarrow \quad \left(\sin^{-1}\frac{x}{2}\right)_0^1 \le \int_0^1 \frac{dx}{\sqrt{4 - x^2 - x^3}} \le \frac{1}{\sqrt{2}}\left(\sin^{-1}\frac{x}{\sqrt{2}}\right)_0^1$$

$$\Rightarrow \quad \frac{\pi}{6} \le \int_0^1 \frac{dx}{\sqrt{4 - x^2 - x^3}} \le \frac{\pi}{4\sqrt{2}}$$

Type V. If m and M be global minimum and global maximum of $f(x)$ respectively in $[a, b]$, then

$$m(b - a) \le \int_a^b f(x)\,dx \le M(b - a).$$

Proof We have, $m \le f(x) \le M$ for all $x \in [a, b]$

$$\Rightarrow \quad \int_a^b m\,dx \le \int_a^b f(x)\,dx \le \int_a^b M\,dx$$

$$\Rightarrow \quad m(b - a) \le \int_a^b f(x)\,dx \le M(b - a)$$

Example 92 Prove that $4 \le \int_1^3 \sqrt{3 + x^3}\,dx \le 2\sqrt{30}$.

Sol. Since, the function $f(x) = \sqrt{3 + x^3}$ increases monotonically on the interval [1, 3].

$$\therefore \quad M = \text{Maximum value of } \sqrt{3 + x^3} = \sqrt{3 + 3^3} = \sqrt{30}$$

and $\quad m = \text{Minimum value of } \sqrt{3 + x^3} = \sqrt{3 + 1^3} = 2$

$\therefore \quad m = 2, M = \sqrt{30}, b - a = 2$

Hence, $\quad 2 \cdot 2 \le \int_1^3 \sqrt{3 + x^3}\, dx \le 2\sqrt{30}$

$\Rightarrow \quad 4 \le \int_1^3 \sqrt{3 + x^3}\, dx \le 2\sqrt{30}$

Example 93 Prove that $1 \le \int_0^1 e^{x^2} dx \le e$.

Sol. For $0 \le x \le 1$, we have $e^0 \le e^{x^2} \le e^1$

$\therefore \quad e^0 (1 - 0) \le \int_0^1 e^{x^2}\, dx \le e^1 (1 - 0)$

$\Rightarrow \quad 1 \le \int_0^1 e^{x^2} dx \le e$

Gamma Function

If n is a positive number, then the improper integral $\int_0^\infty e^{-x}\, x^{n-1}\, dx$ is defined as Gamma function and is denoted by Γn.

i.e. $\quad \Gamma n = \int_0^\infty e^{-x}\, x^{n-1}\, dx$, where $x \in Q^+$.

Example 94 Evaluate

(i) $\Gamma 1$ (ii) $\Gamma 2$

Sol. (i) $\Gamma 1 = \int_0^\infty e^{-x} \cdot x^{1-1}\, dx = \lim_{b \to \infty} \int_0^b e^{-x}\, dx$

$= \lim_{b \to \infty} \left[-e^{-x} \right]_0^b = \lim_{b \to \infty} (-e^{-b} + e^0)$

$= 0 + 1 = 1$

(ii) $\Gamma 2 = \int_0^\infty e^{-\infty}\, x^{2-1}\, dx = \lim_{b \to \infty} \int_0^b e^{-x} \cdot x\, dx$

$= \lim_{b \to \infty} \left[-x\, e^{-x} - e^{-x} \right]_0^b$

$= \lim_{b \to \infty} [(-b\, e^{-b} - e^{-b}) - (0 - 1)]$

$= \lim_{b \to \infty} \left[\frac{-b}{e^b} - \frac{1}{e^b} + 1 \right] = \lim_{b \to \infty} \frac{-(b+1)}{e^b} + 1$

$= \left(\lim_{b \to \infty} -\frac{1}{e^b} \right) + 1$ (using L'Hospital's rule)

$= 1$

Properties of Gamma Function

Gamma function has following properties :

(i) $\Gamma 1 = 1$, $\Gamma 0 = \infty$ and $\Gamma(n+1) = n\, \Gamma n$

e.g. $\Gamma 5 = 4\, \Gamma 4 = 4 \times 3\, \Gamma 3 = 4 \times 3 \times 2\, \Gamma 2$

$= 4 \times 3 \times 2 \times 1\, \Gamma 1 = 4 \times 3 \times 2 \times 1$

(ii) If $n \in N$, then $\Gamma(n+1) = (n)!$

(iii) $\Gamma(1/2) = \sqrt{\pi}$

(iv) $\int_0^{\pi/2} \sin^m x \cdot \cos^n x\, dx = \frac{\Gamma\left(\frac{m+1}{2}\right) \Gamma\left(\frac{n+1}{2}\right)}{2\, \Gamma\left(\frac{m+n+2}{2}\right)}$

(v) $\Gamma n\, \Gamma(1-n) = \frac{\pi}{\sin n\pi}, 0 < n < 1$

(vi) $\Gamma\, m\, \Gamma\left(m + \frac{1}{2}\right) = \frac{\sqrt{\pi}}{2^{2m-1}}\, \Gamma\, 2m$

(vii) $\Gamma \frac{1}{n} \Gamma\left(\frac{2}{n}\right) \ldots \Gamma\left(\frac{n-1}{n}\right) = \frac{(2\pi)^{\frac{n-1}{2}}}{n^{1/2}}$

Example 95 ***Evaluate*** $\int_0^\infty e^{-x}\, x^3\, dx$.

Sol. By definition of Gamma function,

$\int_0^\infty e^{-x}\, x^3\, dx = \int_0^\infty e^{-x}\, x^{4-1}\, dx = \Gamma 4$

$\therefore \quad \int_0^\infty e^{-x}\, x^3\, dx = 6$

Example 96 Evaluate $\int_0^1 \left(\log \frac{1}{x} \right)^{n-1} dx$.

Sol. Let $I = \int_0^1 \left(\log \frac{1}{x} \right)^{n-1} dx$

Put $\log \frac{1}{x} = t \Rightarrow dx = -e^{-t}\, dt$

$\therefore \quad I = \int_\infty^0 t^{n-1} (-e^{-t})\, dt = \int_0^\infty e^{-t}\, t^{n-1}\, dt$

$\therefore \quad \int_0^1 \left(\log \frac{1}{x} \right)^{n-1} dx = \Gamma n$

Beta Function

The beta function is

$$B(m, n) = \int_0^1 x^{m-1} (1 - x)^{n-1}\, dx,$$

where $m, n > 0$

Properties of Beta Function

(i) $B(m, n) = B(n, m)$, where $m, n > 0$

(ii) $B(m, n) = \frac{\Gamma\, m\, \Gamma\, n}{\Gamma\, (m+n)}$, where $m, n > 0$

(iii) $B(m, n) = \int_0^\infty \frac{x^{m-1}}{(1+x)^{m+n}}\, dx$

Example 97 Evaluate $\int_0^1 x^6 \sqrt{(1-x^2)}\, dx$.

Sol. Let, $I = \int_0^1 x^6 \sqrt{(1-x^2)}\, dx$

Put let $x^2 = t$

$\Rightarrow 2x\, dx = dt$

$\therefore \quad I = \frac{1}{2}\int_0^1 t^{5/2}\sqrt{(1-t)}\, dt$

$$I = \frac{1}{2} B\left(\frac{7}{2}, \frac{3}{2}\right) = \frac{1}{2}\cdot\frac{\Gamma\, 7/2\, \Gamma\, 3/2}{\Gamma\left(\frac{3}{2}+\frac{7}{2}\right)}$$

$$= \frac{1}{2}\frac{\frac{5}{2}\cdot\frac{3}{2}\cdot\frac{1}{2}\cdot\sqrt{\pi}\cdot\frac{1}{2}\cdot\sqrt{\pi}}{4\cdot 3\cdot 2\cdot 1} = \frac{5\pi}{256}$$

Walli's Formula

An easy way to evaluate $\int_0^{\pi/2} \sin^m x\cdot\cos^n x\, dx$, where $m, n \in I_+$.

We have, $\int_0^{\pi/2} \sin^m x\cdot\cos^n x\, dx = \int_0^{\pi/2} \sin^n x\cdot\cos^m x\, dx$

$$= \frac{(m-1)(m-3)\ldots(1 \text{ or } 2)\,.\,(n-1)(n-3)\ldots(1 \text{ or } 2)}{(m+n)(m+n-2)\ldots(1 \text{ or } 2)}\cdot\frac{\pi}{2},$$

when both m and $n \in$ even integer.

$$= \frac{(m-1)(m-3)\ldots(1 \text{ or } 2)\cdot(n-1)(n-3)\ldots(1 \text{ or } 2)}{(m+n)(m+n-2)\ldots(1 \text{ or } 2)},$$

when either of m or $n \in$ odd integer.

Remark

If n be a positive integer, then

$$\int_0^{\pi/2} \sin^n x\, dx = \int_0^{\pi/2} \cos^n x\, dx$$

$$= \frac{n-1}{n}\cdot\frac{n-3}{n-2}\cdot\frac{n-5}{n-4}\cdots\frac{3}{4}\cdot\frac{1}{2}\cdot\frac{\pi}{2},\ n \text{ is even.}$$

$$= \frac{n-1}{n}\cdot\frac{n-3}{n-2}\cdot\frac{n-5}{n-4}\cdots\frac{4}{5}\cdot\frac{2}{3}\cdot 1,\ n \text{ is odd.}$$

Example 98 Evaluate $\int_0^{\pi/2} \sin^4 x\cdot\cos^6 x\, dx$.

Sol. Using Gamma function, we have

$$\int_0^{\pi/4} \sin^4 x\cdot\cos^6 x\, dx = \frac{\Gamma(5/2)\,\Gamma(7/2)}{2\,\Gamma\left(\frac{4+6+2}{2}\right)} = \frac{\Gamma(5/2)\,\Gamma(7/2)}{2\,\Gamma 6}$$

$$= \frac{\left(\frac{3}{2}\times\frac{1}{2}\times\Gamma(1/2)\right)\left(\frac{5}{2}\times\frac{3}{2}\times\frac{1}{2}\times\Gamma(1/2)\right)}{2\times 5!} = \frac{3\pi}{512}$$

Example 99 The value of $\int_0^\infty e^{-a^2x^2}\, dx$ is equal to

(a) $\frac{\sqrt{\pi}}{2a}$ (b) $\frac{\pi}{2a}$

(c) $\frac{\pi}{\sqrt{2a}}$ (d) None of these

Sol. Let $I = \int_0^\infty e^{-a^2x^2}\, dx$

$$\therefore \quad I = \int_0^\infty e^{-t}\cdot\frac{1}{2a\sqrt{t}}\, dt = \frac{1}{2a}\int_0^\infty e^{-t}\cdot t^{-1/2}\, dt$$

(put $a^2x^2 = t \Rightarrow 2a^2x\, dx = dt$)

$$= \frac{1}{2a}\int_0^\infty t^{1/2-1}\cdot e^{-t}\cdot dt \qquad (\text{using } \int_0^\infty e^{-x}\, x^{n-1} dx = \Gamma n)$$

$$= \frac{1}{2a}\Gamma\frac{1}{2} = \frac{1}{2a}\sqrt{\pi} \qquad (\text{using } \Gamma\frac{1}{2} = \sqrt{\pi})$$

Hence, (a) is the correct answer.

Exercise for Session 6

1. The value of $f(x)=\int_0^{\pi/2}\frac{\log(1+x\sin^2\theta)}{\sin^2\theta}d\theta, x\geq 0$ is equal to

(a) $\frac{1}{\pi}(\sqrt{1+x}-1)$ (b) $\sqrt{\pi}(\sqrt{1+x}-1)$ (c) $\pi(\sqrt{1+x}-1)$ (d) None of these

2. The value of $\lim_{n\to\infty}\frac{1}{n}\sum_{r-1}^{n}\left(\frac{r}{n+r}\right)$ is equal to

(a) 1– log 2 (b) log 4 – 1 (c) log 2 (d) None of these

3. The value of $\lim_{n\to\infty}\frac{1}{n}\{(n+1)(n+2)(n+3)\ldots(n+n)\}^{1/n}$ is equal to

(a) 4e (b) $\frac{e}{4}$ (c) $\frac{4}{e}$ (d) None of these

4. If $m,n\in N$, then the value of $\int_a^b(x-a)^m(b-x)^n\,dx$ is equal to

(a) $\frac{(b-a)^{m+n}\cdot m!n!}{(m+n)!}$ (b) $\frac{(b-a)^{m+n+1}\cdot m!n!}{(m+n+1)!}$

(c) $\frac{(b-a)^m\cdot m!}{m!}$ (d) None of these

5. The value of $\lim_{n\to\infty}\left(\frac{n!}{n^n}\right)^{\frac{2n^4+1}{5n^5+1}}$ is equal to

(a) e (b) $\frac{2}{e}$ (c) $\left(\frac{1}{e}\right)^{\frac{2}{5}}$ (d) None of these

6. The value of $\lim_{n\to\infty}n\left\{\frac{1}{3n^2+8n+4}+\frac{1}{3n^2+16n+16}+\ldots+\text{to }n\text{ terms}\right\}$ is equal to

(a) $\frac{1}{2}\log\left(\frac{9}{5}\right)$ (b) $\frac{1}{3}\log\left(\frac{9}{5}\right)$

(c) $\frac{1}{4}\log\left(\frac{9}{5}\right)$ (d) None of these

7. The value of $\lim_{n\to\infty}\frac{1}{n^2}\left\{\sin^3\frac{\pi}{4n}+2\sin^3\frac{2\pi}{4n}+\ldots+n\sin^3\frac{n\pi}{4n}\right\}$ is equal to

(a) $\frac{\sqrt{2}}{9\pi^2}(52-15n)$ (b) $\frac{2}{9\pi^2}(52-15n)$

(c) $\frac{1}{9\pi^2}(15n-15)$ (d) None of these

8. The value of $f(k)=\int_0^{\pi/2}\log(\sin^2\theta+k^2\cos^2\theta)\,d\theta$ is equal to

(a) $\pi\log(1+K)-\pi\log 2$ (b) $\pi\log 2-\log(1+K)$ (c) $\log(1+K)-\pi\log 2$ (d) None of these

9. If $m,n\in N$, then $I_{m,n}=\int_0^1 x^m(1-x)^n\,dx$ is equal to

(a) $\frac{m!n!}{(m+n+2)!}$ (b) $\frac{2m!n!}{(m+n+1)!}$ (c) $\frac{m!n!}{(m+n+1)!}$ (d) None of these

10. The value of $I(n)=\int_0^{\pi}\frac{\sin^2 n\theta}{\sin^2\theta}d\theta$ is $(\forall\, n\in N)$

(a) $n\pi$ (b) $\frac{n\pi}{2}$ (c) $\frac{n\pi}{4}$ (d) None of these

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *If* $\int_0^\infty f(x)dx = \frac{\pi}{2}$ *and* $f(x)$ *is an even function, then* $\int_0^\infty f\left(x-\frac{1}{x}\right)dx$ *is equal to*

(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$ (c) π (d) None of these

Sol. Here, $\int_0^\infty f(x)dx = \frac{\pi}{2}$

Put $x = t - \frac{1}{t}$

$\Rightarrow \quad dx = \left(1+\frac{1}{t^2}\right)dt$

$\therefore \quad \int_0^\infty f(x)dx = \int_1^\infty f\left(t-\frac{1}{t}\right)\cdot\left(1+\frac{1}{t^2}\right)dt$

$= \int_1^\infty f\left(t-\frac{1}{t}\right)dt + \int_1^\infty f\left(t-\frac{1}{t}\right)\cdot\frac{1}{t^2}dt$

$= \int_1^\infty f\left(t-\frac{1}{t}\right)dt + \int_1^0 f\left(\frac{1}{y}-y\right)\cdot(-dy) \quad \left(\text{put } t=\frac{1}{y}\right)$

$= \int_1^\infty f\left(t-\frac{1}{t}\right)dt - \int_1^0 f\left(y-\frac{1}{y}\right)dy \quad$ as $f(x)$ is even

$= \int_1^\infty f\left(t-\frac{1}{t}\right)dt + \int_0^1 f\left(t-\frac{1}{t}\right)dt = \int_0^\infty f\left(t-\frac{1}{t}\right)dt$

$\therefore \quad \int_0^\infty f\left(x-\frac{1}{x}\right)dx = \int_0^\infty f(x)dx = \frac{\pi}{2}$

● **Ex. 2** *The value of* $\int_0^1 \left(\prod_{r=1}^{n}(x+r)\right)\left(\sum_{k=1}^{n}\frac{1}{x+k}\right)dx$ *equals to*

(a) n (b) $n!$ (c) $(n+1)!$ (d) $n\cdot n!$

Sol. The given integrand is perfect coefficient of $\prod_{r=1}^{n}(x+r)$

$\therefore \quad I = \left[\prod_{r=1}^{n}(x+r)\right]_0^1 = (n+1)! - n! = n\cdot n!$

Aliter $(x+1)(x+2)(x+3)\ldots(x+n) = e^t$

So that, when $x=0$, then $t = \ln n!$ when $x=1$, then $t = \ln(n+1)!$

$[\ln(x+1) + \ln(x+2) + \ldots\ldots + \ln(x+n)] = t$

$\therefore \quad \left(\frac{1}{(x+1)}+\frac{1}{(x+2)}+\ldots+\frac{1}{(x+n)}\right)dx = dt$

Therefore, $I = \int_{\ln n!}^{\ln(n+1)!} e^t dt = [e^t]_{\ln n!}^{\ln(n+1)!}$

$= e^{\ln(n+1)!} - e^{\ln n!} = (n+1)! - n! = n\cdot n!$

Hence, (d) is the correct answer.

● **Ex. 3** *The true set of values of 'a' for which the inequality* $\int_a^0 (3^{-2x} - 2\cdot 3^{-x})\,dx \geq 0$ *is true, is*

(a) $[0, 1]$ (b) $(-\infty, -1]$ (c) $[0, \infty)$ (d) $(-\infty, -1]\cup[0, \infty)$

Sol. We have, $\int_a^0 3^{-x}(3^{-x}-2)\,dx \geq 0$

Put $3^{-x} = t \Rightarrow 3^{-x}\ln 3\,dx = -dt$

$\Rightarrow \quad \ln 3\int_1^{3^{-a}}(t-2)dt \geq 0 \;= \left[\frac{t^2}{2}-2t\right]_1^{3^{-a}} \geq 0$

$\Rightarrow \quad \left(\frac{3^{-2a}}{2}-2\cdot 3^{-a}\right)-\left(\frac{1}{2}-2\right)\geq 0$

$\Rightarrow \quad 3^{-2a} - 4\times 3^{-a} + 3 > 0 \;\Rightarrow\; (3^{-a}-3)(3^{-a}-1) > 0$

$\Rightarrow \quad 3^{-a} > 3^1 \Rightarrow a < 1 \;$ or $\; 3^{-a} < 3^0 \Rightarrow a > 0$

Thus, $a \in (-\infty, -1]\cup[0, \infty)$

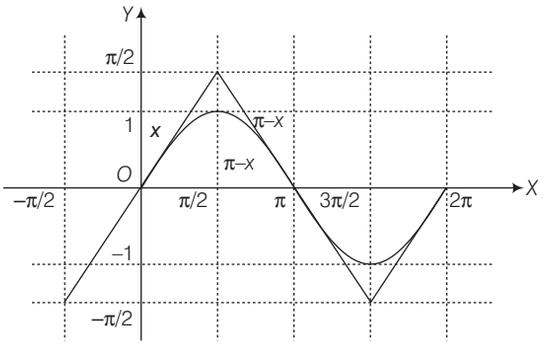
Hence, (d) is the correct answer.

● **Ex. 4** *The value of the definite integral* $\int_0^{2n\pi} \max(\sin x, \sin^{-1}(\sin x))dx$ *equals to (where,* $n \in I$*)*

(a) $\frac{n(\pi^2-4)}{2}$ (b) $\frac{n(\pi^2-4)}{4}$

(c) $\frac{n(\pi^2-8)}{4}$ (d) $\frac{n(\pi^2-2)}{4}$

Sol. Let $I = \int_0^{2n\pi} \max(\sin x, \sin^{-1}(\sin x))dx$



$= n\left[\int_0^{\pi/2} x\,dx + \int_{\pi/2}^{\pi}(\pi - x)dx + \int_{\pi}^{2\pi}(\sin x)\,dx\right]$

$= n\left[\frac{\pi^2}{8}+\frac{\pi^2}{2}-\frac{1}{2}\left(\pi^2-\frac{\pi^2}{4}\right)-2\right]$

$= n\left[\frac{\pi^2}{8}+\frac{\pi^2}{2}-\frac{3\pi^2}{8}-2\right] = \frac{n(\pi^2-8)}{4}$

Hence, (c) is the correct answer.

● **Ex. 5** $\lim_{n\to\infty} n^{-\frac{1}{2}\left(1+\frac{1}{n}\right)}\cdot(1^1\cdot 2^2\cdot 3^3.....n^n)^{\frac{1}{n^2}}$ *is equal to*

(a) $\sqrt{e}$ (b) $\frac{1}{\sqrt{e}}$ (c) $\frac{1}{\sqrt[4]{e}}$ (d) $\sqrt[4]{e}$

Sol. Let $L=\lim_{n\to\infty} n^{-\frac{1}{2}\left(1+\frac{1}{n}\right)}\cdot(1^1\cdot 2^2\cdot 3^3...n^n)^{\frac{1}{n^2}}$

$$\therefore \quad \ln L=\lim_{n\to\infty}-\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n+\frac{1}{n^2}\sum_{k=1}^{n} k\ln k$$

$$=\lim_{n\to\infty}-\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n+\frac{1}{n^2}\sum_{k=1}^{n}(k\ln k-k\ln n+k\ln n)$$

$$=\lim_{n\to\infty}-\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n+\frac{1}{n^2}\sum_{k=1}^{n} k\ln\frac{k}{n}+\frac{\ln n}{n^2}\sum_{k=1}^{n} k$$

$$=\lim_{n\to\infty}-\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n+\frac{1}{n}\sum_{k=1}^{n}\frac{k}{n}\ln\frac{k}{n}+\frac{\ln n}{n^2}\cdot\frac{n(n+1)}{2}$$

$$=-\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n+\int_0^1 x\ln x\,dx+\frac{1}{2}\left(\frac{n+1}{n}\right)\ln n$$

$$=\int_0^1 \underbrace{x}_{\text{II}}\underbrace{\ln x}_{\text{I}}dx=-\frac{1}{4} \quad\Rightarrow\quad L=e^{-\frac{1}{4}}$$

Hence, (c) is the correct answer.

● **Ex. 6** $\lim_{x\to\frac{\pi}{4}}\frac{\int_2^{\sec^2 x} f(t)\,dt}{x^2-\frac{\pi^2}{16}}$ *is equal to* ***[IIT JEE 2007]***

(a) $\frac{8}{\pi}f(2)$ (b) $\frac{2}{\pi}f(2)$ (c) $\frac{2}{\pi}f\left(\frac{1}{2}\right)$ (d) $4f(2)$

Sol. $\lim_{x\to\frac{\pi}{4}}\frac{\int_2^{\sec^2 x} f(t)\,dt}{x^2-\frac{\pi^2}{16}}=\lim_{x\to\frac{\pi}{4}}\frac{f(\sec^2 x)\cdot 2\sec^2 x\tan x-0}{2x}$ (applying L'Hospital rule)

$$=\frac{f(2)\cdot 4}{\pi/2}=\frac{8f(2)}{\pi}$$

Hence, (a) is the correct answer.

● **Ex. 7** *Let f be a non-negative function defined on the interval* $[0,1]$. *If* $\int_0^x\sqrt{1-(f'(t))^2}\,dx=\int_0^x f(t)\,dt, 0\le x\le 1$ *and* $f(0)=0$, *then* ***[IIT JEE 2009]***

(a) $f\left(\frac{1}{2}\right)<\frac{1}{2}$ and $f\left(\frac{1}{3}\right)>\frac{1}{3}$ (b) $f\left(\frac{1}{2}\right)>\frac{1}{2}$ and $f\left(\frac{1}{3}\right)>\frac{1}{3}$

(c) $f\left(\frac{1}{2}\right)<\frac{1}{2}$ and $f\left(\frac{1}{3}\right)<\frac{1}{3}$ (d) $f\left(\frac{1}{2}\right)>\frac{1}{2}$ and $f\left(\frac{1}{3}\right)<\frac{1}{3}$

Sol. Given, $\int_0^x\sqrt{1-(f'(t))^2}dt=\int_0^x f(t)\,dt, 0\le x\le 1$

Applying Leibnitz theorem, we get

$$\sqrt{1-(f'(x))^2}=f(x)$$

$$\Rightarrow \quad 1-(f'(x))^2=f^2(x)$$

$$\Rightarrow \quad (f'(x))^2=1-f^2(x) \Rightarrow f'(x)=\pm\sqrt{1-f^2(x)}$$

$$\Rightarrow \quad \frac{dy}{dx}=\pm\sqrt{1-y^2}, \text{ where } y=f(x)$$

$$\Rightarrow \quad \frac{dy}{\sqrt{1-y^2}}=\pm dx$$

Integrating both the sides, we get $\sin^{-1}(y)=\pm x+C$

$$\therefore \quad f(0)=0 \Rightarrow C=0$$

$$\therefore \quad y=\pm\sin x$$

$$\Rightarrow \quad y=\sin x=f(x), \text{ given } f(x)\ge 0 \text{ for } x\in[0,1]$$

Its known that, $\sin x<x, \forall x\in R^+$

$$\sin\left(\frac{1}{2}\right)<\frac{1}{2} \quad\Rightarrow\quad f\left(\frac{1}{2}\right)<\frac{1}{2} \text{ and } \sin\left(\frac{1}{3}\right)<\frac{1}{3}$$

$$\Rightarrow \quad f\left(\frac{1}{3}\right)<\frac{1}{3}$$

Hence, (c) is the correct answer.

● **Ex. 8** *The value of* $\lim_{x\to 0}\frac{1}{x^3}\int_0^x\frac{t\ln(1+t)}{t^4+4}dt$ ***[IIT JEE 2010]***

(a) 0 (b) $\frac{1}{12}$ (c) $\frac{1}{24}$ (d) $\frac{1}{64}$

Sol. $\lim_{x\to 0}\frac{1}{x^3}\int_0^x\frac{t\log(1+t)}{4+t^4}dt$

Using L'Hospital's rule,

$$\lim_{x\to 0}\frac{\frac{x\log(1+x)}{4+x^4}}{3x^2}=\lim_{x\to 0}\frac{\log(1+x)}{3x}\cdot\frac{1}{4+x^4}=\frac{1}{12}$$

$$\left[\text{using } \lim_{x\to 0}\frac{\log(1+x)}{x}=1\right]$$

Hence, (b) is the correct answer.

● **Ex. 9** *The value(s) of* $\int_0^1\frac{x^4(1-x)^4}{1+x^2}dx$ *is (are)* ***[IIT JEE 2010]***

(a) $\frac{22}{7}-\pi$ (b) $\frac{2}{105}$ (c) 0 (d) $\frac{71}{15}-\frac{3\pi}{2}$

Sol. Let $I=\int_0^1\frac{x^4(1-x)^4}{1+x^2}dx$

$$=\int_0^1\frac{(x^4-1)(1-x)^4+(1-x)^4}{(1+x^2)}dx$$

$$=\int_0^1(x^2-1)(1-x)^4dx+\int_0^1\frac{(1+x^2-2x)^2}{(1+x^2)}dx$$

$$=\int_0^1\left\{(x^2-1)(1-x)^4+(1+x^2)-4x+\frac{4x^2}{(1+x^2)}\right\}dx$$

$$=\int_0^1\left((x^2-1)(1-x)^4+(1+x^2)-4x+4-\frac{4}{1-x^2}\right)dx$$

$$= \int_0^1 \left(x^6 - 4x^5 + 5x^4 + 4 - \frac{4}{1+x^2} \right) dx$$

$$= \frac{1}{7} - \frac{4}{6} + \frac{5}{5} - \frac{4}{3} + 4 - 4\left(\frac{\pi}{4} - 0 \right) = \frac{22}{7} - \pi$$

Hence, (a) is the correct answer.

● ***Ex. 10*** *If* $\int_{\sin\theta}^{\cos\theta} f(x\tan\theta)dx \left(\theta \neq \frac{n\pi}{2}, n \in I \right)$ *is equal to*

(a) $-\cos\theta \int_1^{\tan\theta} f(x\sin\theta)dx$

(b) $-\tan\theta \int_{\cos\theta}^{\sin\theta} f(x)dx$

(c) $\sin\theta \int_1^{\tan\theta} f(x\cos\theta)dx$

(d) $\frac{1}{\tan\theta} \int_{\sin\theta}^{\sin\theta\tan\theta} f(x)dx$

Sol. Let, $I = \int_{\sin\theta}^{\cos\theta} f(x\tan\theta)dx$. Put $x\tan\theta = z\sin\theta$

$\therefore \quad I = \int_{\tan\theta}^{1} f(z\sin\theta)\cos\theta\, dz$

$\Rightarrow \quad dx = \cos\theta\, dz$

$$= -\cos\theta \int_1^{\tan\theta} f(z\sin\theta)\, dz = -\cos\theta \int_1^{\tan\theta} f(x\sin\theta)\, dx$$

Hence, (a) is correct option.

JEE Type Solved Examples :
More than One Correct Option Type Questions

● ***Ex. 11*** *Let* $f(x)$ *be an even function which is mapped from* $(-\pi, \pi)$*. Then, the value of* $\int_{-\pi}^{\pi} \left(\int_0^x f(t)\, dt + [f(x)] \right) dx$ *can be (where,* $[\cdot]$ *denotes greatest integer function)*

(a) 0 (b) π

(c) 2π (d) 4π

Sol. As, $f(x)$ is an even function, then $\int_0^x f(x)\, dx$ is an odd function.

Also, $[f(x)] = 1, 2 \qquad [\text{as } 1 < f(x) < 3]$

$\therefore \quad g(x) = \int_{-\pi}^{\pi} \left(\int_0^x f(t)\, dt \right) dx + \int_{-\pi}^{\pi} [f(x)]\, dx$

$$= 0 + \int_{-\pi}^{\pi} [f(x)]\, dx, \qquad [\because \text{since } [f(x)] = 1 \text{ or } 2]$$

$$= \int_{-\pi}^{\pi} 1\, dx$$

or $\int_{-\pi}^{\pi} 2\, dx = 2\pi$ or 4π

Hence, options (c) and (d) are correct.

● ***Ex. 12*** *Let,* $A_1 = \int_n^{n+1} (\min\{|x-n|, |x-(n+1)|\})\, dx$,

$$A_2 = \int_{n+1}^{n+2} (|x-n| - |x-(n+1)|)\, dx,$$

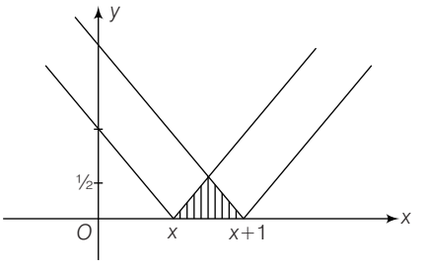
$$A_3 = \int_{n+2}^{n+3} (|x-(n+4)| - |x-(n+3)|)\, dx$$

and $g(x) = A_1 + A_2 + A_3$, then

(a) $A_1 + A_2 + A_3 = 9$ (b) $A_1 + A_2 + A_3 = \frac{9}{4}$

(c) $\sum_{n=1}^{100} g(x) = \frac{900}{4}$ (d) $\sum_{n=1}^{100} g(x) = 300$

Sol. Here, $\min\{|x-n|, |x-(n+1)|\}$ can be shown as



$\therefore \quad A_1 = \int_n^{n+1} (\min\{|x-n|, |x-(n+1)|\})\, dx$

$$= \frac{1}{2} \times 1 \times \frac{1}{2} = \frac{1}{4}$$

Now, $A_2 = \int_{n+1}^{n+2} (|x-n| - |x-(n+1)|)\, dx$

$$= \int_1^2 (|t| - |t-1|)dt \qquad [\text{put } x = n+t \Rightarrow dx = dt]$$

$$= \int_1^2 (t - (t-1))dt = \int_1^2 1dt = (t)_1^2 = 1$$

and $A_3 = \int_{n+2}^{n+3} (|x-(n+4)| - |x-(n+3)|)dx,$

$$= \int_2^3 (|t-4| - |t-3|)dt \qquad [\text{put } x = n+t \Rightarrow dx = dt]$$

$$= \int_2^3 ((4-t) - (3-t))dt = \int_2^3 1\, dt = 1$$

Also, $g(x) = A_1 + A_2 + A_3 = \frac{1}{4} + 1 + 1 = \frac{9}{4}$

$\therefore \quad \sum_{n=1}^{100} g(x) = g(1) + g(2) + g(3) + \ldots + g(100)$

$$= \frac{9}{4} + \frac{9}{4} + \ldots + \frac{9}{4} = \frac{900}{4}$$

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** (Q. Nos. 13 to 15) *For the following questions, choose the correct answers from the codes (a), (b), (c) and (d) defined as follows.*

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I.

(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I.

(c) Statement I is true, Statement II is false.

(d) Statement I is false, Statement II is true.

● ***Ex. 13*** **Statement I** *If* $f(x)=\int_0^1 (x f(t)+1)dt$, *then* $\int_0^3 f(x)dx=12$

Statement II $f(x)=3x+1$

Sol. Let $\int_0^1 f(t)dt=k$, so $f(x)=xk+1$

Now, $\int_0^1 (kt+1)dt=k \Rightarrow \frac{k}{2}+1=k$, so $k=2$

$\therefore \quad f(x)=2x+1$

Also $\int_0^3 f(x)dx=12$

Hence, (c) is the correct answer.

● ***Ex. 14*** **Statement I** *The function* $f(x)=\int_0^x \sqrt{1+t^2}\,dt$ *is an odd function and* $g(x)=f'(x)$ *is an even function.*

Statement II *For a differentiable function* $f(x)$ *if* $f'(x)$ *is an even function, then* $f(x)$ *is an odd function.*

Sol. If $f(x)$ is of odd, then $f'(x)$ is even but converse is not true.

e.g. If $f'(x)=x\sin x$, then $f(x)=\sin x - x\cos x + C$

$$f(-x)=-\sin x + x\cos x + C$$

On adding, $f(x)+f(-x)=$ constant which need not to be zero.

For Statement I $f(x)=\int_0^x \sqrt{1+t^2}dt;\ g(x)=\sqrt{1+x^2}$

$$f(-x)=\int_0^{-x}\sqrt{1+t^2}dt;\ t=-y$$

$$f(-x)=-\int_0^x \sqrt{1+y^2}dy$$

$\therefore \quad f(x)+f(-x)=0$

$\Rightarrow$ f is odd and g is obviously even.

Hence, (c) is the correct answer.

● ***Ex. 15*** *Given,* $f(x)=\sin^3 x$ *and* $P(x)$ *is a quadratic polynomial with leading coefficient unity.*

Statement I $\int_0^{2\pi} P(x)\cdot f'''(x)dx$ *vanishes.*

Statement II $\int_0^{2\pi} f(x)dx$ *vanishes.*

Sol. $P(x)=ax^2+bx+c;\ f(x)=\sin^3 x$

$$I=\int_0^{2\pi} \underbrace{P(x)}_{\text{I}}\cdot \underbrace{f'''(x)}_{\text{II}}dx$$

Using I.B.P. $\underbrace{P(x)\cdot f''(x)\big|_0^{2\pi}}_{\text{zero}} - \int_0^{2\pi} \underbrace{P'(x)}_{\text{I}}\cdot \underbrace{f''(x)}_{\text{II}}dx$

$$=-\left[[P'(x)\cdot f(x)]_0^{2\pi}-\int_0^{2\pi}P''(x)\cdot f(x)dx\right]$$

$$=\int_0^{2\pi}P''(x)\cdot f(x)dx=2\int_0^{2\pi}\sin^3 x\,dx=0$$

Hence, (a) is the correct answer.

JEE Type Solved Examples :
Passage Based Questions

Passage I

(Q. Nos. 16 to 18)

Suppose we define the definite integral using the following formula $\int_a^b f(x)dx=\frac{b-a}{2}(f(a)+f(b))$, *for more accurate result for* $c\in(a,b)$, $F(c)=\frac{c-a}{2}(f(a)+f(c))+\frac{b-c}{2}(f(b)+f(c))$.

When $c=\frac{a+b}{2}$, then $\int_a^b f(x)dx=\frac{b-a}{4}(f(a)+f(b)+2f(c))$.

[IIT JEE 2007]

● ***Ex. 16*** *$\int_0^{\pi/2} \sin x\,dx$ is equal to*

(a) $\frac{\pi}{8}(1+\sqrt{2})$ (b) $\frac{\pi}{4}(1+\sqrt{2})$

(c) $\frac{\pi}{8\sqrt{2}}$ (d) $\frac{\pi}{4\sqrt{2}}$

Sol. $\int_0^{\pi/2}\sin x\,dx = \frac{\frac{\pi}{2}-0}{4}\left(\sin(0)+\sin\left(\frac{\pi}{2}\right)+2\sin\left(\frac{0+\frac{\pi}{2}}{2}\right)\right)=\frac{\pi}{8}(1+\sqrt{2})$

Hence, (a) is the correct answer.

● ***Ex. 17*** *If $f(x)$ is a polynomial and if $\lim_{t\to a}\frac{\int_a^t f(x)dx-\frac{(t-a)}{2}(f(t)+f(a))}{(t-a)^3}=0$ for all a, then the degree of $f(x)$ can atmost be*

(a) 1 (b) 2

(c) 3 (d) 4

Sol. Applying L' Hospital's rule,

$$\lim_{t\to a}\frac{f(t)-\frac{1}{2}(f(t)+f(a))-\frac{(t-a)}{2}f'(t)}{3(t-a)^2}=0$$

$$\Rightarrow \lim_{t\to a}\frac{f(t)-\frac{1}{2}(f(t)+f(a))-\frac{(t-a)}{2}f'(t)}{3(t-a)^2}=0$$

$$\Rightarrow \lim_{t\to a}\frac{f'(t)-\frac{1}{2}(f(t)+f(a))-\frac{(t-a)}{2}f'(t)}{12(t-a)}=0$$

$$\Rightarrow \lim_{t\to a}\frac{f''(t)}{12}=0$$

$$\Rightarrow \lim_{t\to a}\frac{f'(t)-\frac{1}{2}(f(t)+f(a))-\frac{(t-a)}{2}f'(t)}{12(t-a)}=0$$

$\Rightarrow \lim_{t\to a}\frac{f''(t)}{12}=0$ $f''(a)=0$ for any a.

$\Rightarrow$ $f(a)$ is atmost of degree 1.

Hence, (a) is the correct answer.

● ***Ex. 18*** *If $f''(x)<0, \forall\, x\in(a,b)$ and c is a point such that $a<c<b$ and $(c,f(c))$ is the point on the curve for which $F(c)$ is maximum, then $f'(c)$ is equal to*

(a) $\frac{f(b)-f(a)}{b-a}$ (b) $\frac{2(f(b)-f(a))}{b-a}$

(c) $\frac{2f(b)-f(a)}{2b-a}$ (d) 0

Sol. $F'(c)=(b-a)'(c)+f(a)-f(b)$

$F''(c)=f''(c)(b-a)<0$

$\Rightarrow$ $F'(c)=0$

$\Rightarrow$ $f'(c)=\frac{f(b)-f(a)}{b-a}$

Hence, (a) is the correct answer.

Passage II

(Q. Nos. 19 to 20)

Let $f(\alpha,\beta)=\begin{vmatrix}\cos(\alpha+\beta) & -\sin(\alpha+\beta) & \cos 2\beta\\ \sin\alpha & \cos\alpha & \sin\beta\\ -\cos\alpha & \sin\alpha & \cos\beta\end{vmatrix}$.

● ***Ex. 19*** *The value of $I=\int_0^{\pi/2} e^{\beta}\left(f(0,0)+f\left(\frac{\pi}{2},\beta\right)+f\left(\frac{3\pi}{2},\frac{\pi}{2}-\beta\right)\right)d\beta$ is*

(a) $e^{\pi/2}$ (b) 0

(c) $2(2e^{\pi/2}-1)$ (d) None of these

Sol. Here, $f(\alpha,\beta)=2\cos\beta$ i.e. independent of α

$$\therefore\quad I=\int_0^{\pi/2} e^{\beta}\left(f(0,0)+f\left(\frac{\pi}{2},\pi\right)+f\left(\frac{3\pi}{2},\frac{\pi}{2}-\beta\right)\right)d\beta$$

$$=\int_0^{\pi/2} e^{\beta}(2+2\cos\beta+2\sin\beta)d\beta$$

Hence, $=[e^{\beta}(2+2\sin\beta)]_0^{\pi/2}$

$=4e^{\pi/2}-2=2(2e^{\pi/2}-1)$

Hence, (c) is the correct answer.

● ***Ex. 20*** *If $I=\int_{-\pi/2}^{\pi/2}\cos^2\beta\left(f(0,\beta)+f\left(0,\frac{\pi}{2}-\beta\right)\right)d\beta$, then $[I]$ is*

(a) $e^{\pi/2}$ (b) 2

(c) $2(2e^{\pi/2}-1)$ (d) None of these

Sol. Again, $I=\int_{-\pi/2}^{\pi/2}\cos^2\beta\left(f(0,\beta)+f\left(0,\frac{\pi}{2}-\beta\right)\right)d\beta$

$$=\int_{-\pi/2}^{\pi/2}\cos^2\beta(\cos\beta+\sin\beta)\,d\beta$$

$$=\int_{-\pi/2}^{\pi/2}\cos^3\beta\,d\beta+\int_{-\pi/2}^{\pi/2}\cos^2\beta\sin\beta\,d\beta$$

$$=2\int_0^{\pi/2}\cos^3\beta\,d\beta+0$$

$\Rightarrow$ $I=\frac{\theta}{3}\Rightarrow[I]=2$

Hence, (b) is the correct answer.

JEE Type Solved Examples :
Matching Type Questions

● **Ex. 21** *Match the following.*

	Column I	Column II
(A)	The function $f(x)=\dfrac{e^{x\cos x}-1-x}{\sin x^2}$ is not defined at $x=0$. The value of $f(0)$, so that f is continuous at $x=0$, is	(p) -1
(B)	The value of the definite integral $\int_0^1 \dfrac{dx}{\sqrt{x}+\sqrt[3]{x}}$ is equal to $a+b\ln 2$, where a and b are integers, then $(a+b)$ is equal to	(q) 0
(C)	Given, $e^n\int_0^n \dfrac{\sec^2\theta-\tan\theta}{e^\theta}\,d\theta=1$, then the value of tan n is equal to	(r) $1/2$
(D)	Let $a_n=\int_{\frac{n}{n+1}}^{1}\tan^{-1}(nx)\,dx$ and $b_n=\int_{\frac{n}{n+1}}^{1}\sin^{-1}(nx)\,dx$, then $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}$ has the value equal to	(s) 1

Sol. (A) → (r), (B) → (p), (C) → (s), (D) → (r)

(A) $\lim\limits_{x\to 0}\dfrac{e^x\cos x-1-x}{x^2\cdot\dfrac{\sin x^2}{x^2}}=\lim\limits_{x\to 0}\dfrac{e^{x\cos x}-1-x}{x^2}$

(applying L'Hospital's twice)

$=\lim\limits_{x\to 0}\dfrac{e^{x\cos x}\cdot(-x\sin x+\cos x)-1}{2x}$

$=\lim\limits_{x\to 0}\dfrac{e^{x\cos x}(-x\cos x-\sin x-\sin x)+e^{x\cos x}(-x\sin x+\cos x)}{2}$

$=\dfrac{1}{2}$

(B) Put $x=u^6\Rightarrow dx=6u^5\,du$

$\therefore\quad I=\int_0^1\dfrac{6u^5\,du}{u^3+u^2}=6\int_0^1\dfrac{u^3+1-1}{u+1}\,du=5-6\ln 2$

$\Rightarrow a+b=5-6=-1$

(C) $e^n\int_0^n e^{-\theta}(\sec^2\theta-\tan\theta)\,d\theta=1$

Put $-\theta=t\Rightarrow d\theta=-dt$

$-e^n\int_0^{-n}e^t(\sec^2 t+\tan t)\,dt=1$

[use $\int e^x(f(x)+f'(x))=e^x f(x)$]

$\Rightarrow\ -e^n[e^t\tan t]_0^{-n}=1\Rightarrow -e^n[-e^{-n}\tan n]=1\Rightarrow\tan n=+1$

(D) $\lim\limits_{n\to\infty}\dfrac{\int_{1/n+1}^{1/n}\tan^{-1}(nx)\,dx}{\int_{1/n+1}^{1/n}\sin^{-1}(nx)\,dx}$

Put $nx=t\ \Rightarrow\ dx=\dfrac{1}{n}dt$

$\therefore\quad \lim\limits_{n\to\infty}\dfrac{\frac{1}{n}\int_{n/n+1}^{1}\tan^{-1}(t)\,dt}{\frac{1}{n}\int_{n/n+1}^{1}\sin^{-1}(t)\,dt}$ $\left(\dfrac{0}{0}\text{ form}\right)$

Use L'Hospital's rule, $\lim\limits_{n\to\infty}\dfrac{\tan^{-1}\left(\frac{n}{n+1}\right)}{\sin^{-1}\left(\frac{n}{n+1}\right)}=\dfrac{\frac{\pi}{4}}{\frac{\pi}{2}}=\dfrac{1}{2}$

● **Ex. 22** *Match the following* ***[IIT JEE 2006]***

	Column I	Column II
(A)	$\int_{-1}^{1}\dfrac{dx}{1+x^2}$	(p) $\dfrac{1}{2}\log\left(\dfrac{2}{3}\right)$
(B)	$\int_0^1\dfrac{dx}{\sqrt{1-x^2}}$	(q) $\dfrac{1}{2}\log\left(\dfrac{3}{2}\right)$
(C)	$\int_2^3\dfrac{dx}{1-x^2}$	(r) $\dfrac{\pi}{3}$
(D)	$\int_1^2\dfrac{dx}{x\sqrt{x^2-1}}$	(s) $\dfrac{\pi}{2}$

Sol. (A) → (s), (B) → (s), (C) → (q), (D) → (r)

(A) $\int_{-1}^{1}\dfrac{dx}{1+x^2}$

$\because\quad f(x)=\dfrac{1}{1+x^2}$ is an reven function.

$\therefore\quad I=2\int_0^1\dfrac{dx}{1+x^2}=[2(\tan^{-1}x)]_0^1=\dfrac{\pi}{2}$

(B) $\int_0^1\dfrac{dx}{\sqrt{1-x^2}}=[\sin^{-1}x]_0^1=\dfrac{\pi}{2}$

(C) $\int_2^3\dfrac{dx}{1-x^2}=-\int_2^3\dfrac{dx}{x^2-1}=-\left[\dfrac{1}{2}\ln\left|\dfrac{x-1}{x+1}\right|\right]_2^3$

$=-\dfrac{1}{2}\ln\dfrac{2}{3}=\dfrac{1}{2}\ln\left(\dfrac{3}{2}\right)$

(D) Let $I=\int_1^2\dfrac{dx}{x\sqrt{x^2-1}}$ [put $x=\sec\theta\ \Rightarrow\ dx=\sec\theta\tan\theta\,d\theta$]

$=\int_0^{\pi/3}\dfrac{\sec\theta\tan\theta\,d\theta}{\sec\theta\tan\theta}$

$=\int_0^{\pi/3}1\,d\theta=\dfrac{\pi}{3}$

JEE Type Solved Examples :
Single Integer Answer Type Questions

● **Ex. 23** *Let $f:R \to R$ be a continuous function which satisfies $f(x)=\int_0^x f(t)\,dt$. Then, the value of $f(\ln 5)$ is____.*

[IIT JEE 2009]

Sol. **(0)** From given integral equation, $f(0)=0$

Also, differentiating the given integral equation w.r.t. x, we get

$$f'(x)=f(x)$$

If $f(x)\neq 0$, then $\dfrac{f'(x)}{f(x)}=1 \Rightarrow f(x)=e^c e^x$

$\because$ $f(0)=0 \Rightarrow e^c=0$, a contradiction

$\therefore$ $f(x)=0, \forall\, x\in R \Rightarrow f(\ln 5)=0$

● **Ex. 24** *For any real number x, let $[x]$ denotes the largest integer less than or equal to x. Let f be a real valued function defined on the interval $[-10,10]$ by*

$$f(x)=\begin{cases} x-[x], & \text{if } [x] \text{ is odd} \\ 1+[x]-x, & \text{if } [x] \text{ is even} \end{cases}.$$

Then, the value of $\dfrac{\pi^2}{10}\int_{-10}^{10} f(x)\cos \pi x\,dx$ is.

[IIT JEE 2010]

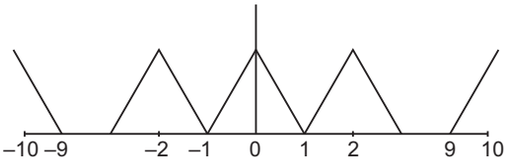
Sol. **(4)** We have, $f(x)=\begin{cases} x-[x], & \text{if } [x] \text{ is odd} \\ 1+[x]-x, & \text{if } [x] \text{ is even} \end{cases}$

$f(x)$ and $\cos \pi x$ are both periodic with period 2 and are both even.

$$\therefore \int_{-10}^{10} f(x)\cos \pi x\,dx = 2\int_0^{10} f(x)\cos \pi x\,dx$$

$$= 10\int_0^2 f(x)\cos \pi x\,dx$$

$$\int_0^1 f(x)\cos \pi x\,dx = \int_0^1 (1-x)\cos \pi x\,dx = -\int_0^1 u\cos \pi u\,du$$



$$\int_1^2 f(x)\cos \pi x\,dx = \int_1^2 (x-1)\cos \pi x\,dx = -\int_0^1 u\cos \pi u\,du$$

$$\therefore \int_{-10}^{10} f(x)\cos \pi x\,dx = -20\int_0^1 u\cos \pi u\,du = \frac{40}{\pi^2}$$

$$\Rightarrow \frac{\pi^2}{10}\int_{-10}^{10} f(x)\cos \pi x\,dx = 4$$

● **Ex. 25** *Let $f(x)$ be a differentiable function satisfying $f(x)+f\left(x+\dfrac{1}{2}\right)=1, \forall x\in R$ and $g(x)=\int_0^x f(t)dt$. If $g(1)=1$, then the value of $\sum_{n=2}^{\infty}\left(\dfrac{8}{\sum_{k=1}^{n}(g(x+k^2)-g(x+k))}\right)$ is.*

Sol. **(6)** Here, $f(x)+f\left(x+\dfrac{1}{2}\right)=1$

Replace x by $\left(x+\dfrac{1}{2}\right)$, we get $f\left(x+\dfrac{1}{2}\right)+f(x+1)=1$

On subtracting, $f(x)=f(x+1)$ ...(i)

Also, $g(x+1^2)=\int_0^{x+1^2} f(t)\,dt=\int_0^x f(t)\,dt+\int_n^{x+1^2} f(t)\,dt$

Since, $f(x+1)=f(x)$

$$\therefore \quad g(x+1^2)=\int_0^x f(t)\,dt+1^2\cdot\int_0^1 f(t)dt$$

$$g(x+2^2)=\int_0^x f(t)\,dt+2^2\cdot\int_0^1 f(t)dt$$

$$g(x+k^2)=\int_0^x f(t)\,dt+k^2\cdot\int_0^1 f(t)dt \quad \text{...(ii)}$$

and $g(x+k)=\int_0^x f(t)\,dt+k\cdot\int_0^1 f(t)dt$ ...(iii)

Thus, $\sum_{k=1}^{n}(g(x+k^2)-g(x+k))=\sum_{k=1}^{n}(k^2-k)\cdot\int_0^1 f(t)\,dt$

$$=\sum_{k=1}^{n}(k^2-k)\cdot g(1), \text{ given } g(x)=\int_0^x f(t)\,dt$$

$$=\left(\frac{n(n+1)(2n+1)}{6}-\frac{n(n+1)}{2}\right)\times 1$$

$$=\frac{n(n-1)(n+1)}{3}$$

$$\therefore \sum_{n=2}^{\infty}\frac{8}{\sum_{k=2}^{n}(g(x+k^2)-g(x+k))}=\sum_{n=2}^{\infty}\frac{8\times 3}{(n-1)n(n+1)}$$

$$=12\sum_{n=2}^{\infty}\left(\frac{(n+1)-(n-1)}{(n-1)\cdot n(n+1)}=\frac{1}{(n-1)n}-\frac{1}{n(n+1)}\right)$$

$$=12\left[\left(\frac{1}{1\times 2}-\frac{1}{2\times 3}\right)+\left(\frac{1}{2\times 3}-\frac{1}{3\times 4}\right)+\right.$$

$$\left.\ldots+\left(\frac{1}{(n-1)n}-\frac{1}{n(n+1)}\right)\right]$$

$$=12\left(\frac{1}{2}-\frac{1}{n(n+1)}\right)_{n\to\infty}=6$$

Subjective Type Questions

● **Ex. 26** *Find the error in steps to evaluate the following integral.*

$$\int_0^{\pi} \frac{dx}{1+2\sin^2 x} = \int_0^{\pi} \frac{\sec^2 x\,dx}{\sec^2 x + 2\tan^2 x} = \int_0^{\pi} \frac{\sec^2 x\,dx}{1+3\tan^2 x}$$

$$= \frac{1}{\sqrt{3}}\left[\tan^{-1}(\sqrt{3}\tan x)\right]_0^{\pi} = 0$$

Sol. Here, the Newton-Leibnitz's formula for evaluating the definite integrals is not applicable because the anti-derivative,

$$f(x) = \frac{1}{\sqrt{3}}\left[\tan^{-1}(\sqrt{3}\tan x)\right]$$

has a discontinuity at the point $x = \frac{\pi}{2}$ which lies in the interval $[0, \pi]$.

$$\text{LHL} = \lim_{h\to 0} \frac{1}{\sqrt{3}} \tan^{-1}\sqrt{3}\left[\tan\left(\frac{\pi}{2} - h\right)\right] \text{ at } x = \frac{\pi}{2}$$

$$= \lim_{h\to 0} \frac{1}{\sqrt{3}} \tan^{-1}(\sqrt{3}\cot h)$$

$$= \lim_{h\to 0} \frac{1}{\sqrt{3}} \tan^{-1}(\infty) = \frac{\pi}{2\sqrt{3}} \quad \text{...(i)}$$

Also, $$\text{RHL} = \lim_{h\to \mathbf{0}} \frac{1}{\sqrt{3}} \tan^{-1}\sqrt{3}\left[\tan\left(\frac{\pi}{2} + h\right)\right] \text{at } x = \frac{\pi}{2}$$

$$= \lim_{h\to 0} \frac{1}{\sqrt{3}} \tan^{-1}(-\sqrt{3}\cot h)$$

$$= \lim_{h\to 0} \frac{1}{\sqrt{3}} \tan^{-1}(-\infty) = -\frac{\pi}{2\sqrt{3}} \quad \text{...(ii)}$$

From Eqs. (i) and (ii), LHL ≠ RHL at $x = \pi/2$

$\Rightarrow$ Anti-derivative $f(x)$ is discontinuous at $x = \pi/2$.

So, the correct solution for above integral;

$$I = \int_0^{\pi} \frac{dx}{1+2\sin^2 x} = \int_0^{\pi} \frac{\sec^2 x\,dx}{1+3\tan^2 x} \quad \text{...(iii)}$$

Using, $\int_0^{2a} f(x)\,dx = \begin{cases} 0, & f(2a-x) = -f(x) \\ 2\int_0^a f(x)\,dx, & f(2a-x) = f(x) \end{cases}$

We know, if $f(x) = \frac{\sec^2 x}{1+3\tan^2 x}$ $f(\pi - x) = f(x)$

$\therefore$ Eq. (iii) reduces to $I = 2\int_0^{\pi/2} \frac{\sec^2 x\,dx}{1+3\tan^2 x}$

$$= 2\cdot\frac{1}{\sqrt{3}}\int_0^{\infty} \frac{dt}{1+t^2} \quad (\text{put } \sqrt{3}\tan x = t \Rightarrow \sqrt{3}\sec^2 x\,dx = dt)$$

$$= \frac{2}{\sqrt{3}}\left[\tan^{-1}(t)\right]_0^{\infty}$$

$$= \frac{2}{\sqrt{3}}(\tan^{-1}\infty - \tan^{-1}0) = \frac{2}{\sqrt{3}}\left(\frac{\pi}{2} - 0\right) = \frac{\pi}{\sqrt{3}}$$

$\therefore$ $$\int_0^{\pi} \frac{dx}{1+2\sin^2 x} = \frac{\pi}{\sqrt{3}}$$

Remark

Students are advised to check continuity of anti-derivatives before substitution of integral limits.

● **Ex. 27** *If* $\int_a^b |\sin x|\,dx = 8$ *and* $\int_0^{a+b} |\cos x|\,dx = 9$, *then find the value of* $\int_a^b x\sin x\,dx$.

Sol. We know, $\int_a^b |\sin x|\,dx$ represents the area under the curve from $x = a$ to $x = b$.

We also know, area from $x = a$ to $x = a + \pi$ is 2.

$\therefore$ $$\int_a^b |\sin x|\,dx = 8$$

$\Rightarrow$ $$b - a = \frac{8\pi}{2} \quad \text{...(i)}$$

Similarly, $$\int_0^{a+b} |\cos x|\,dx = 9$$

$\Rightarrow$ $$a + b - 0 = \frac{9\pi}{2} \quad \text{...(ii)}$$

From Eqs. (i) and (ii), $a = \pi/4, b = 17\pi/4$

Hence, $$\int_a^b x\sin x\,dx = \int_{\pi/4}^{17\pi/4} x\sin x\,dx$$

$$= [-x\cos x]_{\pi/4}^{17\pi/4} + \int_{\pi/4}^{17\pi/4} \cos x\,dx$$

$$= -\frac{17\pi}{4}\cos\frac{17\pi}{4} + \frac{\pi}{4}\cos\frac{\pi}{4} + [\sin x]_{\pi/4}^{17\pi/4}$$

$$= -\frac{4\pi}{\sqrt{2}}$$

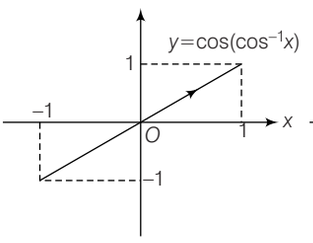
$\therefore$ $$\int_a^b x\sin x\,dx = -2\sqrt{2}\pi$$

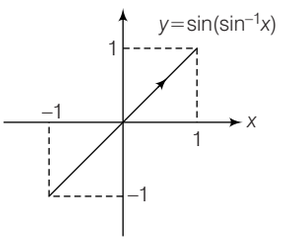
● **Ex. 28** *Evaluate* $\int_{\cos(\cos^{-1}\alpha)}^{\sin(\sin^{-1}\beta)} \left|\frac{\cos(\cos^{-1}x)}{\sin(\sin^{-1}x)}\right| dx$.

Sol. We know, $\cos(\cos^{-1}x)$ and $\sin(\sin^{-1}x)$ could be plotted as

$\therefore$ $\sin(\sin^{-1}x)$ and $\cos(\cos^{-1}x)$ are identical functions.

$\therefore$ $$\int_{\cos(\cos^{-1}\alpha)}^{\sin(\sin^{-1}\beta)} \frac{\cos(\cos^{-1}x)}{\sin(\sin^{-1}x)}\,dx = \int_{\cos(\cos^{-1}\alpha)}^{\sin(\sin^{-1}\beta)} 1\,dx = (\beta - \alpha)$$





● ***Ex. 29*** *Evaluate* $\int_\alpha^\beta \sqrt{\frac{x-\alpha}{\beta-x}}\,dx.$

Sol. Let $I=\int_\alpha^\beta \sqrt{\frac{x-\alpha}{\beta-x}}\,dx$ ...(i)

Put $x=\alpha\cos^2 t+\beta\sin^2 t$

$\therefore\quad x-\alpha=\alpha\cos^2 t+\beta\sin^2 t-\alpha=\beta\,[\sin^2(t)+\alpha(\cos^2 t-1)]$

$=\beta\sin^2 t-\alpha\sin^2 t \;\Rightarrow\; (x-\alpha)=(\beta-\alpha)\sin^2 t$

Similarly, $\beta-x=(\beta-\alpha)\cos^2 t$

$\therefore\quad dx=2(\beta-\alpha)\sin t\cos t\,dt$

where, $x=\alpha\Rightarrow\sin^2 t=0 \;\Rightarrow\; t=0$ $(\because\ \alpha<\beta)$

and $x=\beta\Rightarrow\cos^2 t=0 \;\Rightarrow\; t=\pi/2$

$\therefore$ Eq. (i) reduces to

$$I=\int_0^{\pi/2}\sqrt{\frac{(\beta-\alpha)\sin^2 t}{(\beta-\alpha)\cos^2 t}}\cdot 2(\beta-\alpha)\sin t\cos t\,dt$$

$$=\int_0^{\pi/2}\frac{\sin t}{\cos t}\cdot 2(\beta-\alpha)\sin t\cos t\,dt$$

$$\left[\because\ \sqrt{\frac{\sin^2 t}{\cos^2 t}}=+\frac{\sin t}{\cos t}\ \text{as}\ t\in[0,\pi/2]\right]$$

$$=(\beta-\alpha)\int_0^{\pi/2}2\sin^2 t\,dt=(\beta-\alpha)\int_0^{\pi/2}(1-\cos 2t)\,dt$$

$$=(\beta-\alpha)\left(t-\frac{\sin 2t}{2}\right)_0^{\pi/2}$$

$$=(\beta-\alpha)\left[\left(\frac{\pi}{2}-\frac{1}{2}\sin\pi\right)-\left(0-\frac{1}{2}\sin 0\right)\right]=(\beta-\alpha)\left[\frac{\pi}{2}\right]$$

$\therefore\quad I=\frac{\pi}{2}(\beta-\alpha)$

Aliter Let $I=\int_\alpha^\beta \sqrt{\frac{x-\alpha}{\beta-x}}\,dx$ $\left[\begin{array}{l}\text{put}\ \sqrt{\beta-x}=t\\ \text{or}\ \ \beta-x=t^2\\ \Rightarrow\ -dx=2t\,dt\end{array}\right]$

When $x=\alpha$, then $\beta-\alpha=t^2 \;\Rightarrow\; \sqrt{\beta-\alpha}=t$

When $x=\beta$, then $0=t^2 \;\Rightarrow\; 0=t$

$\therefore\quad I=\int_{\sqrt{\beta-\alpha}}^0 \frac{\sqrt{(\beta-t^2)-\alpha}}{t}(-2t)\,dt$

$$=-2\int_{\sqrt{\beta-\alpha}}^0\sqrt{(\beta-\alpha)-t^2}\,dt$$

$$=2\int_0^{\sqrt{\beta-\alpha}}\sqrt{(\sqrt{\beta-\alpha})^2-t^2}\,dt$$

$$=2\left\{\frac{t}{2}\sqrt{(\beta-\alpha)-t^2}+\frac{(\beta-\alpha)}{2}\sin^{-1}\left(\frac{t}{\sqrt{\beta-\alpha}}\right)\right\}_0^{\sqrt{\beta-\alpha}}$$

$$=2\left[\left\{0+\frac{(\beta-\alpha)}{2}\sin^{-1}(1)\right\}-\left\{0+\frac{(\beta-\alpha)}{2}\sin^{-1}(0)\right\}\right]$$

$$=\frac{2(\beta-\alpha)}{2}\cdot\frac{\pi}{2}=\frac{\pi}{2}(\beta-\alpha)$$

● ***Ex. 30*** *Evaluate* $\int_{\sqrt{(3a^2+b^2)/4}}^{\sqrt{(a^2+b^2)/2}}\frac{x}{\sqrt{(x^2-a^2)(b^2-x^2)}}\,dx.$

Sol. Let $I=\int_{\sqrt{(3a^2+b^2)/4}}^{\sqrt{(a^2+b^2)/2}}\frac{x}{\sqrt{(x^2-a^2)(b^2-x^2)}}\,dx$ ...(i)

Put $x^2=a^2\cos^2 t+b^2\sin^2 t$

$\Rightarrow\quad 2x\,dx=[2a^2\cos t(-\sin t)+2b^2\sin t(\cos t)]\,dt$

$\Rightarrow\quad x\,dx=\frac{1}{2}(b^2-a^2)\sin 2t\,dt$

For $x^2=\frac{a^2+b^2}{2}=a^2\cos^2 t+b^2\sin^2 t,$

$a^2+b^2=2(1-\sin^2 t)a^2+2b^2\sin^2 t$

or $(a^2+b^2)=2a^2+2(b^2-a^2)\sin^2 t$

$\Rightarrow\quad \sin^2 t=\frac{1}{2} \;\Rightarrow\; \cos 2t=0 \;\Rightarrow\; t=\frac{\pi}{4}$

For $x^2=\frac{3a^2+b^2}{4}=a^2\cos^2 t+b^2\sin^2 t,$

$3a^2+b^2=4a^2+4(b^2-a^2)\sin^2 t$

$\Rightarrow\quad \sin^2 t=\frac{1}{4} \;\Rightarrow\; \cos 2t=\frac{1}{2} \;\Rightarrow\; t=\frac{\pi}{6}$

$\therefore$ Eq. (i) reduces to

$$I=\int_{\pi/6}^{\pi/4}\frac{1}{2}\cdot\frac{(b^2-a^2)\sin 2t}{\sqrt{(b^2-a^2)\sin^2 t\,(b^2-a^2)\cos^2 t}}\,dt$$

$$=\int_{\pi/6}^{\pi/4}dt=\left(t\right)_{\pi/6}^{\pi/4}=\left(\frac{\pi}{4}-\frac{\pi}{6}\right)=\frac{\pi}{12}$$

● ***Ex. 31*** *Evaluate* $\int_0^{\pi/4}\frac{e^{\sec x}\left[\sin\left(x+\frac{\pi}{4}\right)\right]}{\cos x\,(1-\sin x)}\,dx.$

Sol. Let $I=\int_0^{\pi/4}\frac{e^{\sec x}\left[\sin\left(x+\frac{\pi}{4}\right)\right]}{\cos x(1-\sin x)}\,dx$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}\frac{e^{\sec x}(\sin x+\cos x)(1+\sin x)}{\cos x(1-\sin^2 x)}\,dx$$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}\frac{e^{\sec x}(\sin x+\cos x)(1+\sin x)}{\cos^2 x\cdot\cos x}\,dx$$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot(\sec x\tan x+\sec x)(\sec x+\tan x)\,dx$$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot[\sec x\tan x(\sec x+\tan x)+\sec^2 x+\sec x\tan x]\,dx$$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot[\sec x\tan x(\sec x+\tan x+1)+\sec^2 x]\,dx$$

$$=\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot\sec x\tan x(\sec x+\tan x+1)+\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot\sec^2 x\,dx$$

Applying integration by parts,

$$I=\frac{1}{\sqrt{2}}\{(\sec x+\tan x+1)\,e^{\sec x}\}_0^{\pi/4}$$
$$-\frac{1}{\sqrt{2}}\int_0^{\pi/4}(\sec x\tan x+\sec^2 x)\cdot e^{\sec x}dx+\frac{1}{\sqrt{2}}\int_0^{\pi/4}e^{\sec x}\cdot\sec^2 x\,dx$$
$$=\frac{1}{\sqrt{2}}\{(\sqrt{2}+1+1)\,e^{\sqrt{2}}-(1+1)\,e\}-\frac{1}{\sqrt{2}}[e^{\sec x}]_0^{\pi/4}$$
$$=\frac{1}{\sqrt{2}}(\sqrt{2}+2)\,e^{\sqrt{2}}-\sqrt{2}e-\frac{1}{\sqrt{2}}(e^{\sqrt{2}}-e)=\frac{1}{\sqrt{2}}(1+\sqrt{2})\,e^{\sqrt{2}}-\frac{e}{\sqrt{2}}$$

● ***Ex. 32*** *Evaluate* $\int_0^{\pi/4}\frac{x^2(\sin 2x-\cos 2x)\,dx}{(1+\sin 2x)\cos^2 x}$.

Sol. Let $I=\int_0^{\pi/4}\frac{x^2(\sin 2x-\cos 2x)\,dx}{(1+\sin 2x)\cos^2 x}$,

$$=\frac{1}{8}\int_0^{\pi/2}\frac{t^2(\sin t-\cos t)}{(1+\sin t)(\cos^2 t/2)}dt \qquad (\text{put } 2x=t)$$
$$I=\frac{1}{4}\int_0^{\pi/2}\frac{t^2(\sin t-\cos t)}{(1+\sin t)(1+\cos t)}dt \qquad \ldots(\text{i})$$
$$\left[\text{using, }\int_0^a f(x)\,dx=\int_0^a f(a-x)\,dx\right]$$
$$I=\frac{1}{4}\int_0^{\pi/2}\frac{\left(\frac{\pi}{2}-t\right)^2\cdot(\cos t-\sin t)}{(1+\cos t)(1+\sin t)}dt \qquad \ldots(\text{ii})$$

Adding Eqs. (i) and (ii), we get

$$2I=\frac{1}{4}\int_0^{\pi/2}\frac{\left(\pi t-\frac{\pi^2}{4}\right)(\sin t-\cos t)}{(1+\cos t)(1+\sin t)}dt \qquad \ldots(\text{iii})$$

where, $\int_0^{\pi/2}\frac{\sin t-\cos t}{(1+\cos t)(1+\sin t)}dt=0$

$$\left[\text{as }\int_0^{2a}f(x)\,dx=0,\text{ if } f(2a-x)=-f(x)\right]$$

∴ Eq. (iii) becomes

$$I=\frac{1}{8}\int_0^{\pi/2}\frac{\pi t(\sin t-\cos t)\,dt}{(1+\cos t)(1+\sin t)}+0$$
$$=\frac{\pi}{8}\int_0^{\pi/2}\frac{t\{(1+\sin t)-(1+\cos t)\}\,dt}{(1+\cos t)(1+\sin t)}$$
$$=\frac{\pi}{8}\int_0^{\pi/2}\frac{t\,dt}{1+\cos t}-\frac{\pi}{8}\int_0^{\pi/2}\frac{t\,dt}{1+\sin t}$$
$$=\frac{\pi}{8}\int_0^{\pi/2}\frac{t\,dt}{1+\cos t}-\frac{\pi}{8}\int_0^{\pi/2}\frac{(\pi/2-t)\,dt}{1+\cos t}$$
$$=\frac{2\pi}{8}\int_0^{\pi/2}\frac{t\,dt}{1+\cos t}-\frac{\pi^2}{16}\int_0^{\pi/2}\frac{dt}{1+\cos t}$$
$$=\frac{\pi}{8}\int_0^{\pi/2}t(\sec^2 t/2)\,dt-\frac{\pi^2}{16}\int_0^{\pi/2}(\sec^2 t/2)\,dt$$
$$=\frac{\pi}{8}\left\{\left(2t\cdot\tan\frac{t}{2}\right)_0^{\pi/2}-\int_0^{\pi/2}1\cdot 2\tan\frac{t}{2}dt\right\}-\frac{\pi^2}{16}\left(2\tan\frac{t}{2}\right)_0^{\pi/2}$$
$$=\frac{\pi}{8}\left\{(\pi-0)+4\left(\log\cos\frac{t}{2}\right)_0^{\pi/2}\right\}-\frac{\pi^2}{8}\{1-0\}$$
$$=\frac{\pi}{8}\left\{\pi+4\log\frac{1}{\sqrt{2}}\right\}-\frac{\pi^2}{8}=\frac{\pi^2}{8}+\pi\log\frac{1}{\sqrt{2}}-\frac{\pi^2}{8}$$
$$=\frac{\pi^2}{8}-\frac{1}{2}\pi\log 2=\frac{\pi^2}{16}-\frac{\pi}{4}\log 2$$

● ***Ex. 33*** *Evaluate* $\int_0^{\pi}\frac{x^2\cos x}{(1+\sin x)^2}dx$.

Sol. Let $I=\int_0^{\pi}\frac{x^2\cos x}{(1+\sin x)^2}dx=\int_0^{\pi}x^2\{(1+\sin x)^{-2}\cos x\}\,dx$

Applying integration by parts,

$$I=\left(x^2\frac{(1+\sin x)^{-1}}{-1}\right)_0^{\pi}-\int_0^{\pi}2x\cdot\frac{(1+\sin x)^{-1}}{-1}dx$$
$$=(-\pi^2+0)+2\int_0^{\pi}\frac{x}{1+\sin x}dx \qquad \ldots(\text{i})$$
$$\left[\text{using, }\int_0^a f(x)\,dx=\int_0^a f(a-x)\,dx\right]$$
$$I=-\pi^2+2\int_0^{\pi}\frac{(\pi-x)}{1+\sin x}dx \qquad \ldots(\text{ii})$$

Adding Eqs. (i) and (ii), we get

$$2I=-2\pi^2+2\int_0^{\pi}\frac{\pi}{1+\sin x}dx$$
$$=-2\pi^2+2\pi\int_0^{\pi}\frac{1-\sin x}{\cos^2 x}dx$$
$$=-2\pi^2+2\pi[\tan x-\sec x]_0^{\pi}$$
$$=-2\pi^2+2\pi[0-(-1-1)]=-2\pi^2+4\pi$$

∴ $I=-\pi^2+2\pi$

● ***Ex. 34*** *Compute the following integrals.*

(i) $\int_0^{\infty}f(x^n+x^{-n})\ln x\frac{dx}{x}=0$

(ii) $\int_0^{\infty}f(x^n+x^{-n})\ln x\frac{dx}{1+x^2}=0$

Sol. (i) Let $t=\ln x \Rightarrow x=e^t$

$$dx=e^t\,dt \quad \text{or} \quad \frac{dx}{x}=dt$$

Also, $x=0 \Rightarrow t=-\infty$

and $x=\infty \Rightarrow t=\infty$

∴ $\int_0^{\infty}f(x^n+x^{-n})\ln x\frac{dx}{x}=\int_{-\infty}^{\infty}f(e^{nt}+e^{-nt})\cdot t\,dt=0$

(∵ integrand is an odd function of t)

(ii) $\int_0^{\infty}f(x^n+x^{-n})\ln x\cdot\frac{dx}{1+x^2}=\int_{-\infty}^{\infty}f(e^{nt}+e^{-nt})\cdot t\cdot\frac{e^t}{1+e^{2t}}\cdot dt$

Now, if $h(t)=f(e^{nt}+e^{-nt})\cdot\dfrac{te^t}{1+e^{2t}}$

Then, $h(-t)=f(e^{-nt}+e^{nt})\cdot(-t)\cdot\dfrac{1}{e^t+e^{-t}}\quad\left(\because\dfrac{e^t}{1+e^{2t}}=\dfrac{1}{e^{-t}+e^t}\right)$

$h(-t)=-h(t)$

Thus, integrand is an odd function and hence

$$\int_0^{\infty} f(x^n+x^{-n})\ln x\cdot\frac{dx}{1+x^2}=0$$

● ***Ex. 35*** *Show that*

(a) $\int_0^{\infty}\sin x\,dx=1$ (b) $\int_0^{\infty}\cos x\,dx=0$

Sol. Let us first evaluate;

$$I=\int e^{-sx}\sin x\,dx \quad\text{and}\quad \mathcal{J}=\int e^{-sx}\cos x\,dx$$

Using integer by parts, we get

$$I=-e^{-sx}\cos x-s\mathcal{J} \qquad ...(i)$$

and $$\mathcal{J}=e^{-sx}\sin x+sI \qquad ...(ii)$$

Subtracting Eqs. (i) and (ii), we get

$$I=-e^{-sx}\left|\frac{\cos x+s\sin x}{1+s^2}\right|$$

$$\Rightarrow\quad \mathcal{J}=e^{-sx}\left|\sin x-\frac{s^2}{s^2+1}\sin x-\frac{s}{1+s^2}\cos x\right|$$

$$=e^{-sx}\left|\frac{\sin x-s\cos x}{1+s^2}\right|$$

Thus, $\int_0^{\infty}e^{-sx}\sin x\,dx=\dfrac{1}{s^2+1}$

and $\int_0^{\infty}e^{-sx}\cos x\,dx=\dfrac{s}{s^2+1}$

Now, $\int_0^{\infty}\sin x\,dx=\lim\limits_{s\to 0}\int_0^{\infty}e^{-sx}\sin x\,dx=\lim\limits_{s\to 0}\dfrac{1}{s^2+1}=1$

and $\int_0^{\infty}\cos x\,dx=\lim\limits_{s\to 0}\int_0^{\infty}e^{-sx}\cos x\,dx=\lim\limits_{s\to 0}\dfrac{s}{s^2+1}=0$

● ***Ex. 36*** *Find a function $g:R\to R$, continuous in $[0,\infty)$ and positive in $(0,\infty)$ satisfying $g(0)=1$ and* $\dfrac{1}{2}\int_0^x g^2(t)\,dt=\dfrac{1}{x}\left(\int_0^x g(t)\,dt\right)^2$.

Sol. Let $$f(x)=\int_0^x g(t)\,dt$$

$$\Rightarrow\quad f'(x)=g(x)$$

$$\Rightarrow\quad \frac{1}{2}\int_0^x (f'(t))^2\,dt=\frac{1}{2}\int_0^x g^2(t)\,dt \qquad ...(i)$$

$$\Rightarrow\quad \frac{1}{2}\left[\int_0^x g(t)\right]^2=\frac{1}{2}(f(x))^2$$

$$\Rightarrow\quad \frac{1}{2}\frac{\left[\int_0^x g(t)\right]^2}{x}=\frac{1}{2}\frac{(f(x))^2}{x}$$

$$\Rightarrow\quad \frac{1}{2}\cdot\frac{1}{2}\left[\int_0^x g^2(t)\right]dt=\frac{1}{2}\frac{(f(x))^2}{x}$$

$$\Rightarrow\quad \frac{1}{2}\int_0^x (f'(t))^2\,dt=\frac{1}{2}\frac{(f(x))^2}{x} \qquad \text{[using Eq. (i)]}$$

Differentiating both the sides w.r.t. x, we get

$$\frac{1}{2}[f'(x)]^2=\frac{x\,2f(x)f'(x)-(f(x))^2}{x^2}$$

$$\Rightarrow\quad \frac{1}{2}[g(x)]^2x^2=2xf(x)(g(x))-(f(x))^2$$

$$\Rightarrow\quad \left(\frac{xg(x)}{f(x)}\right)^2=4\left(\frac{xg(x)}{f(x)}\right)-2$$

$$\Rightarrow\quad t^2-4t+2=0,\ \text{where } t=\frac{xg(x)}{f(x)}$$

$$\Rightarrow\quad t=\frac{4\pm\sqrt{8}}{2}=2\pm\sqrt{2}\quad\text{or}\quad\frac{xf'(x)}{f(x)}=2\pm\sqrt{2}$$

$$\Rightarrow\quad \ln f(x)=2\pm\sqrt{2}\ln x+\text{constant}$$

$$\Rightarrow\quad f(x)=cx^{2+\sqrt{2}}\quad\text{or}\quad cx^{2-\sqrt{2}}$$

$$\Rightarrow\quad g(x)=f'(x)=c_1x^{1+\sqrt{2}}\quad\text{or}\quad c_2x^{1-\sqrt{2}}$$

where, c_1 and c_2 are constants of integration.

But g is continuous on $[0,\infty)$, then $c_2x^{1-\sqrt{2}}$ is ruled out.

Hence, $g(x)=c_1x^{1+\sqrt{2}}$

Also, $g(0)=c^1=1\ \Rightarrow\ g(x)=x^{1+\sqrt{2}}$

● ***Ex. 37*** *Let $I_n=\int_0^{\pi/4}\tan^n x\,dx\ (n>1$ and is an integer). Show that*

(i) $I_n+I_{n-2}=\dfrac{1}{n-1}$ (ii) $\dfrac{1}{2(n+1)}<I_n<\dfrac{1}{2(n-1)}$

Sol. (i) Given, $I_n=\int_0^{\pi/4}\tan^n x\,dx=\int_0^{\pi/4}\tan^{n-2}x\cdot\tan^2x\,dx$

$$=\int_0^{\pi/4}\sec^2x\cdot\tan^{n-2}x\,dx-\int_0^{\pi/4}\tan^{n-2}x\,dx$$

$$=\int_0^1 t^{n-2}\,dt-I_{n-2},\ \text{where } t=\tan x$$

$$I_n+I_{n-2}=\left(\frac{t^{n-1}}{n-1}\right)_0^1\qquad\therefore\ I_n+I_{n-2}=\frac{1}{n-1}$$

(ii) For $0<x<\pi/4$, we have $0<\tan^n x<\tan^{n-2}x$

So that; $$0<I_n<I_{n-2}$$

$$\therefore\quad I_n+I_{n+2}<2I_n<I_n+I_{n-2}$$

$$\Rightarrow\quad \frac{1}{n+1}<2I_n<\frac{1}{n-1}$$

$$\Rightarrow\quad \frac{1}{2(n+1)}<I_n<\frac{1}{2(n-1)}$$

Ex. 38 *If* $U_n = \int_0^{\pi} \frac{1-\cos nx}{1-\cos x}\,dx$, *where n is positive integer or zero, then show that* $U_{n+2} + U_n = 2U_{n+1}$. *Hence, deduce that* $\int_0^{\pi/2} \frac{\sin^2 n\theta}{\sin^2\theta} = \frac{1}{2}n\pi$.

Sol. $U_{n+2} - U_{n+1} = \int_0^{\pi} \frac{[1-\cos(n+2)x] - [1-\cos(n+1)x]}{1-\cos x}\,dx$

$$= \int_0^{\pi} \frac{\cos(n+1)x - \cos(n+2)x}{1-\cos x}\,dx$$

$$= \int_0^{\pi} \frac{2\sin\left(n+\frac{3}{2}\right)x \cdot \sin\frac{x}{2}}{2\sin^2\frac{x}{2}}\,dx$$

$$U_{n+2} - U_{n+1} = \int_0^{\pi} \frac{\sin\left(n+\frac{3}{2}\right)x}{\sin\frac{x}{2}}\,dx \quad \ldots(i)$$

$$\Rightarrow U_{n+1} - U_n = \int_0^{\pi} \frac{\sin\left(n+\frac{1}{2}\right)x}{\sin\frac{x}{2}}\,dx \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$(U_{n+2} - U_{n+1}) - (U_{n+1} - U_n) = \int_0^{\pi} \frac{\sin\left(n+\frac{3}{2}\right)x - \sin\left(n+\frac{1}{2}\right)x}{\sin\frac{x}{2}}\,dx$$

$$U_{n+2} + U_n - 2U_{n+1} = \int_0^{\pi} \frac{2\cos(n+1)x \cdot \sin x/2}{\sin x/2}\,dx$$

$$= 2\int_0^{\pi} \cos(n+1)x\,dx = 2\left(\frac{\sin(n+1)x}{n+1}\right)_0^{\pi} = 0$$

$\Rightarrow U_{n+2} + U_n = 2U_{n+1}$

$\Rightarrow U_n, U_{n+1}, U_{n+2}$ are in AP.

Now, $U_0 = \int_0^{\pi} \frac{1-1}{1-\cos x}\,dx = 0$

$$U_1 = \int_0^{\pi} \frac{1-\cos x}{1-\cos x}\,dx = \pi$$

$U_1 - U_0 = \pi$ (common difference)

$U_n = U_0 + n\pi = n\pi$

$U_n = n\pi$

Now, $I_n = \int_0^{\pi/2} \frac{\sin^2 n\theta}{\sin^2\theta}\,d\theta = \int_0^{\pi/2} \frac{1-\cos 2n\theta}{1-\cos 2\theta}\,d\theta$

$$= \frac{1}{2}\int_0^{\pi} \frac{1-\cos nx}{1-\cos x}\,dx = \frac{1}{2}n\pi$$

Ex. 39 *Prove that for any positive integer K,*

$$\frac{\sin 2Kx}{\sin x} = 2[\cos x + \cos 3x + \ldots + \cos(2K-1)x]$$

Hence, prove that $\int_0^{\pi/2} \sin 2Kx \cdot \cot x\,dx = \frac{\pi}{2}$.

Sol. To prove; $\sin 2Kx = 2\sin x[\cos x + \cos 3x + \cos 5x + \ldots + \cos(2K-1)x]$

Taking RHS, $[2\sin x\cos x + 2\sin x\cos 3x + 2\sin x\cos 5x + \ldots + 2\sin x\cos(2K-1)x]$

$= (\sin 2x) + (\sin 4x - \sin 2x) + [\sin 6x - \sin 4x) + \ldots + (\sin 2Kx - \sin(2K-2)x]$

$= \sin 2Kx$

Now, $\int_0^{\pi/2} \sin 2K\,x \cdot \cot x\,dx = \int_0^{\pi/2} \left(\frac{\sin 2Kx}{\sin x}\right) \cdot \cos x\,dx$

$$= \int_0^{\pi/2} 2\cos x[\cos x + \cos 3x + \ldots + \cos(2K-1)x]\,dx$$

$$= \int_0^{\pi/2} (1+\cos 2x)\,dx + \int_0^{\pi/2} (\cos 4x + \cos 2x)\,dx + \ldots + \int_0^{\pi/2} [\cos 2K\,x + \cos(2K-2)x]\,dx$$

But we know that,

$$\int_0^{\pi/2} (\cos 2nx)\,dx = 0, \forall\, n \in I \quad \text{and} \quad n \neq 0$$

$$\Rightarrow \int_0^{\pi/2} \sin 2Kx \cdot \cot x\,dx = \int_0^{\pi/2} 1\,dx + 0 = \frac{\pi}{2}$$

Ex. 40 *Evaluate* $\int_0^{\sqrt{3}} \frac{1}{1+x^2} \cdot \sin^{-1}\left(\frac{2x}{1+x^2}\right)dx$.

Sol. Let $I = \int_0^{\sqrt{3}} \frac{1}{1+x^2}\sin^{-1}\left(\frac{2x}{1+x^2}\right)dx$

Now, $\sin^{-1}\left(\frac{2x}{1+x^2}\right) = \begin{cases} 2\tan^{-1}x, & \text{if } -1 \le x \le 1 \\ \pi - 2\tan^{-1}x, & \text{if } x > 1 \end{cases}$

$$\therefore I = \int_0^1 \frac{1}{1+x^2}\sin^{-1}\left(\frac{2x}{1+x^2}\right)dx + \int_1^{\sqrt{3}} \frac{1}{1+x^2} \cdot \sin^{-1}\left(\frac{2x}{1+x^2}\right)dx$$

$$= \int_0^1 \frac{2\tan^{-1}x}{1+x^2}\,dx + \int_1^{\sqrt{3}} \frac{\pi - 2\tan^{-1}x}{1+x^2}\,dx$$

$$= 2\int_0^1 \frac{\tan^{-1}x}{1+x^2}\,dx + \pi\int_1^{\sqrt{3}} \frac{1}{1+x^2}\,dx - 2\int_1^{\sqrt{3}} \frac{\tan^{-1}x}{1+x^2}\,dx$$

$$= 2\int_0^{\pi/4} t\,dt + \pi(\tan^{-1}x)_1^{\sqrt{3}} - 2\int_{\pi/4}^{\pi/3} t\,dt \qquad (\text{put } \tan^{-1}x = t)$$

$$= 2\left(\frac{t^2}{2}\right)_0^{\pi/4} + \pi\{\tan^{-1}\sqrt{3} - \tan^{-1}1\} - 2\left(\frac{t^2}{2}\right)_{\pi/4}^{\pi/3}$$

$$= \frac{\pi^2}{16} + \pi\left\{\frac{\pi}{3} - \frac{\pi}{4}\right\} - \left\{\frac{\pi^2}{9} - \frac{\pi^2}{16}\right\} = \frac{7}{72}\pi^2$$

Ex. 41 *Prove that* $\int_0^x e^{xt} \cdot e^{-t^2}\,dt = e^{x^2/4}\int_0^x e^{-t^2/4}\,dt$.

Sol. Let $I = \int_0^x e^{xt} \cdot e^{-t^2}\,dt$. Put $t = \frac{x+z}{2} \Rightarrow dt = \frac{1}{2}dz$

$$\therefore I = \int_0^x e^{tx} \cdot e^{-t^2}\,dt = \frac{1}{2}\int_{-x}^x e^{\left(\frac{x+z}{2}\right)x} \cdot e^{-\left(\frac{x+z}{2}\right)^2}dz$$

$$= \frac{1}{2}\int_{-x}^x e^{\left(\frac{x+z}{2}\right)\left(x - \frac{x+z}{2}\right)}dz = \frac{1}{2}\int_{-x}^x e^{\left(\frac{x+z}{2}\right)\left(\frac{x-z}{2}\right)}dz$$

$$= \frac{1}{2}\int_{-x}^{x} e^{\frac{x^2}{4}-\frac{z^2}{4}}\,dz = \frac{1}{2}e^{x^2/4}\cdot\int_{-x}^{x} e^{-z^2/4}\,dz$$

$$= \frac{1}{2}e^{x^2/4}\int_{-x}^{x} e^{-t^2/4}\,dt = \frac{1}{2}e^{x^2/4}\cdot 2\int_{0}^{x} e^{-t^2/4}\,dt$$

$$\left[\text{using, } \int_{-a}^{a} f(x)\,dx = 2\int_{0}^{a} f(x)\,dx, \text{ when } f(-x)=f(x)\right]$$

$$= e^{x^2/4}\int_{0}^{x} e^{-t^2/4}\,dt$$

$$\Rightarrow \quad \int_{0}^{x} e^{xt}\cdot x^{-t^2}\,dt = e^{x^2/4}\int_{0}^{x} e^{-t^2/4}\,dt$$

● ***Ex. 42*** *If* $f(x) = e^x + \int_0^1 (e^x + te^{-x})\, f(t)\,dt$, *find* $f(x)$.

Sol. We can write $f(x) = Ae^x + Be^{-x}$, where

$$A = 1 + \int_0^1 f(t)\,dt \quad \text{and} \quad B = \int_0^1 tf(t)\,dt$$

$$\therefore \quad A = 1 + \int_0^1 (Ae^t + Be^{-t})\,dt = 1 + (Ae^t - Be^{-t})_0^t$$

$$A = 1 + A(e^1 - 1) - B(e^{-1} - 1)$$

$$\Rightarrow \quad (2-e)A + (e^{-1}-1)B = 1 \qquad \ldots(\text{i})$$

$$B = \int_0^1 t(Ae^t + Be^{-t})\,dt$$

$$= A(te^t - e^t)_0^t + B(-te^{-t} - e^{-t})_0^1$$

$$B = A + B(1 - 2e^{-1})$$

$$\Rightarrow \quad A - 2e^{-1}B = 0 \qquad \ldots(\text{ii})$$

From Eqs. (i) and (ii), we get

$$A = \frac{2(e-1)}{4e-2e^2},\ B = \frac{e-1}{4-2e}$$

Hence, $$f(x) = \frac{2(e-1)}{4e-2e^2}\cdot e^x + \frac{e-1}{4-2e}\cdot e^{-x}$$

● ***Ex. 43*** *If* $|a| < 1$, *show that*

$$\int_0^{\pi} \frac{\log(1 + a\cos x)}{\cos x}\,dx = \pi \sin^{-1} a.$$

Sol. Given, $|a| < 1$

Let $$f(a) = \int_0^{\pi} \frac{\log(1 + a\cos x)}{\cos x}\,dx$$

$$\therefore \quad f'(a) = \int_0^{\pi} \frac{\cos x}{\cos x\cdot(1 + a\cos x)}\,dx = \int_0^{\pi} \frac{dx}{1 + a\cos x}$$

(differentiating w.r.t. 'a' using Leibnitz rule)

$$\left(\begin{array}{l}\text{put } \tan\dfrac{x}{2} = t \Rightarrow \dfrac{dx}{dt} = \dfrac{2}{1+t^2}, \text{ when } x = 0, t = 0\\ \text{and when } x = \pi, t \to \infty\end{array}\right)$$

$$\Rightarrow \quad f'(a) = \int_0^{\infty} \frac{\frac{2dt}{1+t^2}}{1 + a\left(\frac{1-t^2}{1+t^2}\right)}$$

$$= \int_0^{\infty} \frac{2dt}{(1+t^2) + a(1-t^2)} = \int_0^{\infty} \frac{2dt}{(1-a)t^2 + (1+a)}$$

$$= \frac{2}{1-a}\int_0^{\infty} \frac{dt}{t^2 + \left(\sqrt{\frac{1+a}{1-a}}\right)^2}$$

$$= \frac{2}{1-a}\cdot\frac{1}{\sqrt{(1+a)/(1-a)}}\cdot\left(\tan^{-1} t\sqrt{\frac{1-a}{1+a}}\right)_0^{\infty} = \frac{2}{\sqrt{1-a^2}}\cdot\frac{\pi}{2} = \frac{\pi}{\sqrt{1-a^2}}$$

(integrating both the sides w.r.t. 'a')

$$\Rightarrow \quad f(a) = \pi\sin^{-1} a + c$$

But $$f(0) = \int_0^{\pi} \frac{\log(1 + 0\cos x)\,dx}{\cos x} = 0$$

$$\Rightarrow \quad c = 0$$

$$\therefore \quad f(a) = \pi\sin^{-1} a$$

● ***Ex. 44*** *Evaluate* $\int_0^{\pi/2} \operatorname{cosec}\theta\,\tan^{-1}(c\sin\theta)\,d\theta$.

Sol. Let $$f(c) = \int_0^{\pi/2} \operatorname{cosec}\theta\cdot\tan^{-1}(c\sin\theta)\,d\theta$$

$$\therefore \quad f'(c) = \int_0^{\pi/2} \operatorname{cosec}\theta\cdot\frac{(\sin\theta)}{1 + c^2\sin^2\theta}\,d\theta + 0 - 0$$

$$= \int_0^{\pi/2} \frac{d\theta}{1 + c^2\sin^2\theta}$$

$$= \int_0^{\pi/2} \frac{\operatorname{cosec}^2\theta\,d\theta}{c^2 + \operatorname{cosec}^2\theta} = \int_0^{\pi/2} \frac{\operatorname{cosec}^2\theta\,d\theta}{(c^2+1) + \cot^2\theta}$$

$$= -\frac{1}{\sqrt{c^2+1}}\left(\tan^{-1}\frac{\cot\theta}{\sqrt{c^2+1}}\right)_0^{\pi/2}$$

$$f'(c) = \frac{\pi}{2\sqrt{c^2+1}}$$

Integrating both the sides, we get

$$f(c) = \int \frac{\pi\,dc}{2\sqrt{c^2+1}} = \frac{\pi}{2}\log(c + \sqrt{c^2+1}) + A$$

where, $f(0) = A$

But $$f(0) = \int_0^{\pi/2} \operatorname{cosec}\theta\tan^{-1}(0)\,d\theta = 0$$

$$\Rightarrow \quad f(c) = \frac{\pi}{2}\log(c + \sqrt{c^2+1})$$

● ***Ex. 45*** *Evaluate* $\int_0^{\pi/2} \sec\theta\cdot\tan^{-1}(a\cos\theta)\,d\theta$.

Sol. Given definite integral is a function of 'a'. Let its value be $I(a)$.

Then, $$I(a) = \int_0^{\pi/2} \sec\theta\cdot\tan^{-1}(a\cos\theta)\,d\theta$$

$$\Rightarrow \quad I'(a) = \int_0^{\pi/2} \sec\theta\cdot\frac{1}{1 + a^2\cos^2\theta}\cdot\cos\theta\,d\theta + 0 - 0$$

(using Leibnitz rule)

$$= \int_0^{\pi/2} \frac{1}{1 + a^2\cos^2\theta}\,d\theta = \int_0^{\pi/2} \frac{\sec^2\theta}{\sec^2\theta + a^2}\,d\theta$$

$$= \int_0^{\pi/2} \frac{\sec^2\theta}{1+\tan^2\theta + a^2}\, d\theta \qquad (\text{put } \tan\theta = t)$$

$$= \int_0^{\infty} \frac{dt}{t^2 + (a^2+1)} = \frac{1}{\sqrt{a^2+1}} \left(\tan^{-1} \frac{t}{\sqrt{a^2+1}} \right)_0^{\infty}$$

$$= \frac{1}{\sqrt{a^2+1}} \left(\frac{\pi}{2} - 0 \right) \Rightarrow I'(a) = \frac{\pi}{2\sqrt{a^2+1}}$$

Integrating both the sides w.r.t. 'a', we get

$$I(a) = \frac{\pi}{2} \log | a + \sqrt{a^2+1} | + C$$

Since, $I(0) = 0 + C$

$\Rightarrow$ $I(a) = \frac{\pi}{2} \log | a + \sqrt{1+a^2} |$

● **Ex. 46** *Let f be a continuous function on $[a, b]$. Prove that there exists a number $x \in [a, b]$ such that* $\int_a^x f(t)\, dt = \int_x^b f(t)\, dt$.

Sol. Let $g(x) = \int_a^x f(t)\, dt - \int_x^b f(t)\, dt,\ x \in [a, b]$

We have, $g(a) = -\int_a^b f(t)\, dt$ and $g(b) = \int_a^b f(t)\, dt$

$\Rightarrow$ $g(a) \cdot g(b) = -\left(\int_a^b f(t)\, dt \right)^2 \le 0$

Clearly, $g(x)$ is continuous in $[a, b]$ and $g(a) \cdot g(b) \le 0$.

It implies that $g(x)$ will become zero at least once in $[a, b]$.

Hence, $\int_a^x f(t)\, dt = \int_x^b f(t)\, dt$ for atleast one value of $x \in [a, b]$.

● **Ex. 47** *If $f(x) = x + \int_0^1 (xy^2 + x^2 y)\, (f(y))\, dy$, find $f(x)$.*

Sol. Given, $f(x) = x + x \int_0^1 y^2 f(y)\, dy + x^2 \int_0^1 y\, f(y)\, dy$

$$= x \left(1 + \int_0^1 y^2 f(y)\, dy \right) + x^2 \left(\int_0^1 y\, f(y)\, dy \right)$$

$\Rightarrow$ $f(x)$ is a quadratic expression.

$\Rightarrow$ $f(x) = ax + bx^2$ or $f(y) = ay + by^2$ ...(i)

where, $a = 1 + \int_0^1 y^2 f(y)\, dy = 1 + \int_0^1 y^2 (ay + by^2)\, dy$

$$= 1 + \left(\frac{ay^4}{4} + \frac{by^5}{5} \right)_0^1 \quad a = 1 + \left(\frac{a}{4} + \frac{b}{5} \right)$$

$\Rightarrow$ $20a = 20 + 5a + 4b$ or $15a - 4b = 20$ ...(ii)

and $b = \int_0^1 y\, f(y)\, dy = \int_0^1 y(ay + by^2)\, dy$

$$= \left(\frac{ay^3}{3} + \frac{by^4}{4} \right)_0^1 \Rightarrow b = \frac{a}{3} + \frac{b}{4}$$

$\Rightarrow$ $12b = 4a + 3b$ or $9b - 4a = 0$ ...(iii)

From Eqs. (ii) and (iii),

$$a = \frac{180}{119} \quad \text{and} \quad b = \frac{80}{119}$$

$\therefore$ Eq. (i) reduces to

$$f(x) = \frac{80x^2 + 180x}{119}$$

● **Ex. 48** *Prove that*

$$\int_0^x \{ \int_0^u f(t)\, dt \}\, du = \int_0^x (x - u)\, f(u)\, du.$$

Sol. Here, applying integration by parts to

$$\int_0^x \underbrace{1}_{\text{II}} \cdot \underbrace{\{ \int_0^u f(t)\, dt \}\, du}_{\text{I}}$$

i.e. taking '1' as second function and $\int_0^u f(t)\, dt$ as first function, we have

$$\int_0^x 1 \cdot \left\{ \int_0^u f(t)\, dt \right\} du = \left\{ \int_0^u f(t)\, dt \right\}_0^x \cdot (u)_0^x - \int_0^x f(u) \cdot u\, du$$

$$= \left(u \int_0^u f(t)\, dt \right)_0^x - \int_0^x uf(u)\, du$$

$$= x \int_0^x f(t)\, dt - \int_0^x uf(u)\, du$$

$$= \int_0^x (x - u)\, f(u)\, du$$

● **Ex. 49** *Evaluate $\int_0^{3\pi/2} (\log | \sin x |)\, (\cos(2nx))\, dx, n \in N$.*

Sol. Let $I(n) = \int_0^{3\pi/2} (\log | \sin x |)(\cos 2nx)\, dx$

$$I(n) = \left(\underset{\text{I}}{\log | \sin x |} \cdot \underset{\text{II}}{\frac{\sin 2nx}{2n}} \right)_0^{3\pi/2} - \int_0^{3\pi/2} \cot x \cdot \frac{\sin 2nx}{2n}\, dx$$

(using integration by parts)

$$I(n) = 0 - \frac{1}{2n} \int_0^{3\pi/2} \frac{\sin 2nx \cdot \cos x}{\sin x}\, dx = 0 - \frac{1}{2} I_1(n) \qquad ...(i)$$

Let $I_1(n) = \int_0^{3\pi/2} \frac{\sin(2nx) \cos x}{\sin x}\, dx$

$$I_1(n+1) = \int_0^{3\pi/2} \frac{\sin(2n+2)\, x \cdot \cos x}{\sin x}\, dx$$

$\therefore$ $I_1(n+1) - I_1(n) = \int_0^{3\pi/2} \frac{(\sin(2n+2)\, x - \sin 2nx) \cdot \cos x}{\sin x}\, dx$

$$= \int_0^{3\pi/2} \frac{2\cos(2n+1)\, x \cdot \sin x \cdot \cos x}{\sin x}\, dx$$

$$= \int_0^{3\pi/2} (\cos(2n+2)\, x + \cos 2nx)\, dx$$

$$= \left(\frac{\sin(2n+2)\, x}{(2n+2)} + \frac{\sin(2n)\, x}{2n} \right)_0^{3\pi/2} = 0 + 0$$

$\Rightarrow$ $I_1(n+1) = I_1(n) = \ldots = I_1(1)$

$\therefore$ $I_1(1) = \int_0^{3\pi/2} \frac{\sin 2x \cdot \cos x}{\sin x}\, dx = \int_0^{3\pi/2} \frac{2 \sin x \cos x \cdot \cos x}{\sin x}\, dx$

$$= \int_0^{3\pi/2} 2\cos^2 x\, dx = \int_0^{3\pi/2} (1+\cos 2x)\, dx$$

$$= \left(x + \frac{\sin 2x}{2}\right)_0^{3\pi/2}$$

$$\Rightarrow \quad I_1(1) = \frac{3\pi}{2} = I_1(n) \quad \Rightarrow \quad I(n) = -\frac{1}{2n} I_1(n) \qquad \text{[using Eq. (i)]}$$

$$\therefore \quad I(n) = -\frac{3\pi}{4n}$$

● ***Ex. 50*** *Evaluate* $\int_0^{\infty} e^{-x} \sin^n x\, dx$, *if n is an even integer.*

Sol. Here, $I_n = \int_0^{\infty} e^{-x} \sin^n x\, dx$

$$= (-\sin^n x\, e^{-x})_0^{\infty} + n\int_0^{\infty} \sin^{n-1} x \cos x\, e^{-x}\, dx$$

$$= n\int_0^{\infty} (\sin^{n-1} x \cdot \cos x)(e^{-x})\, dx \ [\text{where } (-\sin^n x\, e^{-x})_0^{\infty} = 0]$$

$$\Rightarrow \quad I_n = n[(-\sin^{n-1} \underset{\text{I}}{x} \cdot \cos x\, \underset{\text{II}}{e^{-x}})_0^{\infty}$$

$$+ (n-1)\int_0^{\infty} \sin^{n-2} x \cos^2 x\, e^{-x} dx - \int_0^{\infty} \sin^n x\, e^{-x}\, dx]$$

$$I_n = n(n-1)\int_0^{\infty} e^{-x} \sin^{n-2} x\, dx - n^2 \int_0^{\infty} e^{-x} \sin^n x\, dx$$

$$= n(n-1) I_{n-2} - n^2 I_n$$

$$\Rightarrow \quad (n^2+1) I_n = n(n-1) I_{n-2}$$

$$\therefore \quad I_n = \frac{n(n-1)}{n^2+1} I_{n-2}$$

Replacing n by $(n-2), (n-4), \ldots, 2$, we get

$$I_{n-2} = \frac{(n-2)(n-3)}{(n-2)^2+1} I_{n-4} = \frac{(n-1)(n-3)}{(n-2)^2+1} \cdot \frac{(n-4)(n-5)}{(n-4)^2+1} I_{n-6}$$

... and so on.

$$I_2 = \frac{2(2-1)}{2^2+1} I_0$$

$$\therefore \quad I_n = \frac{n(n-1)}{n^2+1} \cdot \frac{(n-2)(n-3)}{(n-2)^2+1} \cdot \frac{(n-4)(n-5)}{(n-3)^2+1} \cdots \frac{2(2-1)}{2^2+1} I_0$$

$$= \frac{n!}{\prod_{r=1}^{n/2} \{1+(2r)^2\}} \cdot I_0 = \frac{n!}{\prod_{r=1}^{n/2} 1+4r^2} \left(\because I_0 = \int_0^{\infty} e^{-x} dx = 1\right)$$

● ***Ex. 51*** *Evaluate* $\int_0^1 (tx+1-x)^n\, dx, n \in N$ *and t is independent of x. Hence, show*

$$\int_0^1 x^k (1-x)^{n-k}\, dx = \frac{1}{{}^nC_k (n+1)}.$$

Sol. Here, $I = \int_0^1 (tx+1-x)^n\, dx = \int_0^1 ((t-1)x+1)^n\, dx$

$$= \left\{\frac{((t-1)x+1)^{n+1}}{(n+1)(t-1)}\right\}_0^1$$

$$= \frac{1}{n+1}\{t^n + t^{n-1} + t^{n-2} + \ldots + t + 1\} \qquad \ldots(\text{i})$$

Again, $I = \int_0^1 (tx+1-x)^n\, dx = \int_0^1 \{(1-x)+tx\}^n\, dx$

$$= \int_0^1 \{{}^nC_0 (1-x)^n + {}^nC_1 (1-x)^{n-1}(tx) + {}^nC_2 (1-x)^{n-2}$$

$$(tx)^2 + \ldots + {}^nC_r (1-x)^{n-r} (tx)^r + \ldots + {}^nC_n (tx)^n\}\, dx$$

$$= \int_0^1 \left\{\sum_{r=0}^{n} {}^nC_r (1-x)^{n-r} (tx)^r\right\} dx$$

$$= \sum_{r=0}^{n} {}^nC_r\, t^r \int_0^1 \{(1-x)^{n-r} x^r\}\, dx \qquad \ldots(\text{ii})$$

From Eqs. (i) and (ii),

$$\sum_{r=0}^{n} {}^nC_r\, t^r \int_0^1 (1-x)^{n-r} x^r\, dx = \frac{1}{n+1}\{t^n + t^{n-1} + t^{n-2} + \ldots + t + 1\}$$

Equating coefficient of t^k on both the sides, we get

$${}^nC_k \int_0^1 (1-x)^{n-k} x^k\, dx = \frac{1}{n+1}$$

$$\Rightarrow \qquad \int_0^1 (1-x)^{n-k} x^k\, dx = \frac{1}{{}^nC_k (n+1)}$$

● ***Ex. 52*** *Given a real valued function* $f(x)$ *which is monotonic and differentiable, prove that for any real numbers a and b;*

$$\int_a^b \{f^2(x) - f^2(a)\}\, dx = \int_{f(a)}^{f(b)} 2x\{b - f^{-1}(x)\}\, dx$$

Sol. As, $f(x)$ is differentiable and monotonic.

$\therefore$ $f^{-1}(x)$ exists.

Let $\quad f^{-1}(x) = t \Rightarrow x = f(t)$ or $dx = f'(t)\, dt$

As, $\quad x = f(a) \Rightarrow f^{-1}\{f(a)\} = t \Rightarrow t = a$

and $\quad x = f(b) \Rightarrow f^{-1}\{f(b)\} = t \Rightarrow t = b$

$$\therefore \quad \int_{f(a)}^{f(b)} 2x\{b - f^{-1}(x)\}\, dx = \int_a^b 2f(t)(b-t) f'(t)\, dt$$

$$= \int_a^b (b-t)\{2f(t) f'(t)\}\, dt$$

$$= ((b-t)\{f(t)\}^2)_a^b + \int_a^b \{f(t)\}^2\, dt$$

$$= -(b-a)\{f(a)\}^2 + \int_a^b \{f(t)\}^2\, dt$$

$$= \int_a^b (\{f(t)\}^2 - \{f(a)\}^2)\, dt$$

$$= \int_a^b \{f^2(x) - f^2(a)\}\, dx$$

● ***Ex. 53*** *Evaluate*

$$\int_0^1 \frac{\sin\theta\,(\cos^2\theta - \cos^2 \pi/5)(\cos^2\theta - \cos^2 2\pi/5)}{\sin 5\theta}\, d\theta.$$

Sol. We know,

$$z^{10} - 1 = (z^2-1)\left[z^2 - 2\cos\left(\frac{\pi}{5}\right)z + 1\right]\left[z^2 - 2\left(\cos\frac{2\pi}{5}\right)z + 1\right]$$

$$\times\left(z^2 - 2\cos\frac{4\pi}{5}z + 1\right)\left(z^2 - 2\cos\frac{6\pi}{5}z + 1\right)$$

or $$z^5-\frac{1}{z^5}=\left(z-\frac{1}{z}\right)\left(z-2\cos\frac{\pi}{5}+\frac{1}{z}\right)\left(z-2\cos\frac{2\pi}{5}+\frac{1}{z}\right)$$
$$\times\left(z-2\cos\frac{4\pi}{5}+\frac{1}{z}\right)\left(z-2\cos\frac{6\pi}{5}+\frac{1}{z}\right)$$

Put $z=\cos\theta+i\sin\theta$

$\Rightarrow 2i\sin 5\theta=(2i\sin\theta)(2\cos\theta-2\cos\pi/5)(2\cos\theta-2\cos 2\pi/5)$
$\times(2\cos\theta-2\cos 4\pi/5)(2\cos\theta-2\cos 6\pi/5)$

$\Rightarrow \sin 5\theta=16\sin\theta(\cos^2\theta-\cos^2\pi/5)(\cos^2\theta-\cos^2 2\pi/5)$

$\Rightarrow \dfrac{\sin\theta(\cos^2\theta-\cos^2\pi/5)(\cos^2\theta-\cos^2 2\pi/5)}{\sin 5\theta}=\dfrac{1}{16}$

$\therefore \int_0^1 \dfrac{\sin\theta(\cos^2\theta-\cos^2\pi/5)(\cos^2\theta-\cos^2 2\pi/5)}{\sin 5\theta}d\theta$
$=\int_0^1 \dfrac{1}{16}d\theta=\dfrac{1}{16}$

● **Ex. 54** *Show that* $\lim\limits_{n\to\infty}\sum\limits_{k=0}^{n}\dfrac{{}^nC_K}{n^K(K+3)}=e-2$.

Sol. $\lim\limits_{n\to\infty}\sum\limits_{K=0}^{n}\dfrac{{}^nC_K}{n^K(K+3)}=\lim\limits_{n\to\infty}\sum\limits_{K=0}^{n}\dfrac{1}{K+3}{}^nC_K\cdot\dfrac{1}{n^K}$

$=\lim\limits_{n\to\infty}\sum\limits_{K=0}^{n}{}^nC_K\cdot\dfrac{1}{n^K}\int_0^1 x^{K+2}dx\left(\because\dfrac{1}{K+3}=\int_0^1 x^{K+2}dx\right)$

$=\int_0^1\left(x^2\lim\limits_{n\to\infty}\sum\limits_{K=0}^{n}{}^nC_K\cdot\left(\dfrac{x}{n}\right)^K\right)dx$

$=\int_0^1 x^2\left\{\lim\limits_{n\to\infty}\left(1+\dfrac{x}{n}\right)^n\right\}dx$

$=\int_0^1 x^2\cdot e^x dx\qquad\left[\because\lim\limits_{n\to\infty}\left(1+\dfrac{x}{n}\right)^n=e^x\right]$

$=(x^2\cdot e^x)_0^1-\int_0^1 2x\cdot e^x dx=e-2\left\{(xe^x)_0^1-\int_0^1 e^x dx\right\}$

$=e-2\{e-e+1\}=e-2$

● **Ex. 55** *Let* $I=\int_0^{\pi/2}\dfrac{\cos x}{a\cos x+b\sin x}dx$

and $J=\int_0^{\pi/2}\dfrac{\sin x}{a\cos x+b\sin x}dx$, *where* $a>0$ and $b>0$.

Compute the values of I and J.

Sol. $\because$ $$aI+bJ=\frac{\pi}{2}\qquad\text{...(i)}$$

and $$bI-aJ=\int_0^{\pi/2}\frac{b\cos x-a\sin x}{a\cos x+b\sin x}dx$$

$\therefore$ $$bI-aJ=\ln[a\cos x+b\sin x]_0^{\pi/2}$$

$\Rightarrow$ $$bI-aJ=\ln\left(\frac{b}{a}\right)\qquad\text{...(ii)}$$

From Eqs. (i) and (ii),

$$a^2I+abJ=\frac{a\pi}{2}$$
$$\underline{b^2I-abJ=b\ln(b/a)}$$
$$I=\frac{1}{a^2+b^2}\left[\frac{a\pi}{2}+b\ln\left(\frac{b}{a}\right)\right]$$

Again, $$abI+b^2I=\frac{b\pi}{2}$$

and $$\underline{abI-a^2J=a\ln(b/a)}$$

On subtracting, we get $J=\dfrac{1}{a^2+b^2}\left[\dfrac{b\pi}{2}-a\ln\left(\dfrac{b}{a}\right)\right]$

Aliter Convert $a\cos x+b\sin x$ into a single cosine say $\cos(x+\phi)$ and put $(x+\phi)=t$.

● **Ex. 56** *Evaluate* $\int_0^\infty\dfrac{\ln x\,dx}{x^2+2x+4}$.

Sol. $I=\int_0^\infty\dfrac{\ln x\,dx}{x^2+2x+4}$ (put $x=2t\Rightarrow dx=2dt$ to make coefficient of x^2 and constant term same)

$$=2\int_0^\infty\frac{\ln 2+\ln t}{4(t^2+t+1)}dt=\frac{\ln 2}{2}\underbrace{\int_0^\infty\frac{dt}{t^2+t+1}}_{I_1}+\frac{1}{2}\underbrace{\int_0^\infty\frac{\ln t\,dt}{t^2+t+1}}_{I_2=\text{zero}}$$

$$I_2=\int_0^\infty\frac{\ln t\,dt}{t^2+t+1}\left(\text{put } t=\frac{1}{y}\Rightarrow dt=-\frac{1}{y^2}dy\right)$$

$$I_2=\int_\infty^0\frac{\ln y\cdot(+1)}{\left(\dfrac{1}{y^2}+\dfrac{1}{y}+1\right)y^2}dy$$

$$I_2=\int_\infty^0\frac{\ln y\,dy}{y^2+y+1}=-\int_\infty^0\frac{\ln y\,dy}{y^2+y+1}=-I_2$$

Now, $I_1=\int_0^\infty\dfrac{dt}{\left(t+\dfrac{1}{2}\right)^2+\left(\dfrac{\sqrt{3}}{2}\right)^2}=\left[\dfrac{2}{\sqrt{3}}\tan^{-1}\dfrac{[t+(1/2)]^2}{\sqrt{3}}\right]_0^\infty$

$=\dfrac{2}{\sqrt{3}}\left[\dfrac{\pi}{2}-\dfrac{\pi}{6}\right]=\dfrac{2\pi}{3\sqrt{3}}\qquad\therefore I=\dfrac{\ln 2}{2}\cdot\dfrac{2\pi}{3\sqrt{3}}=\dfrac{\pi\ln 2}{3\sqrt{3}}$

Note For $a>0$, $I=\int_0^\infty\dfrac{\ln x\,dx}{ax^2+bx+a}=0$

[**Hint** By putting $x=1/t$, we get $I=-I$, so $I=0$]

● **Ex. 57** *Find a function* f, *continuous for all x (and not zero everywhere) such that* $f^2(x)=\int_0^x\dfrac{f(t)\sin t}{2+\cos t}dt$.

Sol. We have, $f^2(x)=\int_0^x\dfrac{f(t)\sin t}{2+\cos t}dt$

(Note that $f^2(x)$ being an integral function of a continuous function is continuous and differentiable)

$$2f(x)f'(x)=\frac{f(x)\cdot\sin x}{2+\cos x}$$

Integrating, we get $2f(x)=C-\ln(2+\cos x)$

$\because$ $x=0\Rightarrow f(0)=0\Rightarrow C=\ln 3$

$\therefore$ $$f(x)=\frac{1}{2}\ln\frac{3}{2+\cos x}$$

● ***Ex. 58*** *Evaluate* $\int_0^\infty \frac{\tan^{-1} ax - \tan^{-1} x}{x} dx$, *where a is a parameter.*

Sol. Let $I = \int_0^\infty \frac{\tan^{-1} ax - \tan^{-1} x}{x} dx$

$$\therefore \quad \frac{dI}{da} = \int_0^\infty \frac{1 \cdot x}{(1 + a^2x^2)x} dx = \int_0^\infty \frac{dx}{1 + a^2x^2}$$

$$= \frac{1}{a^2} \int_0^\infty \frac{dx}{x^2 + \frac{1}{a^2}} = \frac{1}{a^2} [a \tan^{-1} x]_0^\infty = \frac{\pi}{2a}$$

$$\int dI = \frac{\pi}{2} \int \frac{da}{a} \Rightarrow I = \frac{\pi}{2} \ln a + C$$

When $a = 1$ and $I = 0$ then $C = 0$

Hence, $I = \frac{\pi}{2} \ln a$

● ***Ex. 59*** *Evalute* $\int_0^1 \frac{\ln(1 - a^2x^2)}{x^2\sqrt{(1 - x^2)}} dx \, (a^2 < 1).$

Sol. Let $I = \int_0^1 \frac{\ln(1 - a^2x^2)}{x^2\sqrt{(1 - x^2)}} dx, |a| < 1$

$$\therefore \quad \frac{dI}{da} = \int_0^1 \frac{-2ax^2}{(1 - a^2x^2)} \cdot \frac{dx}{x^2\sqrt{1 - x^2}} \qquad (\text{put } x = \sin\theta)$$

$$= \int_0^{\pi/2} \frac{2a \, d\theta}{a^2 \sin^2\theta - 1} = \int_0^{\pi/2} \frac{2a \sec^2\theta \, d\theta}{a^2 \tan^2\theta - (1 + \tan^2\theta)}$$

$$= -\int_0^{\pi/2} \frac{2a \sec^2\theta \, d\theta}{(1 - a^2)\tan^2\theta + 1} \qquad (\text{put } \tan\theta = 1)$$

$$= \int_0^\infty \frac{2a \, dt}{(1 - a^2)t^2 + 1} \text{ or } -\frac{2a}{(1 - a^2)} \int_0^\infty \frac{dt}{t^2 + \left(\frac{1}{\sqrt{1 - a^2}}\right)^2}$$

$$= -\frac{2a}{\sqrt{1 - a^2}} [\tan^{-1} t\sqrt{1 - a^2}]_0^\infty = -\frac{\pi \cdot 2a}{2\sqrt{1 - a^2}} = -\frac{\pi a}{\sqrt{1 - a^2}}$$

or $I = \pi\sqrt{1 - a^2} + C$

If $a = 0$ and $I = 0$, then $C = -\pi$

$$\therefore \quad I = \pi\left(\sqrt{1 - a^2} - 1\right)$$

● ***Ex. 60*** *Evaluate* $\int_0^{\pi/2} \ln\left(\frac{1 + a\sin x}{1 - a\sin x}\right) \frac{dx}{\sin x} (|a| < 1).$

Sol. Let $I = \int_0^{\pi/2} \ln\left(\frac{1 + a\sin x}{1 - a\sin x}\right) \frac{dx}{\sin x} (|a| < 1)$

$$\therefore \quad \frac{dI}{da} = \int_0^{\pi/2} \frac{2\sin x}{(1 - a^2\sin^2 x)} \cdot \frac{dx}{\sin x}$$

$$= \int_0^{\pi/2} \frac{2\sec^2 x}{1 + \tan^2 x - a^2 \tan^2 x} dx$$

$$= \int_0^{\pi/2} \frac{2\sec^2 x}{(1 - a^2)\tan^2 x + 1} dx \qquad (\text{put } \tan x = t)$$

$$= \int_0^\infty \frac{2 \, dt}{(1 - a^2)t^2 + 1} = \frac{2}{(1 - a^2)} \int_0^\infty \frac{dt}{t^2 + \left(\frac{1}{\sqrt{1 - a^2}}\right)^2}$$

$$\Rightarrow \quad = \frac{2}{\sqrt{1 - a^2}} [\tan^{-1}(t\sqrt{1 - a^2})]_0^\infty = \frac{\pi}{\sqrt{1 - a^2}}$$

$$\Rightarrow \quad dI = \frac{\pi \, da}{\sqrt{1 - a^2}}$$

When $a = 0$ and $I = 0$, then $C = 0$

$$\therefore \quad I = \pi \sin^{-1}(a)$$

Hence, $I = \pi \sin^{-1} a + C$

Definite Integral Exercise 1 :
Single Option Correct Type Questions

1. The value of $\int_0^4 \frac{(y^2-4y+5)\sin(y-2)dy}{(2y^2-8y+1)}$ is

(a) 0 (b) 2
(c) -2 (d) None of these

2. Let $f(x)=x^2+ax+b$ and the only solution of the equation $f(x)=$ minimum $f(x)$ is $x=0$ and $f(x)=0$ has root α and β, then $\int_\alpha^\beta x^3\,dx$ is equal to

(a) $\frac{1}{4}(\beta^4+\alpha^4)$ (b) $\frac{1}{4}(a^2-b^2)$
(c) 0 (d) None of these

3. $\int_{\pi/2}^{x}\sqrt{(3-2\sin^2 t)}\,dt+\int_0^y \cos t\,dt=0$, then $\left(\frac{dy}{dx}\right)$ at $x=\pi$ and $y=\pi$ is

(a) $\sqrt{3}$ (b) $-\sqrt{2}$
(c) $-\sqrt{3}$ (d) None of these

4. $\int_{-4}^{4}\frac{\sin^{-1}(\sin x)+\cos^{-1}(\cos x)}{(1+x^2)\left(1+\left[\frac{x^2}{17}\right]\right)}dx=\log\left(\frac{(1+x^2)}{a}\right)+b\pi\tan^{-1}\left(\frac{c-\pi}{1+c\pi}\right)$ (where, [·] denotes greatest integer function), then number of ways in which $a-(2b+c)$ distinct object can distributed among $\frac{a-5}{c}$ persons equally, is

(a) $\frac{9!}{(3!)^3}$ (b) $\frac{12!}{(4!)^3}$ (c) $\frac{15!}{(5!)^3}$ (d) $\frac{10!}{(6!)^3}\times 3!$

5. The value of the definite integral $\int_0^\infty \frac{dx}{(1+x^a)(1+x^2)}\,(a>0)$ is

(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$
(c) π (d) Some function of a

6. The value of the definite integral $\int_0^{3\pi/4}[(1+x)\sin x+(1-x)\cos x]\,dx$ is

(a) $2\tan\frac{3\pi}{8}$ (b) $2\tan\frac{\pi}{4}$
(c) $2\tan\frac{\pi}{8}$ (d) 0

7. Let $C_n=\int_{1/n+1}^{1/n}\frac{\tan^{-1}(nx)}{\sin^{-1}(nx)}dx$, then $\lim_{n\to\infty} n^2\cdot C_n$ is equal to

(a) 1 (b) 0
(c) -1 (d) $\frac{1}{2}$

8. If x satisfies the equation $\left(\int_0^1 \frac{dt}{t^2+2t\cos\alpha+1}\right)x^2-\left(\int_{-3}^{3}\frac{t^2\sin 2t}{t^2+1}dt\right)x-2=0\,(0<\alpha<\pi)$, then the value of x is

(a) $\pm\sqrt{\frac{\alpha}{2\sin\alpha}}$ (b) $\pm\sqrt{\frac{2\sin\alpha}{\alpha}}$
(c) $\pm\sqrt{\frac{\alpha}{\sin\alpha}}$ (d) $\pm 2\sqrt{\frac{\sin\alpha}{\alpha}}$

9. If $f(x)=e^{g(x)}$ and $g(x)=\int_2^x\frac{t\,dt}{1+t^4}$, then $f'(2)$ is equal to

(a) 2/17 (b) 0
(c) 1 (d) Cannot be determined

10. If a, b and c are real numbers, then the value of $\lim_{t\to 0}\ln\left(\frac{1}{t}\int_0^t(1+a\sin bx)^{c/x}\,dx\right)$ equals

(a) abc (b) $\frac{ab}{c}$
(c) $\frac{bc}{a}$ (d) $\frac{ca}{b}$

11. The value of $\lim_{n\to\infty}\sum_{r=1}^{r=4n}\frac{\sqrt{n}}{\sqrt{r}\,(3\sqrt{r}+4\sqrt{n})^2}$ is equal to

(a) $\frac{1}{35}$ (b) $\frac{1}{14}$
(c) $\frac{1}{10}$ (d) $\frac{1}{5}$

12. Let $f(x)=\int_{-1}^{x}e^{t^2}\,dt$ and $h(x)=f(1+g(x))$ where $g(x)$ is defined for all x, $g'(x)$ exists for all x, and $g(x)<0$ for $x>0$. If $h'(1)=e$ and $g'(1)=1$, then the possible values which $g(1)$ can take

(a) 0 (b) -1
(c) -2 (d) -4

13. Let $f(x)$ be a function satisfying $f'(x)=f(x)$ with $f(0)=1$ and g be the function satisfying $f(x)+g(x)=x^2$.

The value of the integral $\int_0^1 f(x)\,g(x)\,dx$ is

(a) $e-\frac{1}{2}e^2-\frac{5}{2}$ (b) $e-e^2-3$
(c) $\frac{1}{2}(e-3)$ (d) $e-\frac{1}{2}e^2-\frac{3}{2}$

14. Let $f(x)=\int_0^{g(x)} \frac{dt}{\sqrt{1+t^2}}$, where $g(x)=\int_0^{\cos x}(1+\sin t^2)\,dt$. Also, $h(x)=e^{-|x|}$ and $f(x)=x^2\sin\frac{1}{x}$, if $x\neq 0$ and $f(0)=0$, then $f'\left(\frac{\pi}{2}\right)$ is equal to

(a) $l'(0)$ (b) $h'(0^-)$

(c) $h'(0^+)$ (d) $\lim_{x\to 0}\frac{1-\cos x}{x\sin x}$

15. For $f(x)=x^4+|x|$, let $I_1=\int_0^{\pi} f(\cos x)\,dx$ and $I_2=\int_0^{\pi/2} f(\sin x)\,dx$, then $\frac{I_1}{I_2}$ has the value equal to

(a) 1 (b) 1/2

(c) 2 (d) 4

16. Let f be a positive function. Let $I_1=\int_{1-k}^{k}(x)\,f(x(1-x))\,dx; I_2=\int_{1-k}^{k} f(x(1-x))\,dx$, where $2k-1>0$. Then, $\frac{I_2}{I_1}$ is

(a) k (b) 1/2

(c) 1 (d) 2

17. Suppose that the quadratic function $f(x)=ax^2+bx+c$ is non-negative on the interval $[-1,1]$. Then, the area under the graph of f over the interval $[-1,1]$ and the X-axis is given by the formula

(a) $A=f(-1)+f(1)$

(b) $A=f\left(-\frac{1}{2}\right)+f\left(\frac{1}{2}\right)$

(c) $A=\frac{1}{2}[f(-1)+2f(0)+f(1)]$

(d) $A=\frac{1}{3}[f(-1)+4f(0)+f(1)]$

18. Let $I(a)=\int_0^{\pi}\left(\frac{x}{a}+a\sin x\right)^2 dx$, where '$a$' is positive real. The value of 'a' for which $I(a)$ attains its minimum value, is

(a) $\sqrt{\pi\sqrt{\frac{2}{3}}}$ (b) $\sqrt{\pi\sqrt{\frac{3}{2}}}$ (c) $\sqrt{\frac{\pi}{16}}$ (d) $\sqrt{\frac{\pi}{13}}$

19. The set of values of 'a' which satisfy the equation $\int_0^2(t-\log_2 a)\,dt=\log_2\left(\frac{4}{a^2}\right)$, is

(a) $a\in R$ (b) $a\in R^+$

(c) $a<2$ (d) $a>2$

20. $\lim_{x\to\infty}\left(x^3\int_{-1/x}^{1/x}\frac{\ln(1+t^2)}{1+e^t}\,dt\right)$ is equal to

(a) $\frac{1}{3}$ (b) $\frac{2}{3}$

(c) 1 (d) 0

21. The value of $\sqrt{\pi\left(\int_0^{2008} x\,|\sin\pi x|\,dx\right)}$ is equal to

(a) $\sqrt{2008}$ (b) $\pi\sqrt{2008}$ (c) 1004 (d) 2008

22. $\lim_{n\to\infty}\sum_{k=1}^{n}\frac{n}{n^2+k^2x^2}$, $x>0$ is equal to

(a) $x\tan^{-1}(x)$ (b) $\tan^{-1}(x)$

(c) $\frac{\tan^{-1}(x)}{x}$ (d) $\frac{\tan^{-1}(x)}{x^2}$

23. Let $a>0$ and $f(x)$ is monotonic increasing such that $f(0)=0$ and $f(a)=b$, then $\int_0^a f(x)\,dx+\int_0^b f^{-1}(x)\,dx$ is equal to

(a) $a+b$ (b) $ab+b$ (c) $ab+a$ (d) ab

24. If $\int_{-1/\sqrt{3}}^{1/\sqrt{3}}\frac{x^4}{1-x^4}\cos^{-1}\frac{2x}{1+x^2}\,dx=k\int_0^{1/\sqrt{3}}\frac{x^4}{1-x^4}$, then '$k$' is equal to

(a) π (b) 2π (c) 2 (d) 1

25. $\int_0^{\infty} f\left(x+\frac{1}{x}\right)\cdot\frac{\ln x}{x}\,dx$ is equal to

(a) 0 (b) 1

(c) $\frac{1}{2}$ (d) Cannot be evaluated

26. $\lim_{\lambda\to 0}\left(\int_0^1(1+x)^{\lambda}\,dx\right)^{1/\lambda}$ is equal to

(a) $2\ln 2$ (b) $\frac{4}{e}$ (c) $\ln\frac{4}{e}$ (d) 4

27. If $g(x)$ is the inverse of $f(x)$ and $f(x)$ has domain $x\in[1,5]$, where $f(1)=2$ and $f(5)=10$, then the values of $\int_1^5 f(x)\,dx+\int_2^{10} g(y)\,dy$ is equal to

(a) 48 (b) 64 (c) 71 (d) 52

28. The value of the definite integral $\int_0^{\pi/2}\sin x\sin 2x\sin 3x\,dx$ is equal to

(a) $\frac{1}{3}$ (b) $-\frac{2}{3}$ (c) $-\frac{1}{3}$ (d) $\frac{1}{6}$

29. If $f(x)=\int_0^x(f(t))^2\,dt$, $f: R\to R$ be differentiable function and $f(g(x))$ is differentiable function at $x=a$, then

(a) $g(x)$ must be differentiable at $x=a$

(b) $g(x)$ may be non-differentiable at $x=a$

(c) $g(x)$ may be discontinuous at $x=a$

(d) None of the above

30. The number of integral solutions of the equation $4\int_0^{\infty}\frac{\ln t\,dt}{x^2+t^2}-\pi\ln 2=0; x>0$, is

(a) 0 (b) 1 (c) 2 (d) 3

31. $\int_0^{16n^2/\pi}\cos\frac{\pi}{2}\left[\frac{x\pi}{n}\right]dx$ is equal to

(a) 0 (b) 1 (c) 2 (d) 3

32. If $\int_{-2}^{-1}(ax^2-5)\,dx=0$ and $5+\int_{1}^{2}(bx+c)\,dx=0$, then
(a) $ax^2-bx+c=0$ has atleast one root in (1, 2)
(b) $ax^2-bx+c=0$ has atleast one root in (−2, −1)
(c) $ax^2+bx+c=0$ has atleast one root in (−2, −1)
(d) None of the above

33. The value of $\int_0^6 \left(\sqrt{x+\sqrt{12x-36}}+\sqrt{x-\sqrt{12x-36}}\right)dx$ is equal to
(a) $6\sqrt{3}$ (b) $4\sqrt{3}$
(c) $12\sqrt{3}$ (d) None of these

34. If $I_n=\int_{-n}^{n}(\{x+1\}\{x^2+2\}+\{x^2+3\}\{x^3+4\})\,dx$, (where, {} denotes the fractional part), then I_1 is equal to
(a) $-\frac{1}{3}$ (b) $-\frac{2}{3}$ (c) $\frac{1}{3}$ (d) None of these

35. Let $I_n=\int_0^{\pi/2}\frac{\sin(2n-1)x}{\sin x}\,dx$, $\mathcal{J}_n=\int_0^{\pi/2}\frac{\sin^2 nx}{\sin^2 x}$, $n\in N$, then
(a) $\mathcal{J}_{n+1}-\mathcal{J}_n=I_n$ (b) $\mathcal{J}_{n+1}-\mathcal{J}_n=I_{n+1}$
(c) $\mathcal{J}_{n+1}+\mathcal{J}_n=\mathcal{J}_n$ (d) $\mathcal{J}_{n+1}-\mathcal{J}_{n+1}=\mathcal{J}_n$

Definite Integral Exercise 2 : More than One Option Correct Type Questions

36. If $f(x)=[\sin^{-1}(\sin 2x)]$ (where, [] denotes the greatest integer function), then
(a) $\int_0^{\pi/2}f(x)\,dx=\frac{\pi}{2}-\sin^{-1}(\sin 1)$
(b) $f(x)$ is periodic with period π
(c) $\lim_{x\to\frac{\pi}{2}}f(x)=-1$
(d) None of the above

37. Which of the following definite integral(s) vanishes?
(a) $\int_0^{\pi/2}\ln(\cot x)\,dx$ (b) $\int_0^{2\pi}\sin^3 x\,dx$
(c) $\int_{1/e}^{e}\frac{dx}{x(\ln x)^{1/3}}$ (d) $\int_0^{\pi}\sqrt{\frac{1+\cos 2x}{2}}\,dx$

38. The equation $10x^4-3x^2-1=0$ has
(a) atleast one root in (−1, 0)
(b) atleast one root in (0, 1)
(c) atleast two roots in (−1, 1)
(d) no root in (−1, 1)

39. Suppose $I_1=\int_0^{\pi/2}\cos(\pi\sin^2 x)\,dx$;
$I_2=\int_0^{\pi/2}\cos(2\pi\sin^2 x)\,dx$ and $I_3=\int_0^{\pi/2}\cos(\pi\sin x)\,dx$,
then
(a) $I_1=0$ (b) $I_2+I_3=0$
(c) $I_1+I_2+I_3=0$ (d) $I_2=I_3$

40. Let $f(x)=\int_{-1}^{1}(1-|t|)\cos(xt)\,dt$, then which of the following holds true?
(a) $f(0)$ is not defined
(b) $\lim_{x\to 0}f(x)$ exists and is equal to 2
(c) $\lim_{x\to 0}f(x)$ exists and is equal to 1
(d) $f(x)$ is continuous at $x=0$

41. The function f is continuous and has the property $f(f(x))=1-x$ for all $x\in[0,1]$ and $\mathcal{J}=\int_0^1 f(x)\,dx$, then
(a) $f\left(\frac{1}{4}\right)+f\left(\frac{3}{4}\right)=1$
(b) the value of $\mathcal{J}$ equals to 1/2
(c) $f\left(\frac{1}{3}\right)\cdot f\left(\frac{2}{3}\right)=1$
(d) $\int_0^{\pi/2}\frac{\sin x\,dx}{(\sin x+\cos x)^3}$ has the same value as $\mathcal{J}$

42. Let $f(x)$ is a real valued function defined by
$f(x)=x^2+x^2\int_{-1}^{1}tf(t)\,dt+x^3\int_{-1}^{1}f(t)\,dt$,
then which of the following hold(s) good?
(a) $\int_{-1}^{1}t\,f(t)\,dt=\frac{10}{11}$ (b) $f(1)+f(-1)=\frac{30}{11}$
(c) $\int_{-1}^{1}t\,f(t)\,dt>\int_{-1}^{1}f(t)\,dt$ (d) $f(1)-f(-1)=\frac{20}{11}$

43. Let $f(x)$ and $g(x)$ be differentiable functions such that $f(x)+\int_0^x g(t)\,dt=\sin x(\cos x-\sin x)$ and $(f'(x))^2+(g(x))^2=1$, then $f(x)$ and $g(x)$ respectively, can be
(a) $\frac{1}{2}\sin 2x, \sin 2x$ (b) $\frac{\cos 2x}{2}, \cos 2x$
(c) $\frac{1}{2}\sin 2x, -\sin 2x$ (d) $-\sin^2 x, \cos 2x$

44. Let $f(x)=\int_{-x}^{x}(t\sin at+bt+c)dt$, where a, b, c are non-zero real numbers, then $\lim_{x\to 0}\frac{f(x)}{x}$ is
(a) independent of a
(b) independent of a and b, and has the value equals to c
(c) independent a, b and c
(d) dependent only on c

45. Let $L=\lim_{n\to\infty}\int_a^{\infty}\frac{n\,dx}{1+n^2x^2}$, where $a\in R$, then L can be
(a) π (b) $\pi/2$ (c) 0 (d) 1

Definite Integral Exercise 3 : Passage Based Questions

Passage I

(Q. Nos. 46 to 48)

Suppose $\lim_{x\to 0}\dfrac{\int_0^x \dfrac{t^2\,dt}{(a+t^r)^{1/p}}}{bx-\sin x}=l$, *where* $p\in N,\ p\geq 2, a>0, r>0$ *and* $b\neq 0$.

46. If l exists and is non-zero, then
(a) $b>1$ (b) $0<b<1$
(c) $b<0$ (d) $b=1$

47. If $p=3$ and $l=1$, then the value of 'a' is equal to
(a) 8 (b) 3
(c) 6 (d) 3/2

48. If $p=2$ and $a=9$ and l exists, then the value of l is equal to
(a) $\frac{3}{2}$ (b) $\frac{2}{3}$ (c) $\frac{1}{3}$ (d) $\frac{7}{9}$

Passage II

(Q. Nos. 49 to 51)

Suppose $f(x)$ and $g(x)$ *are two continuous functions defined for* $0\leq x\leq 1$. *Given,* $f(x)=\int_0^1 e^{x+1}\cdot f(t)\,dt$ *and* $g(x)=\int_0^1 e^{x+t}\cdot g(t)\,dt+x$.

49. The value of $f(1)$ equals
(a) 0 (b) 1
(c) e^{-1} (d) e

50. The value of $g(0)-f(0)$ equals
(a) $\frac{2}{3-e^2}$ (b) $\frac{3}{e^2-2}$ (c) $\frac{1}{e^2-1}$ (d) 0

51. The value of $\frac{g(0)}{g(2)}$ equals
(a) 0 (b) $\frac{1}{3}$ (c) $\frac{1}{e^2}$ (d) $\frac{2}{e^2}$

Passage III

(Q. Nos. 52 to 54)

We are given the curves $y=\int_{-\infty}^x f(t)dt$ *through the point* $\left(0,\frac{1}{2}\right)$ *any* $y=f(x)$, *where* $f(x)>0$ *and* $f(x)$ *is differentiable,* $\forall\, x\in R$ *through* $(0,1)$. *Tangents drawn to both the curves at the points with equal abscissae intersect on the same point on the X-axis.*

52. The number of solutions $f(x)=2ex$ is equal to
(a) 0 (b) 1
(c) 2 (d) None of these

53. $\lim_{x\to\infty}(f(x))^{f(-x)}$ is
(a) 3 (b) 6
(c) 1 (d) None of these

54. The function $f(x)$ is
(a) increasing for all x (b) non-monotonic
(c) decreasing for all x (d) None of these

Passage IV

(Q. Nos. 55 to 57)

$f(x)=\int_0^x (4t^4-at^3)\,dt$ *and* $g(x)$ *is quadratic satisfying* $g(0)+6=g'(0)-c=g''(c)+2b=0$. $y=h(x)$ and $y=g(x)$ *intersect in* 4 *distinct points with abscissae* x_i; $i=1,2,3,4$ *such that* $\sum\frac{i}{x_i}=8, a, b, c\in R^+$ *and* $h(x)=f'(x)$.

55. Abscissae of point of intersection are in
(a) AP (b) GP
(c) HP (d) None of these

56. 'a' is equal to
(a) 6 (b) 8 (c) 20 (d) 12

57. 'c' is equal to
(a) 25 (b) 25/2 (c) 25/4 (d) 25/8

Passage V

(Q. Nos. 58 to 60)

Let $y=\int_{u(x)}^{v(x)} f(t)\,dt$, *let us define* $\frac{dy}{dx}$ *as* $\frac{dy}{dx}$ $=v'(x)\,f^2(v(x))-u'(x)\,f^2(u(x))$ *and the equation of the tangent at* (a,b) *and* $y-b=\left(\frac{dy}{dx}\right)_{(a,b)}(x-a)$.

58. If $y=\int_x^{x^2} t^2\,dt$, then the equation of tangent at $x=1$ is
(a) $x+y=1$ (b) $y=x-1$
(c) $y=x$ (d) $y=x+1$

59. If $y=\int_{x^2}^{x^4}(\ln t)dt$, then $\lim_{x\to 0^+}\frac{dy}{dx}$ is equal to
(a) 0 (b) 1 (c) 2 (d) −1

60. If $f(x)=\int_1^x e^{t^2/2}(1-t^2)\,dt$, then $\frac{d}{dx}f(x)$ at $x=1$ is
(a) 0 (b) 1
(c) 2 (d) −1

Passage VI (Q. Nos. 61 to 62)

Consider $f:(0,\infty)\to\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$, *defined as* $f(x)=\tan^{-1}\left(\frac{\log_e x}{(\log_e x)^2+1}\right)$.

61. The about function can be classified as
(a) Injective but nor surjective
(b) Surjective but not bijective
(c) Neither injective nor surjective
(d) Both injective and surjective

62. The value of $\int_0^{\infty}[\tan]\,dx$ is equal to (where, [·] denotes the greatest integer function)
(a) $-\frac{\pi}{2}$ (b) $\frac{\pi}{2}$
(c) -1 (d) 1

Definite Integral Exercise 4 : Matching Type Questions

63. Let $\lim_{T\to\infty}\frac{1}{T}\int_0^T(\sin x+\sin ax)^2\,dx=L$, then

	Column I		Column II
(A)	For $a=0$, the value of L is	(p)	0
(B)	For $a=1$, the value of L is	(q)	1/2
(C)	For $a=-1$, the value of L is	(r)	1
(D)	For $a\in R-\{-1,0,1\}$, the value of L is	(s)	2

64. Let $f(\theta=\int_0^1(x+\sin\theta)^2\,dx$ and $g(\theta)=\int_0^1(x+\cos\theta)^2\,dx$ where $\theta\in[0,2\pi]$. The quantity $f(\theta)-g(\theta),\forall\,\theta$ in the interval given in column I, is

	Column I		Column II
(A)	$\left(\frac{\pi}{4},\frac{3\pi}{4}\right)$	(p)	negative
(B)	$\left(\frac{3\pi}{4},\pi\right]$	(q)	positive
(C)	$\left[\frac{3\pi}{2},\frac{7\pi}{4}\right)$	(r)	non-negative
(D)	$\left(0,\frac{\pi}{4}\right)\cup\left(\frac{7\pi}{4},2\pi\right)$	(s)	non-positive

65. Match the following.

	Column I		Column II
(A)	$\int_0^1(1+2008\,x^{2008})\,e^{x^{2008}}\,dx$ equals	(p)	e^{-1}
(B)	The value of the definite integral $\int_0^1 e^{-x^2}\,dx+\int_1^{1/e}\sqrt{-\ln x}\,dx$ is equal to	(q)	$e^{-1/4}$
(C)	$\lim_{n\to\infty}\left(\frac{1^1\cdot2^2\cdot3^3\ldots(n-1)^{n-1}\cdot n^n}{n^{1+2+3+\ldots+n}}\right)^{\frac{1}{n^2}}$ equals	(r)	$e^{1/2}$
		(s)	e

66. Match the following.

	Column I		Column II
(A)	If $f(x)=\int_0^{g(x)}\frac{dt}{\sqrt{1+t^3}}$, where $g(x)=\int_0^{\cos x}(1+\sin t^2)\,dt$, then value of $f'\left(\frac{\pi}{2}\right)$ is	(p)	-2
(B)	If $f(x)$ is a non-zero differentiable function such that $\int_0^x f(t)\,dt=\{f(x)\}^2$, $\forall x\in R$, then $f(2)$ is equal to	(q)	2
(C)	If $\int_a^b(2+x-x^2)\,dx$ is maximum, then $a+b$ is equal to	(r)	1
(D)	If $\lim_{x\to0}\left(\frac{\sin 2x}{x^3}+a+\frac{b}{x^2}\right)=0$, then $3a+b$ has the value	(s)	-1

Definite Integral Exercise 5 :
Single Integer Answer Type Questions

67. If $f(x)=\sum_{n=1}\frac{\sin nx}{4^n}$ and $\int_0^{\pi} f(x)\,dx=\log\left(\frac{m}{n}\right)$, then the value of $(m+n)$ is ...

68. The value of $I=\int_{-\pi/2}^{\pi/2}\frac{\cos x\,dx}{1+2[\sin^{-1}(\sin x)]}$ (where, [·] denotes greatest integer function) is ...

69. If $f(x)=\frac{1}{\pi}\int_0^{\pi/2}\frac{\sin^2 n\theta}{\sin^2\theta}d\theta\,(n\in N)$, then the value of $\frac{f(15)+f(13)}{f(15)-f(a)}$...

70. Let $f(x)=\int_{-2}^{x}e^{(1+t)^2}dt$ and $g(x)=(h/x)$, where $h(x)$ is defined for all $x\in h$. If $g^{1/2}=e^4$ and $h'(2)=1$. Then, absolute value of sun for all possible value of $h(2)$, is ...

71. If $=\int_0^{\pi/2}\sin x\cdot\log(\sin x)dx=\log\left(\frac{K}{e}\right)$. Then, the value of K is ...

Definite Integrals Exercise 6 :
Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

72. The value of $\int_{-\pi/2}^{\pi/2}\frac{x^2\cos x}{1+e^x}dx$ is equal to **[Only One Correct Option 2016]**

(a) $\frac{\pi^2}{4}-2$ (b) $\frac{\pi^2}{4}+2$

(c) $\pi^2-e^{-\pi/2}$ (d) $\pi^2+e^{\pi/2}$

73. The total number of distincts $x\in[0,1]$ for which $\int_0^x\frac{t^2}{1+t^4}dt=2x-1$ is **[Integer Type 2016]**

74. Let $f(x)=7\tan^8 x+7\tan^6 x-3\tan^4 x-3\tan^2 x$ for all $x\in\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$. Then, the correct expression(s) is/are **[More than One Correct Option 2015]**

(a) $\int_0^{\pi/4}x f(x)\,dx=\frac{1}{12}$ (b) $\int_0^{\pi/4}f(x)\,dx=0$

(c) $\int_0^{\pi/4}x f(x)\,dx=\frac{1}{6}$ (d) $\int_0^{\pi/4}f(x)\,dx=1$

75. Let $f'(x)=\frac{192x^3}{2+\sin^4\pi x}$ for all $x\in R$ with $f\left(\frac{1}{2}\right)=0$. If $m\le\int_{t/2}^{1}f(x)\,dx\le M$, then the possible values of m and M are **[More than One Correct Option 2015]**

(a) $m=13,\ M=24$ (b) $m=\frac{1}{4},\ M=\frac{1}{2}$

(c) $m=-11,\ M=0$ (d) $m=1,\ M=12$

76. The option(s) with the values of a and L that satisfy the equation $\frac{\int_0^{4\pi}e^t(\sin^6 at+\cos^4 at)dt}{\int_0^{\pi}e^t(\sin^6 at+\cos^4 at)dt}=L$, is/are **[More than One Correct Option 2015]**

(a) $a=2,\ L=\frac{e^{4\pi}-1}{e^{\pi}-1}$ (b) $a=2,\ L=\frac{e^{4\pi}+1}{e^{\pi}+1}$

(c) $a=4,\ L=\frac{e^{4\pi}-1}{e^{\pi}-1}$ (d) $a=4,\ L=\frac{e^{4\pi}+1}{e^{\pi}+1}$

■ **Directions** (Q. Nos. 77 to 78) Let $F:R\to R$ be a thrice differentiable function. Suppose that $F(1)=0,\ F(3)=-4$ and $F'(x)<0$ for all $x\in(1,3)$. Let $f(x)=xF(x)$ for all $x\in R$.

77. The correct statement(s) is/are **[Passage Based Questions 2015]**

(a) $f'(1)<0$

(b) $f(2)<0$

(c) $f'(x)\neq 0$ for any $x\in(1,3)$

(d) $f'(x)=0$ for some $x\in(1,3)$

78. If $\int_1^3 x^2F'(x)\,dx=-12$ and $\int_1^3 x^3F''(x)\,dx=40$, then the correct expression(s) is/are

(a) $9f'(3)+f'(1)-32=0$ (b) $\int_1^3 f(x)\,dx=12$

(c) $9f'(3)-f'(1)+32=0$ (d) $\int_1^3 f(x)\,dx=-12$

79. Let $f: R \to R$ be a function defined by $f(x) = \begin{cases} [x], & x \le 2 \\ 0, & x > 2 \end{cases}$, where $[x]$ denotes the greatest integer less than or equal to x. If $I = \int_{-1}^{2} \frac{xf(x^2)}{2 + f(x+1)}\, dx$, then the value of $(4I - 1)$ is **[Integer Answer Type 2015]**

80. If $\alpha = \int_0^1 (e^{9x + 3\tan^{-1} x}) \left(\frac{12 + 9x^2}{1 + x^2}\right) dx$, where $\tan^{-1} x$ takes only principal values, then value of $\left(\log_e |1 + \alpha| - \frac{3\pi}{4}\right)$ is **[Integer Answer Type 2015]**

81. The integral $\int_{\pi/4}^{\pi/2} (2 \text{ cosec } x)^{17} dx$ is equal to **[Only One Correct Option 2014]**

(a) $\int_0^{\log(1+\sqrt{2})} 2(e^u + e^{-u})^{16} du$ (b) $\int_0^{\log(1+\sqrt{2})} (e^u + e^{-u})^{17} du$

(c) $\int_0^{\log(1+\sqrt{2})} (e^u - e^{-u})^{17} du$ (d) $\int_0^{\log(1+\sqrt{2})} 2(e^u - e^{-u})^{16} du$

82. Let $f: [0,2] \to R$ be a function which is continuous on $[0, 2]$ and is differentiable on $(0,2)$ with $f(0) = 1$. Let $F(x) = \int_0^{x^2} f(\sqrt{t})\, dt$, for $x \in [0,2]$. If $F'(x) = f'(x), \forall$ $x \in (0,2)$, then $F(2)$ equals **[Only One Correct Option 2014]**

(a) $e^2 - 1$ (b) $e^4 - 1$

(c) $e - 1$ (d) e^4

83. Match the conditions/expressions in Column I with statement in Column II. **[Matching Type 2014]**

	Column I		Column II
A.	$\int_{-1}^{1} \frac{dx}{1+x^2}$	p.	$\frac{1}{2}\log\left(\frac{2}{3}\right)$
B.	$\int_0^1 \frac{dx}{\sqrt{1-x^2}}$	q.	$2\log\left(\frac{2}{3}\right)$
C.	$\int_2^3 \frac{dx}{1-x^2}$	r.	$\frac{\pi}{3}$
D.	$\int_1^2 \frac{dx}{x\sqrt{x^2-1}}$	s.	$\frac{\pi}{2}$

84. Match List I with List II and select the correct answer using codes given below the lists. **[Matching Type 2014]**

	List I		List II
A.	The number of polynomials $f(x)$ with non-negative integer coefficients of degree ≤ 2, satisfying $f(0) = 0$ and $\int_0^1 f(x)\, dx = 1$, is	p.	8
B.	The number of points in the interval $[-\sqrt{13}, \sqrt{13}]$ at which $f(x) = \sin(x^2) + \cos(x^2)$ attains its maximum value, is	q.	2
C.	$\int_{-2}^{2} \frac{3x^2}{1 + e^x} dx$ equals	r.	4
D.	$\frac{\left(\int_{-1/2}^{1/2} \cos 2x \log\left(\frac{1+x}{1-x}\right) dx\right)}{\left(\int_0^{1/2} \cos\ 2x \log\left(\frac{1+x}{1-x}\right) dx\right)}$ equals	s.	0

Codes

	A	B	C	D		A	B	C	D
(a)	r	q	s	p	(b)	q	r	s	p
(c)	r	q	p	s	(d)	q	r	p	s

85. The value of $\int_0^1 4x^3 \left\{\frac{d^2}{dx^2}(1 - x^2)^5\right\} dx$ is **[Integer Answer Type 2014]**

86. The value of the integral $\int_{-\pi/2}^{\pi/2} \left(x^2 + \log\frac{\pi - x}{\pi + x}\right) \cos x\, dx$ is **[Only One Correct Option 2012]**

(a) 0 (b) $\frac{\pi^2}{2} - 4$

(c) $\frac{\pi^2}{2} + 4$ (d) $\frac{\pi^2}{2}$

87. The value of $\int_{\sqrt{\log 2}}^{\sqrt{\log 3}} \frac{x \sin x^2}{\sin x^2 + \sin(\log 6 - x^2)} dx$ is **[Integer Answer Type 2011]**

(a) $\frac{1}{4}\log\frac{3}{2}$ (b) $\frac{1}{2}\log\frac{3}{2}$

(c) $\log\frac{3}{2}$ (d) $\frac{1}{6}\log\frac{3}{2}$

88. Let $f: [1, \infty] \to [2, \infty]$ be differentiable function such that $f(1) = 2$. If $6\int_1^x f(x) = dt = 3x\ f(x) - x^3, \forall\ x \ge 1$ then the value of $f(2)$ is .... **[Integer Answer Type 2011]**

89. The value(s) of $\int_0^1 \frac{x^4 (1-x)^4}{1 + x^2} dx$ is (are) **[Only One Correct Option 2010]**

(a) $\frac{22}{7} - \pi$ (b) $\frac{2}{105}$

(c) 0 (d) $\frac{71}{15} - \frac{3\pi}{2}$

90. For $a \in R$ (the set of all real numbers), $a \ne -1$,

$$\lim_{n \to \infty} \frac{(1^a + 2^a + \ldots + n^a)}{(n+1)^{a-1}[(na+1) + (na+2) + \ldots + (na+n)]} = \frac{1}{60}.$$

Then, a is equal to **[More than One Correct Option 2010]**

(a) 5 (b) 7

(c) $\frac{-15}{2}$ (d) $\frac{-17}{2}$

■ **Directions** (Q Nos. 91 to 92) Let $f(x)=(1-x)^2\sin^2 x+x^2$, $\forall\, x\in R$ and $g(x)=\int_1^x\left(\frac{2(t-1)}{t+1}-\ln t\right)f(t)\,dt\ \forall\, x\in(1,\infty)$.

[Passage Based Questions 2010]

91. Consider the statements

P: There exists some $x\in R$ such that, $f(x)+2x=2(1+x^2)$.

Q: There exists some $x\in R$ such that $2f(x)+1=2x(1+x)$.

Then,

(a) both P and Q are true (b) P is true and Q is false

(c) P is false and Q is true (d) both P and Q are false

92. Which of the following is true?

(a) g is increasing on $(1,\infty)$

(b) g is decreasing on $(1,\infty)$

(c) g is increasing on $(1, 2)$ and decreasing on $(2,\infty)$

(d) g is decreasing on $(1, 2)$ and increasing on $(2,\infty)$

93. For any real number x, let $[x]$ denotes the largest integer less than or equal to x. Let f be a real valued function defined on the interval $[-10, 10]$ by

$$f(x)=\begin{cases}x-[x[, & \text{if } f(x) \text{ is odd}\\ 1+[x[-x, & \text{if } f(x) \text{ is even}\end{cases}$$

Then, the value of $\frac{\pi^2}{10}\int_{-10}^{10} f(x)\cos\pi x\,dx$ is.....

[Integer Answer Type 2010]

94. Let f be a non-negative function defined on the interval $[0, 1]$. If $\int_0^x\sqrt{1-(f'(t))^2}\,dt=\int_0^x f(t)\,dt$, $0\le x\le 1$ and $f(0)=0$, then **[Only One Option Correct 2009]**

(a) $f\left(\frac{1}{2}\right)<\frac{1}{2}$ and $f\left(\frac{1}{3}\right)>\frac{1}{3}$ (b) $f\left(\frac{1}{2}\right)>\frac{1}{2}$ and $f\left(\frac{1}{3}\right)>\frac{1}{3}$

(c) $f\left(\frac{1}{2}\right)<\frac{1}{2}$ and $f\left(\frac{1}{3}\right)<\frac{1}{3}$ (d) $f\left(\frac{1}{2}\right)>\frac{1}{2}$ and $f\left(\frac{1}{3}\right)<\frac{1}{3}$

95. If $I_n=\int_{-\pi}^{\pi}\frac{\sin nx}{(1+\pi^x)\sin x}\,dx$, $n=0,1,2,\ldots$, then

[More than One Correct 2009]

(a) $I_n=I_{n+2}$ (b) $\sum_{m=1}^{10} I_{2m+1}=10\pi$

(c) $\sum_{m=1}^{10} I_{2m}=0$ (d) $I_n=I_{n+1}$

96. Let $S_n=\sum_{k=0}^{n}\frac{n}{n^2+kn+k^2}$ and $T_n=\sum_{k=0}^{n-1}\frac{n}{n^2+kn+k^2}$, for $n=1,2,3,\ldots$, then **[More than One Correct Option 2008]**

(a) $S_n<\frac{\pi}{3\sqrt{3}}$ (b) $S_n>\frac{\pi}{3\sqrt{3}}$

(c) $T_n<\frac{\pi}{3\sqrt{3}}$ (d) $T_n>\frac{\pi}{3\sqrt{3}}$

(ii) JEE Main & AIEEE

97. The integral $\int_{\pi/4}^{3\pi/4}\frac{dx}{1+\cos x}$ is equal to **[2017 JEE Main]**

(a) -1 (b) -2

(c) 2 (d) 4

98. Let $I_n=\int\tan^n x\,dx,(n>1)$. $I_4+I_6=a\tan^5 x+bx^5+C$, where C is a constant of integration, then the ordered pair (a, b) is equal to **[2017 JEE Main]**

(a) $\left(-\frac{1}{5}, 0\right)$ (b) $\left(-\frac{1}{5}, 1\right)$ (c) $\left(\frac{1}{5}, 0\right)$ (d) $\left(\frac{1}{5}, -1\right)$

99. $\lim_{n\to\infty}\left[\frac{(n+1)(n+2)\ldots 3n}{n^{2n}}\right]^{1/n}$ is equal to **[2016 JEE Main]**

(a) $\frac{18}{e^4}$ (b) $\frac{27}{e^2}$ (c) $\frac{9}{e^2}$ (d) $3\log 3-2$

100. The integral $\int_2^4\frac{\log x^2}{\log x^2+\log(36-12x+x^2)}dx$ is equal to **[2015 JEE Main]**

(a) 2 (b) 4 (c) 1 (d) 6

101. The integral $\int_0^{\pi}\sqrt{1+4\sin^2\frac{x}{2}-4\sin\frac{x}{2}}\,dx$ is equal to **[2014 JEE Main]**

(a) $\pi-4$ (b) $\frac{2\pi}{3}-4-4\sqrt{3}$

(c) $4\sqrt{3}-4$ (d) $4\sqrt{3}-4-\pi/3$

102. **Statement I** The value of the integral $\int_{\pi/6}^{\pi/3}\frac{dx}{1+\sqrt{\tan x}}$ is equal to $\pi/6$. **[2013 JEE Main]**

Statement II $\int_a^b f(x)\,dx=\int_a^b f(a+b-x)\,dx$

(a) Statement I is true; Statement II is true; Statement II is a true explanation for Statement I

(b) Statement I is true; Statement II is true; Statement II is not a true explanation for Statement I

(c) Statement I is true; Statement II is false

(d) Statement I is false; Statement II is true

103. The intercepts on X-axis made by tangents to the curve, $y=\int_0^x|t|\,dt$, $x\in R$, which are parallel to the line $y=2x$, are equal to **[2013 JEE Main]**

(a) ± 1 (b) ± 2

(c) ± 3 (d) ± 4

104. If $g(x)=\int_0^x\cos 4t\,dt$, then $g(x+\pi)$ equals **[2012 AIEEE]**

(a) $\frac{g(x)}{g(\pi)}$ (b) $g(x)+g(\pi)$ (c) $g(x)-g(\pi)$ (d) $g(x)\cdot g(\pi)$

105. The value of $\int_0^1\frac{8\log(1+x)}{1+x^2}\,dx$ is **[2011 AIEEE]**

(a) $\frac{\pi}{8}\log 2$ (b) $\frac{\pi}{2}\log 2$ (c) $\log 2$ (d) $\pi\log 2$

106. For $x \in \left(0, \frac{5\pi}{2}\right)$, define $f(x) = \int_0^x \sqrt{t} \sin t \, dt$. Then, f has **[2011 AIEEE]**

(a) local minimum at π and 2π
(b) local minimum at π and local maximum at 2π
(c) local maximum at π and local minimum at 2π
(d) local maximum at π and 2π

107. Let $p(x)$ be a function defined on R such that $\lim_{x \to \infty} \frac{f(3x)}{f(x)} = 1, p'(x) = p'(1-x)$, for all $x \in [0, 1], p(0) = 1$ and $p(1) = 41$. Then, $\int_0^1 p(x)\,dx$ equals **[2010 AIEEE]**

(a) $\sqrt{41}$ (b) 21
(c) 41 (d) 42

108. $\int_0^{\pi} [\cot x]\,dx$, [ ] denotes the greatest integer function, is equal to **[2009 AIEEE]**

(a) $\frac{\pi}{2}$ (b) 1
(c) -1 (d) $-\frac{\pi}{2}$

109. Let $I = \int_0^1 \frac{\sin x}{\sqrt{x}}\,dx$ and $J = \int_0^1 \frac{\cos x}{\sqrt{x}}\,dx$.

Then, which one of the following is true? **[2008 AIEEE]**

(a) $I > \frac{2}{3}$ and $J > 2$ (b) $I < \frac{2}{3}$ and $J < 2$
(c) $I < \frac{2}{3}$ and $J > 2$ (d) $I > \frac{2}{3}$ and $J < 2$

Solutions

1. Let $I = \int_0^4 \frac{(y^2 - 4y + 5)\sin(y-2)dy}{(2y^2 - 8y + 1)}$

Put $y - 2 = z$

$\Rightarrow \quad dy = dz$

$\therefore \quad I = \int_{z=-2}^{2} \frac{(z^2+1)\sin z}{(2z^2 - 7)} dz$

$\Rightarrow \quad I = 0$, as $\int_{-a}^{a} f(x)\,dx = 0$, when $f(-x) = -f(x)$

and $f(z) = \frac{(z^2+1)\sin z}{(2z^2-7)} dz$ is an odd function.

2. Hence, $f(x) = x^2 + ax - b$

The solution of $f(x) = \text{minium } f(x)$ is $x = \frac{-a}{2}$.

Given, $f(x)_{\text{minimum}}$ is at $x = 0$.

$\Rightarrow \quad \frac{-a}{2} = 0 \quad \text{or} \quad a = 0$

$\therefore \quad f(x) = x^2 - b = 0$ has roots α and β.

$\Rightarrow \quad \alpha = \sqrt{b}$ and $\beta = -\sqrt{b}$

$\Rightarrow \quad \int_\alpha^\beta x^3 dx = \int_{\sqrt{b}}^{-\sqrt{b}} x^3 dx = 0$

$\left[\int_{-a}^{a} f(x)dx = 0, \text{ when } f(-x) = f(x)\right]$

3. Here, $\int_{\pi/2}^{x} \sqrt{(3 - 2\sin^2 t)}\,dt + \int_0^y \cos t\,dt = 0$

Differentiating both the sides, we get

$$(\sqrt{3 - 2\sin^2 x}) \cdot 1 + (\cos y)\left(\frac{dy}{dx}\right) = 0$$

$\Rightarrow \quad \frac{dy}{dx} = \frac{-\sqrt{3 - 2\sin^2 x}}{\cos y}$

$\therefore \quad \left(\frac{dy}{dx}\right)_{(\pi,\pi)} = \frac{-\sqrt{3}}{-1} = \sqrt{3}$

4. Here, $-4 \le x \le 4 \Rightarrow \ 0 \le \frac{x^2}{17} < 1$

$\therefore \ \left[\frac{x^2}{17}\right] = 0$ and $\sin^{-1}(\sin x)$ is an odd function.

Let, $I = \int_{-4}^{4} \frac{\sin^{-1}(\sin x)}{(1+x^2)\times 1} dx + \int_{-4}^{4} \frac{\cos^{-1}(\cos x)}{(1+x^2)\times 1} dx$

$= 0 + 2\int_0^\pi \frac{\cos^{-1}(\cos x)}{(1+x^2)} dx$

$I = 2\left[\int_0^\pi \frac{x}{1+x^2} dx + \int_\pi^4 \frac{2\pi}{(1+x^2)} dx\right]$

$= \log(1+\pi^2) + 2\pi(\tan^{-1} x)_\pi^4 - [\log(1+16) - \log(1+\pi^2)]$

$= \log(1+\pi^2) + 2\pi(\tan^{-1} 4 - \tan^{-1}\pi) - \log\frac{17}{1+\pi^2}$

$= \log\frac{(1+\pi^2)\cdot(1+\pi^2)}{17} + 2\pi\tan^{-1}\left[\tan^{-1}\left(\frac{4-\pi}{1+4\pi}\right)\right]$

$= \log\left(\frac{(1+\pi^2)^2}{17}\right) + 2\pi\tan^{-1}\left(\frac{4-\pi}{1+4\pi}\right)$

On comparing with $\log\left(\frac{(1+\pi^2)^2}{a}\right) + b\pi\tan^{-1}\left(\frac{c-\pi}{1+c\pi}\right)$, we get

$a = 17$, $b = 2$ and $c = 4$

$\therefore \quad a - (2b + c) = 17 - 8 = 9$ and $\frac{a-5}{c} = 3$

Thus, the number of ways to distribute 9 distinct bijective into 3 persons equally is $\frac{9!}{(3!)^3}$.

5. Put $x = \tan\theta$

$\therefore \quad I = \int_0^{\pi/2} \frac{d\theta}{1 + (\tan\theta)^a} = \int_0^{\pi/2} \frac{(\cos\theta)^a}{(\sin\theta)^a + (\cos\theta)^a} d\theta \Rightarrow I = \frac{\pi}{4}$

6. $I = \int_0^{3\pi/4} (\sin x + \cos x)\,dx + \int_0^{3\pi/4} \underbrace{x}_{\text{I}} \underbrace{(\sin x - \cos x)}_{\text{II}}\,dx$

$= \int_0^{3\pi/4} (\sin x + \cos x)\,dx$

$+ [x(-\cos x - \sin x)]_0^{3\pi/4} + \int_0^{3\pi/4} (\sin x + \cos x)\,dx$

$= 2\int_0^{3\pi/4} (\sin x + \cos x)\,dx + 0 = 2[-\cos x + \sin x]_0^{3\pi/4}$

$= 2\left[+\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} + 1\right] = 2(\sqrt{2}+1) = 2\tan\frac{3\pi}{8}$

7. We have, $C_n = \int_{\frac{1}{n+1}}^{\frac{1}{n}} \frac{\tan^{-1}(nx)}{\sin^{-1}(nx)} dx$

$C_n = \frac{1}{n}\int_{\frac{n}{n+1}}^{1} \frac{\tan^{-1}(t)}{\sin^{-1}(t)} dt \qquad (\text{put } nx = t)$

Now, $L = \lim_{n\to\infty} n^2 \cdot C_n = \lim_{n\to\infty} n\int_{\frac{n}{n+1}}^{1} \frac{\tan^{-1} t}{\sin^{-1} t} dt\,(\infty \times 0)$

$L = \frac{\int_{\frac{n}{n+1}}^{1} \frac{\tan^{-1} t}{\sin^{-1} t} dt}{\frac{1}{n}} \qquad \left(\frac{0}{0}\text{ form}\right)$

Applying Leibnitz rule,

$$L = \lim_{n\to\infty} \frac{0 - \frac{\tan^{-1}\frac{n}{n+1}}{\sin^{-1}\frac{n}{n+1}}\left(\frac{1}{(n+1)^2}\right)}{-\frac{1}{n^2}} = \frac{\pi}{4}\cdot\frac{2}{\pi} = \frac{1}{2}$$

8. $\int_{-3}^{3} \frac{t^2\sin 2t}{t^2+1} dt = 0$ as the integrand is an odd function.

Also, $\int_0^1 \frac{dt}{t^2 + 2t\cos\alpha + 1}$

$= \frac{1}{\sin\alpha}\left|\tan^{-1}\frac{t+\cos\alpha}{\sin\alpha}\right|_0^1 = \frac{\alpha}{2\sin\alpha}$

Thus, the given equation reduces to

$$x^2 \cdot \frac{\alpha}{2\sin\alpha} - 2 = 0 \quad \Rightarrow \quad x = \pm 2\sqrt{\frac{\sin\alpha}{\alpha}}$$

9. $f'(x) = e^{g(x)} \cdot g'(x)$ and $g'(x) = \dfrac{x}{1+x^4}$

$$\therefore \qquad f'(x) = e^{g(x)} \cdot \frac{x}{1+x^4}\ e^{g(2)} = e^0 = 1$$

Hence, $\qquad f'(2) = e^{g(2)} \cdot g'(2) = e^0 \cdot \dfrac{2}{17} = \dfrac{2}{17}$

10. $\lim\limits_{t\to 0} \ln\left(\dfrac{1}{t}\int_0^t (1 + a\sin bx)^{c/x}\,dx\right)$

$$= \ln \lim_{t\to 0} \frac{\int_0^t (1 + a\sin b\,x)^{c/x}\,dx}{t}$$

$$= \ln \lim_{t\to 0} \frac{(1 + a\sin bt)^{c/t}}{1} = \ln e^{\lim\limits_{t\to 0}\frac{a\sin bt}{t/c}} = \ln e^{abc} = abc$$

11. $T_r = \dfrac{1}{\sqrt{\dfrac{r}{n}} \cdot n\left(3\sqrt{\dfrac{r}{n}} + 4\right)^2}$

$$S = \frac{1}{n}\sum_1^{4n} \frac{1}{\left(3\sqrt{\frac{r}{n}} + 4\right)^2 \cdot \sqrt{\frac{r}{n}}} = \int_0^4 \frac{dx}{\sqrt{x}\,(3\sqrt{x} + 4)^2}$$

Put $3\sqrt{x} + 4 = t \ \Rightarrow\ \dfrac{3}{2} \cdot \dfrac{1}{\sqrt{x}}\,dx = dt$

$$= \frac{2}{3}\int_4^{10} \frac{dt}{t^2} = \frac{2}{3}\left[\frac{1}{t}\right]_{10}^4 = \frac{2}{3}\left[\frac{1}{4} - \frac{1}{10}\right] = \frac{2}{3} \cdot \frac{6}{40} = \frac{1}{10}$$

12. Given, $f(x) = \int_{-1}^{x} e^{t^2}\,dt$; $h(x) = f(1 + g(x))$; $g(x) < 0$ for $x > 0$

Now, $\quad h(x) = \int_{-1}^{1+g(x)} e^{t^2}\,dt = f(1 + g(x))$ (given)

Differentiating, we get $\quad h'(x) = e^{(1+g(x))^2} \cdot g'(x)$

Now, $\qquad h'(1) = e$ (given)

$\therefore \qquad e^{(1+g(1))^2} \cdot g'(1) = e$

$\Rightarrow \qquad (1 + g(1))^2 = 1$

$\Rightarrow \qquad 1 + g(1) = \pm 1$

$\Rightarrow \qquad g(1) = 0$ (not possible)

or $\qquad g(1) = -2$

13. Given, $f'(x) = f(x) \Rightarrow f(x) = Ce^x$

Since, $\quad f(0) = 1 \quad \therefore \quad 1 = f(0) = C$

$\therefore\ f(x) = e^x$ and hence $g(x) = x^2 - e^x$

Thus, $\int_0^1 f(x)\,g(x)\,dx = \int_0^1 (x^2e^x - e^{2x})\,dx$

$$= [x^2e^x]_0^1 - 2\int_0^1 xe^x\,dx - \left[\frac{e^{2x}}{2}\right]_0^1$$

$$= (e - 0) - 2\,[(xe^x)_0^1 - (e^x)_0^1\,] - \frac{1}{2}(e^2 - 1)$$

$$= (e - 0) - 2\,[(e - 0) - (e - 1)] - \frac{1}{2}(e^2 - 1)$$

$$= e - \frac{1}{2}e^2 - \frac{3}{2}$$

14. Here, $\quad f'(x) = \dfrac{1}{\sqrt{1 + g^2(x)}}\,g'(x)$;

Now, $\ f'\left(\dfrac{\pi}{2}\right) = \dfrac{g'(\pi/2)}{\sqrt{1 + g^2(\pi/2)}}$; $\quad g\left(\dfrac{\pi}{2}\right) = 0 = g'\left(\dfrac{\pi}{2}\right)$

But $\qquad g'(x) = [1 + \sin(\cos^2 x)](-\sin x)$

$$g'\left(\frac{\pi}{2}\right) = 1(-1) = -1$$

Hence, $\qquad f'\left(\dfrac{\pi}{2}\right) = -1$ as $h'(0^+) = -1$

15. Clearly, f is an even function, hence

$$I_1 = \int_0^{\pi} f[\cos(\pi - x)]\,dx = \int_0^{\pi} f(-\cos x)\,dx$$

$$= \int_0^{\pi} f(\cos x)\,dx$$

$$\therefore \quad I_1 = 2\int_0^{\pi/2} f(\cos x)\,dx \cdot 2\int_0^{\pi/2} f(\sin x)\,dx = 2I_2$$

$$\Rightarrow \frac{I_1}{I_2} = 2$$

Aliter Let $u = \cos x \Rightarrow du = -\sin x\,dx$

$$\therefore \qquad I_1 = \int_{-1}^{1} \frac{f(u)}{\sqrt{1 - u^2}}\,du$$

$$\Rightarrow \qquad I_1 = 2\int_0^1 \frac{f(u)}{\sqrt{1 - u^2}}\,du \qquad \text{...(i)}$$

Similarly, with $\sin t = t$,

$$I_2 = \int_0^1 \frac{f(t)}{\sqrt{1 - t^2}}\,dt \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), $\dfrac{I_1}{I_2} = 2$

16. Given, $I_1 = \int_{1-k}^{k} x\,f(x(1 - x))\,dx$ and

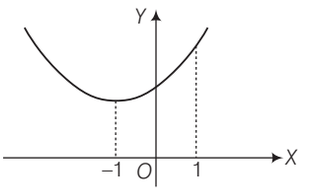
$$I_2 = \int_{1-k}^{k} f(x(1 - x))\,dx$$

Using King's property $\quad I_1 = \int_{1-k}^{k} (1 - x)\,f(x(1 - x))\,dx$

$$2I_1 = \int_{1-k}^{k} f(x(1 - x))\,dx = I_2$$

$$\therefore \qquad \frac{I_2}{I_1} = 2$$

17. $A = \int_{-1}^{1} (ax^2 + bx + c)\,dx = 2\int_0^1 (ax^2 + c)\,dx$



$$= 2\left[\frac{a}{3} + c\right] = \frac{1}{3}[2a + 6c]$$

$$\therefore \qquad A = \frac{1}{3}[f(-1) + 4f(0) + f(1)]$$

18. $I(a)=\int_0^{\pi}\left(\frac{x^2}{a^2}+a^2\sin^2 x+2x\sin x\right)dx \quad \left(\because \int_0^{\pi} x\sin x\,dx=\pi\right)$

$$\therefore \quad I(a)=\frac{\pi^3}{3a^2}+\frac{\pi a^2}{2}+2\pi=\pi\left[\frac{\pi^2}{3a^2}+\frac{a^2}{2}\right]+2\pi$$

$$=\pi\left[\left(\frac{\pi}{\sqrt{3}a}-\frac{a}{\sqrt{2}}\right)^2+\frac{2\pi}{\sqrt{6}}\right]+2\pi$$

$I(a)$ is minimum when $\frac{\pi}{\sqrt{3}a}=\frac{a}{\sqrt{2}} \Rightarrow a^2=\pi\sqrt{\frac{2}{3}}$

$$\Rightarrow \quad a=\sqrt{\pi\sqrt{\frac{2}{3}}}$$

Also, $[I(a)]_{\min}=2\pi+\pi^2\sqrt{\frac{2}{3}}$

19. $\left[\frac{t^2}{2}-\log_2 a\cdot t\right]_0^2=2-\log_2(a^2) \quad (\because a>0)$

$$\Rightarrow \quad (2-2\log_2 a)=2-2\log_2 a$$

$$\Rightarrow \quad 2\log_2 a=2\log_2 a \Rightarrow a\in R^+$$

20. Consider $I=\int_{-1/x}^{1/x}\frac{\ln(1+t^2)}{1+e^t}dt$ ...(i)

$$\Rightarrow \quad I=\int_{-1/x}^{1/x}\frac{\ln(1+t^2)}{1+e^{-t}}dt \quad \text{(using King' property)}$$

$$I=\int_{-1/x}^{1/x}\frac{\ln(1+t^2)\,e^t}{1+e^t}dt \quad ...(ii)$$

On adding Eqs. (i) and (ii), we get

$$2I=\int_{-1/x}^{1/x}\ln(1+t^2)\,dt=2\int_0^{1/x}\ln(1+t^2)\,dt$$

$$\Rightarrow \quad I=\int_0^{1/x}\ln(1+t^2)\,dt$$

Hence, $l=\lim_{x\to\infty}x^3\int_0^{1/x}\ln(1+t^2)\,dt$

$$=\lim_{x\to\infty}\frac{\int_0^{1/x}\ln(1+t^2)\,dt}{x^{-3}} \quad \left(\frac{0}{0}\text{ form}\right)$$

Using L' Hospital's rule,

$$l=\lim_{x\to 0}\frac{x^4\ln\left(1+\frac{1}{x^2}\right)\cdot\left(-\frac{1}{x^2}\right)}{-3}=\frac{1}{3}\lim_{x\to\infty}x^2\ln\left(1+\frac{1}{x^2}\right)$$

$$=\frac{1}{3}\lim_{x\to\infty}\ln\left(1+\frac{1}{x^2}\right)^{x^2} \quad (1^{\infty}\text{ form})$$

$$=\lim_{x\to\infty}\frac{1}{3}x^2\left(1+\frac{1}{x^2}-1\right)=\frac{1}{3}$$

21. Put $\pi x=t \Rightarrow dx=\frac{dt}{\pi}$

$$\therefore \quad I=\frac{1}{\pi}\cdot\frac{\pi}{\pi}\int_0^{2008\pi}t\,|\sin t|\,dt=\frac{1}{\pi}\int_0^{2008\pi}t\,|\sin t|\,dt \quad ...(i)$$

$$\Rightarrow \quad I=\frac{1}{\pi}\int_0^{2008\pi}(2008\pi-t)\,|\sin t|\,dt \quad ...(ii)$$

On adding Eqs. (i) and (ii), we get

$$2I=\frac{2008\pi}{\pi}\int_0^{2008\pi}|\sin t|\,dt=(2008)^2\cdot\int_0^{\pi}|\sin t|\,dt$$

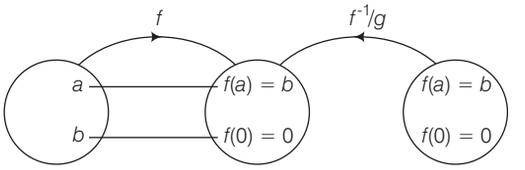
$$\Rightarrow \quad I=(2008)^2 \quad \Rightarrow \sqrt{I}=2008$$

22. $T_n=\frac{n}{n^2+k^2x^2}=\frac{1}{n[1+(k/n)^2x^2]}$;

$$S=\frac{1}{n}\sum_{k=1}^{n}\frac{1}{1+\underbrace{(k/n)^2}_{t}x^2}=\int_0^1\frac{dt}{1+t^2x^2}$$

$$=\frac{1}{x^2}\int_0^1\frac{dt}{t^2+(1/x^2)}=\left[\frac{1}{x}\tan^{-1}(tx)\right]_0^1=\frac{\tan^{-1}(x)}{x}$$

23. Let $y=f(x) \Rightarrow x=g(y)$ and $dy=f'(x)\,dx$



$$I=\int_0^a f(x)\,dx+\int_0^b g(y)\,dy; y=f(x)$$

$$\Rightarrow \quad x=f^{-1}(y)=g(y)=\int_0^a f(x)dx+\int_0^a xf'(x)\,dx$$

$$=\int_0^a(f(x)+xf'(x))\,dx=[xf(x)]_0^a=a\,f(a)=ab$$

24. Let $I=\int_{-1/\sqrt{3}}^{1/\sqrt{3}}\frac{x^4}{1-x^4}\cos^{-1}\frac{2x}{1+x^2}dx$ ...(i)

$$\Rightarrow I=\int_{-1/\sqrt{3}}^{1/\sqrt{3}}\frac{x^4}{1-x^4}\cos^{-1}\left(\frac{-2x}{1-x^4}\right)dx \quad \text{(using King's property)}$$

$$\Rightarrow \quad I=\int_{-1/\sqrt{3}}^{1/\sqrt{3}}\frac{x^4}{1-x^4}\left(\pi-\cos^{-1}\frac{2x}{1-x^4}\right)dx \quad ...(ii)$$

On adding Eqs. (i) and (ii), we get

$$\therefore \quad 2I=\pi\int_{-1/\sqrt{3}}^{1/\sqrt{3}}\frac{x^4}{1-x^4}dx \Rightarrow 2I=2\pi\int_0^{1/\sqrt{3}}\frac{x^4}{1-x^4}dx$$

$$\therefore \quad k=\pi$$

25. Put $\ln x=t$ or $x=e^t \Rightarrow dx=e^t\,dt$

$$\therefore \quad I=\int_{-\infty}^{\infty}f(e^t+e^{-t})\frac{t}{e^t}e^t\,dt=\int_{-\infty}^{\infty}f(e^t+e^{-t})\,t\,dt=0$$

(as the function is odd)

Aliter I Put $x=\tan\theta$

$$\int_0^{\pi/2}f\left(\tan\theta+\frac{1}{\tan\theta}\right)\frac{\ln\tan\theta}{\tan\theta}\cdot\sec^2\theta\,d\theta$$

$$=\int_0^{\pi/2}f\left(\tan\theta+\frac{1}{\tan\theta}\right)\frac{\ln\tan\theta}{\sin\theta\cos\theta}d\theta$$

Aliter II Put $x=1/t \Rightarrow I=-1 \Rightarrow 2I=0 \Rightarrow I=0$

26. $\lim_{\lambda\to 0}\left(\int_0^1(1+x)^{\lambda}\,dx\right)^{1/\lambda}=\lim_{\lambda\to 0}\left(\left|\frac{(1+x)^{\lambda+1}}{\lambda+1}\right|_0^1\right)^{1/\lambda}$

$$=\lim_{\lambda\to 0}\left(\frac{2^{\lambda+1}-1}{\lambda+1}\right)^{1/\lambda} \quad (1^{\infty}\text{ form})$$

$$=e^{\lim_{\lambda\to 0}\frac{1}{\lambda}\left(\frac{2^{\lambda+1}-1-\lambda-1}{\lambda+1}\right)}=e^{\lim_{\lambda\to 0}\left(\frac{2^{\lambda+1}-2-\lambda}{\lambda(\lambda+1)}\right)}$$

$$=e^{\lim_{\lambda\to 0}\left(\frac{2(2^{\lambda}-1)}{\lambda}-1\right)}=e^{2\ln 2-1}=e^{\ln\left(\frac{4}{e}\right)}=\frac{4}{e}$$

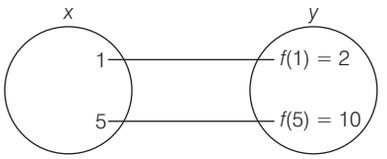
27. Let $y = f(x) \Rightarrow x = f^{-1}(y) = g(y)$

$$dy = f'(x)\,dx$$

$$\therefore \quad I = \int_1^5 f(x)\,dx + \int_1^5 xf'(x)\,dx$$

When $y = 2$, then $x = 1$

and when $y = 1$, then $x = 5$



$$\therefore \quad I = \int_1^5 (f(x) + x\,f'(x))dx = |x\,f(x)|_1^5$$

$$= 5f(5) - f(1) = 5 \cdot 10 - 2 = 48$$

28. $I = \int_0^{\pi/2} \sin x \sin 2x \sin 3x\,dx$ ...(i)

$$= \int_0^{\pi/2} \sin\left(\frac{\pi}{2} - x\right) \sin 2\left(\frac{\pi}{2} - x\right) \sin 3\left(\frac{\pi}{2} - x\right) dx$$

$$\Rightarrow \quad I = \int_0^{\pi/2} -\cos x \sin 2x \cos 3x\,dx \qquad \text{...(ii)}$$

$$\therefore \quad 2I = \int_0^{\pi/2} -\sin 2x\,(\cos x \cos 3x - \sin 3x \sin x)\,dx$$

$$= \int_0^{\pi/2} -\sin 2x \cos(4x)\,dx$$

$$= -\int_0^{\pi/2} \sin 2x\,(2\cos^2 2x - 1)\,dx$$

Put $\cos 2x = t \Rightarrow -\sin 2x \times 2\,dx = dt$

$$\therefore \quad 2I = \int_1^{-1} \frac{1}{2}(2t^2 - 1)\,dt = \frac{1}{2}\left[\frac{2t^3}{3} - t\right]_1^{-1}$$

$$= \frac{1}{2}\left[\frac{2}{3}(-1)^3 - (-1) - \left(\frac{2}{3}(1)^3 - 1\right)\right]$$

$$= \frac{1}{2}\left[-\frac{2}{3} + 1 - \frac{2}{3} + 1\right] = \frac{1}{2}\left[\frac{2}{3}\right] \quad \Rightarrow \quad I = \frac{1}{6}$$

29. Here, $f'(x) = (f(x))^2 > 0$; $\dfrac{d}{dx} f(g(x))|_{x=a}$

$$= f'(g(x)) \lim_{x \to a} \frac{g(x) - g(a)}{x - a}$$

It implies that $g(x)$ must be differentiable at $x = a$.

30. On putting $t = \dfrac{x^2}{z}$ and then solving,

$$\int_0^\infty \frac{\ln x}{x^2 + t^2}\,dt = \frac{2\pi \ln x}{x}$$

$$\Rightarrow \quad \frac{\ln x}{x} = \frac{\ln 2}{x}$$

$$\Rightarrow \quad x = 2 \text{ and } 4 \text{ i.e. two solutions.}$$

31. Put $\dfrac{x\pi}{n} = t$

$$\therefore \int_0^{\frac{16n^2}{\pi}} \cos\frac{\pi}{2}\left[\frac{\pi x}{n}\right] dx = \frac{n}{\pi}\int_0^{16n} \cos\frac{\pi}{2}[t]\,dt$$

$$= \frac{4n^2}{\pi}\int_0^4 \cos\frac{\pi}{2}[t]\,dt = 0$$

32. $\int_{-2}^{-1} (ax^2 - 5)\,dx + \int_1^2 (bx + c)\,dx + 5$

$$= \int_{-2}^{-1} (ax^2 - 5 - bx + c + 5)\,dx = 0$$

Hence, $ax^2 - bx + c = 0$ has atleast one root in $(-2, -1)$.

33. $I = \int_3^6 ((\sqrt{x-3} + \sqrt{3}) + (\sqrt{3} - \sqrt{x-3}))\,dx = 6\sqrt{3}$

34. $I_1 = \int_{-1}^1 (\{x\} + \{x^3\})\{x^2\}\,dx$

$$= -2\int_0^1 \{x^2\}\,dx = \left[-2 \times \frac{x^3}{3}\right]_0^1 = -\frac{2}{3}$$

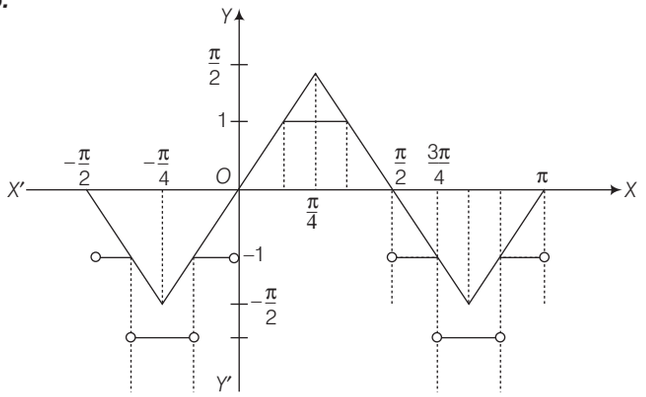
35. $\mathcal{J}_n - \mathcal{J}_{n-1} = \int_0^{\pi/2} \dfrac{\sin^2 nx - \sin^2(n-1)x}{\sin^2 x}\,dx$

$$= \int_0^{\pi/2} \frac{\sin(2n-1)x \cdot \sin x}{\sin^2 x}\,dx = I_n$$

i.e. $\quad \mathcal{J}_n - \mathcal{J}_{n-1} = I_n$

$\Rightarrow \quad \mathcal{J}_{n+1} - \mathcal{J}_n = I_{n+1}$

36.



37. (a) $I = \int_0^{\pi/2} \ln(\cot x)\,dx \Rightarrow I = \int_0^{\pi/2} \ln(\tan x)\,dx$

$$I = -\int_0^{\pi/2} \ln(\cot x)\,dx \Rightarrow I = -I \Rightarrow I = 0$$

(b) $I = \int_0^{2\pi} \sin^3 x\,dx = -\int_0^{2\pi} \sin^3 x\,dx \Rightarrow I = 0$

(c) At $x = \dfrac{1}{t}$, $I = \int_e^{1/e} \dfrac{-(1/t^2)\,dt}{-1/t\,(\ln t)^{1/3}} = -\int_{1/e}^e \dfrac{dt}{t(\ln t)^{1/3}}$

$$I = -1 \quad \text{or} \quad I = 0$$

(d) $\sqrt{\dfrac{1 + \cos 2x}{2}} > 0 \quad \Rightarrow \quad \int_0^\pi \sqrt{\dfrac{1 + \cos 2x}{2}}\,dx > 0$

38. $I = \int_0^1 (10x^4 - 3x^2 - 1)\,dx = [2x^5 - x^3 - x]_0^1 = 0$

Since, $f(x)$ is even, hence must have a root in $(-1, 0)$.

39. We have, $I_1 = \int_0^{\pi/2} \cos(\pi \sin^2 x)\,dx$

$$I_1 = \int_0^{\pi/2} \cos(\pi \cos^2 x)\,dx$$

On adding, $2I_1 = \int_0^{\pi/2} \cos(\pi \sin^2 x) + \cos(\pi \cos^2 x)\,dx$

$$= \int_0^{\pi/2} 2\cos\left(\frac{\pi}{2}\right) \cdot \cos\left(\frac{\pi}{2}\cos 2x\right) dx = 0$$

$$\Rightarrow \quad I_1 = 0 \qquad \text{...(i)}$$

Now, $I_2 = \int_0^{\pi/2} \cos\{\pi(1-\cos 2x)\}\,dx$

$= -\int_0^{\pi/2} \cos(\pi \cos 2x)\,dx$

$= -\frac{1}{2}\int_0^{\pi} \cos(\pi \cos t)\,dt$ (put $2x = t$)

$= -\frac{2}{2}\int_0^{\pi/2} \cos(\pi \cos t)\,dt = I_3$

$\Rightarrow \quad I_2 + I_3 = 0$

$I_3 = -\int_0^{\pi/2} \cos(\pi \sin t)\,dt$

$\therefore \quad I_2 + I_3 = 0$ ...(ii)

Hence, $I_1 + I_2 + I_3 = 0$

40. $f(x) = 2\int_0^1 \underbrace{(1-t)}_{\text{I}} \underbrace{\cos(xt)}_{\text{II}}\,dt$

$= 2\left[(1-t)\frac{\sin xt}{x}\Big|_0^t + \frac{1}{x}\int_0^1 \sin xt\,dt\right] = 2\left[\left|0 - \frac{1}{x^2}\cos xt\right|_0^1\right]$

$f(x) = 2\left[\frac{1-\cos x}{x^2}\right] \qquad (x \neq 0)$

If $x = 0$, then $f(x) = \int_{-1}^{1}(1-|t|)\,dt = 2\int_0^1 (1-t)\,dt = 1$

$\therefore$ option (c) is correct.

Hence, $f(x) = \begin{cases} 2\left(\frac{1-\cos x}{x^2}\right), & \text{if } x \neq 0 \\ 1, & \text{if } x = 0 \end{cases}$

$\therefore$ f is continuous at $x = 0$.

$\therefore$ option (d) is correct.

41. Given, $f(f(x)) = -x + 1$

Replacing x by $f(x)$, we get

$f(f(f(x))) = -f(x) + 1$

$f(1-x) = -f(x) + 1$

$f(x) + f(1-x) = 1$ ...(i)

Now, $\mathcal{I} = \int_0^1 f(x)\,dx = \int_0^1 f(1-x)\,dx$ (using King's property)

$\Rightarrow \quad 2\mathcal{I} = \int_0^1 (f(x) + f(1-x))\,dx$

$\Rightarrow \quad 2\mathcal{I} = \int_0^1 dx = 1 \Rightarrow \mathcal{I} = \frac{1}{2}$

Put $x = \frac{1}{4}$ in Eq. (i),

$F\left(\frac{1}{4}\right) + F\left(1 - \frac{1}{4}\right) = 1 \Rightarrow F\left(\frac{1}{4}\right) + F\left(\frac{3}{4}\right) = 1$

Now $I = \int_0^{\pi/2} \frac{\sin x}{(\sin x + \cos x)^3}\,dx$

$I = \int_0^{\pi/2} \frac{\sin\left(\frac{\pi}{2} - x\right)}{\left(\sin\left(\frac{\pi}{2} - x\right) + \cos\left(\frac{\pi}{2} - x\right)\right)^3}\,dx$

$\Rightarrow \quad I = \int_0^{\pi/2} \frac{\cos x}{(\cos x + \sin x)^3}\,dx$

$\therefore \quad 2I = \int_0^{\pi/2} \frac{1}{(\sin x + \cos x)^2}\,dx = \frac{1}{2}\int_0^{\pi/2} \frac{dx}{\left(\frac{1}{\sqrt{2}}\sin x + \frac{1}{\sqrt{2}}\cos x\right)^2}$

$= \frac{1}{2}\int_0^{\pi/2} \frac{dx}{\sin^2\left(\frac{\pi}{4} + x\right)}$

$= \frac{1}{2}\int_0^{\pi/2} \operatorname{cosec}^2\left(\frac{\pi}{4} + x\right)dx = -\frac{1}{2}\left[\cot\left(\frac{\pi}{4} + x\right)\right]_0^{\pi/2}$

$= -\frac{1}{2}[-1-1] = 1 \qquad \Rightarrow I = \frac{1}{2}$

42. We have, $f(x) = x^2 + ax^2 + bx^3$

where, $a = \int_{-1}^{1} t\,f(t)\,dt$ and $b = \int_{-1}^{1} f(t)\,dt$

Now, $a = \int_{-1}^{1} t\,[(a+1)t^2 + bt^3]\,dt$

$\Rightarrow \quad a = 2b\int_0^1 t^4 dt = \frac{2b}{5}$ . ..(i)

Again, $b = \int_{-1}^{1} f(t)\,dt = \int_{-1}^{1} ((a+1)t^2 + bt^3)\,dt$

$\Rightarrow \quad b = 2\int_0^1 (a+1)t^2\,dt$

$\Rightarrow \quad b = \frac{2(a+1)}{3}$ ...(ii)

From Eqs. (i) and (ii), $\frac{5a}{2} = \frac{2(a+1)}{3}$

$\Rightarrow \quad \left(\frac{5}{2} - \frac{2}{3}\right)a = \frac{2}{3} \quad \Rightarrow \quad \frac{11}{6}a = \frac{2}{3}$

$\Rightarrow \quad a = \frac{4}{11}$ and $b = \frac{10}{11}$

Hence, $\int_{-1}^{1} t\,f(t)\,dt = \frac{4}{11}$ and $\int_{-1}^{1} f(t)\,dt = \frac{10}{11}$

$\therefore \quad f(x) = (a+1)x^2 + bx^3$

$f(1) = (a+1) + b$

$f(-1) = (a+1) - b$

$\Rightarrow \quad f(1) + f(-1) = 2(a+1) = \frac{30}{11}$

and $f(1) - f(-1) = 2b = \frac{20}{11}$

43. Given, $(f'(x))^2 + (g(x))^2 = 1$

$f(x) + \int_0^x g(t)\,dt = \sin x(\cos x - \sin x)$

Differentiating both the sides, we get

$f'(x) + g(x) = \cos 2x - \sin 2x$ ...(i)

Squaring both the sides of Eq. (i), we get

$(f'(x))^2 + (g(x))^2 = 2f'(x)\cdot g(x) = 1 - \sin 4x$

$\Rightarrow \quad 1 + 2f'(x)\cdot g(x) = 1 - \sin 4x$

$\therefore \quad 2f'(x)\,g(x) = -\sin 4x$

Now, substituting $g(x) = -\frac{\sin 4x}{2f'(x)}$ in Eq. (i), we get

$$f'(x) - \frac{\sin 4x}{2f'(x)} = \cos 2x - \sin 2x$$

Put $f'(x) = t$

$\Rightarrow 2t^2 - 2(\cos 2x - \sin 2x)\, t - \sin 4x = 0$

$\Rightarrow t = \dfrac{2(\cos 2x - \sin 2x) \pm \sqrt{4(1 - \sin 4x) + 8 \sin 4x}}{4}$

$\therefore \quad 4t = 2(\cos 2x - \sin 2x) \pm \sqrt{4(1 - \sin 4x) + 8 \sin 4x}$

$\Rightarrow 2t = (\cos 2x - \sin 2x) \pm \sqrt{1 + \sin 4x}$

Taking + ve sign, $2t = \cos 2x - \sin 2x + \cos 2x + \sin 2x$

$\Rightarrow \quad t = \cos 2x$

Taking – ve sign, $t = -\sin 2x$

Since, $f'(x) = \cos 2x$ or $f'(x) = -\sin 2x$

$$f(x) = \frac{1}{2}\sin 2x + C_1 \quad \text{or} \quad f(x) = \frac{\cos 2x}{2} + C_2$$

$f(0) = 0$

$\Rightarrow \quad C_1 = 0$ and $C_2 = -1/2$

$\therefore \quad f(x) = \dfrac{1}{2}\sin 2x$ or $f(x) = \dfrac{\cos 2x - 1}{2}$

If $f'(x) = \cos 2x$, then $g(x) = -\sin 2x$

If $f'(x) = -\sin 2x$, then $g(x) = \cos 2x$

i.e. $f(x) = \dfrac{1}{2}\sin 2x$ and $g(x) = -\sin 2x$

$\Rightarrow f(x) = \dfrac{\cos 2x - 1}{2}$ and $g(x) = \cos 2x$

44. Consider $f(x) = \int_{-x}^{x} (\underbrace{t \sin at}_{\text{even}} + \underbrace{bt}_{\text{odd}} + \underbrace{c}_{\text{even}})\, dt$

$$= 2\int_0^x (t \sin at + c)\, dt$$

$$= 2\left[\left|-t\,\frac{\cos at}{a}\right|_0^x + \int_0^x \frac{\cos at}{a}\, dt + |ct|_0^x\right] \text{(using I.B.P.)}$$

$$= 2\left[\frac{-x\cos ax}{a} + \frac{1}{a^2}\sin ax + cx\right]$$

$$\therefore \quad \lim_{x\to 0}\frac{f(x)}{x} = \lim_{x\to 0} 2\left[-\frac{\cos ax}{a} + \frac{\sin ax}{a \cdot ax} + c\right]$$

$$= 2\left[-\frac{1}{a} + \frac{1}{a} + c\right] = 2c$$

45. Consider $I = \int_a^{\infty} \dfrac{n\, dx}{n^2\left(x^2 + \dfrac{1}{n^2}\right)} = \dfrac{1}{n} \cdot n\,(\tan^{-1} nx)_0^{\infty} = \left(\dfrac{\pi}{2} - \tan^{-1} an\right)$

$$\therefore \quad L = \lim_{n\to\infty}\left(\frac{\pi}{2} - \tan^{-1} an\right) = \begin{cases} \pi, & \text{if } a < 0 \\ \pi/2, & \text{if } a = 0 \\ 0, & \text{if } a > 0 \end{cases}$$

46. $\lim\limits_{x\to 0} \dfrac{\int_0^x \dfrac{t^2 dt}{(a + t^r)^{1/p}}}{bx - \sin x} = \lim\limits_{x\to 0} \dfrac{\dfrac{x^2}{(a + x^r)^{1/p}}}{b - \cos x}$ Using L'Hospital's rule

For existence of limit, $\lim\limits_{x\to 0}$ denominator = 0

$\therefore \quad b - 1 = 0 \Rightarrow \quad b = 1$

47. $l = \lim\limits_{x\to 0} \dfrac{x^2}{(a + x^r)^{1/p}} \cdot \dfrac{x^2}{(1 - \cos x)} \cdot \dfrac{1}{x^2}$

$$= 2\lim_{x\to 0} \frac{1}{(a + x^r)^{1/p}} = \frac{2}{a^{1/p}}$$

If $p = 3$ and $l = 1$, then $1 = \dfrac{2}{a^{1/3}} \Rightarrow a = 8$

48. If, $p = 2$ and $a = 9$, then $l = \dfrac{2}{9^{1/2}} = \dfrac{2}{3}$

49. Here, $f(x) = e^x \underbrace{\int_0^1 e^t \cdot f(t)\, dt}_{A\,(\text{say})}$

$f(x) = Ae^x$ ...(i)

$\Rightarrow \quad f(t) = Ae^t$

where, $A = \int_0^1 e^t \cdot f(t)\, dt$

$\Rightarrow \quad A = \int_0^1 e^t \cdot Ae^t\, dt; \quad A = A\int_0^1 e^{2t}\, dt$

Now, $A\left[\int_0^1 e^{2t} dt - 1\right] = 0 \Rightarrow A = 0$, as $\int_0^1 e^{2t}\, dt \neq 0$

Hence, $f(x) = 0 \Rightarrow f(1) = 0$

50. Again, $g(x) = e^x \int_0^1 e^t\, g(t)\, dt + x$

$\Rightarrow \quad g(x) = Be^x + x$ ...(ii)

$\Rightarrow \quad g(t) = Be^t + t$

where, $B = \int_0^1 e^t\, g(t)\, dt \Rightarrow B = \int_0^t e^t\,(Be^t + t)\, dt$

$\Rightarrow \quad B = B\int_0^1 e^{2t}\, dt + \int_0^1 e^t \cdot t\, dt$

But $\int_0^1 e^{2t}\, dt = \dfrac{1}{2}(e^2 - 1)$ and $\int_0^1 te^t\, dt = 1$

$\therefore \quad B = \dfrac{B}{2}(e^2 - 1) + 1$

$\Rightarrow \quad 2B = B(e^2 - 1) + 2$

$\Rightarrow \quad 3B = Be^2 + 2 \quad \Rightarrow \quad B = \dfrac{2}{3 - e^2}$

From Eq. (ii), $g(x) = \left(\dfrac{2}{3 - e^2}\right)e^x + x \Rightarrow g(0) = \dfrac{2}{3 - e^2}$

Also, $f(0) = 0$

$\therefore \quad g(0) - f(0) = \dfrac{2}{3 - e^2} - 0 = \dfrac{2}{3 - e^2}$

51. $g(2) = \dfrac{2e^2}{3 - e^2} + 2 = \dfrac{6}{3 - e^2}$

$\therefore \quad \dfrac{g(0)}{g(2)} = \dfrac{2}{3 - e^2} \cdot \dfrac{3 - e^2}{6} = \dfrac{1}{3}$

Solutions (Q. Nos. 52 to 54)

We have the equations of the tangents to the curve $y = \int_{-\infty}^{x} f(t)dt$ and $y = f(x)$ at arbitrary points on them are

$$Y - \int_{-x}^{x} f(t)\, dt = f(x)\,(X - x) \quad \text{...(i)}$$

and $Y - f(x) = f'(x)\,(X - x)$ ...(ii)

As Eqs. (i) and (ii) intersect at the same point on the X-axis

Putting $Y = 0$ and equating x-coordinates, we have

$$x - \frac{f(x)}{f'(x} = x - \frac{\int_{-\infty}^{x} f(t)\,dt}{f(x)}$$

$$\Rightarrow \quad \frac{f(x)}{\int_{-\infty}^{x} f(t)\,dt} = \frac{f'(x)}{f(x)}$$

$$\Rightarrow \quad \int_{-\infty}^{x} f(t)\,dt = cf(x) \qquad \text{...(iii)}$$

As, $f(0) = 1 \Rightarrow \int_{-\infty}^{0} f(t)\,dt = c \times 1 \Rightarrow c = \frac{1}{2}$

$\Rightarrow \int_{-\infty}^{x} f(t)\,dt = \frac{1}{2} f(x)$; differentiating both the sides and integrating and using boundary conditions, we get $f(x) = e^{2x}$; $y = 2ex$ is tangent to $y = e^{2x}$.

$\therefore$ Number of solutions = 1.

Cearly, $f(x)$ is increasing for all x.

$\therefore \quad \lim_{x \to \infty} (e^{2x})^{e^{-2x}} = 1 \qquad (\infty^0 \text{ form})$

Solutions (Q. Nos. 55 to 57)

We have, $g(x) = g(0) + xg'(0) + \frac{x^2}{2} g''(0) = -bx^2 + cx - 6$

$h(x) = g(x) = 4x^4 - ax^3 + bx^2 - cx + 6 = 0$ has 4 distinct real roots. Using Descarte's rule of signs.

Given biquadratic equation has 4 distinct positive roots.

Let the roots be x_1, x_2, x_3 and x_4.

Now, $\frac{\frac{1}{x_1} + \frac{2}{x_2} + \frac{3}{x_3} + \frac{4}{x_4}}{4} \geq \sqrt[4]{\frac{24}{x_1\ x_2\ x_3\ x_4}}$

$\Rightarrow \quad 2 \geq 2 \Rightarrow \frac{1}{x_1} = \frac{2}{x_2} = \frac{3}{x_3} = \frac{4}{x_4} = k$

$\Rightarrow \quad \frac{1}{x_1} \cdot \frac{2}{x_2} \cdot \frac{3}{x_3} \cdot \frac{4}{x_4} = k^4$

$\Rightarrow \quad \frac{24}{3/2} = k^4 \ \Rightarrow \ k = 2$

$\therefore$ Roots are $\frac{1}{2}$, 1, $\frac{3}{2}$ and 2. Also, $a = 20$ and $c = 25$

58. At $x = 1$, $y = 0$, $\frac{dy}{dx} = 2x \cdot (x^4)^2 - (x^2)^2 = 1$

$\therefore$ Equation of the tangent is $y = x - 1$.

59. $\frac{dy}{dx} = 4x^3(\ln x^4)^2 - 3x^2 (\ln x^3)^2$

$= 64x^3 (\ln x)^2 - 27x^2 (\ln x)^2$

$\therefore \lim_{x \to 0^+} \frac{dy}{dx} = 64 \lim_{x \to 0^+} x^3 (\ln x)^2 - 27 \lim_{x \to 0^+} x^2 (\ln x)^2 = 0$

60. We have, $f(x) = \int_1^x e^{t^2/2} (1 - t^2)\,dt$

$\therefore \quad f'(x) = [e^{x^2/2} (1 - x^2)]^2$

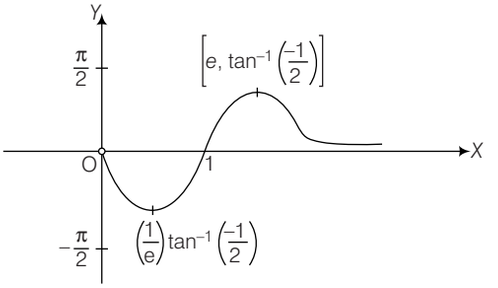
Now, $f'(1) = e^{1/2} \cdot 0 = 0$

61. Here, $f(x) = \tan^{-1}\left(\frac{\log_e x}{\log_e x + 1}\right), 0 < x < \infty$

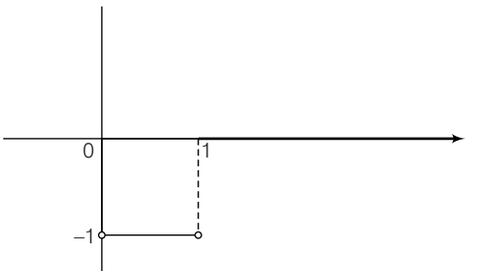
attains minimum at $x = \frac{1}{e}$ and maximum at $x = e$.

Also, $f(x)$ has $y = 0$ as asymptotes.

$\therefore \quad f(x)$ can be shown as



Clearly, $f(x)$ is neither injective nor subjective, also graph for $[f(x)]$ can be shown, as



62. $\int_0^{\infty} [f(x)]dx = \int_0^1 -1 \cdot dx + \int_1^{\infty} 0 \cdot dx = -(x)\frac{1}{0} = -1$

63. (A) For $a = 0$, $I = \int_0^T \sin^2 x\,dx$

$= \int_0^T \frac{1 - \cos 2x}{2}\,dx$

$= \left[\frac{x}{2} - \frac{1}{4} \sin 2x\right]_0^T = \frac{T}{2} - \frac{1}{4} \sin 2T$

$\therefore \quad L = \frac{1}{2} - \lim_{T \to \infty} \frac{1}{4} \frac{\sin 2T}{T} = \frac{1}{2}$

(B) For $a = 1$, $\int_0^T 4 \sin^2 x\,dx \Rightarrow L = 2$

(C) For $a = -1$, $\int_0^T 0\,dx = 0 \Rightarrow L = 0$

(D) For $a \neq 0, -1, 1$,

$I = \int_0^T (\sin^2 x + \sin^2 ax + 2 \sin x \cdot \sin ax)\,dx$

$= \int_0^T \left(\frac{1 - \cos 2x}{2} + \frac{1 - \cos 2ax}{2} + \cos(a-1)x - \cos(a+1)x\right)dx$

$= \left[x - \frac{1}{4} \sin 2x - \frac{1}{4a} \sin 2ax \frac{\sin(a-1)\,x}{a-1} - \frac{\sin(a+1)\,x}{a+1}\right]_0^T$

$\therefore L = \lim_{T \to \infty} \frac{T}{T} - \lim_{T \to \infty} \frac{1}{T}$

$\left[\frac{1}{4} \sin 2x - \frac{1}{4a} \sin 2ax + \frac{\sin(a-1)\,x}{a-1} - \frac{\sin(a+1)\,x}{a+1}\right]_0^T$

$\Rightarrow \quad L = 1$

64. $\because \quad f(\theta)=\left[\frac{(x+\sin\theta)^3}{3}\right]_0^1=\frac{(1+\sin\theta)^3-\sin^3\theta}{3}$

and $g(\theta)=\left[\frac{(x+\cos\theta)^3}{3}\right]_0^1=\frac{(1+\cos\theta)^3-\cos^3\theta}{3}$

$\therefore f(\theta)=\frac{1+3\sin\theta+3\sin^2\theta}{3}$ and $g(\theta)=\frac{1+3\cos\theta+3\cos^2\theta}{3}$

Now, $f(\theta)-g(\theta)=(\sin\theta-\cos\theta)+(\sin^2\theta-\cos^2\theta)$

and $f(\theta)-g(\theta)=(\sin\theta-\cos\theta)(1+\sin\theta+\cos\theta)$

Now verify all matchings.

65. (A) Let $a=2008$, then

$I=\int_0^1(1+ax^a)\,e^{x^a}\,dx$

$I=\int_0^1(e^{x^a}+ax^a\,e^{x^a})\,dx \qquad (\text{note}: ax^a=ax\cdot x^{a-1})$

$\therefore \quad I=\int_0^1(e^{x^a}+e^{x^a}\cdot x\cdot ax^{a-1})\,dx$

$=\int_0^1(f(x)+x\,f'(x))\,dx$, where $f(x)=e^{x^a}$

Hence, $I=[xe^{x^a}]_0^1=e$

(B) $\quad I=I_1+I_2$

Consider $I_2=\int_1^{1/e}\sqrt{-\ln x}\,dx$

Put $\sqrt{-\ln x}=t\Rightarrow -\ln x=t^2\Rightarrow x=e^{-t^2}$

$\Rightarrow \qquad dx=-2t\,e^{-t^2}\,dt$

$\therefore \quad I_2=\int_0^1\underbrace{t}_{\text{I}}\cdot\underbrace{(-2te^{-t^2})}_{\text{II}}\,dt=[te^{-t^2}]_0^1-\int_0^1e^{-t^2}dt=\frac{1}{e}-\int_0^1e^{-t^2}dt$

Hence, $\quad I_2=\int_0^1e^{-x}\,dx+\frac{1}{e}-\int_0^1e^{-t^2}\,dt=\frac{1}{e}=e^{-1}$

Note that, if $f(x)=e^{-x^2}$, then $f^{-1}(x)=\sqrt{-\ln x}$

(C) $L=\lim_{n\to\infty}\left[\left(\frac{1}{n}\right)^1\cdot\left(\frac{2}{n}\right)^2\cdot\left(\frac{3}{n}\right)^3\cdots\left(\frac{n}{n}\right)^n\right]^{\frac{1}{n^2}}$

$\Rightarrow \quad \ln L=\lim_{n\to\infty}\frac{1}{n^2}$

$\left[1\cdot\ln\left(\frac{1}{n}\right)+2\cdot\ln\left(\frac{2}{n}\right)+3\cdot\ln\left(\frac{3}{n}\right)+\ldots+n\cdot\ln\left(\frac{n}{n}\right)\right]$

General term of $\ln L=\frac{r}{n^2}\ln\frac{r}{n}$

$$\text{Sum}=\frac{1}{n}\cdot\sum_{r=1}^{n}\frac{r}{n}\ln\left(\frac{r}{n}\right)$$

$\ln L=\int_0^1 x\ln x\,dx=\left[\frac{x^2\cdot\ln x}{2}\right]_0^1-\frac{1}{2}\int_0^1x^2\,\frac{1}{x}\,dx$

$=\left[0-\frac{1}{2}\,\frac{x^2}{2}\right]_0^1=-\frac{1}{4}$

$\therefore \quad L=e^{-1/4}$

66. (A) We have, $f'(x)=\frac{g'(x)}{\sqrt{1+g^3(x)}}$

and $g'(x)=(1+\sin(\cos^2 x))(-\sin x)$

Hence, $\quad f'(x)=\frac{(1+\sin(\cos^2 x))(-\sin x)}{\sqrt{1+g^3(x)}}$

$$f'\left(\frac{\pi}{2}\right)=\frac{1+0}{\sqrt{1+g^3\left(\frac{\pi}{2}\right)}}=-1,\ g\left(\frac{\pi}{2}\right)=0$$

$\therefore \quad f'\left(\frac{\pi}{2}\right)=-1$

(B) We have, $\int_0^x f(x)\,dx=\{f(x)\}^2$

Differentiating both the sides, we get

$$f(x)=2f(x)\cdot f'(x)\ \Rightarrow\ f'(x)=\frac{1}{2}$$

Integrating both the sides, $f(x)=\frac{1}{2}x+C$

where, $\quad f(0)=0\ \Rightarrow\ C=0$

$\Rightarrow \qquad f(x)=\frac{x}{2}\ \Rightarrow\ f(2)=1$

(C) Maximum when $a=-1, b=2\Rightarrow a+b=1$

(D) If $\quad \lim_{x\to0}\frac{\sin 2x}{x^3}+a+\frac{b}{x^2}=0$, then

$$\lim_{x\to0}\frac{\sin 2x+ax^3+bx}{x^3}=0$$

For limit to exist $2+b=0\Rightarrow b=-2$

$\therefore \quad \lim_{x\to0}\frac{\sin 2x+ax^3-2x}{x^3}=0$

Using left hand rule and solving, we get $a=\frac{4}{3}$

$\therefore \qquad 3a+b=2$

67. Let $B=\sum_{n=1}\frac{\sin nx}{4^n}=\frac{\sin x}{4}+\frac{\sin 2x}{4^2}+\ldots$

and $\quad A=1+\cos\frac{x}{4}+\cos\frac{2x}{4^2}+\ldots$

$\therefore A+iB=1+\frac{e^{ix}}{4}+\frac{e^{i2x}}{4^2}+\ldots=\frac{1}{1-\frac{e^{ix}}{4}}$

Thus, B imaginary part of $\frac{1}{1-\frac{e^{ix}}{4}}=\frac{4}{4-\cos x-i\sin x}$

$\therefore \qquad B=\frac{4\sin x}{17-\theta\cos x}\Rightarrow f(x)=\frac{4\sin x}{17-\theta\cos x}$

and $\int_0^\pi f(x)dx=\int_0^\pi\frac{4\sin x}{17-\theta\cos x}=\frac{1}{2}\log\left(\frac{25}{9}\right)$

$=\log\left(\frac{5}{3}\right)=\log\left(\frac{m}{n}\right)$

$\therefore \qquad m+n=8$

68. Here, $I=\int_{-\pi/2}^{\pi/2}\frac{\cos x dx}{1+2[\sin^{-1}(\sin x)]}$

$=\int_{-\pi/2}^{-1}\frac{\cos x}{-3}dx+\int_{-1}^{0}\frac{\cos x\,dx}{-1}+\int_0^1\cos x\,dx+\int_1^{\pi/2}\frac{\cos x}{3}dx$

$=\frac{1}{3}\int_{-1}^{-\pi/2}\cos x dx+\int_0^{-1}\cos x\,dx+\int_0^1\cos x\,dx+\frac{1}{3}\int_1^{\pi/2}\cos x\,dx$

$=\frac{1}{3}\int_0^{\pi/2}\cos t(-dt)+\int_0^1\cos(t)\cdot(-dt)$

$+\int_0^1\cos x\,dx+\frac{1}{3}\int_1^{\pi/2}\cos x\,dx$

$=0$

69. Here, $f(x+1)-f(x)=\frac{1}{\pi}\int_0^{\pi/2}\frac{\sin^2(n+1)\theta-\sin^2 n\theta}{\sin^2\theta}d\theta$

$=\frac{1}{\pi}\int_0^{\pi/2}\frac{\sin(2n+1)\theta\cdot\sin\theta}{\sin^2\theta}d\theta$

$=\frac{1}{\pi}\int_0^{\pi/2}\frac{\sin(2n+1)\theta}{\sin^2\theta}d\theta$

$=\frac{1}{\pi}\left(\int_0^{\pi/2}\frac{\sin 2n\theta\cdot\cos\theta}{\sin\theta}d\theta+\int_0^{\pi/2}\cos 2n\theta\, d\theta\right)$

Using, $\cos\theta+\cos3\theta+\cos5\theta+....+\cos(2n-1)\theta$

$=\frac{\sin\frac{n\cdot(2\theta)}{2}}{\sin\left(\frac{2\theta}{2}\right)}\cdot\cos(\theta+(n-1)\theta)$

i.e. $\cos\theta+\cos3\theta+\cos5\theta+...+\cos(2n-1)\theta=\frac{1}{2}\left(\frac{\sin2n\theta}{\sin\theta}\right)$

$\therefore f(n+1)-f(n)=\frac{1}{\pi}$

$\left[2\int_0^{\pi/2}\cos\theta+\cos3\theta+...+\cos(2n-1)\theta\cdot\cos\theta\,d\theta+0\right]$

$=\frac{1}{\pi}\int_0^{\pi/2}\{(2\cos\theta\cos\theta)+(2\cos3\theta\cos\theta)$

$+\ldots(2\cos(2n-1)\cdot\cos\theta)\}d\theta$

$=\frac{1}{\pi}\int_0^{\pi/2}1\cdot d\theta,\ \text{as}\int_0^{\pi/2}\cos2n\theta\,d\theta=0$

$\therefore\quad f(n+1)-f(n)=\frac{1}{2}$

If $n=1$, $f(2)-f(1)=\frac{1}{2}\left(\text{as}\,f(1)=\frac{1}{2}\right)\Rightarrow f(2)=\frac{2}{2}$

If $n=2$, $f(3)-f(2)=\frac{1}{2}$

$\Rightarrow f(3)=\frac{3}{2}$ and so on $\quad\therefore f(n)=\frac{n}{2}$

Hence, $\frac{f(15)+f(3)}{f(15)-f(9)}=\frac{\frac{15}{2}+\frac{3}{2}}{\frac{15}{2}-\frac{9}{2}}=3$

70. Here, $g(x)=\int_{-2}^{h(x)}e^{(1+t)^2}dt$

$\Rightarrow\quad g'(x)=h'(x)\cdot e^{(1+h(x))}$

$\Rightarrow\quad g'(x)=h'(x)\cdot e$

$\Rightarrow\quad g'(2)=h'(2)\cdot e^{(1+h(x))^2}$

$\Rightarrow e^4=1\cdot e^{(1+h(2))^2}$, given $g'(2)=e^4$ and $h'(2)=1$

$\therefore\quad (1+h(2))^2=4$

$\Rightarrow\quad 1+h(2)=2,-2$

$\therefore\quad h(2)=-3,1$

$\therefore$ Absolute sum for all possible values of $h(2)=|-3+1|=2$

71. Let $I=\int_0^{\pi/2}\sin x\cdot\log(\sin x)dx=\frac{1}{2}\int_0^{\pi/2}\sin x\cdot\log(\sin^2 x)dx$

$=\frac{1}{2}\int_0^{\pi/2}\sin x\cdot\log(1-\cos^2 x)dx$

Put $\cos x=t\Rightarrow-\sin x\,dx=dt$

$\therefore\quad I=\frac{1}{2}\int_0^1\log(1-t^2)dt$

$=\frac{1}{2}\int_0^1\left(-t^2-\frac{(-t^2)^2}{2}+\frac{(-t^2)^3}{2}...\right)dt$

$=\frac{1}{2}\left[\frac{-t^3}{3}-\frac{t^5}{10}+\frac{t^7}{21}...\right]_0^1=\frac{1}{2}\left[\frac{-1}{3}-\frac{1}{10}+\frac{1}{21}...\right]$

$=-\frac{1}{2}\left[\frac{1}{3}+\frac{1}{10}+\frac{1}{21}+...\right]=-\left[\frac{1}{2\times3}+\frac{1}{20}+\frac{1}{42}+...\right]$

$=-\left[\left(\frac{1}{2}-\frac{1}{3}\right)+\left(\frac{1}{4}-\frac{1}{5}\right)+\left(\frac{1}{6}-\frac{1}{7}\right)+...\right]$

$=\log_e 2-1=\log_e\left(\frac{2}{e}\right)$

$\therefore\quad K=2$

72. Let $I=\int_{-\pi/2}^{\pi/2}\frac{x^2\cos x}{1+e^x}dx$ ...(i)

$\left[\because\int_a^b f(x)dx=\int_a^b f(a+b-x)\,dx\right]$

$\Rightarrow\quad I=\int_{-\pi/2}^{\pi/2}\frac{x^2\cos(-x)}{1+e^{-x}}dx$ ...(ii)

On adding Eqs. (i) and (ii), we get

$2I=\int_{-\pi/2}^{\pi/2}x^2\cos x\left[\frac{1}{1+e^x}+\frac{1}{1+e^{-x}}\right]dx$

$=\int_{-\pi/2}^{\pi/2}x^2\cos x\cdot(1)\,dx$

$\left[\because\int_{-a}^{a}f(x)dx=2\int_0^a f(x)dx,\ \text{when}\ f(-x)=f(x)\right]$

$\Rightarrow\quad 2I=2\int_0^{\pi/2}x^2\cos x\,dx$

Using integration by parts, we get

$2I=2\left[x^2(\sin x)-(2x)(-\cos x)+(2)(-\sin x)\right]_0^{\pi/2}$

$\Rightarrow\quad 2I=2\left[\frac{\pi^2}{4}-2\right]$

$\therefore\quad I=\frac{\pi^2}{4}-2$

73. Let $f(x)=\int_0^x\frac{t^2}{1+t^4}dt$

$\Rightarrow f'(x)=\frac{x^2}{1+x^4}>0$, for all $x\in[0,1]$

$\therefore f(x)$ is increasing.

At $x=0$, $f(0)=0$ and at $x=1$,

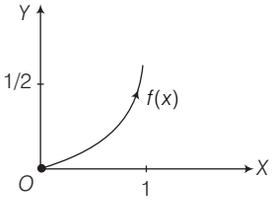
$f(1)=\int_0^1\frac{t^2}{1+t^4}dt$

Because, $\quad 0<\frac{t^2}{1+t^4}<\frac{1}{2}$

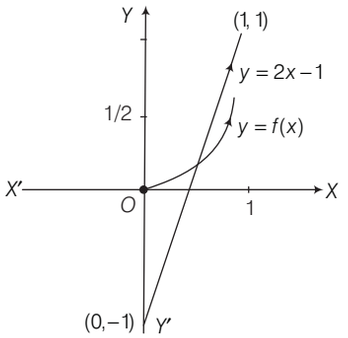
$\Rightarrow\quad\int_0^1 0\cdot dt<\int_0^1\frac{t^2}{1+t^4}dt<\int_0^1\frac{1}{2}\cdot dt$

$\Rightarrow\quad 0<f(1)<\frac{1}{2}$

Thus, $f(x)$ can be plotted as



$\therefore$ $y = f(x)$ and $y = 2x - 1$ can be shown as



From the graph, the total number of distinct solutions for $x \in (0, 1] = 1$. [as they intersect only at one point]

74. Here, $f(x) = 7\tan^8 x + 7\tan^6 x - 3\tan^4 x - 3\tan^2 x$

for all $x \in \left(\frac{-\pi}{2}, \frac{\pi}{2}\right)$

$$\therefore \quad f(x) = 7\tan^6 x \sec^2 x - 3\tan^2 x \sec^2 x$$
$$= (7\tan^6 x - 3\tan^2 x)\sec^2 x$$

Now, $\int_0^{\pi/4} x f(x)dx = \int_0^{\pi/4} \underset{\text{I}}{x}\,(7\tan^6 x - \underset{\text{II}}{3\tan^2 x})\sec^2 x\,dx$

$$= [x(\tan^7 x - \tan^3 x)]_0^{\pi/4} - \int_0^{\pi/4} 1\,(\tan^7 x - \tan^3 x)dx$$
$$= 0 - \int_0^{\pi/4} \tan^3 x(\tan^4 x - 1)dx$$
$$= -\int_0^{\pi/4} \tan^3 x\,(\tan^2 x - 1)\sec^2 x\,dx$$

Put $\tan x = t \Rightarrow \sec^2 x\,dx = dt$

$$\therefore \quad \int_0^{\pi/4} x f(x)dx = -\int_0^1 t^3(t^2 - 1)dt$$
$$= \int_0^1 (t^3 - t^5)dt = \left[\frac{t^4}{4} - \frac{t^5}{5}\right]_0^1 = \frac{1}{4} - \frac{1}{6} = \frac{1}{12}$$

Also, $\int_0^{\pi/4} f(x)dx = \int_0^{\pi/4} (7\tan^6 x - 3\tan^2 x)\ \sec^2 x\,dx$

$$= \int_0^1 (7t^6 - 3t^2)dt = [t^7 - t^3]_0^1 = 0$$

75. Here, $f'(x) = \dfrac{192\,x^3}{2 + \sin^4 \pi x}$

$$\therefore \quad \frac{192x^3}{3} \le f'(x) \le \frac{192x^3}{2}$$

On integrating between the limits $\frac{1}{2}$ to x, we get

$$\int_{1/2}^x \frac{192x^3}{3}dx \le \int_{1/2}^x f'(x)dx \le \int_{1/2}^x \frac{192x^3}{2}dx$$

$$\Rightarrow \quad \frac{192}{12}\left(x^4 - \frac{1}{16}\right) \le f(x) - f(0) \le 24x^4 - \frac{3}{2}$$

$$\Rightarrow \quad 16x^4 - 1 \le f(x) \le 24x^4 - \frac{3}{2}$$

Again, integrating between the limits $\frac{1}{2}$ to 1, we get

$$\int_{1/2}^1 (16x^4 - 1)dx \le \int_{1/2}^1 f(x)dx \le \int_{1/2}^1 \left(24x^4 - \frac{3}{2}\right)dx$$

$$\Rightarrow \quad \left[\frac{16x^5}{5} - x\right]_{1/2}^1 \le \int_{1/2}^1 f(x)dx \le \left[\frac{24x^5}{5} - \frac{3}{2}x\right]_{1/2}^1$$

$$\Rightarrow \quad \left(\frac{11}{5} + \frac{2}{5}\right) \le \int_{1/2}^1 f(x)dx \le \left(\frac{33}{10} + \frac{6}{10}\right)$$

$$\Rightarrow \quad 2.6 \le \int_{1/2}^1 f(x)dx \le 3.9$$

76. Let $I_1 = \int_0^{4\pi} e^t(\sin^6 at + \cos^6 at)dt$

$$= \int_0^{\pi} e^t(\sin^6 at + \cos^6 at)dt + \int_{\pi}^{2\pi} e^t(\sin^6 at + \cos^6 at)dt$$
$$+ \int_{2\pi}^{3\pi} e^t(\sin^6 at + \cos^6 at)dt + \int_{3\pi}^{4\pi} e^t(\sin^6 at + \cos^6 at)dt$$

$$\therefore \quad I_1 = I_2 + I_3 + I_4 + I_5 \qquad \ldots(\text{i})$$

Now, $I_3 = \int_{\pi}^{2\pi} e^t(\sin^6 at + \cos^6 at)dt$

Put $t = \pi + t \Rightarrow dt = dt$

$$\therefore \quad I_3 = \int_0^{\pi} e^{\pi + t} \cdot (\sin^6 at + \cos^6 at)dt$$
$$= e^t \cdot I_2 \qquad \ldots(\text{ii})$$

Now, $I_4 = \int_{2\pi}^{3\pi} e^t(\sin^6 at + \cos^6 at)dt$

Put $t = 2\pi + t \Rightarrow dt = dt$

$$\therefore \quad I_4 = \int_0^{\pi} e^{t + 2\pi}(\sin^6 at + \cos^6 at)dt$$
$$= e^{2\pi} \cdot I_2 \qquad \ldots(\text{iii})$$

and $I_5 = \int_{3\pi}^{4\pi} e^t(\sin^6 at + \cos^6 at)dt$

Put $t = 3\pi + t$

$$\therefore \quad I_5 = \int_0^{\pi} e^{3\pi + t}(\sin^6 at + \cos^6 at)dt$$
$$= e^{3\pi} \cdot I_2 \qquad \ldots(\text{iv})$$

From Eqs. (i), (ii), (iii) and (iv), we get

$$I_1 = I_2 + e^{\pi} \cdot I_2 + e^{2\pi} \cdot I_2 + e^{3\pi} \cdot I_2 = (1 + e^{\pi} + e^{2\pi} + e^{3\pi})\, I_2$$

$$\therefore \quad L = \frac{\int_0^{4\pi} e^t(\sin^6 at + \cos^6 at)dt}{\int_0^{\pi} e^t(\sin^6 at + \cos^6 at)dt}$$
$$= (1 + e^{\pi} + e^{2\pi} + e^{3\pi}) = \frac{1 \cdot (e^{4\pi} - 1)}{e^{\pi} - 1} \text{ for } a \in R$$

77. According to the given data, $F(x) < 0,\ \forall x \in (1, 3)$

We have, $f(x) = xF(x)$

$$\Rightarrow \quad f'(x) = F(x) + xF'(x) \qquad \ldots(\text{i})$$

$\Rightarrow$ $f'(1) = F(1) + F'(1) < 0$ [given $F(1) = 0$ and $F'(x) < 0$]

Also, $f(2) = 2F(2) < 0$ [using $F(x) < 0, \forall x \in (1, 3)$]

Now, $f'(x) = F(x) + xF'(x) < 0$ [using $F(x) < 0,\ \forall x \in (1,3)$]

$\Rightarrow$ $f'(x) < 0$

78. Given, $\int_1^3 x^2F'(x)dx=-12$

$\Rightarrow \quad [x^2F(x)]_1^3-\int_1^3 2x\cdot F(x)dx=-12$

$\Rightarrow \quad 9F(3)-F(1)-2\int_1^3 f(x)dx=-12\ [\because xF(x)=f(x), \text{given}]$

$\Rightarrow \quad -36-0-2\int_1^3 f(x)dx=-12$

$\therefore \quad \int_1^3 f(x)dx=-12$

and $\int_1^3 x^3F''(x)dx=40$

$\Rightarrow \quad [x^3F'(x)]_1^3-\int_1^3 3x^2F'(x)dx=40$

$\Rightarrow \quad [x^2(xF'(x)]_1^3-3\times(-12)=40$

$\Rightarrow \quad \{x^2\cdot[f'(x)-F(x)]\}_1^3=4$

$\Rightarrow 9[f'(3)-F(3)]-[f'(1)-F(1)]=4$

$\Rightarrow \quad 9[f'(3)+4]-[f'(1)-0]=4$

$\Rightarrow \quad 9f'(3)-f'(1)=-32$

79. Here, $f(x)=\begin{cases}[x], & x\le 2\\ 0, & x>2\end{cases}$

$\therefore \quad I=\int_{-1}^2 \frac{xf(x^2)}{2+f(x+1)}dx$

$=\int_{-1}^0 \frac{xf(x^2)}{2+f(x+1)}dx+\int_0^1 \frac{xf(x^2)}{2+f(x+1)}dx$

$+\int_1^{\sqrt2} \frac{xf(x^2)}{2+f(x+1)}dx+\int_{\sqrt2}^{\sqrt3} \frac{xf(x^2)}{2+f(x+1)}dx$

$+\int_{\sqrt3}^2 \frac{xf(x^2)}{2+f(x+1)}dx$

$=\int_{-1}^0 0\,dx+\int_0^1 0\,dx+\int_1^{\sqrt2} \frac{x\cdot1}{2+0}dx+\int_{\sqrt2}^{\sqrt3} 0\,dx+\int_{\sqrt3}^2 0\,dx$

$\because -1<x<0\Rightarrow 0<x^2<1\Rightarrow[x^2]=0,$

$0<x<1\Rightarrow 0<x^2<1\Rightarrow[x^2]=0,$

$1<x<\sqrt2\Rightarrow\begin{cases}1<x^2<2 & \Rightarrow[x^2]=1\\ 2<x+1<1+\sqrt2 & \Rightarrow f(x+1)=0,\end{cases}$

$\sqrt2<x<\sqrt3\ \Rightarrow 2<x^2<3\Rightarrow f(x^2)=0,$

and $\sqrt3<x<2\Rightarrow 3<x^2<4\Rightarrow f(x^2)=0$

$\Rightarrow \quad I=\int_1^{\sqrt2}\frac{x}{2}dx=\left[\frac{x^2}{4}\right]_1^{\sqrt2}=\frac14(2-1)=\frac14$

$\therefore \quad 4I=1\ \Rightarrow\ 4I-1=0$

80. Here, $\alpha=\int_0^1 e^{(9x+3\tan^{-1}x)}\left(\frac{12+9x^2}{1+x^2}\right)dx$

Put $9x+3\tan^{-1}x=t$

$\Rightarrow \quad \left(9+\frac{3}{1+x^2}\right)dx=dt$

$\therefore \quad \alpha=\int_0^{9+3\pi/4} e^t\,dt=[e^t]_0^{9+3\pi/4}=e^{9+3\pi/4}-1$

$\Rightarrow \quad \log_e|1+\alpha|=9+\frac{3\pi}{4}$

$\Rightarrow \quad \log_e|\alpha+1|-\frac{3\pi}{4}=9$

81. **Plan** This type of question can be done using appropriate substitution.

Given, $I=\int_{\pi/4}^{\pi/2}(2\ \text{cosec}\ x)^{17}\,dx$

$=\int_{\pi/4}^{\pi/2}\frac{2^{17}(\text{cosec}\ x)^{16}\ \text{cosec}\ x(\text{cosec}\ x+\cot x)}{(\text{cosec}\ x+\cot x)}dx$

Let $\text{cosec}\ x+\cot x=t$

$\Rightarrow (-\text{cosec}\ x\cdot\cot x-\text{cosec}^2x)\,dx=dt$

and $\text{cosec}\ x-\cot x=1/t$

$\Rightarrow \quad 2\ \text{cosec}\ x=t+\frac1t$

$\therefore \quad I=-\int_{\sqrt2+1}^1 2^{17}\left(\frac{t+\frac1t}{2}\right)^{16}\frac{dt}{t}$

Let $t=e^u\ \Rightarrow\ dt=e^u du.$ When $t=1, e^u=1\Rightarrow u=0$

and when $t=\sqrt2+1, e^u=\sqrt2+1$

$\Rightarrow \quad u=\ln(\sqrt2+1)$

$\Rightarrow \quad I=-\int_{\ln(\sqrt2+1)}^0 2(e^u+e^{-u})^{16}\frac{e^u du}{e^u}$

$=2\int_0^{\ln(\sqrt2+1)}(e^u+e^{-u})^{16}\,du$

82. **Plan** Newton-Leibnitz's formula

$\frac{d}{dx}\left[\int_{\phi(x)}^{\psi(x)} f(t)\,dt\right]=f\{\psi(x)\}\left\{\frac{d}{dx}\psi(x)\right\}-f\{\phi(x)\}\left\{\frac{d}{dx}\phi(x)\right\}$

Given, $F(x)=\int_0^{x^2} f(\sqrt t)\,dt$

$\therefore \quad F'(x)=2x\,f(x)$

Also, $F'(x)=f'(x)$

$\Rightarrow \quad 2x\,f(x)=f'(x)$

$\Rightarrow \quad \frac{f'(x)}{f(x)}=2x$

$\Rightarrow \quad \int\frac{f'(x)}{f(x)}dx=\int 2x\,dx$

$\Rightarrow \quad \text{In}\ f(x)=x^2+c\ \Rightarrow\ f(x)=e^{x^2+c}$

$\Rightarrow \quad f(x)=K\,e^{x^2}\qquad [K=e^c]$

Now, $f(0)=1$

$\therefore \quad 1=K$

Hence, $f(x)=e^{x^2}$

$F(2)=\int_0^4 e^t dt=[e^t]_0^4=e^4-1$

83. (A) Let $I=\int_{-1}^1\frac{dx}{1+x^2}$

Put $x=\tan\theta$

$\Rightarrow dx=\sec^2\theta\,d\theta$

$\therefore \quad I=2\int_0^{\pi/4}d\theta=\frac{\pi}{2}$

(B) Let $I = \int_0^1 \frac{dx}{\sqrt{1-x^2}}$

Put $x = \sin\theta \Rightarrow dx = \cos\theta\, d\theta$

$\therefore \quad I = \int_0^{\pi/2} 1\, d\theta = \frac{\pi}{2}$

(C) $\int_2^3 \frac{dx}{1-x^2} = \frac{1}{2}\left[\log\left(\frac{1+x}{1-x}\right)\right]_2^3$

$= \frac{1}{2}\left[\log\left(\frac{4}{-2}\right) - \log\left(\frac{3}{-1}\right)\right] = \frac{1}{2}\left[\log\left(\frac{2}{3}\right)\right]$

(D) $\int_1^2 \frac{dx}{x\sqrt{x^2-1}} = [\sec^{-1} x]_1^2 = \frac{\pi}{3} - 0 = \frac{\pi}{3}$

84. (A) **Plan**

(p) A polynomial satisfying the given conditions is taken.

(q) The other conditions are also applied and the number of polynomial is taken out.

Let $f(x) = ax^2 + bx + c$

$f(0) = 0 \Rightarrow c = 0$

Now, $\int_0^1 f(x)\, dx = 1 \Rightarrow \left(\frac{ax^3}{3} + \frac{bx^2}{2}\right)_0^1 = 1$

$\Rightarrow \quad \frac{\alpha}{3} + \frac{\beta}{2} = 1 \Rightarrow \quad 2a + 3b = 6$

As a, b are non-negative integers.

So, $a = 0, b = 2$ or $a = 3, b = 0$

$\therefore \quad f(x) = 2x$ or $f(x) = 3x^2$

(B) **Plan** Such type of questions are converted into only sine or cosine expression and then the number of points of maxima in given interval are obtained.

$f(x) = \sin(x^2) + \cos(x^2)$

$= \sqrt{2}\left[\frac{1}{\sqrt{2}}\cos(x^2) + \frac{1}{\sqrt{2}}\sin(x^2)\right]$

$= \sqrt{2}\left[\cos x^2 \cos\frac{\pi}{4} + \sin\frac{\pi}{4}\sin(x^2)\right] = \sqrt{2}\cos\left(x^2 - \frac{\pi}{4}\right)$

For maximum value, $x^2 - \frac{\pi}{4} = 2n\pi \Rightarrow x^2 = 2n\pi + \frac{\pi}{4}$

$\Rightarrow \quad x = \pm\sqrt{\frac{\pi}{4}}$, for $n = 0$

$x = \pm\sqrt{\frac{9\pi}{4}}$, for $n = 1$

So, $f(x)$ attains maximum at 4 points in $[-\sqrt{13}, \sqrt{13}]$.

(C) **Plan**

(p) $\int_{-a}^a f(x)\, dx = \int_{-a}^a f(-x)\, dx$

(q) $\int_{-a}^a f(x)\, dx = 2\int_0^a f(x)\, dx$, if $f(-x) = f(x)$, i.e. f is an even function.

$I = \int_{-2}^2 \frac{3x^2}{1+e^x}\, dx$ and $I = \int_{-2}^2 \frac{3x^2}{1+e^{-x}}\, dx$

$\Rightarrow \quad 2I = \int_{-2}^2 \left(\frac{3x^2}{1+e^x} + \frac{3x^2(e^x)}{e^x+1}\right) dx$

$2I = \int_{-2}^2 3x^2\, dx \quad \Rightarrow \quad 2I = 2\int_0^2 3x^2\, dx$

$I = [x^3]_0^2 = 8$

(D) **Plan** $\int_{-a}^a f(x)\, dx = 0$

If $f(-x) = -f(x)$, i.e. $f(x)$ is an odd function.

Let $f(x) = \cos 2x \log\left(\frac{1+x}{1-x}\right)$

$f(-x) = \cos 2x \log\left(\frac{1-x}{1+x}\right) = -f(x)$

Hence, $f(x)$ is an odd function.

So, $\int_{-1/2}^{1/2} f(x)\, dx = 0$

(A) $\to$ (q); (B) $\to$ (r); (C) $\to$ (p); (D) $\to$ (s)

85. **Plan** Integration by parts

$$\int f(x)\, g(x)\, dx = f(x)\int g(x)\, dx - \int\left(\frac{d}{dx}[f(x)]\int g(x)\, dx\right) dx$$

Given, $I = \int_0^1 \underset{\text{I}}{4x^3}\, \frac{d^2}{dx^2}\underset{\text{II}}{(1-x^2)^5}\, dx$

$= \left[4x^3\frac{d}{dx}(1-x^2)^5\right]_0^1 - \int_0^1 12x^2\frac{d}{dx}(1-x^2)^5\, dx$

$= \left[4x^3 \times 5(1-x^2)^4(-2x)\right]_0^1$

$- 12\left[[x^2(1-x^2)^5]_0^1 - \int_0^1 2x(1-x^2)^5\, dx\right]$

$= 0 - 0 - 12(0-0) + 12\int_0^1 2x(1-x^2)^5\, dx$

$= 12 \times \left[-\frac{(1-x^2)^6}{6}\right]_0^1 = 12\left[0 + \frac{1}{6}\right] = 2$

86. $I = \int_{-\pi/2}^{\pi/2}\left[x^2 + \log\left(\frac{\pi - x}{\pi + x}\right)\right]\cos x\, dx$

As, $\int_{-a}^a f(x)\, dx = 0$, when $f(-x) = -f(x)$

$\therefore \quad I = \int_{-\pi/2}^{\pi/2} x^2 \cos x\, dx + 0 = 2\int_0^{\pi/2}(x^2\cos x)\, dx$

$= 2\{(x^2\sin x)_0^{\pi/2} - \int_0^{\pi/2} 2x\cdot\sin x\, dx\}$

$= 2\left[\frac{\pi^2}{4} - 2\{(-x\cdot\cos x)_0^{\pi/2} - \int_0^{\pi/2} 1\cdot(-\cos x)\, dx\}\right]$

$= 2\left[\frac{\pi^2}{4} - 2(\sin x)_0^{\pi/2}\right] = 2\left[\frac{\pi^2}{4} - 2\right] = \left(\frac{\pi^2}{2} - 4\right)$

87. Put $x^2 = t \Rightarrow x\, dx = dt/2$

$\therefore \quad I = \int_{\log 2}^{\log 3} \frac{\sin t \cdot \frac{dt}{2}}{\sin t + \sin(\log 6 - t)}$ ...(i)

Using, $\int_a^b f(x)\, dx = \int_a^b f(a+b-x)\, dx$

$= \frac{1}{2}\int_{\log 2}^{\log 3} \frac{\sin(\log 2 + \log 3 - t)}{\sin(\log 2 + \log 3 - t) + \sin(\log 6 - (\log 2 + \log 3 - t))}\, dt$

$= \frac{1}{2}\int_{\log 2}^{\log 3} \frac{\sin(\log 6 - t)}{\sin(\log 6 - t) + \sin(t)}\, dt$

$\therefore \quad I = \int_{\log 2}^{\log 3} \frac{\sin(\log 6 - t)}{\sin(\log 6 - t) + \sin t}\, dt$ ...(ii)

On adding Eqs. (i) and (ii), we get

$$2I = \frac{1}{2}\int_{\log 2}^{\log 3} \frac{\sin t + \sin(\log 6 - t)}{\sin(\log 6 - t) + \sin t}\, dt$$

$$\Rightarrow \quad 2I = \frac{1}{2}(t)_{\log 2}^{\log 3} = \frac{1}{2}(\log 3 - \log 2)$$

$$\therefore \quad I = \frac{1}{4}\log\left(\frac{3}{2}\right)$$

88. Given, $f(1) = \frac{1}{3}$ and $6\int_1^x f(t)dt = 3x\, f(x) - x^3,\ \forall\ x \geq 1$

Using Newton-Leibnitz formula.

Differentiating both sides

$$\Rightarrow \quad 6f(x)\cdot 1 - 0 = 3f(x) + 3xf'(x) - 3x^2$$

$$\Rightarrow\ 3xf'(x) - 3f(x) = 3x^2 \quad \Rightarrow \quad f'(x) - \frac{1}{x}f(x) = x$$

$$\Rightarrow \quad \frac{xf'(x) - f'(x)}{x^2} = 1 \qquad \Rightarrow \qquad \frac{d}{dx}\left\{\frac{x}{x}\right\} = 1$$

On integrating both sides, we get

$$\Rightarrow \quad \frac{f(x)}{x} = x + c \qquad \left[\because\ f(1) = \frac{1}{3}\right]$$

$$\frac{1}{3} = 1 + c \ \Rightarrow\ c = \frac{2}{3} \text{ and } f(x) = x^2 - \frac{2}{3}x$$

$$\therefore \quad f(2) = 4 - \frac{4}{3} = \frac{8}{3}$$

Note Here, $f(1) = 2$, does not satisfy given function.

$$\therefore \quad f(1) = \frac{1}{3}$$

For that $f(x) = x^2 - \frac{2}{3}x$ and $f(2) = 4 - \frac{4}{3} = \frac{8}{3}$

89. Let $I = \int_0^1 \frac{x^4(1-x)^4}{1+x^2}dx$

$$= \int_0^1 \frac{(x^4-1)(1-x)^4 + (1-x)^4}{(1+x^2)}dx$$

$$= \int_0^1 (x^2-1)(1-x)^4\, dx + \int_0^1 \frac{(1+x^2-2x)^2}{(1+x^2)}dx$$

$$= \int_0^1 \left\{(x^2-1)(1-x)^4 + (1+x^2) - 4x + \frac{4x^2}{(1+x^2)}\right\}dx$$

$$= \int_0^1 \left((x^2-1)(1-x)^4 + (1+x^2) - 4x + 4 - \frac{4}{1+x^2}\right)dx$$

$$= \int_0^1 \left(x^6 - 4x^5 + 5x^4 - 4x^2 + 4 - \frac{4}{1+x^2}\right)dx$$

$$= \left[\frac{x^7}{7} - \frac{4x^6}{6} + \frac{5x^5}{5} - \frac{4x^3}{3} + 4x - 4\tan^{-1}x\right]_0^1$$

$$= \frac{1}{7} - \frac{4}{6} + \frac{5}{5} - \frac{4}{3} + 4 - 4\left(\frac{\pi}{4} - 0\right) = \frac{22}{7} - \pi$$

90. Converting infinite series into definite integral

i.e. $\lim_{n\to\infty} \frac{h(n)}{n}$

$$\lim_{n\to\infty} \frac{1}{n}\sum_{r=g(n)}^{h(n)} f\left(\frac{r}{n}\right) = \int f(x)dx$$

$\lim_{n\to\infty} \frac{g(n)}{n}$, where, $\frac{r}{n}$ is replaced with x.

Σ is replaced with integral.

Here, $\lim_{n\to\infty} \frac{1^a + 2^a + \ldots + n^a}{(n+1)^{a-1}\{(na+1) + (na+2) + \ldots + (na+n)\}} = \frac{1}{60}$

$$\Rightarrow \lim_{n\to\infty} \frac{\sum_{r=1}^{n} r^a}{(n+1)^{a-1}\cdot\left[n^2a + \frac{n(n+1)}{2}\right]} = \frac{1}{60}$$

$$\Rightarrow \lim_{n\to\infty} \frac{2\sum_{r=1}^{n}\left(\frac{r}{n}\right)^a}{\left(1+\frac{1}{n}\right)^{a-1}\cdot(2na+n+1)} = \frac{1}{60}$$

$$\Rightarrow \lim_{n\to\infty} \frac{1}{n}\left(2\sum_{r=1}^{n}\left(\frac{r}{n}\right)^a\right)\cdot \lim_{n\to\infty} \frac{1}{\left(1+\frac{1}{n}\right)^{a-1}\cdot\left(2a+1+\frac{1}{n}\right)} = \frac{1}{60}$$

$$\Rightarrow \quad 2\int_0^1 (x^a)dx \cdot \frac{1}{1\cdot(2a+1)} = \frac{1}{60}$$

$$\Rightarrow \quad \frac{2\cdot[x^{a+1}]_0^1}{(2a+1)\cdot(a+1)} = \frac{1}{60}$$

$$\therefore \quad \frac{2}{(2a+1)(a+1)} = \frac{1}{60}$$

$$\Rightarrow \quad (2a+1)(a+1) = 120$$

$$\Rightarrow \quad 2a^2 + 3a + 1 - 120 = 0$$

$$\Rightarrow \quad 2a^2 + 3a - 119 = 0$$

$$\Rightarrow \quad (2a+17)(a-7) = 0$$

$$\Rightarrow \quad a = 7, \frac{-17}{2}$$

91. Here, $f(x) + 2x = (1-x)^2\cdot\sin^2 x + x^2 + 2x$ ...(i)

where, $P: f(x) + 2x = 2(1+x)^2$ ...(ii)

$$\therefore \quad 2(1+x^2) = (1-x)^2\sin^2 x + x^2 + 2x$$

$$\Rightarrow \quad (1-x)^2\sin^2 x = x^2 - 2x + 2$$

$$\Rightarrow \quad (1-x)^2\sin^2 x = (1-x)^2 + 1 \ \Rightarrow (1-x)^2\cos^2 x = -1$$

which is never possible.

$\therefore$ P is false.

Again, let $Q: h(x) = 2f(x) + 1 - 2x(1+x)$

where, $h(0) = 2f(0) + 1 - 0 = 1$

$h(1) = 2f(1) + 1 - 4 = -3$, as $h(0)\,h(1) < 0$

$\Rightarrow$ $h(x)$ must have a solution.

$\therefore$ Q is true.

92. Here, $f(x) = (1-x)^2\cdot\sin^2 x + x^2 \geq 0,\ \forall\ x.$

and $g(x) = \int_1^x \left(\frac{2(t-1)}{t+1} - \log t\right) f(t)\, dt$

$$\Rightarrow \quad g'(x) = \left\{\frac{2(x-1)}{(x+1)} - \log x\right\}\cdot \underbrace{f(x)}_{+\text{ ve}} \qquad \ldots(i)$$

For $g'(x)$ to be increasing or decreasing,

let $\phi(x) = \frac{2(x-1)}{(x+1)} - \log x$

$$\phi'(x)=\frac{4}{(x+1)^2}-\frac{1}{x}=\frac{-(x-1)^2}{x(x+1)^2}$$

$\phi'(x)<0$, for $x>1 \Rightarrow \phi(x)<\phi(1) \Rightarrow \phi(x)<0$ ...(ii)

From Eqs. (i) and (ii), we get

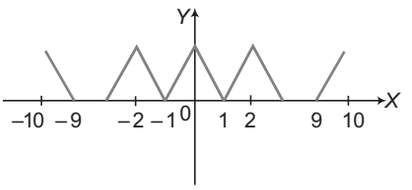
$$g'(x)<0 \text{ for } x\in(1,\infty)$$

$\therefore$ $g(x)$ is decreasing for $x\in(1,\infty)$.

93. Given, $f(x)=\begin{cases} x-[x], & \text{if } [x] \text{ is odd.}\\ 1+[x]-x, & \text{if } [x] \text{ is even.}\end{cases}$

$f(x)$ and $\cos\pi x$ both are periodic with period 2 and both are even.

$$\therefore \quad \int_{-10}^{10} f(x)\cos\pi x\,dx=2\int_0^{10} f(x)\cos\pi x\,dx$$



$$=10\int_0^2 f(x)\cos\pi x\,dx$$

Now, $\int_0^1 f(x)\cos\pi x\,dx=\int_0^1(1-x)\cos\pi x\,dx=-\int_0^1 u\cos\pi u\,du$

and $\int_1^2 f(x)\cos\pi x\,dx=\int_1^2(x-1)\cos\pi x\,dx=-\int_0^1 u\cos\pi u\,du$

$$\therefore \quad \int_{-10}^{10} f(x)\cos\pi x\,dx=-20\int_0^1 u\cos\pi u\,du=\frac{40}{\pi^2}$$

$$\Rightarrow \quad \frac{\pi^2}{10}\int_{-10}^{10} f(x)\cos\pi x\,dx=4$$

94. Given $\int_0^x\sqrt{1-\{f'(t)\}^2}\,dt=\int_0^x f(t)\,dt,\ 0\le x\le 1$

Differentiating both sides w.r.t. x by using Leibnitz's rule, we get

$$\sqrt{1-\{f'(x)\}^2}=f(x) \Rightarrow f'(x)=\pm\sqrt{1-\{f(x)\}^2}$$

$$\Rightarrow \int\frac{f'(x)}{\sqrt{1-\{f(x)\}^2}}\,dx=\pm\int dx$$

$$\Rightarrow \quad \sin^{-1}\{f(x)\}=\pm x+c$$

Put $x=0 \Rightarrow \sin^{-1}\{f(0)\}=c$

$\Rightarrow$ $c=\sin^{-1}(0)=0$ $[\because f(0)=0]$

$\therefore$ $f(x)=\pm\sin x$

but $f(x)\ge 0,\ \forall\ x\in[0,1]$

$\therefore$ $f(x)=\sin x$

As we know that,

$$\sin x<x,\ \forall\ x>0$$

$$\therefore \quad \sin\left(\frac{1}{2}\right)<\frac{1}{2} \text{ and } \sin\left(\frac{1}{3}\right)<\frac{1}{3}$$

$$\Rightarrow \quad f\left(\frac{1}{2}\right)<\frac{1}{2} \text{ and } f\left(\frac{1}{3}\right)<\frac{1}{3}$$

95. Given $I_n=\int_{-\pi}^{\pi}\frac{\sin nx}{(1+\pi^x)\sin x}\,dx$ ...(i)

Using $\int_a^b f(x)\,dx=\int_a^b f(b+a-x)\,dx$, we get

$$I_n=\int_{-\pi}^{\pi}\frac{\pi^x\sin nx}{(1+\pi^x)\sin x}\,dx \quad \text{...(ii)}$$

On adding Eqs. (i) and (ii), we have

$$2I_n=\int_{-\pi}^{\pi}\frac{\sin nx}{\sin x}\,dx=2\int_0^{\pi}\frac{\sin nx}{\sin x}\,dx$$

$$[\because f(x)=\frac{\sin nx}{\sin x} \text{ is an even function}]$$

$$\Rightarrow \quad I_n=\int_0^{\pi}\frac{\sin nx}{\sin x}\,dx$$

Now, $I_{n+2}-I_n=\int_0^{\pi}\frac{\sin(n+2)x-\sin nx}{\sin x}\,dx$

$$=\int_0^{\pi}\frac{2\cos(n+1)\,x\cdot\sin x}{\sin x}\,dx$$

$$=2\int_0^{\pi}\cos(n+1)x\,dx=2\left[\frac{\sin(n+1)\,x}{(n+1)}\right]_0^{\pi}=0$$

$\therefore$ $I_{n+2}=I_n$ ...(iii)

Since, $I_n=\int_0^{\pi}\frac{\sin nx}{\sin x}\,dx \Rightarrow I_1=\pi$ and $I_2=0$

From Eq. (iii) $I_1=I_3=I_5=....=\pi$ and $I_2=I_4=I_6=...=0$

$$\Rightarrow \quad \sum_{m=1}^{10} I_{2m+1}=10\pi \text{ and } \sum_{m=1}^{10} I_{2m}=0$$

$\therefore$ Correct options are (a), (b), (c).

96. Given, $S_n=\sum_{k=0}^{n}\frac{n}{n^2+kn+k^2}$

$$=\sum_{k=0}^{n}\frac{1}{n}\cdot\left(\frac{1}{1+\frac{k}{n}+\frac{k^2}{n^2}}\right)<\lim_{n\to\infty}\sum_{k=0}^{n}\frac{1}{n}\left(\frac{1}{1+\frac{k}{n}+\left(\frac{k}{n}\right)^2}\right)$$

$$=\int_0^1\frac{1}{1+x+x^2}\,dx=\left[\frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{2}{\sqrt{3}}\left(x+\frac{1}{2}\right)\right)\right]_0^1$$

$$=\frac{2}{\sqrt{3}}\cdot\left(\frac{\pi}{3}-\frac{\pi}{6}\right)=\frac{\pi}{3\sqrt{3}} \quad \text{i.e. } S_n<\frac{\pi}{3\sqrt{3}}$$

Similarly, $T_n>\frac{\pi}{3\sqrt{3}}$

97. $I=\int_{\pi/4}^{3\pi/4}\frac{dx}{1+\cos x}$ ...(i)

$$I=\int_{\pi/4}^{3\pi/4}\frac{dx}{1-\cos x} \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii)

$$2I=\int_{\pi/4}^{3\pi/4}\frac{2}{\sin^2 x}\,dx \Rightarrow I=\int_{\pi/4}^{3\pi/4}\text{cosec}^2\,x\,dx$$

$$I=-(\cot\,x)_{\pi/4}^{3\pi/4}=2$$

98. $I_4+I_6=\int(\tan^4 x+\tan^6 x)\,dx=\int\tan^4 x\sec^2 x\,dx$

$$=\frac{1}{5}\tan^5 x+c \quad \Rightarrow \quad a=\frac{1}{5},\ b=0$$

99. (b) Let $l=\lim_{n\to\infty}\left[\frac{(n+1)\cdot(n+2)\ldots(3n)}{n^{2n}}\right]^{\frac{1}{n}}$

$$=\lim_{n\to\infty}\left[\frac{(n+1)\cdot(n+2)\ldots(n+2n)}{n^{2n}}\right]^{\frac{1}{n}}$$

$$=\lim_{n\to\infty}\left[\left(\frac{n+1}{n}\right)\left(\frac{n+2}{n}\right)\cdots\left(\frac{n+2n}{n}\right)\right]^{\frac{1}{n}}$$

Taking log on both sides, we get

$$\log l=\lim_{n\to\infty}\frac{1}{n}\left[\log\left\{\left(1+\frac{1}{n}\right)\left(1+\frac{2}{n}\right)\ldots\left(1+\frac{2n}{n}\right)\right\}\right]$$

$$\Rightarrow\ \log l=\lim_{n\to\infty}\frac{1}{n}\left[\log\left(1+\frac{1}{n}\right)+\log\left(1+\frac{2}{n}\right)+\ldots+\log\left(1+\frac{2n}{n}\right)\right]$$

$$\Rightarrow\ \log l=\lim_{n\to\infty}\frac{1}{n}\sum_{r=1}^{2n}\log\left(1+\frac{r}{n}\right)$$

$$\Rightarrow\quad \log l=\int_0^2\log(1+x)\,dx$$

$$\Rightarrow\quad \log l=\left[\log(1+x)\cdot x-\int\frac{1}{1+x}\cdot x\,dx\right]_0^2$$

$$\Rightarrow\quad \log l=[\log(1+x)\cdot x]_0^2-\int_0^2\frac{x+1-1}{1+x}\,dx$$

$$\Rightarrow\quad \log l=2\cdot\log 3-\int_0^2\left(1-\frac{1}{1+x}\right)dx$$

$$\Rightarrow\quad \log l=2\cdot\log 3-\left[x-\log|1+x|\right]_0^2$$

$$\Rightarrow\quad \log l=2\cdot\log 3-[2-\log 3]$$

$$\Rightarrow\quad \log l=3\cdot\log 3-2\ \Rightarrow\ \log l=\log 27-2$$

$$\therefore\quad l=e^{\log 27-2}=27\cdot e^{-2}=\frac{27}{e^2}$$

100. **Central Idea** Apply the property $\int_a^b f(x)dx=\int_a^b f(a+b-x)dx$ and then add. Let

$$I=\int_2^4\frac{\log x^2}{\log x^2+\log(36-12x+x^2)}dx$$

$$=\int_2^4\frac{2\log x}{2\log x+\log(6-x)^2}dx$$

$$=\int_2^4\frac{2\log x\,dx}{2[\log x+\log(6-x)]}$$

$$\Rightarrow\quad I=\int_2^4\frac{\log x\,dx}{[\log x+\log(6-x)]}\qquad\ldots(i)$$

$$\Rightarrow\quad I=\int_2^4\frac{\log(6-x)}{\log(6-x)+\log x}dx\qquad\ldots(ii)$$

$$\left[\because\int_a^b f(x)dx=\int_a^b f(a+b-x)dx\right]$$

On adding Eqs. (i) and (ii), we get

$$2I=\int_2^4\frac{\log x+\log(6-x)}{\log x+\log(6-x)}dx$$

$$\Rightarrow\quad 2I=\int_2^4 dx=[x]_2^4$$

$$\Rightarrow\quad 2I=2\ \Rightarrow\ I=1$$

101. **Plan** Use the formula, $|x-a|=\begin{cases}x-a, & x\geq a\\ -(x-a), & x<a\end{cases}$ to break given integral in two parts and then integrate separately.

$$\int_0^\pi\sqrt{\left(1-2\sin\frac{x}{2}\right)^2}dx=\int_0^\pi\left|1-2\sin\frac{x}{2}\right|dx$$

$$=\int_0^{\frac{\pi}{3}}\left(1-2\sin\frac{x}{2}\right)dx-\int_{\frac{\pi}{3}}^\pi\left(1-2\sin\frac{x}{2}\right)dx$$

$$=\left(x+4\cos\frac{x}{2}\right)_0^{\frac{\pi}{3}}-\left(x+4\cos\frac{x}{2}\right)_{\frac{\pi}{3}}^\pi=4\sqrt{3}-4-\frac{\pi}{3}$$

102. Let $\quad I=\int_{\pi/6}^{\pi/3}\frac{dx}{1+\sqrt{\tan x}}\qquad\ldots(i)$

$$\therefore\quad I=\int_{\pi/6}^{\pi/3}\frac{dx}{1+\sqrt{\tan\left(\frac{\pi}{2}-x\right)}}=\int_{\pi/6}^{\pi/3}\frac{dx}{1+\sqrt{\cot x}}$$

$$\Rightarrow\quad I=\int_{\pi/6}^{\pi/3}\frac{\sqrt{\tan x}\,dx}{1+\sqrt{\tan x}}\qquad\ldots(ii)$$

On adding Eqs. (i) and (ii), we get

$$2I=\int_{\pi/6}^{\pi/3}dx\ \Rightarrow\ 2I=[x]_{\pi/6}^{\pi/3}dx$$

$$\Rightarrow\quad I=\frac{1}{2}\left[\frac{\pi}{3}-\frac{\pi}{6}\right]=\frac{\pi}{12}$$

Statement I is false.

But $\int_a^b f(x)dx=\int_a^b f(a+b-x)dx$ is a true statement by property of definite integrals.

103. Given, $y=\int_0^x|t|\,dt$

$$\therefore\quad \frac{dy}{dx}=|x|\cdot 1-0=|x|\qquad\text{[by Leibnitz's rule]}$$

$\because$ Tangent to the curve $y=\int_0^x|t|\,dt$, $x\in R$ are parallel to the line $y=2x$

$\therefore$ Slope of both are equal $\Rightarrow\ x=\pm 2$

Points, $\quad y=\int_0^{\pm 2}|t|\,dt=\pm 2$

Equation of tangent is

$$y-2=2(x-2)\ \text{ and }\ y+2=2(x+2)$$

For x intercept put $y=0$, we get

$$0-2=2(x-2)\ \text{ and }\ 0+2=2(x+2)$$

$$\Rightarrow\quad x=\pm 1$$

104. Given integral $g(x)=\int_0^x\cos 4t\,dt$

To find $g(x+\pi)$ in terms of $g(x)$ and $g(\pi)$.

$$g(x)=\int_0^x\cos 4t\,dt$$

$$\Rightarrow\quad g(x+\pi)=\int_{t=0}^{t=x+\pi}\cos 4t\,dt$$

$$=\int_0^x\cos 4t\,dt+\int_x^{x+\pi}\cos 4t\,dt$$

$$=g(x)+I_1\qquad\text{(say)}$$

$$I_1=\int_x^{x+\pi}\cos 4t\,dt=\int_0^\pi\cos 4t\,dt$$

(definite integral property)

$$=g(\pi)$$

$\Rightarrow \quad g(x+\pi) = g(x) + g(\pi)$

But the value of I_1 is zero.

$\Rightarrow \quad I_1 = \left[\frac{\sin 4t}{4}\right]_0^{\pi} = \left(\frac{\sin 4\pi}{4} - \frac{\sin 0}{4}\right) = 0$

$\Rightarrow \quad g(x+\pi) = g(x) - g(\pi)$

In my opinion, the examiner has made this question keeping $g(x) + g(\pi)$ as the only answer in his/her mind. However, he/she did not realise that the value of the integral I_1 is actually zero. Hence, it does not matter whether you add to or subtract from $g(x)$.

105. $I = \int_0^1 \frac{8\log(1+x)}{(1+x^2)}\,dx$

Put $x = \tan\theta \Rightarrow dx = \sec^2\theta\, d\theta$

When $x = 0 \Rightarrow \tan\theta = 0$

$\therefore \quad \theta = 0$

When $x = 1 = \tan\theta$

$\Rightarrow \quad \theta = \frac{\pi}{4}$

$\therefore \quad I = \int_0^{\pi/4} \frac{8\log[1+\tan\theta]}{1+\tan^2\theta} \cdot \sec^2\theta\, d\theta$

$I = 8\int_0^{\pi/4} \log(1+\tan\theta)\, d\theta \qquad \ldots(i)$

Using $\int_0^a f(x)\,dx = \int_0^a f(a-x)\,dx$, we get

$I = 8\int_0^{\pi/4} \log\left\{1+\tan\left(\frac{\pi}{4}-\theta\right)\right\} d\theta$

$= 8\int_0^{\pi/4} \log\left\{1+\frac{1-\tan\theta}{1+\tan\theta}\right\} d\theta$

$= 8\int_0^{\pi/4} \log\left\{\frac{2}{1+\tan\theta}\right\} d\theta \qquad \ldots(ii)$

Adding Eqs. (i) and (ii), we get

$2I = 8\int_0^{\pi/4} \left[\log\{1+\tan\theta\} + \log\left\{\frac{2}{1+\tan\theta}\right\}\right] d\theta$

$\Rightarrow \quad I = 4\int_0^{\pi/4} \log 2\, d\theta = 4\cdot\log 2(\theta)_0^{\pi/4}$

$= 4\log 2\cdot\left(\frac{\pi}{4}-0\right) = \pi\log 2$

106. If $\phi(x)$ and $\psi(x)$ are defined on $[a, b]$ and differentiable for every x and $f(t)$ is continuous, then

$$\frac{d}{dx}\left[\int_{\phi(x)}^{\psi(x)} f(t)dt\right] = f[\psi(x)]\cdot\frac{d}{dx}\psi(x) - f[\phi(x)]\frac{d}{dx}\phi(x)$$

Here, $f(x) = \int_0^x \sqrt{t}\sin t\, dt$, where $x \in \left(0, \frac{5\pi}{2}\right)$

$f'(x) = \{\sqrt{x}\sin x - 0\} \qquad \ldots(i)$

(using Newton-Leibnitz formula)

$\therefore \quad f'(x) = \sqrt{x}\sin x = 0$

$\Rightarrow \quad \sin x = 0$

$\therefore \quad x = \pi, 2\pi$

$f''(x) = \sqrt{x}\cos x + \frac{1}{2\sqrt{x}}\sin x$

At $x = \pi$, $f''(\pi) = -\sqrt{\pi} < 0$

$\therefore$ Local maximum at $x = \pi$. At $x = 2\pi$, $f''(2\pi) = \sqrt{2\pi} > 0$

$\therefore$ Local minimum at $x = 2\pi$.

107. We have, $p'(x) = p'(1-x),\ \forall\ x \in [0,1],\ p(0) = 1,\ p(1) = 41$

$\Rightarrow \quad p(x) = -p(1-x) + C$

$\Rightarrow \quad 1 = -41 + C$

$\Rightarrow \quad C = 42$

$\therefore \quad p(x) + p(1-x) = 42$

Now, $I = \int_0^1 p(x)dx = \int_0^1 p(1-x)dx$

$\Rightarrow \quad 2I = \int_0^1 (p(x)+p(1-x))dx = \int_0^1 42\,dx = 42$

$\Rightarrow \quad I = 21$

108. Let $I = \int_0^{\pi} [\cot x]\,dx \qquad \ldots(i)$

$\Rightarrow I = \int_0^{\pi} [\cot(\pi - x)]\,dx = \int_0^{\pi} [-\cot x]\,dx \qquad \ldots(ii)$

On adding Eqs. (i) and (ii),

$2I = \int_0^{\pi} [\cot x]\,dx + \int_0^{\pi} [-\cot x]\,dx = \int_0^{\pi} (-1)\,dx$

$[\because [x] + [-x] = -1$, if $x \notin z$ and 0, if $x \in z]$

$= [-x]_0^{\pi} = -\pi$

$\therefore \quad I = -\frac{\pi}{2}$

109. Since, $I = \int_0^1 \frac{\sin x}{\sqrt{x}}dx < \int_0^1 \frac{x}{\sqrt{x}}dx$,

because in $x \in (0,1), x > \sin x$.

$I < \int_0^1 \sqrt{x}\,dx = \frac{2}{3}[x^{3/2}]_0^1 \Rightarrow I < \frac{2}{3}$

and $\quad J = \int_0^1 \frac{\cos x}{\sqrt{x}}dx < \int_0^1 x^{-\frac{1}{2}}dx = 2$

$J < 2$

Session 1

Sketching of Some Common Curves, Some More Curves which Occur Frequently in Mathematics in Standard Forms, Asymptotes, Areas of Curves Given by Cartesian Equations

Sketching of Some Common Curves

For finding the area of a given region, we require the knowledge of some standard curves.

(i) Straight Line

Every first degree equation in x, y represents a straight line. So, the general equation of a line is $ax + by + c = 0$. To draw a straight line find the points, where it meets with the coordinate axes by putting $y = 0$ and $x = 0$ respectively in its equation.

By joining these two points we get the sketch of the line. Sometimes the equation of a line is given in the form $y = mx$. This equation represents a line passing through the origin and inclined at an angle $\tan^{-1} m$ with the positive direction of X-axis. The equation of the form $x = a$ and $y = b$ represents straight lines parallel to Y-axis and X-axis, respectively.

Region Represented by a Linear Inequality

To find the region represented by linear inequality $ax + by \le c$ and $ax + by \ge c$, we proceed as follows

(i) Convert the inequality into equality to obtain a linear equation in x, y.

(ii) Draw the straight line represented by it.

(iii) The straight line obtained in (ii) divides the XY-plane in two parts.

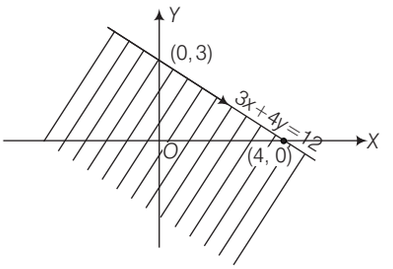
To determine the region represented by the inequality choose some convenient points; e.g. origin or some points on the coordinate axes.

If the coordinates of a point satisfy the inequality, then region containing the points is the required region, otherwise the region not containing the point is required region.

Example 1 Mark the region represented by $3x + 4y \le 12$.

Sol. Converting the inequality into equation, we get $3x + 4y = 12$.

This line meets the coordinate axes at (4, 0) and (0, 3), respectively. Join these points to obtain straight line represented by $3x + 4y = 12$.



This straight line divides the plane in two parts. One part contains the origin and the other does not contains the origin. Clearly, (0, 0) satisfy the inequality $3x + 4y < 12$. So, the region represented by $3x + 4y < 12$ is region containing the origin as shown in the figure.

(ii) Circle

The general equation of a circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0$$

$\therefore$ The second degree equation in x, y such that coeff. of x^2 = coeff. of y^2 and there is no term containing xy; it always represents a circle. To draw a sketch of a circle, we write the equation instandard form $(x - h)^2 + (y - k)^2 = r^2$, whose centre is (h, k) and radius is r.

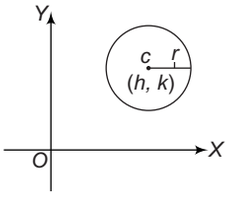


Figure 3.1

Remarks

1. The inequality $(x - a)^2 + (y - b)^2 < r^2$ represents the interior of a circle.
2. The inequality $(x - a)^2 + (y - b)^2 > r^2$ represents the exterior of a circle (i.e. region lying outside the circle).

(iii) Parabola

It is the locus of points such that its distance from a fixed point is equal to its distance from a fixed straight line.

Taking the fixed straight line $x = -a, a > 0$ and fixed point $(a, 0)$, we get the equation of parabola $y^2 = 4ax$.

Steps to Sketch the Curve

(i) It passes through (0, 0).

(ii) It is symmetrical about axis of X.

(iii) No part of the curve lies on the negative side of axis of X.

(iv) Curve turns at (0, 0) which is called the vertex of the curve.

(v) The curve extends to infinity. It is not a closed curve.

(1) $y^2 = 4ax$ (Standard equation of parabola)

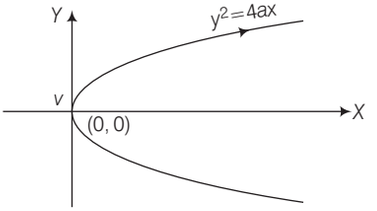

Figure 3.2

(2) $y^2 = 4a(x - h)$; where a and h are positive.

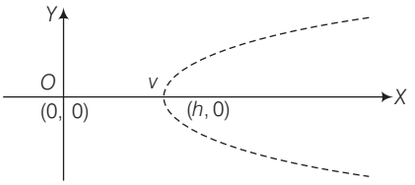

Figure 3.3

(3) $y^2 = 4a(x + h)$; where a and h are positive.

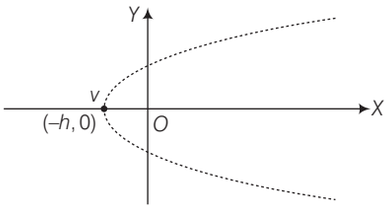

Figure 3.4

(4) $y^2 = -4ax$; $a > 0$

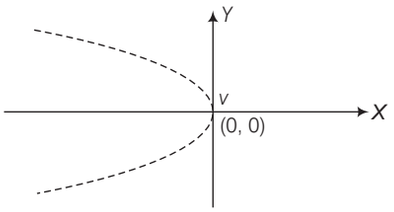

Figure 3.5

(5) $y^2 = -4a(x - h)$; $a, h > 0$

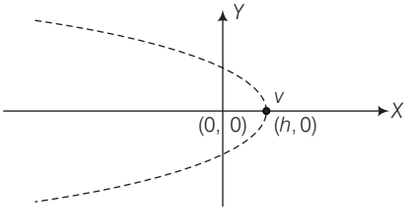

Figure 3.6

(6) $y^2 = -4a(x + h)$; $a, h > 0$

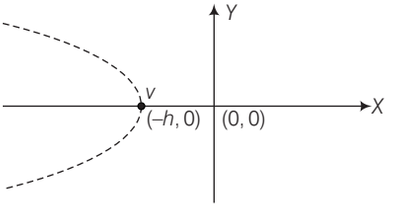

Figure 3.7

(7) $x^2 = 4ay$; $a > 0$

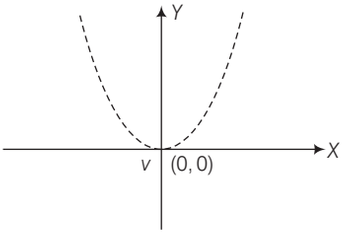

Figure 3.8

(8) $x^2 = 4a(y + k)$; $a > 0, k > 0$

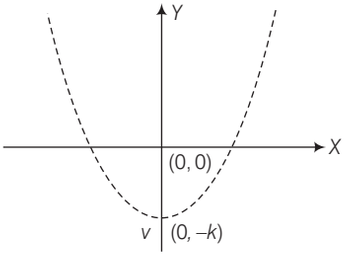

Figure 3.9

(9) $x^2 = 4a(y - k)$; $a, k > 0$

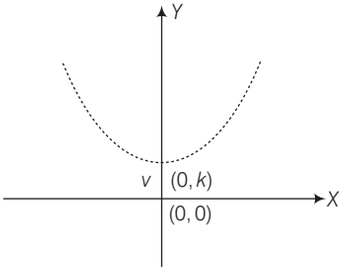

Figure 3.10

(10) $x^2 = -4ay;\ a > 0$

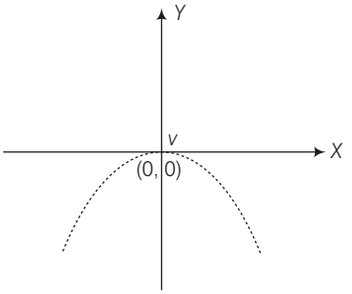

Figure 3.11

(11) $x^2 = -4a(y+k);\ a, k > 0$

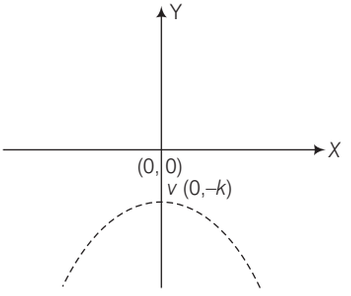

Figure 3.12

(12) $x^2 = -4a(y-k);\ a, k > 0$

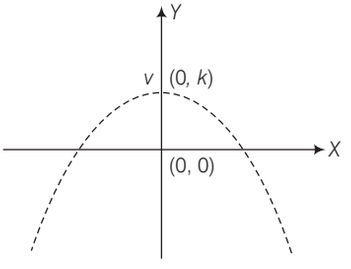

Figure 3.13

(iv) Ellipse

Basics of Ellipse

Definition 1. An ellipse is the locus of a moving point such that the ratio of its distance from a fixed point to its distance from a fixed line is a constant less than unity. This constant is termed the eccentricity of the ellipse. The fixed point is the focus while the fixed line is the directrix.

The symmetrical nature of the ellipse ensures that there will be two foci and two directrices.

Definition 2. An ellipse is the locus of a moving point such that the sum of the its distances from two fixed points is constant. The two fixed points are the two foci of the ellipse. To plot the ellipse, we can use the peg-and-thread method described earlier.

Stantard Equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

	If $a > b$	**If $a < b$**
Vertices	$(a, 0)$ and $(-a, 0)$	$(0, b)$ and $(0, -b)$
Foci	$(ae, 0)$ and $(-ae, 0)$	$(0, be)$ and $(0, -be)$
Major axis	$2a$ (along x-axis)	$2b$ (along y-axis)
Minor axis	$2b$ (along y-axis)	$2a$ (along x-axis)
Directrices	$x = \frac{a}{e}$ and $x = -\frac{a}{e}$	$y = \frac{b}{e}$ and $y = -\frac{b}{e}$
Eccentricity e	$\sqrt{1 - \frac{b^2}{a^2}}$	$\sqrt{1 - \frac{a^2}{b^2}}$
Latus-rectum	$\frac{2b^2}{a}$	$\frac{2a^2}{b}$
Focal distances of (x, y)	$a \pm ex$	$b \pm ey$

And lastly, if the equation of the ellipse is

$$\frac{(x-\alpha)^2}{a^2} + \frac{(y-\beta)^2}{b^2} = 1$$

instead of the usual standard form, we can use the transformation $X \to x - \alpha$ and $Y \to y - \beta$ (basically a translation of the axes so the axes so that the origin of the new system coincides with (α, β). The equation then becomes

$$\frac{X^2}{a^2} + \frac{Y^2}{b^2} = 1$$

We can now work on this form, use all the standard formulae that we'd like to and obtain whatever it is that we wish to obtain. The final result (in the x-y system) is obtained using the reverse transformation $x \to X + \alpha$ and $y \to Y + \beta$.

(1) $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1;\ a > 0, b > 0$ (Standard equation of the ellipse)

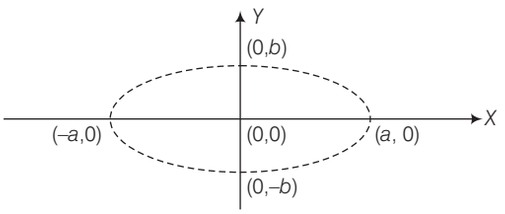

Figure 3.14

(2) $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1;\ b>a>0$ (Conjugate ellipse)

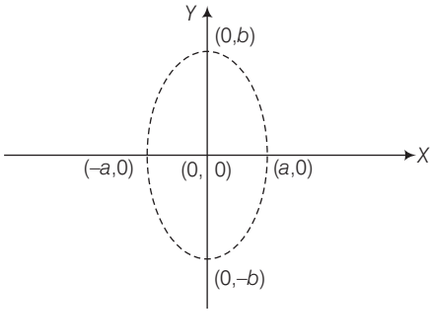

Figure 3.15

(3) $\frac{(x-h)^2}{a^2}+\frac{(y-k)^2}{b^2}=1;\ a>0, b>0$ and $a>b$

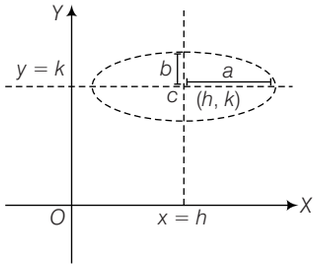

Figure 3.16

(4) $\frac{(x-h)^2}{a^2}+\frac{(y-k)^2}{b^2}=1$, where $a<b$

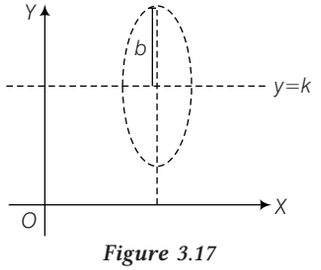

Figure 3.17

(v) Hyperbola

A hyperbola is the locus of a moving point such that the **difference** of its distances from two fixed points is always constant. The two fixed point are called the foci of the hyperbola. Constrast this with the definition of the ellipse where we had the sum of focal distances (instead of difference) as constant. As in the case of the ellipse, we have

Focal distance of $P(x, y)$

$$d_1 = e(PF) = e\left(x-\frac{a}{e}\right) = ex - a$$

$$d_2 = e(PF') = e\left(x+\frac{a}{e}\right) = ex + a$$

Latus-Rectum

The chord(s) of the hyperbola passing through the focus F (or F') and perpendicular to the transverse axis. The length of the latus-rectum can be evaluated by substituting $x = \pm ae$ in the equation for the hyperbola :

$$\frac{x^2}{a^2}-\frac{y^2}{a^2(e^2-1)}=1$$

$$\Rightarrow \quad e^2-\frac{y^2}{a^2(e^2-1)}=1$$

$$\Rightarrow \quad y^2 = a^2(e^2-1)^2 = \frac{a^2\cdot b^4}{a^4}=\frac{b^4}{a^2}$$

$$\Rightarrow \quad y=\pm\frac{b^2}{a}.$$

Thus, the length of the latus-rectum is $\frac{2b^2}{a}$.

We discussed in the unit of Ellipose that an ellipse with centre at (α, β) instead of the origin and the major and minor axis parallel to the coordinate axes will have the equation

$$\frac{(x-\alpha)^2}{a^2}+\frac{(y-\beta)}{b^2}=1 \text{ or } \frac{X^2}{a^2}+\frac{Y^2}{b^2}=1$$

where $X \to x-\alpha$ and $Y \to y-\beta$.

The same holds true for a hyperbola. Any hyperbola with centre at (α, β) and the transverse and conjugate axis parallel to the coordinate axes will have the form

$$\frac{(x-\alpha)^2}{a^2}-\frac{(y-\beta)^2}{b^2}=1$$

or

$$\frac{X^2}{a^2}-\frac{Y^2}{b^2}=1$$

where $X \to x-\alpha$ and $Y \to y-\beta$.

We can, using the definition of a hyperbola, write the equation of any hyperbola with an arbitrary focus and directrix, but we will rarely have the occassion to use it.

(1) $\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$ (Standard equation of hyperbola)

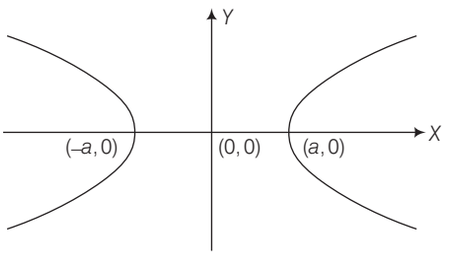

Figure 3.18

(2) $\frac{y^2}{b^2} - \frac{x^2}{a^2} = 1$ (Conjugate hyperbola)

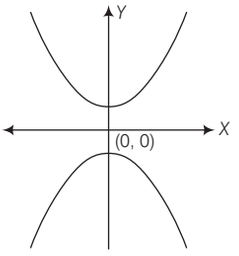

Figure 3.19

(3) $xy = c^2$ (Rectangular hyperbola)

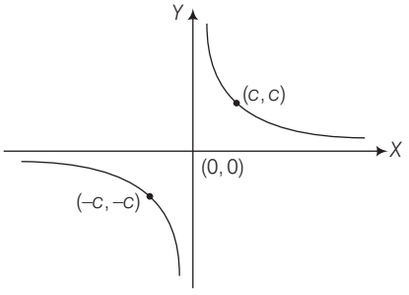

Figure 3.20

(4) $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1; a > b > 0$

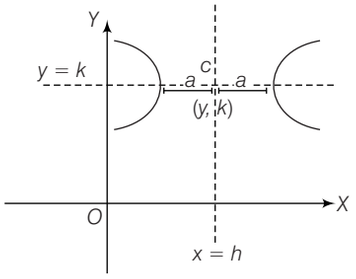

Figure 3.21

(5) $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = -1$

7. The Astroid

Its cartesian equation is $x^{2/3} + y^{2/3} = a^{2/3}$

Its parametric equation is $x = a\cos^3 t, y = a\sin^3 t$

and it could be plotted as

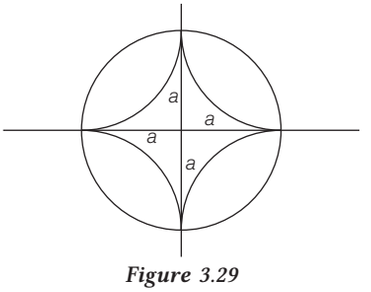

Figure 3.29

Curve Sketching

For the evaluation of area of bounded regions it is very essential to know the rough sketch of the curves. The following points are very useful to draw a rough sketch of a curve.

(i) Symmetry

(a) **Symmetry about *X*-axis** If all powers of y in the equation of the given curve are even, then it is symmetric about X-axis, i.e. the shape of the curve above X-axis is exactly identical to its shape below X-axis. **e.g.** $y^2 = 4ax$ is symmetric about X-axis.

(b) **Symmetry about *Y*-axis** If all powers of x in the equation of the given curve are even, then it is symmetric about Y-axis. **e.g.** $x^2 = 4ay$ is symmetric about Y-axis.

(c) **Symmetry in opposite quadrants** If by putting $-x$ for x and $-y$ for y, the equation of curve remains same, then it is symmetric in opposite quadrants.

e.g. $xy = c^2$, $x^2 + y^2 = a^2$ are symmetric in opposite quadrants.

(d) **Symmetric about the line $y = x$** If the equation of a given curve remains unaltered by interchanging x and y, then it is symmetric about the line $y = x$ which passes through the origin and makes an angle of 45° with positive direction of X-axis.

(ii) Origin and Tangents at the Origin

See whether the curve passes through origin or not. If the point (0, 0) satisfies the equation of the curve, then it passes through the origin and in such a case to find the equations of the tangents at the origin, equate the lowest degree term to zero. **e.g.** $y^2 = 4ax$ passes through the origin. The lowest degree term in this equation is $4ax$. Equating $4ax$ to zero, we get $x = 0$.

So, $x = 0$ i.e. Y-axis is tangent at the origin to $y^2 = 4ax$.

(iii) Points of Intersection of Curve with the Coordinate Axes

By putting $y = 0$ in the equation of the given curve, find points where the curve crosses the X-axis. Similarly, by putting $x = 0$ in the equation of the given curve we can find points where the curve crosses the Y-axis.

e.g. To find the points where the curve $xy^2 = 4a^2(2a - x)$ meets X-axis, we put $y = 0$ in the equation which gives $4a^2(2a - x) = 0$ or $x = 2a$. So the curve $xy^2 = 4a^2(2a - x)$, meets X-axis at $(2a, 0)$. This curve does not intersect Y-axis, because by putting $x = 0$ in the equation of the given curve get an absurd result.

(iv) Regions where the Curve Does Not Exist

Determine the regions in which the curve does not exist. For this, find the value of y in terms of x from the equation of the curve and find the value of x for which y is imaginary. Similarly, find the value of x in terms of y and determine the values of y for which x is imaginary. The curve does not exist for these values of x and y.

e.g. The values of y obtained from $y^2 = 4ax$ are imaginary for negative values of x. So, the curve does not exist on the left side of Y-axis. Similarly, the curve $a^2y^2 = x^2(a - x)$ does not exist for $x > a$ as the values of y are imaginary for $x > a$.

(v) Special Points

Find the points at which $\frac{dy}{dx} = 0$. At these points the tangent to the curve is parallel to X-axis.

Find the points at which $\frac{dx}{dy} = 0$. At these points the tangents to the curve is parallel to Y-axis.

(vi) Sign of dy/dx and Points of Maxima and Minima

Find the interval in which $\frac{dy}{dx} > 0$. In this interval, the function is monotonically increasing, find the interval in which $\frac{dy}{dx} < 0$. In this interval, the function is monotonically decreasing.

Put $\frac{dy}{dx} = 0$ and check the sign of $\frac{d^2y}{dx^2}$ at the points so obtained to find the points of maxima and minima.

Keeping the above facts in mind and plotting some points on the curve one can easily have a rough sketch of the curve. Following examples will clear the procedure.

Example 2 *Sketch the curve* $y = x^3$.

Sol. We observe the following points about the given curve

(i) The equation of the curve remains unchanged, if x is replaced by $-x$ and y by $-y$. So, it is symmetric in opposite quadrants. Consequently, the shape of the curve is similar in the first and the third quadrants.

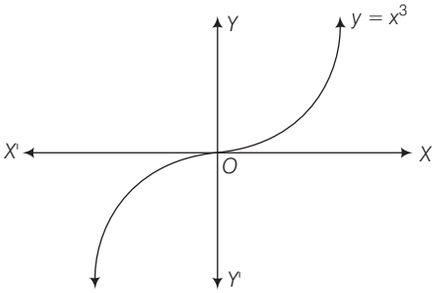
(ii) The curve passes through origin. Equating lowest degree term y to zero, we get $y = 0$ i.e. X-axis is the tangent at the origin.

(iii) Putting $y = 0$ in the equation of the curve, we get $x = 0$. Similarly, when $x = 0$, we get $y = 0$. So, the curve meets the coordinate axes at (0, 0) only.

(iv) $y = x^3 \Rightarrow \frac{dy}{dx} = 3x^2, \frac{d^2y}{dx^2} = 6x$ and $\frac{d^3y}{dx^3} = 6$

Clearly, $\frac{dy}{dx} = 0 = \frac{d^2y}{dx^2}$ at the origin but $\frac{d^3y}{dx^3} \neq 0$.

So, the origin is a point of inflexion.



(v) As x increases from 0 to ∞, y also increases from 0 to ∞. Keeping all the above points in mind, we obtain a sketch of the curve as shown in figure.

Example 3 Sketch the curve $y = x^3 - 4x$.

Sol. We note the following points about the curve

(i) The equation of the curve remains same, if x is replaced by $(-x)$ and y by $(-y)$, so it is symmetric in opposite quadrants.

Consequently, the curve in the first quadrant is identical to the curve in third quadrant and the curve in second quadrant is similar to the curve in fourth quadrant.

(ii) The curve passes through the origin. Equating the lowest degree term $y + 4x$ to zero, we get $y + 4x = 0$ or $y = -4x$. So, $y = -4x$ is tangent to the curve at the origin.

(iii) Putting $y = 0$ in the equation of the curve, we obtain $x^3 - 4x = 0 \Rightarrow x = 0, \pm 2$. So, the curve meets X-axis at (0, 0), (2, 0), (−2, 0).

Putting $x = 0$ in the equation of the curve, we get $y = 0$. So, the curve meets Y-axis at (0, 0) only.

(iv) $y = x^3 - 4x \Rightarrow \frac{dy}{dx} = 3x^2 - 4$

Now, $\frac{dy}{dx} > 0 \Rightarrow 3x^2 - 4 > 0$

$\Rightarrow \left(x - \frac{2}{\sqrt{3}}\right)\left(x + \frac{2}{\sqrt{3}}\right) > 0$

$\Rightarrow x < -\frac{2}{\sqrt{3}}$ or $x > \frac{2}{\sqrt{3}}$ (using number line rule)

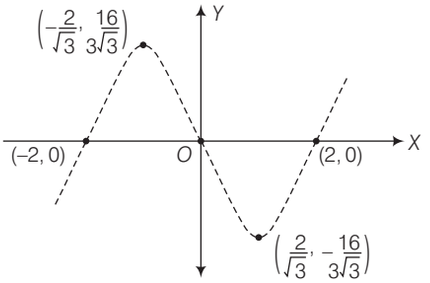
and $\frac{dy}{dx} < 0 \Rightarrow -\frac{2}{\sqrt{3}} < x < \frac{2}{\sqrt{3}}$

So, the curve is decreasing in the interval $(-2/\sqrt{3}, 2/\sqrt{3})$ and increasing for $x > \frac{2}{\sqrt{3}}$ or $x < -\frac{2}{\sqrt{3}}$.

$x = -\frac{2}{\sqrt{3}}$ is a point of local maximum and $x = \frac{2}{\sqrt{3}}$ is point of local minimum.

When $x = \frac{2}{\sqrt{3}}$, then $y = -\frac{16}{3\sqrt{3}}$

When $x = -\frac{2}{\sqrt{3}}$, then $y = \frac{16}{3\sqrt{3}}$



Keeping above points in mind, we sketch the curve as shown in figure.

Example 4 Sketch the curve $y = (x-1)(x-2)(x-3)$.

Sol. We note the following points about the given curve

(i) The curve does not have any type of symmetry about the coordinate axes and also in opposite quadrants.

(ii) The curve does not pass through the origin.

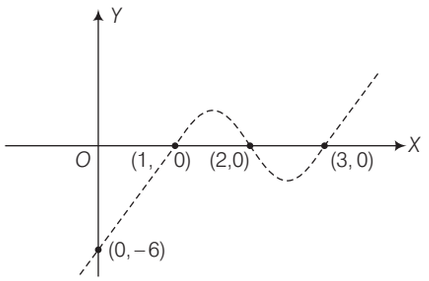
(iii) Putting $y = 0$ in the equation of the curve, we get $(x-1)(x-2)(x-3) = 0 \Rightarrow x = 1, 2, 3$. So, the curve meets X-axis at (1, 0), (2, 0) and (3, 0).

Putting $x = 0$ in the equation of the curve, we get $y = -6$. So, the curve crosses Y-axis at $(0, -6)$.

We observe that

$$x < 1 \quad \Rightarrow \quad y < 0$$
$$1 < x < 2 \quad \Rightarrow \quad y > 0$$
$$2 < x < 3 \quad \Rightarrow \quad y < 0$$

and $$x > 3 \quad \Rightarrow \quad y > 0$$



Clearly, y decreases as x decreases for all $x < 1$ and y increases as x increases for $x > 3$.

Keeping all the above points in mind, we sketch the curve as shown in figure.

Example 5 Sketch the graph for $y = x^2 - x$.

Sol. We note the following points about the curve

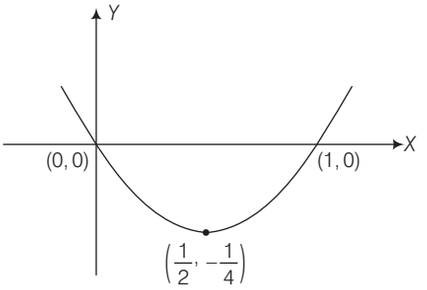
(i) The curve does not have any kind of symmetry.

(ii) The curve passes through the origin and the tangent at the origin is obtained by equating the lowest degree term to zero.

The lowest degree term is $x + y$. Equating it to zero, we get $x + y = 0$ as the equation of tangent at the origin.

(iii) Putting $y = 0$ in the equation of curve, we get $x^2 - x = 0 \Rightarrow x = 0, 1$. So, the curve crosses X-axis at (0, 0) and (1, 0).

Putting $x = 0$ in the equation of the curve, we obtain $y = 0$. So, the curve meets Y-axis at (0, 0) only.



(iv) $y = x^2 - x \Rightarrow \frac{dy}{dx} = 2x - 1$ and $\frac{d^2y}{dx^2} = 2$

Now, $$\frac{dy}{dx} = 0 \Rightarrow x = \frac{1}{2}$$

At $$x = \frac{1}{2}, \ \frac{d^2y}{dx^2} > 0$$

So, $x = \frac{1}{2}$ is point of local minima.

(v) $\frac{dy}{dx} > 0 \Rightarrow 2x - 1 > 0 \Rightarrow x > \frac{1}{2}$

So, the curve increases for all $x > \frac{1}{2}$ and decreases for all $x < \frac{1}{2}$. Keeping above points in mind, we sketch the curve as shown in figure.

Example 6 Sketch the curve $y = \sin 2x$.

Sol. We note the following points about the curve

(i) The equation of the curve remains unchanged, if x is replaced by $(-x)$ and y by $(-y)$, so it is symmetric in opposite quadrants. Consequently, the shape of the curve is similar in opposite quadrants.

(ii) The curve passes through origin.

(iii) Putting $x = 0$ in the equation of the curve, we get $y = 0$. So, the curve crosses the Y-axis at (0, 0) only.

Putting $y = 0$ in the equation of the curve, we get

$$\sin 2x = 0 \Rightarrow 2x = n\pi, \ n \in Z$$

$$\Rightarrow \quad x = \frac{n\pi}{2}, n \in Z$$

So, the curve cuts the X-axis at the points

$$\ldots, (-\pi, 0), (-\pi/2, 0), (0, 0), (\pi/2, 0), (\pi, 0), \ldots$$

(iv) $y = \sin 2x \Rightarrow \dfrac{dy}{dx} = 2\cos 2x$ and $\dfrac{d^2y}{dx^2} = -4\sin 2x$

Now, $\dfrac{dy}{dx} = 0 \Rightarrow \cos 2x = 0$

$\Rightarrow 2x = \pm\dfrac{\pi}{2}, \pm\dfrac{3\pi}{2}, \ldots$

$\Rightarrow x = \pm\dfrac{\pi}{4}, \pm\dfrac{3\pi}{4}, \ldots$

Clearly, $\dfrac{d^2y}{dx^2} < 0$ at $x = \dfrac{\pi}{4}, \dfrac{5\pi}{4}, \ldots$

and at $x = -\dfrac{3\pi}{4}, -\dfrac{7\pi}{4}, \ldots$

and $\dfrac{d^2y}{dx^2} > 0$ at $x = \dfrac{3\pi}{4}, \dfrac{7\pi}{4}, \ldots$

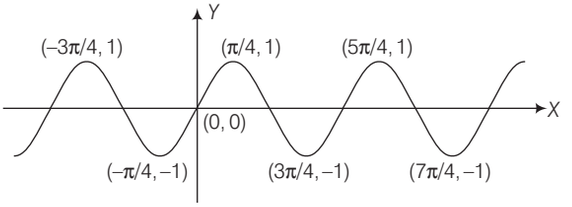
and at $x = -\dfrac{\pi}{4}, -\dfrac{5\pi}{4}, \ldots$

So, the points $x = \dfrac{\pi}{4}, \dfrac{5\pi}{4}, \dfrac{7\pi}{4}, \ldots$

and $x = -\dfrac{3\pi}{4}, -\dfrac{7\pi}{4}, \ldots$ are points of local maximum and local maximum values at these points are 1.

Similarly, $x = -\dfrac{\pi}{4}, -\dfrac{5\pi}{4}, \ldots$ and $x = \dfrac{3\pi}{4}, \dfrac{7\pi}{4}, \ldots$ are points of local minimum and local minimum value at these points is (-1).

(v) $\sin 2(x + \pi) = \sin 2x$ for all x. So, the periodicity of the function is π. This means that the pattern of the curve repeats at intervals of length π.



Thus, keeping in mind, we sketch the curve as shown in figure.

Example 7 Sketch the curve $y = \sin^2 x$.

Sol. We note the following points about the curve

(i) The equation of the curve remains same, if x is replaced by $(-x)$. So, the curve is symmetric about Y-axis, i.e. the curve on the left side of Y-axis is identical to the curve on its right side.

(ii) The curve meets the coordinate axes at the same points where $y = \sin x$ meets them.

(iii) $y = \sin^2 x \Rightarrow \dfrac{dy}{dx} = \sin 2x$ and $\dfrac{d^2y}{dx^2} = 2\cos 2x$

Now, $\dfrac{dy}{dx} = 0 \Rightarrow \sin 2x = 0 \Rightarrow 2x = n\pi, n \in Z$

$\Rightarrow x = \dfrac{n\pi}{2}, \ n \in Z \Rightarrow x = \pm\pi/2, \pm\pi, \pm 3\pi/2, \pm 2\pi, \ldots$

Clearly, $\dfrac{d^2y}{dx^2} < 0$ at $x = \pm\pi/2, \pm 3\pi/2, \pm 5\pi/2, \ldots$

and $\dfrac{d^2y}{dx^2} > 0$ at $x = \pm\pi, \pm 2\pi, \pm 3\pi \ldots$

So, $x = \pm\pi/2, \pm 3\pi/2, \pm 5\pi/2, \ldots$ are the points of local maximum and local maximum value at these points is 1. Points $x = \pm\pi, \pm 2\pi, \pm 3\pi, \ldots$ are points of local minimum and the local minimum value at these points is 0.

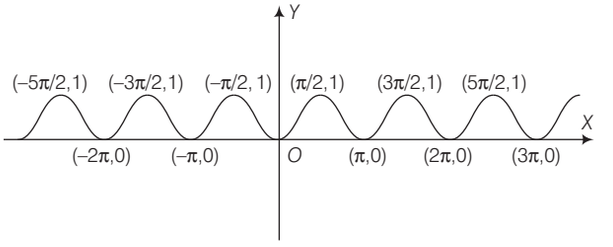
(iv) $y = \sin^2 x \Rightarrow \dfrac{dy}{dx} = \sin 2x$

Clearly, $\dfrac{dy}{dx} > 0$ when $0 < x < \dfrac{\pi}{2}$

and $\dfrac{dy}{dx} < 0$ when $\dfrac{\pi}{2} < x < \pi$.

So, the given curve is increasing in the interval $[0, \pi/2]$ and decreasing in $[\pi/2, \pi]$.

(v) $\sin^2(\pi + x) = \sin^2 x$ for all x. So, the periodicity of the function is π. This means that the shape of the curve repeats at the interval of length π.



Keeping the above facts in mind, we sketch the curve as shown in figure.

Asymptotes

The straight line AB is called the asymptote of curve $y = f(x)$, if the distance MK from M a point on the curve $y = f(x)$ to the straight line AB tends to zero as M recedes infinity.

In other words, the straight line AB meets the curve $y = f(x)$ at infinity (K is a point on AB). Thus,

1. If $f(x) \to \pm\infty$ for $x \to a$, then the straight line $x = a$ is the asymptote of the curve $y = f(x)$.

2. If in the right hand member of the equation of the curve $y = f(x)$ it is possible to single out a linear part so that the remaining part tends to zero as $x \to \pm\infty$, i.e. if $y = f(x) = Kx + b + g(x)$ and $g(x) \to 0$ for $x \to \pm\infty$, then the straight line $y = Kx + b$ is the asymptote of the curve.
3. If there exist finite limits $\lim_{x \to \pm\infty} \frac{f(x)}{x} = K$ and $\lim_{x \to \pm\infty} [f(x) - Kx] = b$, then the straight line $y = Kx + b$ is the asymptote of the curve.

Methods to Sketch Curves

While constructing the graphs of functions, it is expedient to follow the procedure given below

(1) Find the domain of definition of the function.
(2) Determine the odd-even nature of the function.
(3) Find the period of the function if its periodic.
(4) Find the asymptotes of the function.
(5) Check the behaviour of the function for $x \to 0 \pm$
(6) Find the values of x, if possible for which $f(x) \to 0$.
(7) The interval of increase and decrease of the function in its range. Hence, determine the greatest and the least values of the function if any.

Remark

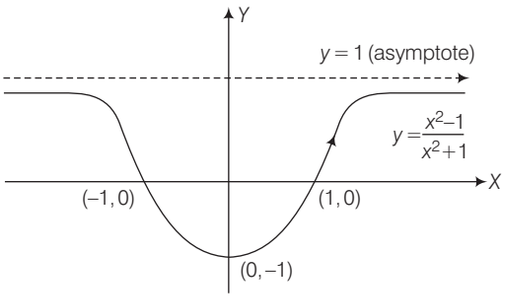
(5), (6) and (7) gives the points where the function cuts the coordinate axes.

Example 8 *Construct the graph for* $f(x) = \frac{x^2 - 1}{x^2 + 1}$.

Sol. Here, $f(x) = \frac{x^2 - 1}{x^2 + 1} = 1 - \frac{2}{x^2 + 1}$

(1) The function $f(x)$ is well defined for all real x.
$\Rightarrow$ Domain of $f(x) \in R$.
(2) $f(-x) = f(x)$, so it is an even function.
(3) Since, algebraic $\to$ non-periodic function.
$f(x) \to 1$ for $x \to \pm\infty$
and $f(x) \to -1$ for $x \to 0 \pm$
It may be observed that $f(x) < 1$ for any $x \in R$ and consequently its graph lies below the line $y = 1$ which is asymptote to the graph of the given function.
Again, $\frac{2}{x^2 + 1}$ decreases for $(0, \infty)$ and increases for $(-\infty, 0)$, thus $f(x)$ increases for $(0, \infty)$ and decreases for $(-\infty, 0)$ in its range.
(4) The greatest value $\to 1$ for $x \to \pm\infty$ and the least value is -1 for $x = 0$.

Thus, its graph is as shown in figure



Example 9 Construct the graph for $f(x) = x + \frac{1}{x}$.

Sol. The function is defined for all x except for $x = 0$.

It is an odd function for $x \neq 0$.

It is not a periodic function.

For $x \to 0+$, $f(x) \to +\infty$; for $x \to 0-$, $f(x) \to -\infty$

For $x \to -\infty$, $f(x) \to -\infty$; for $x \to \infty$, $f(x) \to \infty$

$\therefore \lim_{x \to \pm\infty} (f(x) - x) = 0$

$\therefore$ The straight lines $x = 0$ and $y = x$ are the asymptotes of the graph of the given function.

Now, consider $f(x_2) - f(x_1)$ (for $x_2 > x_1$)

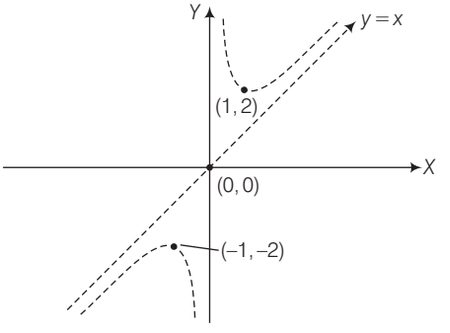
$$= (x_2 - x_1) + \frac{1}{x_2} - \frac{1}{x_1}$$

$$= (x_2 - x_1)\left[1 - \frac{1}{x_1 x_2}\right] < 0 \text{ for } x_1 x_2 \in (0, 1]$$

and it is > 0 for $x_1 x_2 \in [1, \infty)$.

Thus, $f(x)$ increases for $x \in [1, \infty)$ and decreases for $x \in (0, 1]$.

Thus, the least value of the function is at $x = 1$ which is $f(1) = 2$. Thus, its graph can be drawn as



Example 10 Construct the graph for $f(x) = \frac{1}{1 + e^{1/x}}$.

Sol. The function is defined for all x except for $x = 0$. It is neither even nor an odd function. It is not a periodic function.

For $x \to 0+$ $f(x) \to 0$; for $x \to 0-$, $f(x) \to 1$

For $x \to \infty \quad f(x) \to \frac{1}{2}$; for $x \to -\infty, \quad f(x) \to \frac{1}{2}$

$\therefore \quad \lim_{x \to \pm\infty} f(x) = \frac{1}{2}$

$\therefore$ The straight line $y = \frac{1}{2}$ is asymptote of the graph of the given function.

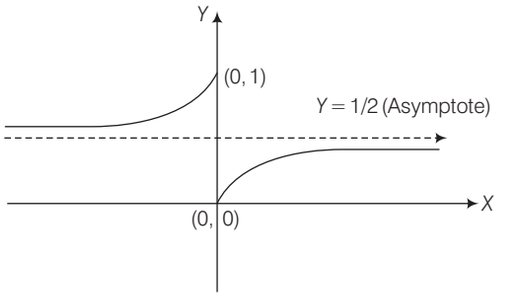
As x increases from $(0, \infty)$, $\frac{1}{x}$ decreases from $(0, \infty)$ and $e^{1/x}$ decreases from $(0, \infty)$. Thus, $(1 + e^{1/x})$ decreases from $(2, \infty)$.

$\therefore$ $f(x)$ increases from $\left(0, \frac{1}{2}\right)$ for $x \in (0, \infty)$.

Similarly, $f(x)$ increases from $(1/2, 1)$ for $x \to (-\infty, 0)$.

i.e. $f(x)$ is an increasing function except for $x = 0$.

Thus, its graph can be drawn as shown in figure



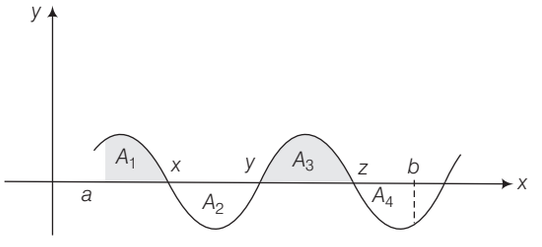
Areas of Curves

(1) Suppose that $f(x) < 0$ on some interval $[a, b]$. Then, the area under the curve $y = f(x)$ from $x = a$ to $x = b$ will be negative in sign, i.e.

$$\int_a^b f(x)\, dx \leq 0$$

This is obvious once you consider how the definite integral was arrived at in the first place; as a limit of the sum of the n rectangles $(n \to \infty)$. Thus, if $f(x) < 0$ in some interval then the area of the rectangles in that interval will also be negative.

This property means that for example, if $f(x)$ has the following form



then $\int_a^b f(x)\, dx$ will equal $A_1 - A_2 + A_3 - A_4$ and not $A_1 + A_2 + A_3 + A_4$.

If we need to evaluate $A_1 + A_2 + A_3 + A_4$ (the magnitude of the bounded area), we will have to calculate

$$\int_a^x f(x)\, dx + \left| \int_x^y f(x)\, dx \right| \int_y^z f(x)\, dx + \left| \int_z^b f(x)\, dx \right|$$

From this, it should also be obvious that

$$\left| \int_a^b f(x)\, dx \right| \leq \int_a^b |f(x)|\, dx$$

(2) The area under the curve $y = f(x)$ from $x = a$ to $x = b$ is equal in magnitude but opposite in sign to the area under the same curve from $x = b$ to $x = a$, i.e.

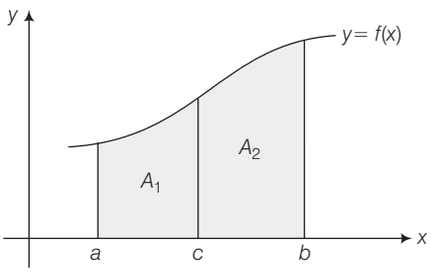
$$\int_a^b f(x)\, dx = -\int_b^a f(x)\, dx$$

This property is obvious if you consider the Newton-Leibnitz formula. If $g(x)$ is the anti-derivative of $x(f)$, then $\int_a^b f(x)\, dx$ is $g(b) - g(a)$ while $\int_a^b f(x)\, dx$ is $g(a) - g(b)$

(3) The area under the curve $y = f(x)$ from $x = a$ to $x = b$ can be written as the sum of the area under the curve from $x = a$ to $x = c$ and from $x = c$ to $x = b$, that is

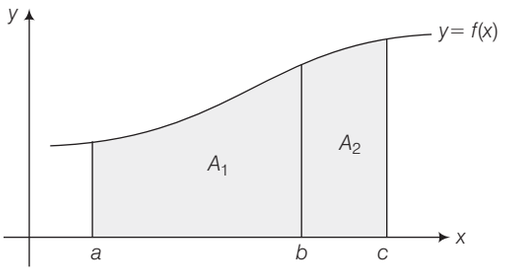
$$\int_a^b f(x)\, dx = \int_a^c f(x)\, dx + \int_c^b f(x)\, dx$$

Let us consider an example of this. Let $c \in (a, b)$



It is clear that the area under the curve from $x = a$ to $x = b$, A is $A_1 + A_2$.

Note that c need not lie between a and b for this relation to hold true. Suppose that $c > b$.



Observe that $A = \int_a^b f(x)\,dx = (A + A_1) - A_1$

$$= \int_a^c f(x)\,dx - \int_b^c f(x)\,dx$$

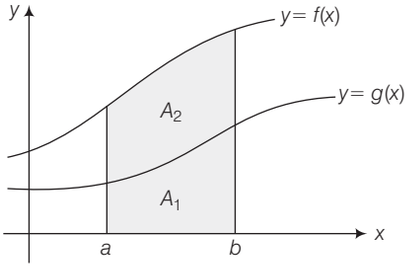
$$= \int_a^c f(x)\,dx + \int_a^b f(x)\,dx$$

Analytically, this relation can be proved easily using the Newton Leibnitz's formula.

(4) Let $f(x) > g(x)$ on the interval $[a, b]$. Then,

$$\int_a^b f(x)\,dx > \int_a^b g(x)\,dx$$

This is because the curve of $f(x)$ lies above the curve of $g(x)$, or equivalently, the curve of $f(x) - g(x)$ lies above the x-axis for $[a, b]$



This is an example where $f(x) > g(x) > 0$.

$$\int_a^b f(x)\,dx = A_1 + A_2$$

while $$\int_a^b g(x)\,dx = A_1$$

Similarly, if $f(x) < g(x)$ on the interval $[a, b]$, then

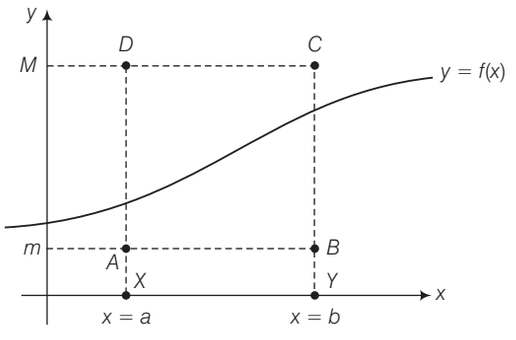
$$\int_a^b f(x)\,dx < \int_a^b g(x)\,dx$$

(5) For the interval $[a, b]$, suppose $m < f(x) < M$.

That is, m is a lower-bound for $f(x)$ while M is an upper bound.

Then $$m(b - a) < \int_a^b f(x)\,dx < M(b - a)$$

This is obvious once we consider the figure below :



Observe that area (rect $AXYB$) $< \int_a^b f(x)\,dx <$ area (rect $DXYC$)

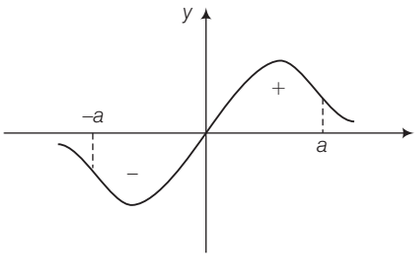
(6) Let us consider the integral of $f_1(x) + f_2(x)$ from $x = a$ to $x = b$. To evaluate the area under $f_1(x) + f_2(x)$, we can separately evaluate the area under $f_1(x)$ and the area under $f_2(x)$ and add the two area (algebraically).

Thus, $\int_a^b (f_1(x) + f_2(x))\,dx = \int_a^b f_1(x)\,dx + \int_a^b f_2(x)\,dx$

Now consider the integral of $kf(x)$ from $x = a$ to $x = b$. To evaluate the area under $kf(x)$, we can first evaluate the area under $f(x)$ and then multiply it by k, that is :

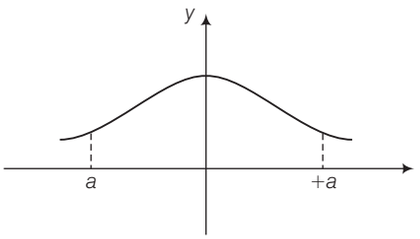
$$\int_a^b kf(x)\,dx = k\int_a^b f(x)\,dx$$

(7) Consider the odd function $f(x)$, i.e. $f(x) = -f(-x)$. This meas that the graph of $f(x)$ is symmetric about the origin.

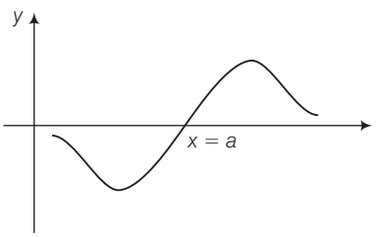


From the figure, it should be obvious that $\int_{-a}^a f(x)\,dx = 0$, because the area on the left side and that on the right algebraically add to 0.

Similarly, if $f(x)$ was even, i.e. $f(x) = f(-x)$



$\int_{-a}^a f(x)\,dx = 2\int_0^a f(x)\,dx$ because the graph is symmetrical about the y-axis. If you recall the discussion in the unit on functions, a function can also be even or odd about any arbitrary point $x = a$. Let us suppose that $f(x)$ is odd about $x = a$, i.e. $f(x) = -f(2a - x)$

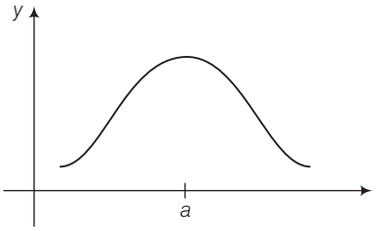


The points x and $2a - x$ lie equidistant from $x = a$ at either sides of it.

Suppose for example, that we need to calculate $\int_a^{2a} f(x)\,dx$.

It is obvious that this will be 0, since we are considering equal variation on either side of $x = a$, the area from $x = 0$ to $x = a$ and the area from $x = a$ to $x = 2a$ will add algebraically to 0.

Similarly, if $f(x)$ is even about $x = a$, i.e. $f(x) = f(2a - x)$

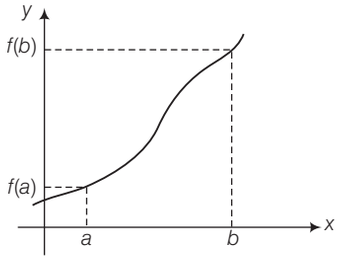


then we have, for example

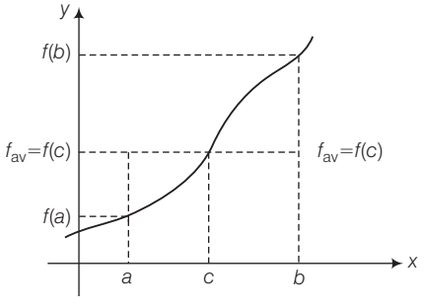
$$\int_0^{2a} f(x)\,dx = 2\int_0^a f(x)\,dx$$

From the discussion, you will get a general idea as to how to approach such issues regarding even/odd functions.

(8) Let us consider a function $f(x)$ on $[a, b]$



We want to somehow define the "average" value that $f(x)$ takes on the interval $[a, b]$. What would be an appropriate way to define such an average? Let f_{av} be the average value that we are seeking. Let it be such that it is obtained at some $x = c \in [a, b]$



We can measure f_{av} by saying that the area under $f(x)$ from $x = a$ to $x = b$ should equal the area under the average value from $x = a$ to $x = b$. This seems to be the only logical way to define the average (and this is how it is actually defined!).

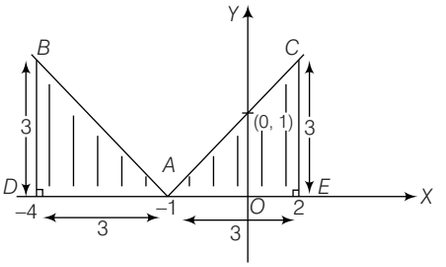
Thus $f_{av}(b - a) = \int_a^b f(x)\,dx \Rightarrow f_{av} = \frac{1}{b-a}\int_a^b f(x)\,dx$

This value is attained for at least one $c \in (a, b)$ (under the constraint that f is continuous, of course).

Example 11 ***Sketch the graph*** $y = |x + 1|$. ***Evaluate*** $\int_{-4}^{2} |x+1|\,dx$. ***What does the value of this integral represents on the graph.***

Sol. Here, $y = |x + 1| = \begin{cases} (x+1), & \text{if } x \geq -1 \\ -(x+1), & \text{if } x \leq -1 \end{cases}$

which can be shown as



$$\therefore \int_{-4}^{2} |x+1|dx = \int_{-4}^{-1} |x+1|dx + \int_{-1}^{2} |x+1|dx$$

$$= \int_{-4}^{-1} -(x+1)dx + \int_{-1}^{2} |x+1|dx + \int_{-1}^{2} (x+1)dx$$

$$= -\left[\frac{x^2}{2} + x\right]_{-4}^{-1} + \left[\frac{x^2}{2} + x\right]_{-1}^{2} = 9$$

Representation of the value 9 of integral on graph.

$\therefore \int_{-4}^{2} |x+1|dx = 9$ represents the area bounded by the curve $y = |x + 1|$. X-axis and the lines $x = -4$ and $x = 2$, i.e. if is equal to the sum of the ares of ΔABD and ACE,

i.e. $$\frac{1}{2}(3)(3) + \frac{1}{3}(3)(3) = \frac{9}{2} + \frac{9}{2} = 9$$

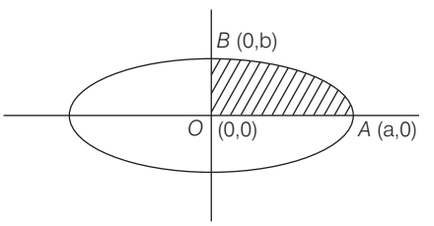
$$(\because \text{ area of triangle} = \frac{1}{2} \times \text{base} \times \text{height})$$

Example 12 Find the area of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$.

Sol. Using the symmetry of the figure; required area is given by

$$A = 4\,(\text{area } OABO)$$

$$= 4\int_0^a y\,dx, \text{ where } \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$



$$\therefore \quad \frac{y^2}{b^2} = 1 - \frac{x^2}{a^2}$$

$$\Rightarrow \quad y^2 = \frac{b^2}{a^2}(a^2 - x^2)$$

$$\Rightarrow \quad y = \pm \frac{b}{a}\sqrt{a^2 - x^2}$$

In the first quadrant,

$$y = \frac{b}{a}\sqrt{a^2 - x^2}$$

$$A = 4\int_0^a \frac{b}{a}\sqrt{a^2 - x^2}\, dx = 4\frac{b}{a}\int_0^a \sqrt{a^2 - x^2}\, dx$$

$$= 4\frac{b}{a}\left\{\frac{x}{2}\sqrt{a^2 - x^2} + \frac{a^2}{2}\sin^{-1}\frac{x}{a}\right\}_0^a$$

$$= 4\frac{b}{a}\left[\left\{0 + \frac{a^2}{2}\sin^{-1}\frac{a}{a}\right\} - \{0+0\}\right] = \frac{4b}{a}\cdot\frac{a^2}{2}\sin^{-1}(1)$$

$$= 2ab\left(\frac{\pi}{2}\right)$$

$$A = \pi ab \text{ sq units}$$

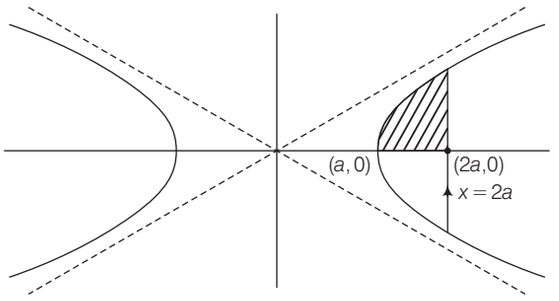
Example 13 Find the area bounded by the hyperbola $x^2 - y^2 = a^2$ between the straight lines $x = a$ and $x = 2a$.

Sol. We use the symmetry of figure.

Required area, $A = 2\int_a^{2a} y\, dx$, where $x^2 - y^2 = a^2$

i.e. $x^2 - a^2 = y^2$

$$\therefore \quad y = \pm\sqrt{x^2 - a^2}$$



In the first quadrant; $y = +\sqrt{x^2 - a^2}$

$$\therefore\ A = 2\int_a^{2a}\sqrt{x^2 - a^2}\, dx$$

$$= 2\left[\frac{x}{2}\sqrt{x^2 - a^2} - \frac{a^2}{2}\log\left(x + \sqrt{x^2 - a^2}\right)\right]_a^{2a}$$

$$= 2\left[\left\{a\sqrt{4a^2 - a^2} - \frac{a^2}{2}\log\left(2a + \sqrt{4a^2 - a^2}\right)\right\} - \left\{0 - \frac{a^2}{2}\log a\right\}\right]$$

$$= 2\left[a\sqrt{3a^2} - \frac{a^2}{2}\log(2a + a\sqrt{3}) + \frac{a^2}{2}\log a\right]$$

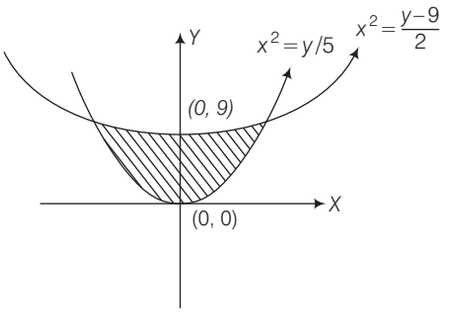
$$= 2\left[a^2\sqrt{3} - \frac{a^2}{2}\log\left(\frac{2a + a\sqrt{3}}{a}\right)\right]$$

$$= 2a^2\sqrt{3} - a^2\log(2 + \sqrt{3}) \text{ sq units}$$

Example 14 Find the area common to the parabola $5x^2 - y = 0$ and $2x^2 - y + 9 = 0$.

Sol. Given curves are $y = 5x^2$ ...(i)

and $y = 2x^2 + 9$ ...(ii)



Remark

In such examples, figure is the most essential thing. Without figure it just becomes difficult to judge whether y_1 to be subtracted from y_2 or otherwise.

Let us solve Eqs. (i) and (ii) simultaneously,

$$\therefore \quad 5x^2 = 2x^2 + 9$$

$$\Rightarrow \quad 3x^2 = 9 \Rightarrow x^2 = 3$$

$$\therefore \quad x = -\sqrt{3}$$

or $x = \sqrt{3}$

In the usual notations, the required area is given by

$$A = \int_{-\sqrt{3}}^{\sqrt{3}} (y_1 - y_2)\, dx$$

We have to find which curve is above and which is below w.r.t. X-axis in order to decide y_1 and y_2.

Take any point between $x = -\sqrt{3}$ and $x = \sqrt{3}$

Let us take $x = 0$, which lies between

$$x = -\sqrt{3} \text{ and } x = \sqrt{3}$$

When $x = 0$ from Eq. (i) $y = 0$

When $x = 0$ from Eq. (ii) $y = 9$

Now, $9 > 0$

$\therefore$ Parabola Eq. (ii) is above parabola Eq. (i) between

$$x = -\sqrt{3}$$

and $x = \sqrt{3}$.

$\therefore$ y of the curve (ii) is to be taken as y_1 and y of the curve (i) is to be taken as y_2.

$$\therefore \quad \text{Area}\,(A) = \int_{-\sqrt{3}}^{\sqrt{3}} \{(2x^2 + 9) - 5x^2\}\, dx$$

$$= \int_{-\sqrt{3}}^{\sqrt{3}} (9 - 3x^2)\, dx$$

$$= 2\int_0^{\sqrt{3}} (9 - 3x^2)\, dx$$

$$= 2\,[9x - x^3]_0^{\sqrt{3}}$$

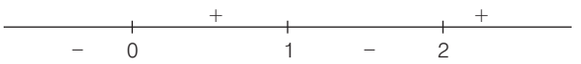
$$= 2\,[9\sqrt{3} - 3\sqrt{3}]$$

$$\text{Area} = 12\sqrt{3} \text{ sq units}$$

Example 15 Find the area enclosed by $y = x(x-1)(x-2)$ and X-axis.

Sol. The given curve is $y = x(x-1)(x-2)$. It passes through (0, 0), (1, 0) and (2, 0).

The sign scheme for $y = x(x-1)(x-2)$ is as shown in figure.



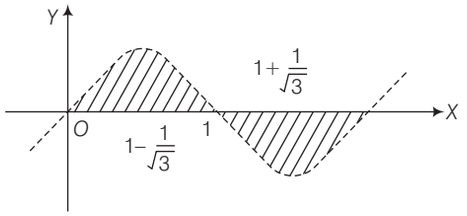
From the sign scheme it is clear that the curve is + ve when $0 < x < 1$ or $x > 2$, hence in these regions the curve lies above X-axis while in the rest regions the curve lies below X-axis.

Remark

Sometimes the discussion of monotonicity of function helps us in sketching polynomials. In the present case, $\frac{dy}{dx} = 3x^2 - 6x + 2$

When $\frac{dy}{dx} = 0$, then ; $x = 1 \pm \frac{1}{\sqrt{3}}$. Sign scheme for $\frac{dy}{dx}$ is

Thus, it is clear that the curve increases in $\left(-\infty, 1-\frac{1}{\sqrt{3}}\right)$, decreases in $\left(1-\frac{1}{\sqrt{3}}, 1+\frac{1}{\sqrt{3}}\right)$ and again increases in $\left(1+\frac{1}{\sqrt{3}}, \infty\right)$. Therefore, the graph of the curve is as below



Hence, required area

$$= \int_0^1 x(x-1)(x-2)\, dx + \left| \int_1^2 x(x-1)(x-2)\, dx \right|$$

$$= \int_0^1 (x^3 - 3x^2 + 2x)\, dx + \left| \int_1^2 (x^3 - 3x^2 + 2x)\, dx \right|$$

$$= \left(\frac{x^4}{4} - x^3 + x^2 \right)_0^1 + \left| \left(\frac{x^4}{4} - x^3 + x^2 \right)_1^2 \right|$$

$$= \left(\frac{1}{4} - 1 + 1 \right) + \left| (4 - 8 + 4) - \left(\frac{1}{4} - 1 + 1 \right) \right|$$

$$= \frac{1}{4} + \frac{1}{4} = \frac{1}{2} \text{ sq unit}$$

Example 16 ***Find the area between the curves $y = 2x^4 - x^2$, the X-axis and the ordinates of two minima of the curve.***

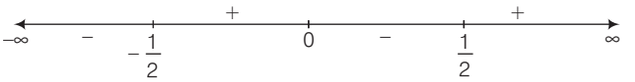
Sol. The given curve is $y = 2x^4 - x^2$.

When $y = 0$, then $x = 0, 0, \pm\frac{1}{\sqrt{2}}$

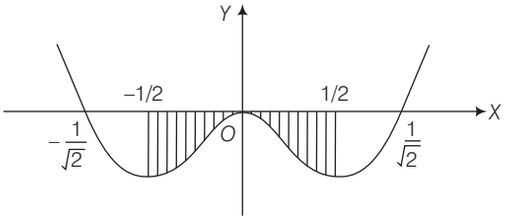
The sign scheme is as shown below

Therefore, it is clear that the curve cuts the X-axis at $x = -\frac{1}{\sqrt{2}}, 0$ and $\frac{1}{\sqrt{2}}$.

The curve is –ve in $\left(-\frac{1}{\sqrt{2}}, 0\right)$ and $\left(0, \frac{1}{\sqrt{2}}\right)$ while positive in the rest. Now, $\frac{dy}{dx} = 8x^3 - 2x$. The sign scheme for $\frac{dy}{dx}$ is as below



i.e. The curve decreases in $(-\infty, -1/2)$ and $(0, 1/2)$ and increases in the rest of portions. Also, the function possess minimum at $x = -1/2$ and $1/2$ while maximum at $x = 0$. Therefore, the graph of the curve is as shown below



$$\therefore \text{ Required area} = 2\int_0^{1/2} |\, 2x^4 - x^2 \,|\, dx$$

$$= 2\int_0^{1/2} -(2x^4 - x^2)dx = -2\left[2\frac{x^5}{5} - \frac{x^3}{3} \right]_0^{1/2}$$

$$= \frac{7}{120} \text{ sq unit}$$

Exercise for Session 1

1. Draw a rough sketch of $y = \sin 2x$ and determine the area enclosed by the curve, X-axis and the lines $x = \pi/4$ and $x = 3\pi/4$.
2. Find the area under the curve $y = (x^2 + 2)^2 + 2x$ between the ordinates $x = 0$ and $x = 2$.
3. Find the area of the region bounded by the curve $y = 2x - x^2$ and the X-axis.
4. Find the area bounded by the curve $y^2 = 2y - x$ and the Y-axis.
5. Find the area bounded by the curve $y = 4 - x^2$ and the line $y = 0$ and $y = 3$.
6. Find the area bounded by $x = at^2$ and $y = 2at$ between the ordinates corresponding to $t = 1$ and $t = 2$.
7. Find the area of the parabola $y^2 = 4ax$ and the latusrectum.
8. Find the area bounded by $y = 1 + 2\sin^2 x$, X-axis, $x = 0$ and $x = \pi$.
9. Sketch the graph of $y = \sqrt{x} + 1$ in [0, 4] and determine the area of the region enclosed by the curve, the axis of X and the lines $x = 0, x = 4$.
10. Find the area of the region bounded by the curve $xy - 3x - 2y - 10 = 0$, X-axis and the lines $x = 3, x = 4$.

Session 2

Area Bounded by Two or More Curves

Area Bounded by Two or More Curves

Area bounded by the curves $y = f(x)$, $y = g(x)$ and the lines $x = a$ and $x = b$.

Let the curves $y = f(x)$ and $y = g(x)$ be represented by AB and CD, respectively. We assume that the two curves do not intersect each other in the interval $[a, b]$.

Thus, shaded area = Area of curvilinear trapezoid $APQB$ − Area of curvilinear trapezoid $CPQD$

$$= \int_a^b f(x)\,dx - \int_a^b g(x)\,dx = \int_a^b \{f(x) - g(x)\}\,dx$$

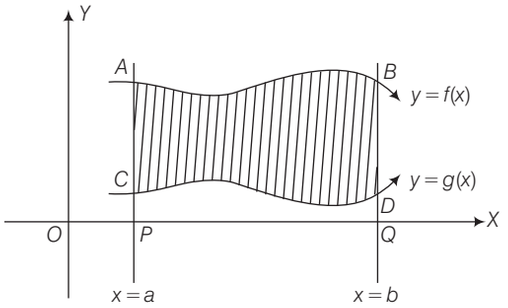


Figure 3.32

Now, consider the case when $f(x)$ and $g(x)$ intersect each other in the interval $[a, b]$.

First of all we should find the intersection point of $y = f(x)$ and $y = g(x)$. For that we solve $f(x) = g(x)$. Let the root is $x = c$. (We consider only one intersection point to illustrate the phenomenon).

Thus, required (shaded) area

$$= \int_a^c \{f(x) - g(x)\}dx + \int_c^b \{g(x) - f(x)\}\,dx$$

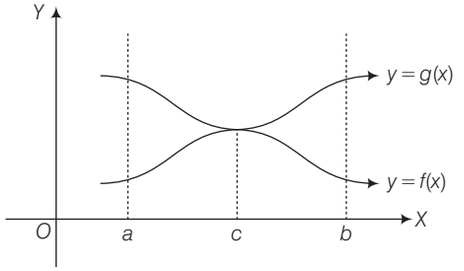

Figure 3.33

If confusion arises in such case evaluate $\int_a^b |f(x) - g(x)|\,dx$ which gives the required area.

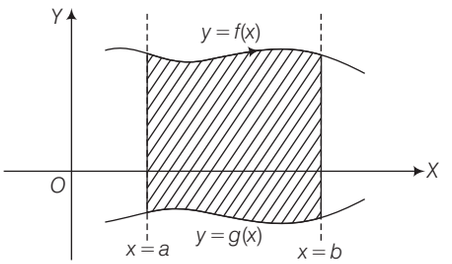

Figure 3.34

Area between two curves $y = f(x)$, $y = g(x)$ and the lines $x = a$ and $x = b$ is always given by $\int_a^b \{f(x) - g(x)\}\,dx$ provided $f(x) > g(x)$ in $[a, b]$; the position of the graph is immaterial. As shown in Fig. 3.34, Fig. 3.35, Fig. 3.36.

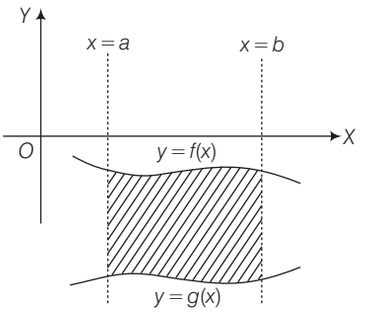

Figure 3.35

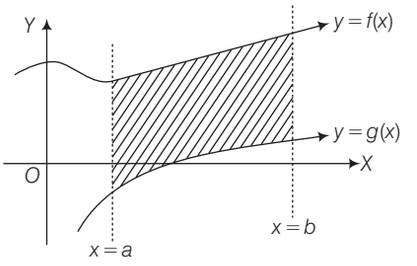

Figure 3.36

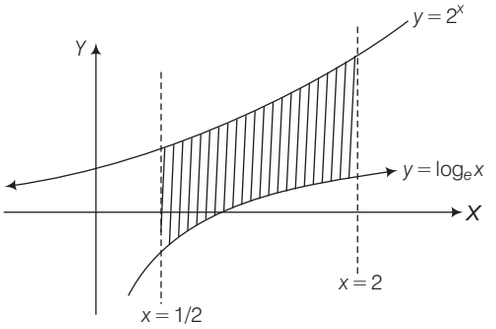
Example 17 Sketch the curves and identify the region bounded by $x = 1/2$, $x = 2$, $y = \log_e x$ and $y = 2^x$. Find the area of this region. ***[IIT JEE 1991]***

Sol. The required area is the shaded portion in the following figure.



In the region $\frac{1}{2} \le x \le 2$; the curve $y = 2^x$ lies above as compared to $y = \log_e x$.

Hence, required area $= \int_{1/2}^{2} (2^x - \log x)\, dx$

$$= \left[\frac{2^x}{\log 2} - (x \log x - x) \right]_{1/2}^{2}$$

$$= \left(\frac{4 - \sqrt{2}}{\log 2} - \frac{5}{2} \log 2 + \frac{3}{2} \right) \text{sq units}$$

Example 18 Find the area given by $x + y \le 6, x^2 + y^2 \le 6y$ and $y^2 \le 8x$.

Sol. Let us consider the curves

$$P \equiv y^2 - 8x = 0 \quad \text{...(i)}$$

$$C \equiv x^2 + y^2 = 6y$$

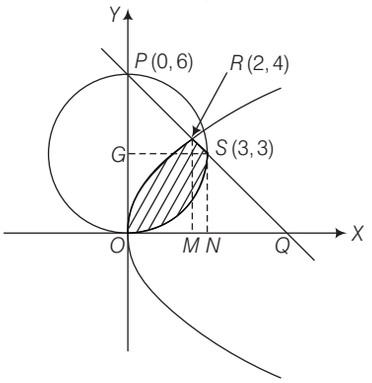
i.e. $$x^2 + (y - 3)^2 - 9 = 0 \quad \text{...(ii)}$$

and $$S \equiv x + y - 6 = 0 \quad \text{...(iii)}$$

The intersection points of the curves (ii) and (iii) are given by

$$(6 - y)^2 + y^2 - 6y = 0$$

i.e. $$y = 3, 6$$



Therefore, the points are (0, 6) and (3, 3). The intersection points of the curves (i) and (iii) are given by

$$y^2 = 8(6 - y), \quad \text{i.e. } y = 4, -12$$

Therefore, the point of intersection in 1st quadrant is (2, 4).

Now, we know that

$C \le 0$ denotes the region, inside the circle $C = 0$.

$P \le 0$ denotes the region, inside the parabola $P = 0$.

$S \le 0$ denotes the region, which is negative side of the line $S = 0$.

$\therefore$ Required area = Area of curvilinear $\Delta OMRO$ + Area of trapezium $MNSR$ − Area of curvilinear $\Delta ONSO$

$$= \int_0^2 \sqrt{8x}\, dx + \frac{1}{2}(MR + NS) \cdot MN - (\text{Area of square } ONSG - \text{Area of sector } OSGO)$$

$$= \int_0^2 \sqrt{8x}\, dx + \frac{1}{2}(4 + 3) \cdot 1 - \left(3^2 - \frac{\pi \cdot 3^2}{4} \right)$$

$$= \left(\frac{9\pi}{4} - \frac{1}{6} \right) \text{sq units}$$

Example 19 Find the area of the region $\{(x, y) : 0 \le y \le x^2 + 1, 0 \le y \le x + 1, 0 \le x \le 2\}$.

Sol. Let $R = \{(x, y) : 0 \le y \le x^2 + 1, 0 \le y \le x + 1, 0 \le x \le 2\}$

$$= \{(x, y) : 0 \le y \le x^2 + 1\} \cap \{(x, y) : 0 \le y \le x + 1\} \cap \{(x, y) : 0 \le x \le 2\}$$

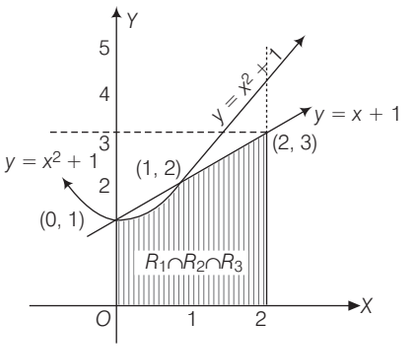
$$= R_1 \cap R_2 \cap R_3$$

where, $R_1 = \{(x, y) : 0 \le y \le x^2 + 1\}$

$R_2 = \{(x, y) : 0 \le y \le x + 1\}$

and $R_3 = \{(x, y) : 0 \le x \le 2\}$

Thus, the sketch of R_1, R_2 and R_3 are



From the above figure,

$$\text{Required area} = \int_0^1 (x^2 + 1)\, dx + \int_1^2 (x + 1)\, dx$$

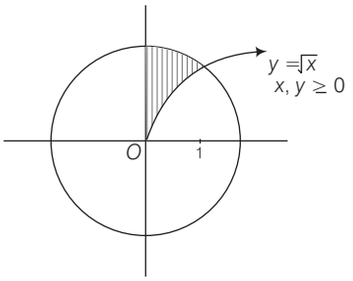
$$= \left(\frac{x^3}{3} + x \right)_0^1 + \left(\frac{x^2}{2} + x \right)_1^2 = \frac{23}{6} \text{ sq units}$$

Example 20 The area common to the region determined by $y \ge \sqrt{x}$ and $x^2 + y^2 < 2$ has the value

(a) π sq units (b) $(2\pi - 1)$ sq units

(c) $\left(\frac{\pi}{4} - \frac{1}{6} \right)$ sq units (d) None of these

Sol. The region formed by $y \geq \sqrt{x}$ is the outer region of the parabola $y^2 = x$, when $y \geq 0$ and $x \geq 0$ and $x^2 + y^2 < 2$ is the region inner to circle $x^2 + y^2 = 2$ shown as in figure.



Now, to find the point of intersection put $y^2 = x$ in $x^2 + y^2 = 2$.

$$\Rightarrow \quad x^2 + x - 2 = 0$$

$$\Rightarrow \quad (x+2)(x-1) = 0$$

$$\Rightarrow \quad x = 1, \text{ as } x \geq 0$$

$$\therefore \text{ Required area} = \int_0^1 (\sqrt{2 - x^2} - \sqrt{x})\, dx$$

$$= \left[\frac{x\sqrt{2-x^2}}{2} + \sin^{-1}\frac{x}{\sqrt{2}} - \frac{2}{\sqrt{3}} x^{3/2} \right]_0^1$$

$$= \frac{1}{2} + \frac{\pi}{4} - \frac{2}{3} = \left(\frac{\pi}{4} - \frac{1}{6} \right) \text{ sq units}$$

Hence, (c) is the correct answer.

Example 21 Find the area of the region enclosed by the curve $5x^2 + 6xy + 2y^2 + 7x + 6y + 6 = 0$.

Sol. Comparing $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$, we get $a = 5, b = 2, h = 3, g = 7/2, f = 3$ and $c = 6$

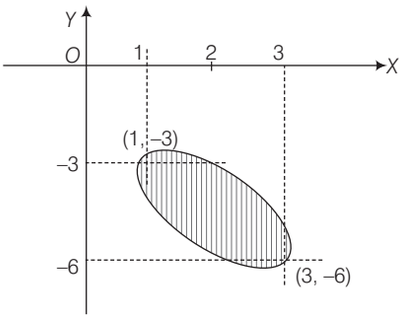
$$\Rightarrow \quad h^2 - ab = -1 < 0$$

So, the above equation represents an ellipse.

$$\therefore \quad 2y^2 + 6(1+x)y + (5x^2 + 7x + 6) = 0$$

$$\Rightarrow \quad y = \frac{-3(1+x) \pm \sqrt{(3-x)(x-1)}}{2}$$

Clearly, the values of y are real for all $x \in [1, 3]$. Thus, the graph is as shown below



Thus, required area

$$= \left| \int_1^3 \left(\frac{-3(1+x) - \sqrt{(3-x)(x-1)}}{2} \right) - \left(\frac{-3(1+x) + \sqrt{(3-x)(x-1)}}{2} \right) dx \right|$$

$$= \left| -\int_1^3 \sqrt{(3-x)(x-1)}\, dx \right| = \left| \int_1^3 \sqrt{1^2 - (x-2)^2}\, dx \right|$$

$$= \left| -\left\{ \frac{1}{2}(x-2)\sqrt{-x^2 + 4x - 3} + \frac{1}{2}\sin^{-1}\left(\frac{x-2}{1} \right) \right\}_1^3 \right|$$

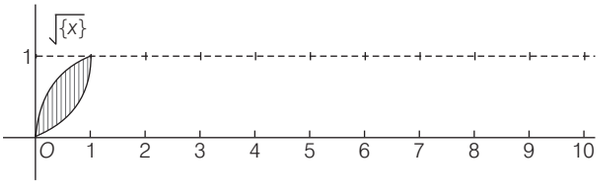
$$= \frac{\pi}{2} \text{ sq units}$$

Example 22 ***If*** $f(x) = \begin{cases} \sqrt{\{x\}}, & x \notin Z \\ 1, & x \in Z \end{cases}$ ***and*** $g(x) = \{x\}^2$ ***(where, {.} denotes fractional part of*** x***), then the area bounded by*** $f(x)$ ***and*** $g(x)$ ***for*** $x \in [0, 10]$ ***is***

(a) $\frac{5}{3}$ sq units (b) 5 sq units

(c) $\frac{10}{3}$ sq units (d) None of these

Sol. As, $f(x) = \begin{cases} \sqrt{\{x\}}, & x \notin z \\ 1, & x \in z \end{cases}$ and $g(x) = \{x\}^2$, where both $f(x)$ and $g(x)$ are periodic with period '1' shown as



Thus, required area $= 10\int_0^1 [\sqrt{\{x\}} - \{x\}^2]\, dx$

$$= 10\int_0^1 [(x)^{1/2} - x^2]\, dx$$

$$= 10\left[\frac{x^{3/2}}{3/2} - \frac{x^3}{3} \right]_0^1$$

$$= 10\left(\frac{2}{3} - \frac{1}{3} \right) = \frac{10}{3} \text{ sq units}$$

Hence, (c) is the correct answer.

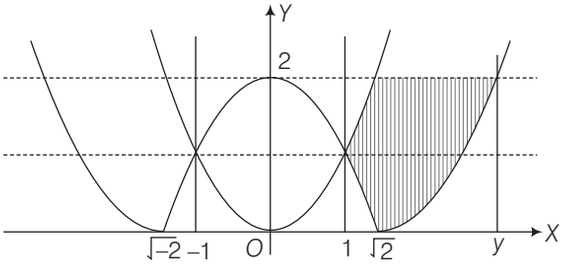
Example 23 Find the area of the region bounded by the curves $y = x^2$, $y = |2 - x^2|$ and $y = 2$, which lies to the right of the line $x = 1$. ***[IIT JEE 2002]***

Sol. The region bounded by given curves on the right side of $x = 1$ is shown as

Required area $= \int_1^{\sqrt{2}} \{x^2 - (2 - x^2)\}\, dx + \int_{\sqrt{2}}^2 \{4 - x^2\}\, dx$

$$= \int_1^{\sqrt{2}} (2x^2 - 2)\, dx + \int_{\sqrt{2}}^{2} (4 - x^2)\, dx$$

$$= \left(2 \cdot \frac{x^3}{3} - 2x\right)_1^{\sqrt{2}} + \left(4x - \frac{x^3}{3}\right)_{\sqrt{2}}^{2}$$



$$= \left(\frac{4\sqrt{2}}{3} - 2\sqrt{2}\right) - \left(\frac{2}{3} - 2\right) + \left(8 - \frac{8}{3}\right) - \left(4\sqrt{2} - \frac{2\sqrt{2}}{3}\right)$$

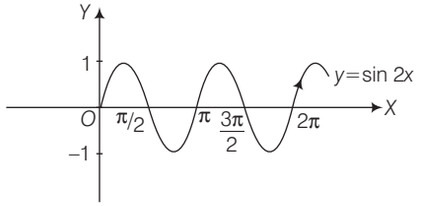
$$= \left(-4\sqrt{2} + \frac{20}{3}\right) = \left(\frac{20 - 12\sqrt{2}}{3}\right) \text{ sq units}$$

Example 24 The area enclosed by the curve $|y| = \sin 2x$, when $x \in [0, 2\pi]$ is

(a) 1 sq unit (b) 2 sq units

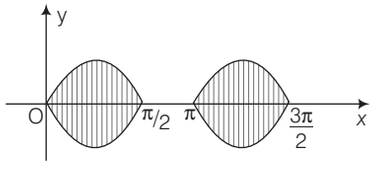
(c) 3 sq units (d) 4 sq units

Sol. As, we know $y = \sin 2x$ could be plotted as



Thus, $|y| = \sin 2x$ is whenever positive, y can have both positive and negative values, i.e. the curve is symmetric about the axes.

$\sin 2x$ is positive only in $0 \le x \le \frac{\pi}{2}$ and $\pi \le x \le \frac{3\pi}{2}$. Thus, the curve consists of two loops one in $\left[0, \frac{\pi}{2}\right]$ and another in $\left[\pi, \frac{3\pi}{2}\right]$.



Thus, required area $= 4\int_0^{\pi/2} (\sin 2x)\, dx$

$$= 4\left(-\frac{\cos 2x}{2}\right)_0^{\pi/2} = -2(\cos \pi - \cos 0)$$

$$= -2(-1 - 1) = 4 \text{ sq units}$$

Hence, (d) is the correct answer.

Example 25 Let $f(x) = x^2$, $g(x) = \cos x$ and $\alpha, \beta\ (\alpha < \beta)$ be the roots of the equation $18x^2 - 9\pi x + \pi^2 = 0$. Then, the area bounded by the curves $y = fog(x)$, the ordinates $x = \alpha$, $x = \beta$ and the X-axis is

(a) $\frac{1}{2}(\pi - 3)$ sq units (b) $\frac{\pi}{3}$ sq units

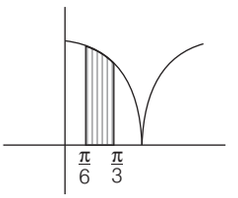
(c) $\frac{\pi}{4}$ sq units (d) $\frac{\pi}{12}$ sq units

Sol. Here, $y = fog(x) = f\{g(x)\} = (\cos x)^2 = \cos^2 x$

Also, $18x^2 - 9\pi x + \pi^2 = 0$

$\Rightarrow$ $(3x - \pi)(6x - \pi) = 0$

$\Rightarrow$ $x = \frac{\pi}{6}, \frac{\pi}{3}$ (as α, β)



$\therefore$ Required area of curve

$$= \int_{\pi/6}^{\pi/3} \cos^2 x\, dx = \frac{1}{2}\int_{\pi/6}^{\pi/3} (1 + \cos 2x)\, dx$$

$$= \frac{1}{2}\left\{x + \frac{\sin 2x}{2}\right\}_{\pi/6}^{\pi/3} = \frac{1}{2}\left\{\left(\frac{\pi}{3} - \frac{\pi}{6}\right) + \frac{1}{2}\left(\sin\frac{2\pi}{3} - \sin\frac{2\pi}{6}\right)\right\}$$

$$= \frac{1}{2}\left\{\frac{\pi}{6} + \frac{1}{2}\left(\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{2}\right)\right\} = \frac{\pi}{12}$$

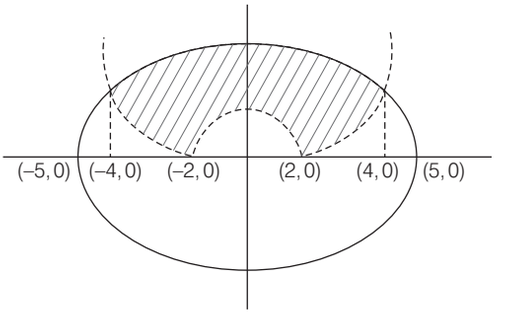
Hence, (d) is the correct answer.

Example 26 ***Find the area bounded by the curves*** $x^2 + y^2 = 25, 4y = |4 - x^2|$ ***and*** $x = 0$ ***above the*** X***-axis.***

Sol. The 1st curve is a circle of radius 5 with centre at (0, 0).

The 2nd curve is $y = \left|\frac{4 - x^2}{4}\right| = \left|1 - \frac{x^2}{4}\right|$

which can be traced easily by graph transformation.



When the two curves intersect each other, then

$$x^2 + \left(1 - \frac{x^2}{4}\right)^2 = 25 \Rightarrow x = \pm 4$$

Hence, required area $= 2\int_0^4 \left(\sqrt{25 - x^2} - \left|1 - \frac{x^2}{4}\right|\right) dx$

$$= 2\left[\int_0^4 \sqrt{25 - x^2}\,dx - \int_0^2 \left(1 - \frac{x^2}{4}\right)dx + \int_2^4 \left(1 - \frac{x^2}{4}\right)dx\right]$$

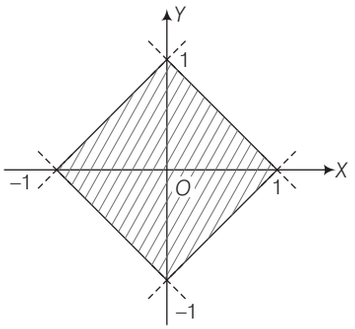
$$= 2\left[6 + \frac{25}{2}\sin^{-1}\left(\frac{4}{5}\right) - \frac{4}{3} - \frac{8}{3}\right] = \left\{25\sin^{-1}\left(\frac{4}{5}\right) + 4\right\}$$

Example 27 ***Find the area enclosed by*** $|x| + |y| = 1$.

Sol. From the given equation, we have

$$|y| = 1 - |x| \geq 0 \qquad [\because |y| \geq 0]$$

$$\Rightarrow \qquad -1 \leq x \leq 1$$



Therefore, the curve exists for $x \in [-1, 1]$ only

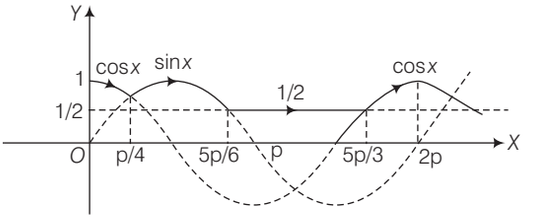
and for $-1 \leq x \leq 1$; $\quad y = \pm(1 - |x|)$ i.e. $y = \begin{cases} |x| - 1 \\ -(|x| - 1) \end{cases}$

Thus, the required graph is as given in figure.

$\therefore$ Required area $= (\sqrt{2})^2 = 2$ sq units

Example 28 Let $f(x) = \max\left\{\sin x, \cos x, \frac{1}{2}\right\}$, then determine the area of region bounded by the curves $y = f(x)$, X-axis, Y-axis and $x = 2\pi$.

Sol. We have, $f(x) = \max\left\{\sin x, \cos x, \frac{1}{2}\right\}$. Graphically, $f(x)$ could be drawn as



Here, the graph is plotted between 0 to 2π and between the points of intersection the maximum portion is included, thus the shaded part is required area

	Interval	Value of $f(x)$
i.e. for	$0 \leq x < \pi/4$	$\cos x$
for	$\pi/4 \leq x < 5\pi/6$	$\sin x$
for	$5\pi/6 \leq x < 5\pi/3$	$1/2$
for	$5\pi/3 \leq x < 2\pi$	$\cos x$

Hence, required area

$$I = \int_0^{\pi/4} \cos x\,dx + \int_{\pi/4}^{5\pi/6} \sin x\,dx + \int_{5\pi/6}^{5\pi/3} \frac{1}{2}\,dx + \int_{5\pi/3}^{2\pi} \cos x\,dx$$

$$= (\sin x)_0^{\pi/4} - (\cos x)_{\pi/4}^{5\pi/6} + \frac{1}{2}(x)_{5\pi/6}^{5\pi/3} + (\sin x)_{5\pi/3}^{2\pi}$$

$$= \left(\frac{1}{\sqrt{2}} - 0\right) - \left(-\frac{\sqrt{3}}{2} - \frac{1}{\sqrt{2}}\right) + \frac{1}{2}\left(\frac{5\pi}{3} - \frac{5\pi}{6}\right) + \left(0 + \frac{\sqrt{3}}{2}\right)$$

$$= \left(\frac{5\pi}{12} + \sqrt{2} + \sqrt{3}\right) \text{ sq units}$$

Exercise for Session 2

1. The area of the region bounded by $y^2 = 2x + 1$ and $x - y - 1 = 0$ is

(a) 2/3 (b) 4/3 (c) 8/3 (d) 16/3

2. The area bounded by the curve $y = 2x - x^2$ and the straight line $y = x$ is given by

(a) 9/2 (b) 43/6 (c) 35/6 (d) None of these

3. The area bounded by the curve $y = x|x|$, X-axis and the ordinates $x = -1$, $x = 1$ is given by

(a) 0 (b) 1/3 (c) 2/3 (d) None of these

4. Area of the region bounded by the curves $y = 2^x$, $y = 2x - x^2$, $x = 0$ and $x = 2$ is given by

(a) $\frac{3}{\log 2} - \frac{4}{3}$ (b) $\frac{3}{\log 2} + \frac{4}{3}$ (c) $3\log 2 - \frac{4}{3}$ (d) None of these

5. The area of the figure bounded by the cuves $y = e^x$, $y = e^{-x}$ and the straight line $x = 1$ is

(a) $e + \frac{1}{e}$ (b) $e - \frac{1}{e}$ (c) $e + \frac{1}{e} - 2$ (d) None of these

6. Area of the region bounded by the curve $y^2 = 4x$, Y-axis and the line $y = 3$ is

(a) 2 (b) 9/4 (c) $6\sqrt{3}$ (d) None of these

7. The area of the figure bounded by $y = \sin x$, $y = \cos x$ is the first quadrant is

(a) $2(\sqrt{2-1})$ (b) $\sqrt{3}+1$ (c) $2(\sqrt{3}-1)$ (d) None of these

8. The area bounded by the curves $y = xe^x$, $y = xe^{-x}$ and the line $x = 1$ is

(a) $\frac{2}{e}$ (b) $1-\frac{2}{e}$ (c) $\frac{1}{e}$ (d) $1-\frac{1}{e}$

9. The areas of the figure into which the curve $y^2 = 6x$ divides the circle $x^2 + y^2 = 16$ are in the ratio

(a) $\frac{2}{3}$ (b) $\frac{4\pi-\sqrt{3}}{8\pi+\sqrt{3}}$ (c) $\frac{4\pi+\sqrt{3}}{8\pi-\sqrt{3}}$ (d) None of these

10. The area bounded by the Y-axis, $y = \cos x$ and $y = \sin x$, $0 \geq x \leq \pi/2$ is

(a) $2(\sqrt{2}-1)$ (b) $\sqrt{2}-1$ (c) $(\sqrt{2}+1)$ (d) $\sqrt{2}$

11. The area bounded by the curve $y = \frac{3}{|x|}$ and $y + |2-x| = 2$ is

(a) $\frac{4-\log 27}{3}$ (b) $2-\log 3$ (c) $2+\log 3$ (d) None of these

12. The area bounded by the curves $y = x^2 + 2$ and $y = 2|x| - \cos + x$ is

(a) 2/3 (b) 8/3 (c) 4/3 (d) 1/3

13. The are bounded by the curve $y^2 = 4x$ and the circle $x^2 + y^2 - 2x - 3 = 0$ is

(a) $2\pi + \frac{8}{3}$ (b) $4\pi + \frac{8}{3}$ (c) $\pi + \frac{8}{3}$ (d) $\pi - \frac{8}{3}$

14. A point P moves inside a triangle formed by $A(0,0), B\left(1, \frac{1}{\sqrt{3}}\right), C(2, 0)$ such that min $\{PA, PB, PC\} = 1$, then the area bounded by the curve traced by P, is

(a) $3\sqrt{3} - \frac{3\pi}{2}$ (b) $\sqrt{3} + \frac{\pi}{2}$ (c) $\sqrt{3} - \frac{\pi}{2}$ (d) $3\sqrt{3} + \frac{3\pi}{2}$

15. The graph of $y^2 + 2xy + 40|x| = 400$ divides the plane into regions. The area of the bounded region is

(a) 400 (b) 800 (c) 600 (c) None of these

16. The area of the region defined by $||x| - |y|| \leq 1$ and $x^2 + y^2 \leq 1$ in the xy- plane is

(a) π (b) 2π (c) 3π (d) 1

17. The area of the region defined by $1 \leq |x-2| + |y+1| \leq 2$ is

(a) 2 (b) 4 (c) 6 (d) None of these

18. The area of the region enclosed by the curve $|y| = -(1-|x|)^2 + 5$, is

(a) $\frac{8}{3}(7+5\sqrt{5})$ sq units (b) $\frac{2}{3}(7+5\sqrt{5})$ sq units (c) $\frac{2}{3}(5\sqrt{5}-7)$ sq units (d) None of these

19. The area bounded by the curve $f(x) = ||\tan x + \cot x| - |\tan x - \cot x||$ between the lines $x = 0, x = \frac{\pi}{2}$ and the X-axis is

(a) log 4 (b) $\log\sqrt{2}$ (c) 2log2 (d) $\sqrt{2}\log 2$

20. If $f(x) = \max\left\{\sin x, \cos x, \frac{1}{2}\right\}$, then the area of the region bounded by the curves $y = f(x)$, X-axis, Y-axis and $x = \frac{5\pi}{3}$ is

(a) $\left(\sqrt{2}-\sqrt{3}+\frac{5\pi}{12}\right)$ sq units (b) $\left(\sqrt{2}+\sqrt{3}+\frac{5\pi}{2}\right)$ sq units

(c) $\left(\sqrt{2}+\sqrt{3}+\frac{5\pi}{2}\right)$ sq units (d) None of these

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *If A denotes the area bounded by* $f(x)=\left|\frac{\sin x+\cos x}{x}\right|$, *X-axis,* $x=\pi$ *and* $x=3\pi$, *then*

(a) $1<A<2$ (b) $0<A<2$

(c) $2<A<3$ (d) None of these

Sol. $\frac{2\sqrt{2}}{2\pi}<\int_{\pi}^{2\pi}\frac{|\sin x+\cos x|}{x}dx<\frac{2\sqrt{2}}{2\pi}$

$\left[\because \pi<x<2\pi \Rightarrow \frac{1}{2\pi}<\frac{1}{x}<\frac{1}{\pi}\right]$ ...(i)

$\frac{2\sqrt{2}}{3\pi}<\int_{2\pi}^{3\pi}\frac{|\sin x+\cos x|}{x}dx<\frac{2\sqrt{2}}{2\pi}$ ...(ii)

On adding Eqs. (i) and (ii), we get

$$\frac{5\sqrt{2}}{3\pi}<A<\frac{3\sqrt{2}}{\pi}$$

$\Rightarrow$ $0.75<A<1.3$

Hence, (b) is the correct answer.

● **Ex. 2** *If* $f(x)\geq 0, \forall x\in(0,2)$ *and* $y=f(x)$ *makes positive intercepts of* 2 *and* 1 *unit on X and Y-axes respectively and encloses an area of* 3/4 *unit with axes, then* $\int_0^2 xf'(x)\,dx$ *is*

(a) $\frac{3}{4}$ (b) 1 (c) $\frac{5}{4}$ (d) $-\frac{3}{4}$

Sol. $I=xf(x)|_0^2-\int_0^2 f(x)\,dx=0-\frac{3}{4}=-\frac{3}{4}$

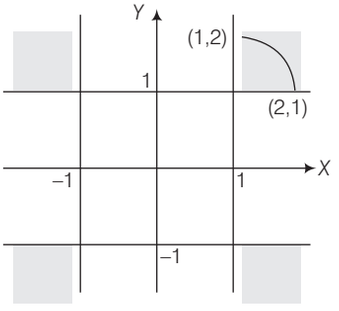
Hence, (d) is the correct answer.

● **Ex. 3** *The area of the region included between the regions satisfying* $\min(|x|,|y|)\geq 1$ *and* $x^2+y^2\leq 5$ *is*

(a) $\frac{5}{2}\left(\sin^{-1}\frac{2}{\sqrt{5}}-\sin^{-1}\frac{1}{\sqrt{5}}\right)-4$ (b) $10\left(\sin^{-1}\frac{2}{\sqrt{5}}-\sin^{-1}\frac{1}{\sqrt{5}}\right)-4$

(c) $\frac{2}{5}\left(\sin^{-1}\frac{2}{\sqrt{5}}-\sin^{-1}\frac{1}{\sqrt{5}}\right)-4$ (d) $15\left(\sin^{-1}\frac{2}{\sqrt{5}}-\sin^{-1}\frac{1}{\sqrt{5}}\right)-4$

Sol. Shaded region depicts $\min(|x|,|y|)\geq 1$



Required area $=4\int_1^2(\sqrt{5-x^2}-1)\,dx$

$$=10\left(\sin^{-1}\frac{2}{\sqrt{5}}-\sin^{-1}\frac{1}{\sqrt{5}}\right)-4$$

Hence, (b) is the correct answer.

● **Ex. 4** *The area of the region between the curves* $y=\sqrt{\frac{1+\sin x}{\cos x}}$ *and* $y=\sqrt{\frac{1-\sin x}{\cos x}}$ *and bounded by the lines* $x=0$ *and* $x=\frac{\pi}{4}$ *is* ***[IIT JEE 2008]***

(a) $\int_0^{\sqrt{2}-1}\frac{t}{(1+t^2)\sqrt{1-t^2}}dt$

(b) $\int_0^{\sqrt{2}-1}\frac{4t}{(1+t^2)\sqrt{1-t^2}}dt$

(c) $\int_0^{\sqrt{2}+1}\frac{4t}{(1+t^2)\sqrt{1-t^2}}dt$

(d) $\int_0^{\sqrt{2}+1}\frac{t}{(1+t^2)\sqrt{1-t^2}}dt$

Sol. Required area $=\int_0^{\pi/4}\left(\sqrt{\frac{1+\sin x}{\cos x}}-\sqrt{\frac{1-\sin x}{\cos x}}\right)dx$

$\left(\because \frac{1+\sin x}{\cos x}>\frac{1-\sin x}{\cos x}>0\right)$

$$=\int_0^{\pi/4}\left(\sqrt{\frac{1+\frac{2\tan\frac{x}{2}}{1+\tan^2\frac{x}{2}}}{\frac{1-\tan^2\frac{x}{2}}{1+\tan^2\frac{x}{2}}}}-\sqrt{\frac{1-\frac{2\tan\frac{x}{2}}{1+\tan^2\frac{x}{2}}}{\frac{1-\tan^2\frac{x}{2}}{1+\tan^2\frac{x}{2}}}}\right)dx$$

$$=\int_0^{\pi/4}\left(\sqrt{\frac{1+\tan\frac{x}{2}}{1-\tan\frac{x}{2}}}-\sqrt{\frac{1-\tan\frac{x}{2}}{1+\tan\frac{x}{2}}}\right)dx$$

$$=\int_0^{\pi/4}\frac{1+\tan\frac{x}{2}-1+\tan\frac{x}{2}}{\sqrt{1-\tan^2\frac{x}{2}}}dx=\int_0^{\pi/4}\frac{2\tan\frac{x}{2}}{\sqrt{1-\tan^2\frac{x}{2}}}dx$$

Put $\tan\frac{x}{2}=t$

$\therefore$ Area $=\int_0^{\sqrt{2}-1}\frac{4t}{(1+t^2)\sqrt{1-t^2}}dt$

Hence, (b) is the correct answer.

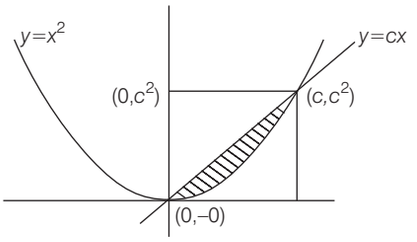
JEE Type Solved Examples :
More than One Correct Option Type Questions

● **Ex. 5** *Let T be the triangle with vertices* $(0,0),(0,c^2)$ *and* (c,c^2) *and let R be the region between* $y=cx$ *and* $y=x^2$, *where* $c>0$, *then*

(a) Area $(R)=\dfrac{c^3}{6}$ (b) Area of $R=\dfrac{c^3}{3}$

(c) $\lim\limits_{c\to 0^+}\dfrac{\text{Area}\,(T)}{\text{Area}\,(R)}=3$ (d) $\lim\limits_{c\to 0^+}\dfrac{\text{Area}\,(T)}{\text{Area}\,(R)}=\dfrac{3}{2}$

Sol. Area $(T)=\dfrac{c\cdot c^2}{2}=\dfrac{c^3}{2}$



$$\text{Area}\,(R)=\frac{c^3}{2}-\int_0^c x^2\,dx=\frac{c^3}{2}-\frac{c^3}{3}=\frac{c^3}{6}$$

$$\therefore\quad \lim_{c\to 0^+}\frac{\text{Area}(T)}{\text{Area}\,(R)}=\lim_{c\to 0^+}\frac{c^3}{2}\cdot\frac{6}{c^3}=3$$

Hence, (a) and (c) are the correct answers.

● **Ex. 6** *Suppose f is defined from* $R\to[-1,1]$ *as* $f(x)=\dfrac{x^2-1}{x^2+1}$ *where R is the set of real number. Then, the statement which does not hold is*

(a) f is many-one onto

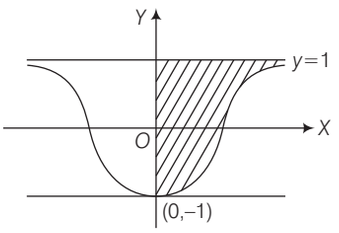
(b) f increases for $x>0$ and decreases for $x<0$

(c) minimum value is not attained even though f is bounded

(d) the area included by the curve $y=f(x)$ and the line $y=1$ is π sq units

Sol. $y=f(x)=\dfrac{x^2-1}{x^2+1}=1-\dfrac{2}{x^2+1}$

$f'(x)=\dfrac{4x}{(x^2+1)^2}$ $x>0$, f is increasing and $x<0$ f is decreasing.



$\Rightarrow$ (b) is true; range is $[-1,1)$ $\Rightarrow$ into $\Rightarrow$ (a) is false; minimum value occurs at $x=0$ and $f(0)=-1$ $\Rightarrow$ (c) is false.

$$A=2\int_0^\infty\left(1-\frac{x^2-1}{x^2+1}\right)dx=4\int_0^\infty\frac{dx}{x^2+1}$$

$$=[4\cdot\tan^{-1}x]_0^\infty=4\cdot\frac{\pi}{2}=2\pi\ \Rightarrow\ \text{(d) is false.}$$

Hence, (a), (c) and (d) are the correct answers.

● **Ex. 7** *Consider* $f(x)=\begin{cases}\cos\,x, & 0\le x<\dfrac{\pi}{2}\\ \left(\dfrac{\pi}{2}-x\right)^2, & \dfrac{\pi}{2}\le x<\pi\end{cases}$ *such that f is periodic with period* π, *then*

(a) the range of f is $\left[0,\dfrac{\pi^2}{4}\right)$

(b) f is continuous for all real x, but not differentiable for some real x

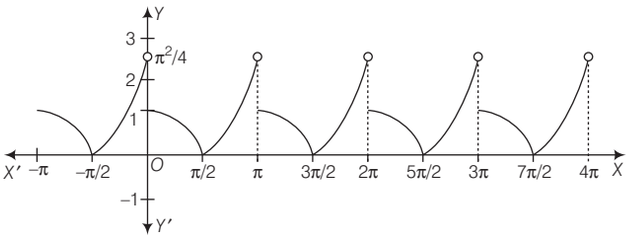
(c) f is continuous for all real x

(d) the area bounded by $y=f(x)$ and the X-axis from $x=-n\pi$ to $x=n\pi$ is $2n\left(1+\dfrac{\pi^2}{24}\right)$ for a given $n\in N$

Sol. Given, $f(x)=\begin{cases}\cos x, & 0\le x<\dfrac{\pi}{2}\\ \left(\dfrac{\pi}{2}-x\right)^2, & \dfrac{\pi}{2}\le x<\pi\end{cases}$ and f is periodic with period π. Let us draw the graph of $y=f(x)$

From the graph, the range of the function is $\left[0,\dfrac{\pi^2}{4}\right)$.

It is discontinuous at $x=n\pi$, $n\in I$. It is not differentiable at $x=\dfrac{n\pi}{2}$, $n\in I$.



Area bounded by $y=f(x)$ and the X-axis from $-n\pi$ to $n\pi$ for $n\in N$

$$=2n\int_0^\pi f(x)\,dx=2n\left[\int_0^{\pi/2}\cos x\,dx+\int_{\pi/2}^{\pi}\left(\frac{\pi}{2}-x\right)^2dx\right]$$

$$=2n\left(1+\frac{\pi^3}{24}\right)$$

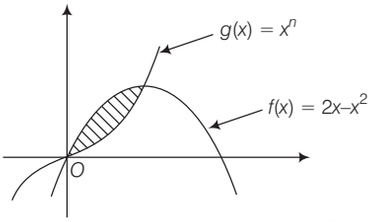
Hence, (a) and (d) are the correct answers.

● **Ex. 8** *Consider the functions $f(x)$ and $g(x)$, both defined from $R \to R$ and are defined as $f(x) = 2x - x^2$ and $g(x) = x^n$ where $n \in N$. If the area between $f(x)$ and $g(x)$ is 1/2, then n is a divisor of*

(a) 12 (b) 15 (c) 20 (d) 30

Sol. Solving, $f(x) = 2x - x^2$ and $g(x) = x^n$ we have

$2x - x^2 = x^n \Rightarrow x = 0$ and $x = 1$



$$A = \int_0^1 (2x - x^2 - x^n)\, dx = \left[x^2 - \frac{x^3}{3} - \frac{x^{n+1}}{n+1}\right]_0^1$$

$$= 1 - \frac{1}{3} - \frac{1}{n+1} = \frac{2}{3} - \frac{1}{n+1}$$

Since, $\frac{2}{3} - \frac{1}{n+1} = \frac{1}{2} \Rightarrow \frac{2}{3} - \frac{1}{2} = \frac{1}{n+1}$

$\Rightarrow \frac{4-3}{6} = \frac{1}{n+1} \Rightarrow n + 1 = 6$

$\Rightarrow n = 5$

Thus, n is a divisor of 15, 20, 30.

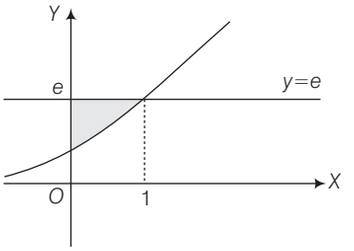
Hence, (b), (c) and (d) are the correct answers.

● **Ex. 9** *Area of the region bounded by the curve $y = e^x$ and lines $x = 0$ and $y = e$ is* **[IIT JEE 2009]**

(a) $e - 1$ (b) $\int_1^e \ln(e + 1 - y)\, dy$

(c) $e - \int_0^1 e^x\, dx$ (d) $\int_1^e \ln y\, dy$

Sol. Shaded area $= e - \left(\int_0^1 e^x\, dx\right) = 1$



Also, $\int_1^e \ln(e + 1 - y)\, dy$

Put $e + 1 - y = t$

$\Rightarrow -dy = dt$

$$= \int_0^1 \ln t(-dt) = \int_0^e \ln t\, dt$$

$$= \int_1^e \ln y\, dy = 1$$

Hence, (b), (c) and (d) are the correct answers.

JEE Type Solved Examples : Passage Based Questions

Passage I

(Q. Nos. 10 to 12)

Consider the function $f(x) = x^3 - 8x^2 + 20x - 13$.

● **Ex. 10** *Number of positive integers x for which $f(x)$ is a prime number, is*

(a) 1 (b) 2
(c) 3 (d) 4

Sol. $f(x) = (x-1)(x^2 - 7x + 13)$ for $f(x)$ to be prime atleast one of the factors must be prime.

Therefore, $x - 1 = 1$

$\Rightarrow x = 2$

or $x^2 - 7x + 13 = 1$

$\Rightarrow x^2 - 7x + 12 = 0$

$\Rightarrow x = 3$ or 4

$\Rightarrow x = 2, 3, 4$

Hence, (c) is the correct answer.

● **Ex. 11** *The function $f(x)$ defined for $R \to R$*

(a) is one-one onto
(b) is many-one onto
(c) has 3 real roots
(d) is such that $f(x_1) \cdot f(x_2) < 0$ where x_1 and x_2 are the roots of $f'(x) = 0$

Sol. $f(x)$ is many-one as it increases and decreases, also range of $f(x) \in R \Rightarrow$ many-one onto.

Hence, (b) is the correct answer.

● **Ex. 12** *Area enclosed by $y = f(x)$ and the coordinate axes is*

(a) 65/12 (b) 13/12
(c) 71/12 (d) None of these

Sol. $A = \left|\int_0^1 f(x)\, dx\right| = -\int_0^1 (x^3 - 8x^2 + 20x - 13)\, dx = \frac{65}{12}$

Hence, (a) is the correct answer.

Passage II

(Q. Nos. 13 to 15)

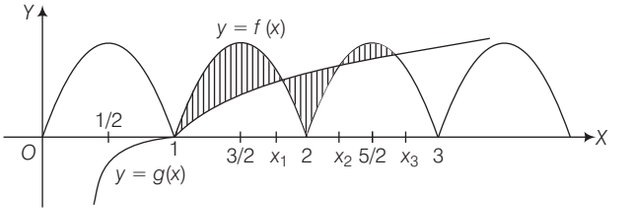
Let $h(x) = f(x) - g(x)$, where $f(x) = \sin^4 \pi x$ and $g(x) = \ln x$. Let $x_0, x_1, x_2, \ldots, x_{n+1}$ be the roots *of $f(x) = g(x)$ in increasing order.*

● ***Ex. 13*** *The absolute area enclosed by $y = f(x)$ and $y = g(x)$ is given by*

(a) $\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^r h(x)\,dx$ (b) $\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^{r+1} h(x)\,dx$

(c) $2\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^r h(x)\,dx$ (d) $\frac{1}{2}\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^{r+1} h(x)\,dx$

Sol.



Hence, (a) is the correct answer.

● ***Ex. 14*** *In the above question, the value of n is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. $x_{n+1} = x_3 \Rightarrow n = 2$.

Hence, (b) is the correct answer.

● ***Ex. 15*** *The whole area bounded by $y = f(x), y = g(x)$ and $x = 0$ is*

(a) $\frac{11}{8}$ (b) $\frac{8}{3}$ (c) 2 (d) $\frac{13}{3}$

Sol. Required area $= \int_0^1 \sin^4 \pi x\,dx - \int_0^1 \ln\ x\,dx = \frac{11}{8}$

Hence, (a) is the correct answer.

Passage III

(Q. Nos. 16 to 18)

Consider the function defined implicitly by the equation $y^3 - 3y + x = 0$ on various intervals in the real line. If $x \in (-\infty, -2) \cup (2, \infty)$, the equation implicitly defines a unique real-valued differentiable function $y = f(x)$. If $x \in (-2, 2)$, the equation implicitly defines a unique real-valued differentiable function $y = g(x)$ satisfying $g(0) = 0$. ***[IIT JEE 2008]***

● ***Ex. 16*** *If $f(-10\sqrt{2}) = 2\sqrt{2}$, then $f''(-10\sqrt{2})$ is equal to*

(a) $\frac{4\sqrt{2}}{7^3 3^2}$ (b) $-\frac{4\sqrt{2}}{7^3 3^2}$ (c) $\frac{4\sqrt{2}}{7^3 3}$ (d) $-\frac{4\sqrt{2}}{7^3 3}$

Sol. $\therefore$ $y^3 - 3y + x = 0$

On differentiating, we get $3y^2 y' - 3y' - 1 = 0$

$$\Rightarrow \quad y' = \frac{1}{3(1 - y^2)}$$

$$\Rightarrow \quad y'(-10\sqrt{2}) = \frac{1}{3\{1 - (2\sqrt{2})^2\}} \qquad \ldots(i)$$

$$\Rightarrow \quad y'(-10\sqrt{2}) = \frac{1}{3\{1 - (2\sqrt{2})^2\}} = \frac{1}{3(1-8)} = -\frac{1}{21}$$

Again differentiating Eq. (i), we get

$$y'' = \frac{6yy'^2}{3(1 - y^2)}$$

$$y''(-10\sqrt{2}) = \frac{6 \cdot 2\sqrt{2} \cdot \left(\frac{1}{21}\right)^2}{3(1-8)} = -\frac{4\sqrt{2}}{7^3 \cdot 3^2}$$

Hence, (b) is the correct answer.

● ***Ex. 17*** *The area of the region bounded by the curve $y = f(x)$, the X-axis and the line $x = a$ and $x = b$, where $-\infty < a < b < -2$ is*

(a) $\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}dx + bf(b) - af(a)$

(b) $-\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}dx - bf(b) + af(a)$

(c) $\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}dx - bf(b) + af(a)$

(d) $-\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}dx - bf(b) + af(a)$

Sol. Required area $= \int_a^b f(x)\,dx = [xf(x)]_a^b - \int_a^b xf'(x)\,dx$

$$= bf(b) - af(a) + \int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}\,dx$$

Hence, (a) is the correct answer.

● ***Ex. 18*** $\int_{-1}^{1} g'(x)\,dx$ *is equal to*

(a) $2g(-1)$ (b) 0 (c) $-2g(1)$ (d) $2g(1)$

Sol. $I = \int_{-1}^{1} g'(x)\,dx = [g(x)]_{-1}^{1} = g(1) - g(-1)$

Since, $y^3 - 3y + x = 0$ ...(i)

and $y = g(x)$

Since, $\{g(x)\}^3 - 3g(x) + x = 0$ [by Eq. (i)]

At $x = 1$, $\{g(1)\}^3 - 3g(1) + 1 = 0$ ...(ii)

At $x = -1$, $\{g(-1)\}^3 - 3g(-1) - 1 = 0$ ...(iii)

On adding Eqs. (i) and (ii), we get

$$\{g(1)\}^3 + \{g(-1)\}^3 - 3\{g(1) + g(-1)\} = 0$$

$$\{g(1) + g(-1)\}\{g(1)^2 + g(-1)^2 - g(1)g(-1) - 3\} = 0$$

$\Rightarrow$ $g(1) + g(-1) = 0,\ g(1) = -g(-1)$

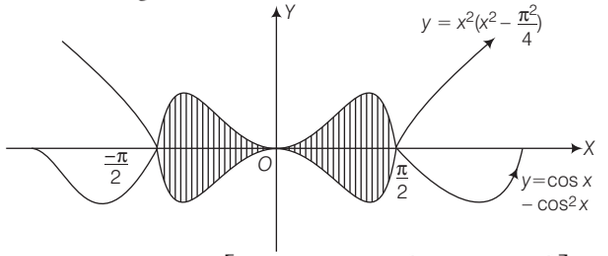
$\Rightarrow$ $I = g(1) - g(-1) = g(1) - (-g(1)) = 2g(1)$

Hence, (d) is the correct answer.

Subjective Type Questions

● **Ex. 19** *Find the total area bounded by the curves* $y = \cos x - \cos^2 x$ *and* $y = x^2\left(x^2 - \frac{\pi^2}{4}\right)$.

Sol. Here, $y = \cos x - \cos^2 x$ and $y = x^2\left(x^2 - \frac{\pi^2}{4}\right)$ could be drawn as in figure.



Thus, the area $= 2\int_0^{\pi/2}\left[(\cos x - \cos^2 x) - \left\{x^2\left(x^2 - \frac{\pi^2}{4}\right)\right\}\right]dx$

$= 2\int_0^{\pi/2}\left(\cos x - \cos^2 x - x^4 + \frac{\pi^2}{4}x^2\right)dx$

$= 2\left[\sin x - \frac{x}{2} - \frac{\sin 2x}{4} - \frac{x^5}{5} + \frac{\pi^2 x^3}{12}\right]_0^{\pi/2}$

$= \left(2 - \frac{\pi}{2} + \frac{\pi^5}{120}\right)$

● **Ex. 20** *A curve* $y = f(x)$ *passes through the point* $P(1,1)$, *the normal to the curve at* P *is* $a(y-1)+(x-1)=0$. *If the slope of the tangent at any point on the curve is proportional to the ordinate of that point, determine the equation of the curve. Also obtain the area bounded by the Y-axis, the curve and the normal to the curve at P.*

Sol. Here, slope of the normal at $P(x, y)$.

$\Rightarrow$ Slope of the line $a(y-1)+(x-1)=0$ is $-\frac{1}{a}$

$\therefore$ Slope of the tangent at $P = a$,

$$\left(\frac{dy}{dx}\right)_P = a \qquad \text{...(i)}$$

It is given that the slope of the tangent at any point on the curve $y = f(x)$ is proportional to the ordinate of the point.

$\therefore \quad \frac{dy}{dx} \propto y \Rightarrow \frac{dy}{dx} = \lambda y$

$\Rightarrow \quad \left(\frac{dy}{dx}\right)_{(1,1)} = \lambda \Rightarrow a = \lambda$

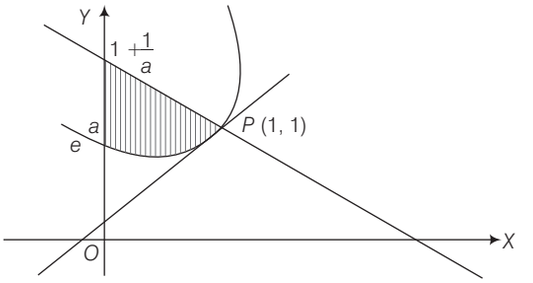
$\therefore \quad \frac{dy}{dx} = ay \Rightarrow \frac{dy}{y} = a\,dx$

$\Rightarrow \quad \log y = ax + \log c$

$\Rightarrow \quad y = ce^{ax}$, which passes through $P(1, 1)$

$\therefore \quad c = e^{-a}$

$\Rightarrow$ Curve is $y = e^{-a}e^{ax} \Rightarrow y = e^{a(x-1)}$



$\therefore$ Required area $= \frac{1}{a}\int_{e^{-a}}^{1}(\log y + a)\,dy + \int_1^{1+1/a}\{(1+a) - ay\}dy$

$= \frac{1}{a}\{y(\log y - 1) + ay\}_{e^{-a}}^{1} + \left\{(1+a)y - \frac{a}{2}y^2\right\}_a^{1+\frac{1}{a}}$

$= \frac{1}{a}\{(-1+a) - e^{-a}(-a-1) - ae^{-a}\}$

$+\left[(1+a)\left(1+\frac{1}{a}-1\right) - \frac{a}{2}\left\{\left(1+\frac{1}{a}\right)^2 - 1^2\right\}\right]$

$= \frac{1}{a}[-1+a+ae^{-a}+e^{-a}-ae^{-a}] + \left[\frac{1+a}{a} - \frac{a}{2}\left(2+\frac{1}{a}\right)\frac{1}{a}\right]$

$= \frac{1}{a}(-1+a+e^{-a}) + \left(\frac{1}{a}+1-1-\frac{1}{2a}\right) = \left(1 + \frac{e^{-a}}{a} - \frac{1}{2a}\right)$ sq units

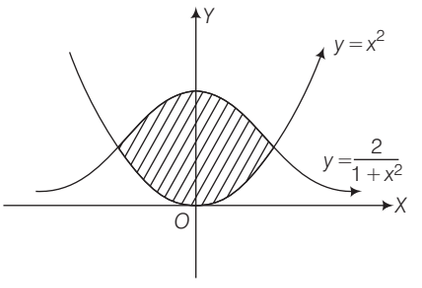
● **Ex. 21** *Sketch the region bounded by the curves* $y = x^2$ *and* $y = \frac{2}{1+x^2}$. *Find the area.*

Sol. For intersection point, $x^2 = \frac{2}{1+x^2}$

i.e. $x^4 + x^2 - 2 = 0$

i.e. $(x^2+2)(x^2-1) = 0$

i.e. $x = \pm 1$



Hence, required area $= 2\int_0^1 \left(\frac{2}{1+x^2} - x^2\right) dx$

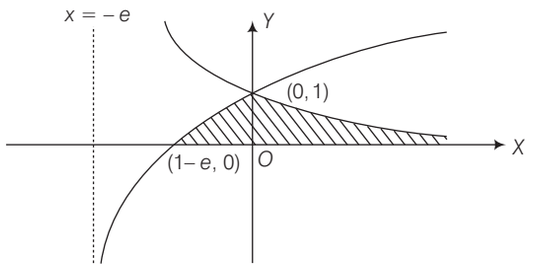
$$= 2\left[2\tan^{-1} x - \frac{x^3}{3}\right]_0^1 = 2\left(\frac{\pi}{2} - \frac{1}{3}\right)$$

● ***Ex. 22*** *Find the area enclosed between the curves* $y = \log(x+e);\ x = \log_e\left(\frac{1}{y}\right)$ *and X-axis.*

Sol. The given curves are $y = \log(x+e)$ and

$$x = \log_e\left(\frac{1}{y}\right) \Rightarrow \frac{1}{y} = e^x \Rightarrow y = e^{-x}$$

Using graph transformation we can sketch the curves.



Hence, required area $= \int_{1-e}^{0} \log(x+e)\,dx + \int_0^{\infty} e^{-x}\,dx$

$$= \int_1^e \log(t)\,dt + \int_0^{\infty} e^{-x}\,dx \qquad \text{(putting } x+e=t\text{)}$$

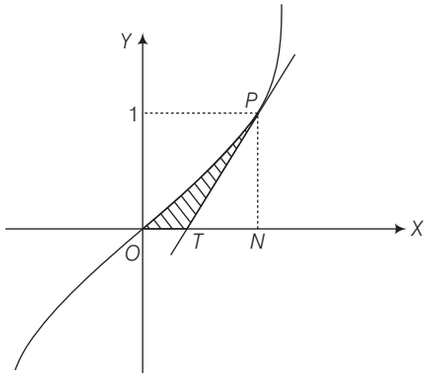
$$= [t\log t - t]_1^e - [e^{-x}]_0^{\infty} = 1 + 1 = 2$$

● ***Ex. 23*** *Find the area of the region bounded by the curve* $c: y = \tan x$, *tangent drawn to c at* $x = \pi/4$ *and the X-axis.*

Sol. The given curve is $y = \tan x$

$$\therefore \quad \frac{dy}{dx} = \sec^2 x$$

$$\left(\frac{dy}{dx}\right)_{x=\pi/4} = \sec^2\frac{\pi}{4} = 2$$



Also, at $x = \frac{\pi}{4};\ y = 1$

$\therefore$ The equation of the tangent to the curve at the point $\left(\frac{\pi}{4}, 1\right)$ is $\quad y - 1 = 2\left(x - \frac{\pi}{4}\right)$

when $\qquad y = 0;\ x = \frac{\pi}{4} - \frac{1}{2} = OT$

Now, the required area = Area of curvilinear ΔOPN − Area of ΔPTN

$$= \int_0^{\pi/4} (\tan x)\,dx - \frac{1}{2}\cdot NT\cdot PN$$

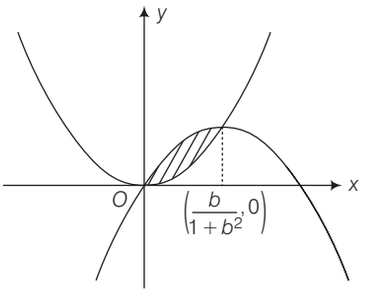
$$= [\log(\sec x)]_0^{\pi/4} - \frac{1}{2}\left(\frac{\pi}{4} - \frac{\pi}{4} + \frac{1}{2}\right)\cdot 1 = \frac{1}{2}\left(\log 2 - \frac{1}{2}\right)$$

● ***Ex. 24*** *Find all the possible values of* $b > 0$, *so that the area of the bounded region enclosed between the parabolas* $y = x - bx^2$ *and* $y = \frac{x^2}{b}$ *is maximum.*

Sol. Eliminating y from $y = \frac{x^2}{b}$ and $y = x - bx^2$, we get

$$x^2 = bx - b^2x^2$$

$$\Rightarrow \qquad x = 0,\ \frac{b}{1+b^2}$$



Thus, the area enclosed between the parabolas,

$$A = \int_0^{b/(1+b^2)} \left(x - bx^2 - \frac{x^2}{b}\right) dx$$

$$= \int_0^{b/1+b^2} \left\{x - x^2\left(\frac{1+b^2}{b}\right)\right\} dx$$

$$= \left(\frac{x^2}{2} - \frac{x^3}{3}\cdot\frac{1+b^2}{b}\right)_0^{b/1+b^2} = \frac{1}{6}\cdot\frac{b^2}{(1+b^2)^2}$$

For maximum value of A, $\frac{dA}{db} = 0$

But $\frac{dA}{db} = \frac{1}{6}\cdot\frac{(1+b^2)^2\cdot 2b - b^2\cdot 2(1+b^2)\cdot 2b}{(1+b^2)^4} = \frac{1}{3}\cdot\frac{b(1-b^2)}{(1+b^2)^3}$

Hence, $\frac{dA}{db} = 0$ gives $b = -1,\ 0,\ 1$ since $b > 0$

Therefore, we consider only $b = 1$

Sign scheme for $\frac{dA}{db}$ around $b = 1$ is as below

From sign scheme it is clear that A is maximum.

● **Ex. 25** *Let C_1 and C_2 be the graphs of the function $y = x^2$ and $y = 2x, 0 \le x \le 1$, respectively. Let C_3 be the graph of a function $y = f(x); 0 \le x \le 1, f(0) = 0$. For a point P on C_1, let the lines through P parallel to the axes, meets C_2 and C_3 at Q and R respectively. If for every position of P on (C_1), the areas of the shaded region OPQ and ORP are equal, determine the function $f(x)$.* ***[IIT JEE 1998]***

Sol. On the curve C_1, i.e. $y = x^2$.

Let P be (α, α^2). So, ordinate of point Q on C_2 is also α^2.

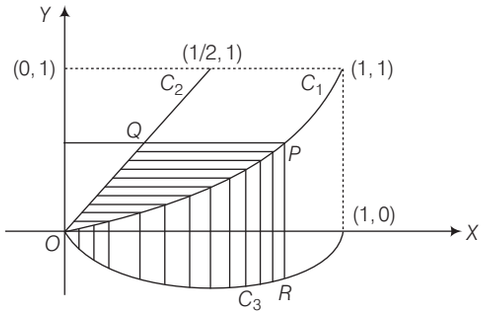
Now, C_2 ($y = 2x$) the abscissae of Q is given by $x = \dfrac{y}{2} = \dfrac{\alpha^2}{2}$.

$\therefore$ Q is $\left(\dfrac{\alpha^2}{2}, \alpha\right)$ and R on C_3 is $\{\alpha, f(x)\}$.

Now, area of $\Delta OPQ = \int_0^{\alpha^2} (x_1 - x_2)\, dy = \int_0^{\alpha^2} \left(\sqrt{y} - \dfrac{y}{2}\right) dy$

$$= \frac{2}{3}\alpha^3 - \frac{\alpha^4}{4} \qquad \ldots(i)$$

Again, area of $\Delta ORP = \int_0^{\alpha} (y_1 - y_2) dx = \int_0^{\alpha^2} \{x^2 - f(x)\}\, dx$ ...(ii)



Thus, from Eqs. (i) and (ii), we get

$$\frac{2\alpha^3}{3} - \frac{\alpha^4}{4} = \int_0^{\alpha} \{x^2 - f(x)\}\, dx$$

Differentiating both the sides w.r.t. α, we get

$$2\alpha^2 - \alpha^3 = \alpha^2 - f(\alpha)$$

$$\Rightarrow \qquad f(\alpha) = \alpha^3 - \alpha^2 \;\Rightarrow\; f(x) = x^3 - x^2$$

● **Ex. 26** *Find the area of the region bounded by the curves $y = ex \log x$ and $y = \dfrac{\log x}{ex}$.* ***[IIT JEE 1990]***

Sol. Both the curves are defined for $x > 0$. Both are positive when $x > 1$ and negative when $0 < x < 1$.

We know that, $\lim\limits_{x \to 0^+} \log x \to -\infty$

Therefore, $\lim\limits_{x \to 0^+} \dfrac{\log x}{ex} \to -\infty$

Thus, Y-axis is asymptote of second curve.

and $\lim\limits_{x \to 0^+} ex \log x$ [(0) $(-\infty)$ form]

$$= \lim_{x \to 0^+} \frac{e \log x}{1/x} \qquad \left(-\frac{\infty}{\infty} \text{ form}\right)$$

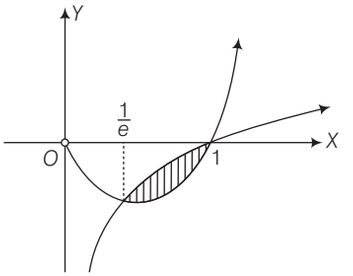
$$= \lim_{x \to 0^+} \frac{e(1/x)}{(-1/x^2)} = 0 \quad \text{(using L'Hospital's rule)}$$

Thus, the first curve starts from (0, 0) but does not include (0, 0). Now, the given curves intersect therefore

$$ex \log x = \frac{\log x}{ex}$$

i.e. $\qquad (e^2x^2 - 1) \log x = 0$

i.e. $\qquad x = 1, \dfrac{1}{e} \qquad (\because\ x > 0)$



Therefore, using the above results figure could be drawn as

$\therefore$ Required area $= \int_{1/e}^{1} \left(\dfrac{\log x}{ex} - ex \log x\right) dx$

$$= \frac{1}{e}\left[\frac{(\log x)^2}{2}\right]_{1/e}^{1} - e\left[\frac{x^2}{4}(2\log x - 1)\right]_{1/e}^{1} = \frac{e^2 - 5}{4e}$$

● **Ex. 27** *Let A_n be the area bounded by the curve $y = (\tan x)^n$ and the lines $x = 0, y = 0$ and $x = \dfrac{\pi}{4}$. Prove that for $n > 2$; $A_n + A_{n-2} = \dfrac{1}{n-1}$ and deduce that $\dfrac{1}{2n+2} < A_n < \dfrac{1}{2n-2}$.*

Sol. **First part** We have, $A_n = \int_0^{\pi/4} (\tan x)^n\, dx$

Hence, $\qquad A_{n-2} = \int_0^{\pi/4} (\tan x)^{n-2}\, dx$

$\therefore$ $\qquad A_n + A_{n-2} = \int_0^{\pi/4} (\tan x)^{n-2} (\tan^2 x + 1)\, dx$

$$= \int_0^{\pi/4} (\tan x)^{n-2} \cdot \sec^2 x\, dx$$

Let $\tan x = t$, so that $\sec^2 x\, dx = dt$

$$\therefore \qquad A_n + A_{n-2} = \int_0^1 t^{n-2}\, dt = \left(\frac{t^{n-1}}{n-1}\right)_0^1 = \frac{1}{n-1} \qquad \ldots(i)$$

Second part

Since, $\qquad 0 \le x \le \pi/4 \;\;\therefore\;\; 0 \le \tan x \le 1$

$$\Rightarrow \qquad \tan^{n+2} x < \tan^n x < \tan^{n-2} x$$

$$\Rightarrow \quad \int_0^{\pi/4} \tan^{n+2} x\, dx < \int_0^{\pi/4} \tan^n x\, dx < \int_0^{\pi/4} \tan^{n-2} x\, dx$$

$$\Rightarrow \qquad A_{n+2} < A_n < A_{n-2} \Rightarrow A_n + A_{n+2} < 2A_n < A_n + A_{n-2}$$

$$\therefore \quad \frac{1}{n+1} < 2A_n < \frac{1}{n-1}$$

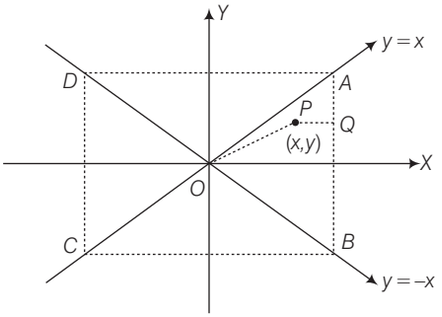
$$\Rightarrow \quad \frac{1}{2(n+1)} < A_n < \frac{1}{2(n-1)} \qquad \text{[using Eq. (i)]}$$

● ***Ex. 28*** *Consider a square with vertices at* (1, 1) (−1, 1), (−1, −1) *and* (1, −1). *Let S be the region consisting of all points inside the square which are nearer to the origin than to any edge. Sketch the region S and find its area.*

[IIT JEE 1995]

Sol. For the points lying in the ΔOAB the edge AB, i.e. $x = 1$ is the closest edge. Therefore, if the distance of a point $P(x, y)$ (lying in the ΔOAB) from origin is less than that of its distance from the edge $x = 1$ it will fall in the region S.

$$\therefore \quad OP \le PQ$$



$$\Rightarrow \quad \sqrt{x^2 + y^2} \le 1 - x$$

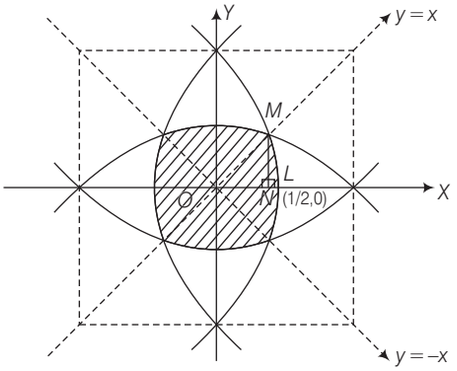
$$\Rightarrow \quad x^2 + y^2 \le x^2 - 2x + 1$$

$$\Rightarrow \quad y^2 \le 1 - 2x$$

Similarly, for points lying in the ΔOAD the side $y = 1$ is the closest side and therefore the region S is determined by

$$x^2 \le 1 - 2y$$

Since, the edges are symmetric about the origin. Hence, by the above inequality and by symmetry, the required area will be the shaded portion in the figure given below



Now, when the curves $y^2 = 1 - 2x$ and $y = x$ intersect each other, then

$$x^2 = 1 - 2x \;\Rightarrow\; x^2 + 2x - 1 = 0$$

$$\Rightarrow \quad x = \sqrt{2} - 1, -\sqrt{2} - 1$$

Hence, the intersection points in the first quadrant is $(\sqrt{2} - 1, \sqrt{2} - 1)$.

$\therefore$ Required area = 8 [Area of curvilinear ΔOLM]

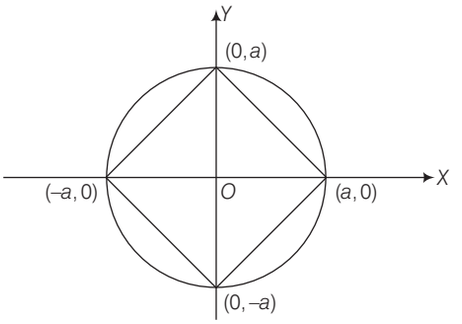
$$= 8\left[\frac{1}{2}(\sqrt{2}-1)(\sqrt{2}-1) + \int_{\sqrt{2}-1}^{1/2} \sqrt{1-2x}\, dx\right]$$

$$= 8\left[\frac{1}{2}(3 - 2\sqrt{2}) + \left(\frac{2(1-2x)^{3/2}}{3(-2)}\right)_{\sqrt{2}-1}^{1/2}\right]$$

$$= \frac{4}{3}(4\sqrt{2} - 5)$$

● ***Ex. 29*** *Sketch the region included between the curves* $x^2 + y^2 = a^2$ *and* $\sqrt{|x|} + \sqrt{|y|} = \sqrt{a}\ (a > 0)$ *and find its area.*

Sol. The graphs $|x| + |y| = a$ and $|x|^2 + |y|^2 = a^2$ are as shown in figure.



From the figure it can be concluded that when powers of $|x|$ and $|y|$ both is reduced to half the straight lines get stretched inside taking the shape as above.

Thus, required area = 4 [shaded area in the first quadrant]

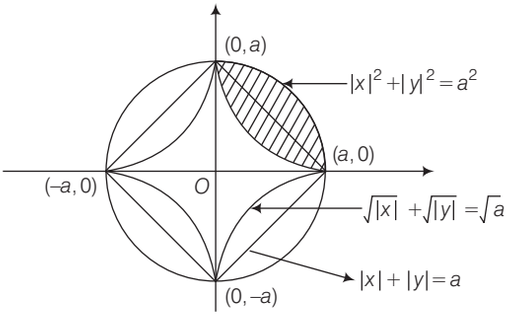
$$= 4\left[\frac{\pi a^2}{4} - \int_0^a (\sqrt{a} - \sqrt{x})^2\, dx\right]$$

(since in 1st quadrant $x, y > 0$), hence

$$\sqrt{|x|} + \sqrt{|y|} = \sqrt{a}$$

$$\Rightarrow \quad \sqrt{x} + \sqrt{y} = \sqrt{a}$$

$$\Rightarrow \quad y = (\sqrt{a} - \sqrt{x})^2$$



Hence, required the area $= \left(\pi - \frac{2}{3}\right) a^2$

● ***Ex. 30*** *Show that the area included between the parabolas* $y^2 = 4a(x+a)$ *and* $y^2 = 4b(b-x)$ *is* $\frac{8}{3}(a+b)\sqrt{ab}$.

Sol. Given parabolas are

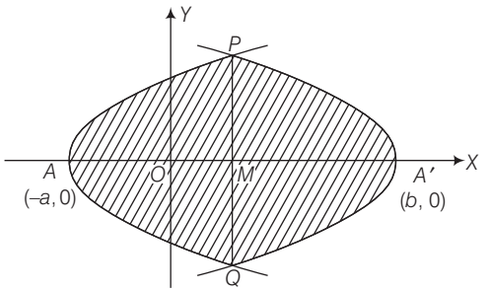
$$y^2 = 4a(x+a) \quad \ldots(i)$$

and $$y^2 = 4b(b-x) \quad \ldots(ii)$$

Solving Eqs. (i) and (ii), we get

$$x = (b-a) \quad \text{and} \quad y = \pm 2\sqrt{ab}$$

$\therefore$ P and Q are $(b-a, 2\sqrt{ab})$ and $(b-a, -2\sqrt{ab})$ respectively, and the points A and A' are $(-a, 0)$ and $(b, 0)$, respectively.



Now, required area = Area $APA'QA$ = 2 Area $APA'A$

$$= 2[\text{Area } APMA + \text{Area } MPA'M]$$

$$= 2\left[\int_{-a}^{b-a} 2\sqrt{a(a+x)}\,dx + \int_{b-a}^{b} 2\sqrt{b(b-x)}\,dx\right]$$

$$= 4\sqrt{a}\int_{-a}^{b-a}\sqrt{a+x}\,dx + 4\sqrt{b}\int_{b-a}^{b}\sqrt{b-x}\,dx$$

$$= 4\sqrt{a}\left[\frac{2}{3}(a+x)^{3/2}\right]_{-a}^{b-a} + 4\sqrt{b}\left[-\frac{2}{3}(b-x)^{3/2}\right]_{b-a}^{b}$$

$$= \frac{8}{3}\sqrt{a}\,(b)^{3/2} + \frac{8\sqrt{b}}{3}(a)^{3/2} = \frac{8}{3}\sqrt{ab}(a+b) \text{ sq units}$$

● ***Ex. 31*** *Determine the area of the figure bounded by two branches of the curve* $(y-x)^2 = x^3$ *and the straight line* $x = 1$.

Sol. Given curves are $(y-x)^2 = x^3$

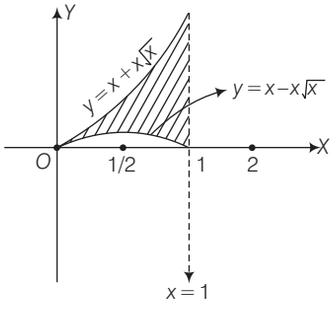
$$y - x = \pm x\sqrt{x}$$

$$y = x + x\sqrt{x} \quad \ldots(i)$$

$$y = x - x\sqrt{x} \quad \ldots(ii)$$

and $$x = 1 \quad \ldots(iii)$$

Which could be drawn as; shown in figure.



Hence, required area

$$= \int_0^1 \{(x + x\sqrt{x}) - (x - x\sqrt{x})\}\,dx$$

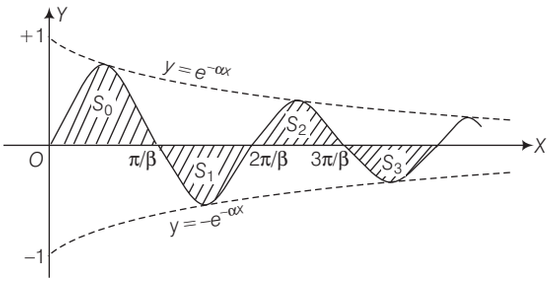
$$= \int_0^1 (2x\sqrt{x})\,dx$$

$$= 2\int_0^1 x^{3/2}\,dx = \frac{4}{5} \text{ sq unit}$$

● ***Ex. 32*** *Prove that the areas* $S_0, S_1, S_2, \ldots$ *bounded by the X-axis and half-waves of the curve* $y = e^{-\alpha x}\sin\beta x$, $x \mid 0$. *form a geometric progression with the common ratio* $g = e^{-\pi\alpha/\beta}$.

Sol. The curve $y = e^{-\alpha x}\sin\beta x$ intersects the positive X-axis at the points where $y = 0$.

$\therefore$ $$e^{-\alpha x}\sin\beta x = 0$$



$$\Rightarrow \quad \sin\beta x = 0 \;\Rightarrow\; x_n = \frac{n\pi}{\beta},\ n = 0, 1, 2, \ldots$$

The function $y = e^{-\alpha x}\sin\beta x$ is positive in the interval (x_{2K}, x_{2K+1}) and negative in (x_{2K+1}, x_{2K+2}), i.e. the sign of the function in the interval (x_n, x_{n+1}), therefore

$$S_n = \left|\int_{n\pi/\beta}^{(n+1)\pi/\beta} e^{-\alpha x}\sin\beta x\,dx\right|$$

$$= \left|\left\{\frac{(-1)^{n+1}e^{-\alpha x}}{\alpha^2+\beta^2}(\alpha\sin\beta x + \beta\cos\beta x)\right\}_{n\pi/\beta}^{(n+1)\pi/\beta}\right|$$

$$= \frac{\beta e^{-n\pi\alpha/\beta}}{(\alpha^2+\beta^2)}\{1 + e^{-\pi\alpha/\beta}\}$$

Hence, $$g = \frac{S_{n+1}}{S_n} = \frac{\dfrac{\beta e^{-(n+1)\pi\alpha/\beta}\{1+e^{-\pi\alpha/\beta}\}}{(\alpha^2+\beta^2)}}{\dfrac{\beta e^{-n\pi\alpha/\beta}\{1+e^{-\pi\alpha/\beta}\}}{\alpha^2+\beta^2}} = e^{-\pi\alpha/\beta}$$

which completes the proof.

● ***Ex. 33*** *Let* $b \neq 0$ *and for* $j = 0, 1, 2, \ldots, n$. *Let* S_j *be the area of the region bounded by Y-axis and the curve* $x \cdot e^{ay} = \sin by$, $\frac{j\pi}{b} \le y \le \frac{(j+1)\pi}{b}$. *Show that* $S_0, S_1, S_2, \ldots, S_n$ *are in geometric progression. Also, find their sum for* $a = -1$ *and* $b = \pi$.

Sol. Here, $$S_j = \left|\int_{j\pi/b}^{(j+1)\pi/b} x\,dy\right| = \left|\int_{j\pi/b}^{(j+1)\pi/b} e^{-ay}\sin by\,dy\right|$$

$$= \left| \left\{ \frac{e^{-ay}}{a^2+b^2}(-a\sin by - b\cos by) \right\}_{j\pi/b}^{(j+1)\pi/b} \right|$$

$$= \left| \frac{e^{-a(j+1)\pi/b}}{a^2+b^2} \times (-b)(-1)^{j+1} - \frac{e^{-aj\pi/b}}{a^2+b^2}(-b)(-1)^{j} \right|$$

$$= |b| \left\{ \frac{e^{-a(j+1)\pi/b}}{a^2+b^2} + \frac{e^{-aj\pi/b}}{a^2+b^2} \right\}$$

$$= |b| \frac{e^{-aj\pi/b}}{a^2+b^2}\{e^{-a\pi/b}+1\};\ \{j = 0, 1, 2, ..., n\}$$

Now, $\frac{S_{j+1}}{S_j} = |b| \frac{e^{-a(j+1)\pi/b}}{a^2+b^2}\{e^{-a\pi/b}+1\} \mid b \mid \frac{e^{-aj\pi/b}}{a^2+b^2}\{e^{-a\pi/b}+1\}$

$= e^{-a\pi/b}$ for all $j = 0, 1, 2, ..., n$

Hence, $S_0, S_1, S_2, ..., S_n$ are in GP with common ratio $e^{-a\pi/b}$.

For $a = -1$ and $b = \pi$, we have

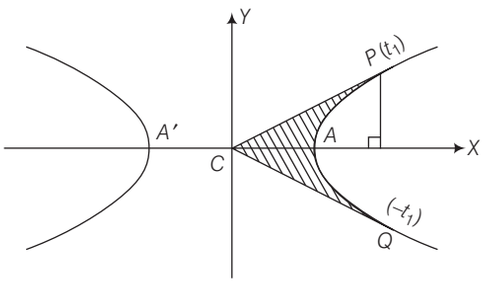
$$S_j = \frac{e^j \pi (e+1)}{\pi^2+1};\ j = 0, 1, 2, ..., n$$

$$\therefore \quad \sum_{j=0}^{n} S_j = \sum_{j=0}^{n} \frac{e^{j\pi}(e+1)}{\pi^2+1} = \frac{(e+1)\pi}{\pi+1}\left\{\frac{e^{n+1}-1}{e-1}\right\}$$

● ***Ex. 34*** *For any real* $t, x = 2 + \frac{e^t + e^{-t}}{2}, y = 2 + \frac{e^t - e^{-t}}{2}$ *is a point on the hyperbola* $x^2 - y^2 - 4x + 4y - 1 = 0$. *Find the area bounded by the hyperbola and the lines joining the centre to the points corresponding to* t_1 *and* $-t_1$.

Sol. The points $x = 2 + \frac{e^t + e^{-t}}{2}, y = 2 + \frac{e^t - e^{-t}}{2}$ is on the curve

$(x-2)^2 - (y-2)^2 = 1$ or $x^2 - y^2 - 4x + 4y - 1 = 0$



Put $(x-2) = x, (y-2) = y$

$$\therefore \quad x^2 - y^2 = 1 \quad \text{and} \quad x = \frac{e^t + e^{-t}}{2}, y = \frac{e^t - e^{-t}}{2}$$

We have to find the area of the region bounded by the curve $x^2 - y^2 = 1$ and the lines joining the centre $x = 0, y = 0$ to the point (t_1) and $(-t_1)$.

$$\therefore \text{Required area} = 2\left[\text{Area of } \Delta PCN - \int_1^{\frac{e^{t_1}+e^{-t_1}}{2}} y\,dx\right]$$

$$= 2\left[\frac{1}{2}\left(\frac{e^{t_1}+e^{-t_1}}{2}\right)\left(\frac{e^{t_1}-e^{-t_1}}{2}\right) - \int_1^{t_1} y\frac{dx}{dt}\,dt\right]$$

$$= 2\left[\left(\frac{e^{2t_1}-e^{-2t_1}}{8}\right) - \int_0^{t_1}\left(\frac{e^t - e^{-t}}{2}\right)^2 dt\right]$$

$$= \frac{e^{2t_1}-e^{-2t_1}}{4} - \frac{1}{2}\int_0^{t_1}(e^{2t} + e^{-2t} - 2)\,dt$$

$$= \frac{e^{2t_1}-e^{-2t_1}}{4} - \frac{1}{2}\left[\frac{e^{2t_1}}{2} - \frac{e^{-2t_1}}{2} - 2t_1\right]_0^{t_1}$$

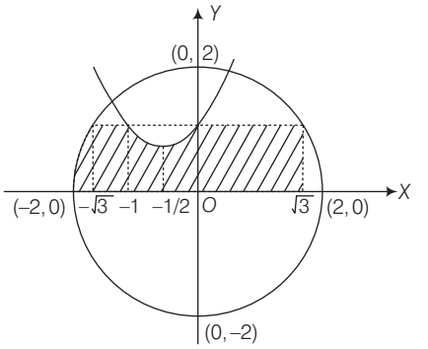
$$= \frac{e^{2t_1}-e^{-2t_1}}{4} - \frac{1}{2}\left[\frac{e^{2t_1}}{2} - \frac{e^{-2t_1}}{2} - 2t_1\right] = t_1$$

● ***Ex. 35*** *Find the area enclosed by circle* $x^2 + y^2 = 4$, *parabola* $y = x^2 + x + 1$, *the curve* $y = \left[\sin^2\frac{x}{4} + \cos\frac{x}{4}\right]$ *and X-axis (where, [.] is the greatest integer function).*

Sol. $\because \quad y = \left[\sin^2\frac{x}{4} + \cos\frac{x}{4}\right]$

$\because \quad 1 < \sin^2\frac{x}{4} + \cos\frac{x}{4} < 2 \quad$ for $x \in (-2, 2]$

$\therefore \quad y = \left[\sin^2\frac{x}{4} + \cos\frac{x}{4}\right] = 1$



Now, we have to find out the area enclosed by the circle $x^2 + y^2 = 4$, parabola $\left(y - \frac{3}{4}\right) = \left(x + \frac{1}{2}\right)^2$, line $y = 1$ and X-axis. Required area is shaded area in the figure.

Hence, required area

$$= \sqrt{3}\times 1 + (\sqrt{3}-1)\times 1 + \int_{-1}^{0}(x^2 + x + 1)\,dx + 2\int_{\sqrt{3}}^{2}(\sqrt{4-x^2})\,dx$$

$$= (2\sqrt{3}-1) + \left[\frac{x^3}{3} + \frac{x^2}{2} + x\right]_{-1}^{0} + 2\left[\frac{x}{2}\sqrt{4-x^2} + 2\sin^{-1}\left(\frac{x}{2}\right)\right]_{\sqrt{3}}^{2}$$

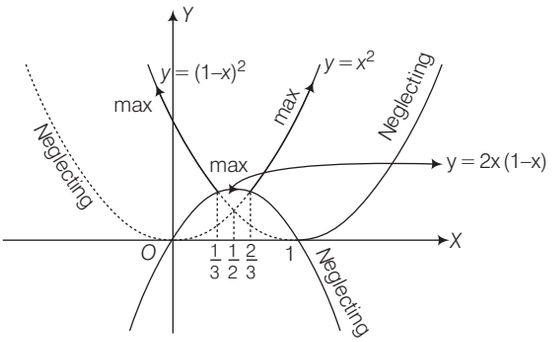
$$= (2\sqrt{3}-1) + \left[0 - \left(-\frac{1}{3} + \frac{1}{2} - 1\right)\right] + 2\left[(0+\pi) - \left(\frac{\sqrt{3}}{2} + \frac{2\pi}{3}\right)\right]$$

$$= (2\sqrt{3}-1) + \frac{5}{6} + \frac{2\pi}{3} - \sqrt{3} = \left(\frac{2\pi}{3} + \sqrt{3} - \frac{1}{6}\right) \text{ sq units}$$

● ***Ex. 36*** *Let* $f(x) = \max\{x^2, (1-x)^2, 2x(1-x)\}$, *where* $0 \le x \le 1$. *Determine the area of the region bounded by the curves* $y = f(x)$, *X-axis,* $x = 0$ *and* $x = 1$. ***[IIT JEE 1997]***

Sol. We have, $f(x) = \max\{x^2, (1-x^2), 2x(1-x)\}$

Graphically it could be shown as;



For figure it is clear that maximum graph (i.e. above max graph is considered and others are neglected).

$\therefore$ For $x \in \left[0, \frac{1}{3}\right]$, $x^2 \le 2x(1-x) \le (1-x)^2$

For $x \in \left[\frac{1}{3}, \frac{1}{2}\right]$, $x^2 \le (1-x)^2 \le 2x(1-x)$

For $x \in \left[\frac{1}{2}, \frac{2}{3}\right]$, $(1-x)^2 \le x^2 \le 2x(1-x)$

For $x \in \left[\frac{2}{3}, 1\right]$, $(1-x)^2 \le 2x(1-x) \le x^2$

Hence, $f(x)$ can be written as

$$f(x) = \begin{cases} (1-x)^2, & \text{for } 0 \le x \le 1/3 \\ 2x(1-x), & \text{for } 1/3 \le x \le 2/3 \\ x^2, & \text{for } 2/3 \le x \le 1 \end{cases}$$

Hence, the area bounded by the curve $y = f(x)$; X-axis and the lines $x = 0$ and $x = 1$ is given by

$$= \int_0^{1/3} (1-x)^2\,dx + \int_{1/3}^{2/3} 2x(1-x)\,dx + \int_{2/3}^{1} (x^2)\,dx$$

$$= \frac{17}{27} \text{ sq unit}$$

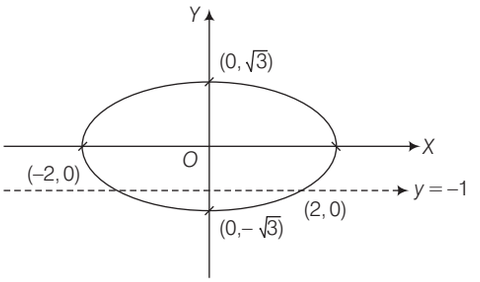
● ***Ex. 37*** *Find the ratio in which the curve,* $y = [-0.01x^4 - 0.02x^2]$ *[where, [·] denotes the greatest integer function) divides the ellipse* $3x^2 + 4y^2 = 12$.

Sol. Here, $y = [-0.01x^4 - 0.02x^2]$

i.e. $y = -1$, when $-2 < x < 2$

$y = -1$ cut the ellipse $3x^2 + 4y^2 = 12$

At $x^2 = \frac{8}{3}$ or $x = \pm\frac{2\sqrt{2}}{\sqrt{3}}$



$$\text{Required area} = \int_{-2\sqrt{6}/3}^{2\sqrt{6}/3} \left\{\sqrt{\frac{12-3x^2}{4}} - 1\right\} dx$$

$$= \frac{\sqrt{3}}{2}\int_{-2\sqrt{6}/3}^{2\sqrt{6}/3} \sqrt{4-x^2}\,dx - \int_{-2\sqrt{6}/3}^{2\sqrt{6}/3} 1\,dx$$

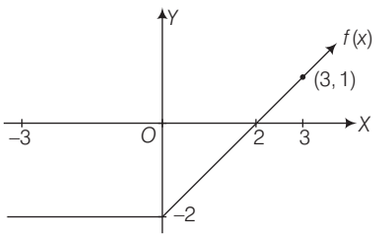
$$= 2\sin^{-1}\sqrt{\frac{2}{3}} + \frac{2}{3} - \frac{4}{3}\sqrt{6}$$

● ***Ex. 38*** *Let* $f(x) = \begin{cases} -2, -3 \le x \le 0 \\ x - 2, 0 < x \le 3 \end{cases}$, *where* $g(x) = \min\{f(|x|) + |f(x)|, f(|x|) - |f(x)|\}$. *Find the area bounded by the curve* $g(x)$ *and the X-axis between the ordinates at* $x = 3$ and $x = -3$.

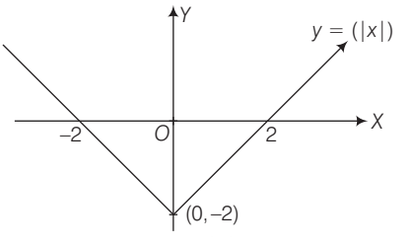
Sol. Here, $f(|x|) = \begin{cases} -x - 2, -3 \le x \le 0 \\ x - 2, 0 < x \le 3 \end{cases}$

$$|f(x)| = \begin{cases} 2, & -3 \le x \le 0 \\ -x + 2, & 0 < x \le 2 \\ x - 2, & 2 < x \le 3 \end{cases}$$

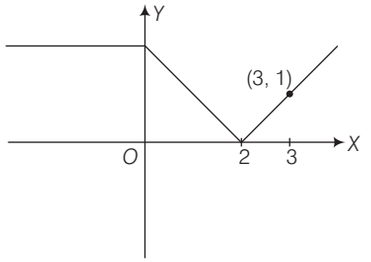
$$\therefore\ f(|x|) - |f(x)| = \begin{cases} -x - 4, -3 \le x \le 0 \\ 2x - 4, & 0 < x \le 2 \\ 0, & 2 < x \le 3 \end{cases}$$



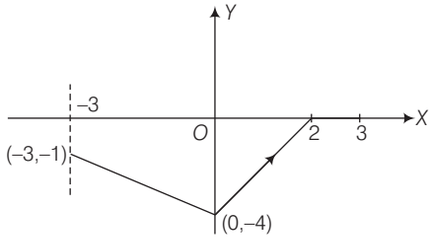
Graph of $f(x)$



Graph of $f(|x|)$



Graph of $|f(x)|$



Graph of $g(x)$

Since, $|f(x)|$ is always positive.

$$g(x) = f(|x|) - |f(x)|$$

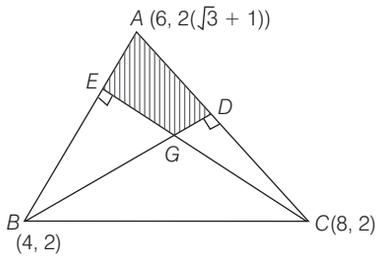
where the graphs could be drawn as shown in above figures.

From the graph, required area

$$= \frac{1}{2}(1+4)\times 3 + \left(\frac{1}{2}\times 2\times 4\right) + 0 = \frac{23}{2} \text{ sq units}$$

● ***Ex. 39*** *Let ABC be a triangle with vertices* $A \equiv (6, 2(\sqrt{3}+1)), B \equiv (4, 2)$ *and* $C \equiv (8, 2)$. *Let R be the region consisting of all those points P inside* ΔABC *which satisfy* $d(P, BC) \geq \max\{d(P, AB), d(P, AC)\}$, where $d(P, L)$ denotes the distance of the point P from the line L. Sketch the region R and find its area.

Sol. It is easy to see that ABC is an equilateral triangle with side of length 4. BD and CE are angle bisectors of angle B and C, respectively. Any point inside the ΔAEC is nearer to AC than BC and any point inside the ΔBDA is nearer to AB than BC. So any point inside the quadrilateral $AEGC$ will satisfy the given condition. Hence, shaded region is the required region, whose area is to be found, shown as in figure



Thus, required area $= 2$ Area of $\Delta EAG = 2\times\frac{1}{2}\,AE\times EG$

$$= \frac{1}{2}\,AB\times\frac{1}{3}\,CE = \frac{1}{6}\times 4\times\sqrt{4^2-2^2}$$

$$= \frac{4\sqrt{3}}{3} \text{ sq units}$$

● ***Ex. 40*** *Let* $O(0,0)$, $A(2,0)$ *and* $B\left(1, \frac{1}{\sqrt{3}}\right)$ *be the vertices of a triangle. Let R be the region consisting of all those points P inside* ΔOAB *which satisfy* $d(P, OA) \leq min\{d(P, OB), d(P, AB)\}$, *when 'd' denotes the distance from the point to the corresponding line. Sketch the region R and find its area.* ***[IIT JEE 1997]***

Sol. Let the coordinate of P be (x, y).

Equation of line $OA \equiv y = 0$

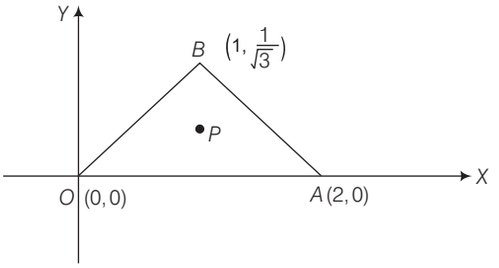
Equation of line $OB \equiv \sqrt{3}y = x$

Equation of line $AB = \sqrt{3}y = 2 - x$

$d(P, OA) =$ Distance of P from line $OA = y$

$d(P, OB) =$ Distance of P from line $OB = \dfrac{|\sqrt{3}y - x|}{2}$

$d(P, AB) =$ Distance of P from line $AB = \dfrac{|\sqrt{3}y + x - 2|}{2}$



Given, $d(P, OA) \leq \min\{d(P, OB), d(P, AB)\}$

$$y \leq \min\left\{\frac{|\sqrt{3}y - x|}{2}, \frac{|\sqrt{3}y + x - 2|}{2}\right\}$$

$$\Rightarrow \quad y \leq \frac{|\sqrt{3}y - x|}{2} \qquad \text{...(i)}$$

and $$y \leq \frac{|\sqrt{3}y + x - 2|}{2} \qquad \text{...(ii)}$$

Case I If $y \leq \dfrac{|\sqrt{3}y - x|}{2}$

$$\therefore \quad y \leq \frac{x - \sqrt{3}y}{2}, \text{ i.e. } x > \sqrt{3}y \qquad (\because \sqrt{3}y - x < 0)$$

$$\Rightarrow \quad (2+\sqrt{3})\,y \leq x$$

$$\Rightarrow \quad y \leq (2-\sqrt{3})\,x$$

$$\Rightarrow \quad y \leq x\tan 15^\circ \qquad \text{...(iii)}$$

$(\because y = x\tan 15^\circ$ is an acute angle bisector of $\angle AOB)$

Case II If $y \leq \dfrac{|\sqrt{3}y + x - 2|}{2}$

$$\Rightarrow \quad 2y \leq 2 - x - \sqrt{3}y \qquad (\text{i.e. } \sqrt{3}y + x - 2 < 0)$$

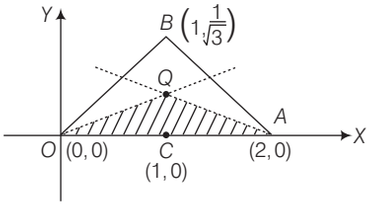
$$\Rightarrow \quad (2+\sqrt{3})\,y \leq 2 - x$$

$$\Rightarrow \quad y \leq -(2-\sqrt{3})\,(x-2)$$

$$\Rightarrow \quad y \leq -(\tan 15^\circ)\,(x-2) \qquad \text{...(iv)}$$

$[\because y = (x-2)\tan 15^\circ$ is an acute angle bisector of $CA]$

From Eqs. (iii) and (iv), P moves inside the triangle as shown in figure.



As $\angle QOB = \angle OBQ = 15°$, ΔOQB is an isosceles triangle

$\Rightarrow$ $OC = AC = 1$ unit

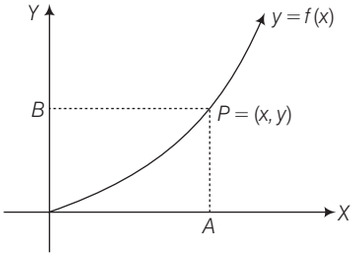
Area of shaded region = area of $\Delta OQA = \frac{1}{2}$ (base) $\times$ (height)

$$= \frac{1}{2}(2)(1 \tan 15°) = \tan 15°$$

$$= (2 - \sqrt{3}) \text{ sq units}$$

● ***Ex. 41*** *A curve $y = f(x)$ passes through the origin and lies entirely in the first quadrant. Through any point $P(x, y)$ on the curve, lines are drawn parallel to the coordinate axes. If the curve divides the area formed by these lines and coordinate axes in $m : n$, find $f(x)$.*

Sol. Area of $(OAPB) = xy$, Area of $(OAPO) = \int_0^x f(t)\,dt$



Therefore, area of $(OBPO) = xy - \int_0^x f(t)\,dt$

According to the given condition,

$$\frac{xy - \int_0^x f(t)\,dt}{\int_0^x f(t)\,dt} = \frac{m}{n}$$

$\Rightarrow$ $n\,xy = (m + n)\int_0^x f(t)\,dt$

Differentiating w.r.t. x, we get

$$n\left(x\frac{dy}{dx} + y\right) = (m + n)\,f(x) = (m + n)\,y, \text{ as } y = f(x)$$

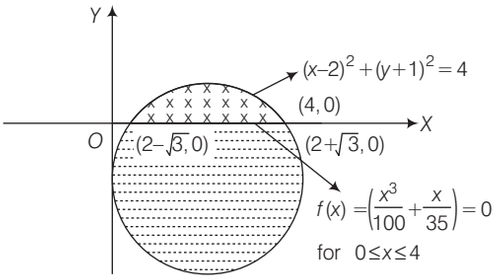
$$\frac{m}{n} \cdot \frac{dx}{x} = \frac{dy}{y} \Rightarrow \frac{m}{n} \cdot (\log x) = \log y - \log c, \text{ where } c \text{ is a constant.}$$

$\Rightarrow$ $y = cx^{m/n}$

● ***Ex. 42*** *Find the ratio of the areas in which the curve $y = \left[\frac{x^3}{100} + \frac{x}{35}\right]$ divides the circle $x^2 + y^2 - 4x + 2y + 1 = 0$ (where, [.] denotes the greatest integer function).*

Sol. We have, $x^2 + y^2 - 4x + 2y + 1 = 0$

or $(x - 2)^2 + (y + 1)^2 = 4$ ...(i)



Now, for $0 \le x \le 4$,

$$0 \le \frac{x^3}{100} + \frac{x}{35} < 1 \Rightarrow \left[\frac{x^3}{100} + \frac{x}{35}\right] = 0$$

So, we have to find out the ratio in which X-axis divides the circle (i).

Now, at X-axis, $y = 0$

So, $(x - 2)^2 = 3$

So, it cuts the X-axis at $(2 - \sqrt{3}, 0)$ and $(2 + \sqrt{3}, 0)$.

Therefore, required area, $A = \int_{2-\sqrt{3}}^{2+\sqrt{3}} (\sqrt{4 - (x - 2)^2} - 1)\,dx$

$$= \frac{4\pi - 3\sqrt{3}}{3}$$

$\therefore$ Required ratio $= \frac{A}{4\pi - A} = \frac{4\pi - 3\sqrt{3}}{8\pi + 3\sqrt{3}}$

● ***Ex. 43*** *Area bounded by the line $y = x$, curve $y = f(x), (f(x) > x, \forall x > 1)$ and the lines $x = 1, x = t$ is $(t + \sqrt{1 + t^2}) - (1 + \sqrt{2})$ for all $t > 1$. Find $f(x)$.*

Sol. The area bounded by $y = f(x)$ and $y = x$ between the lines $x = 1$ and $x = t$ is $\int_{+1}^{t} (f(x) - x)\,dx$. But it is equal to $(t + \sqrt{1 + t^2}) - (1 + \sqrt{2})$.

So, $\int_1^t (f(x) - x)\,dx = (t + \sqrt{1 + t^2}) - (1 + \sqrt{2})$

Differentiating both the sides w.r.t. t, we get

$$f(t) - t = 1 + \frac{t}{\sqrt{1 + t^2}} \Rightarrow f(t) = 1 + t + \frac{t}{\sqrt{1 + t^2}}$$

or $f(x) = 1 + x + \frac{x}{\sqrt{1 + x^2}}$

● ***Ex. 44*** *The area bounded by the curve $y = f(x)$, X-axis and ordinates $x = 1$ and $x = b$ is $(b - 1)\sin(3b + 4)$, find $f(x)$.*

Sol. We know that the area bounded by the curve $y = f(x)$, X-axis and the ordinates $x = 1$ and $x = b$ is $\int_1^b f(x)\,dx$.

From the question; $\int_1^b f(x)\,dx = (b - 1)\sin(3b + 4)$

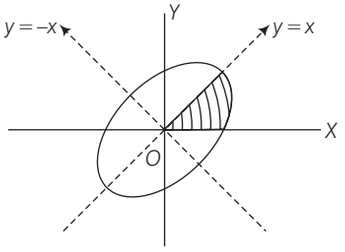
Differentiating w.r.t. b, we get

$$f(b) \cdot 1 = 3(b - 1)\cos(3b + 4) + \sin(3b + 4)$$

$\Rightarrow$ $f(x) = 3(x - 1)\cos(3x + 4) + \sin(3x + 4)$

● ***Ex. 45*** *Find the area of region enclosed by the curve* $\frac{(x-y)^2}{a^2}+\frac{(x+y)^2}{b^2}=2\,(a>b)$, the line $y=x$ and the positive X-axis.

Sol. The given curve $\frac{(x-y)^2}{a^2}+\frac{(x+y)^2}{b^2}=2$ is an ellipse major and minor axes are $x-y=0$ and $x+y=0$, respectively.
The required area is shown with shaded region.



Instead of directly solving the problem we can solve equivalent problem with equivalent ellipse whose axes are $x=0$ and $y=0$.
The equivalent region is shown as $(OA'B'O)$ where the equation of ellipse is $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$.

$\therefore$ Required area = Area $(\Delta OA'A''+A'A''B')$

where, $A'=\left(\frac{ab}{\sqrt{a^2+b^2}},\frac{ab}{\sqrt{a^2+b^2}}\right)$

Area $\Delta OA'A''=\frac{1}{2}\times\frac{ab}{\sqrt{a^2+b^2}}\times\frac{ab}{\sqrt{a^2+b^2}}=\frac{1}{2}\left(\frac{a^2b^2}{a^2+b^2}\right)$ ...(i)

Area of $A'B'A''=\int_{\frac{ab}{\sqrt{a^2+b^2}}}^{a} b\sqrt{\left(1-\frac{x^2}{a^2}\right)}\,dx$

$=\frac{b}{a}\cdot\int_{\frac{ab}{\sqrt{a^2+b^2}}}^{a}\sqrt{a^2-x^2}\,dx$

$=\frac{b}{a}\left[\frac{x}{2}\sqrt{a^2-x^2}+\frac{a^2}{2}\sin^{-1}\frac{x}{a}\right]_{ab/\sqrt{a^2+b^2}}^{a}$

$=\frac{b}{a}\left[0+\frac{a^2}{2}\cdot\frac{\pi}{2}-\frac{ab}{2\sqrt{a^2+b^2}}\cdot\sqrt{\left(a^2-\frac{a^2b^2}{a^2+b^2}\right)}\right.$
$\left.-\frac{a^2}{2}\sin^{-1}\frac{b}{\sqrt{a^2+b^2}}\right]$

$=\frac{b}{a}\left[\frac{\pi a^2}{4}-\frac{a^2}{2}\sin^{-1}\left(\frac{b}{\sqrt{a^2+b^2}}\right)-\frac{a^3b}{2(a^2+b^2)}\right]$

$=\frac{\pi ab}{4}-\frac{ab}{2}\sin^{-1}\left(\frac{b}{\sqrt{a^2+b^2}}\right)-\frac{a^2b^2}{2(a^2+b^2)}$ ...(ii)

Hence, required area = Sum of Eqs. (i) and (ii)

$=\frac{\pi ab}{4}-\frac{ab}{2}\sin^{-1}\left(\frac{b}{\sqrt{a^2+b^2}}\right)$

● ***Ex. 46*** *Let* $f(x)$ *be a function which satisfy the equation* $f(xy)=f(x)+f(y)$ *for all* $x>0, y>0$ *such that* $f'(1)=2$. *Find the area of the region bounded by the curves* $y=f(x), y=|x^3-6x^2+11x-6|$ *and* $x=0$.

Sol. Take $x=y=1\Rightarrow f(1)=0$

Now, $y=\frac{1}{x}$

$\Rightarrow\quad 0=f\left(x\cdot\frac{1}{x}\right)=f(x)+f\left(\frac{1}{x}\right)\Rightarrow f\left(\frac{1}{x}\right)=-f(x)$

$\therefore f\left(\frac{x}{y}\right)=f(x)+f\left(\frac{1}{y}\right)=f(x)-f(y)$ ...(i)

Now, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$

$=\lim_{h\to 0}\frac{f\left(\frac{x+h}{x}\right)}{h}$ [using Eq. (i)]

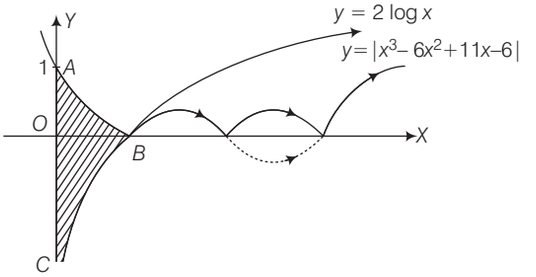
$=\lim_{h\to 0}\frac{f\left(1+\frac{h}{x}\right)-f(1)}{\frac{h}{x}\cdot x}=\frac{f'(1)}{x}$ [$\because f(1)=0$]

$f'(x)=\frac{2}{x}$

$\Rightarrow\quad f(x)=2\log x+c$ [since, $f(1)=0\Rightarrow c=0$]

$\Rightarrow\quad f(x)=2\log x$

Thus, $f(x)=2\log x$ and $y=|x^3-6x^2+11x-6|$ could be plotted as



Hence, required area

$=\int_0^1(x^3-6x^2+11x-6)\,dx+\int_{-\infty}^{0}e^{y/2}\,dy$

$=\left(\frac{x^4}{4}-\frac{6x^3}{3}+\frac{11x^2}{2}-6x\right)_0^1+2\,(e^{y/2})_{-\infty}^{0}$

$=\left(\frac{1}{4}-2+\frac{11}{2}-6\right)-(0)+2\,(e^0-e^{-\infty})$

$=\frac{1}{4}+\frac{11}{2}-8+2=-\frac{1}{4}$ sq unit

● ***Ex. 47*** *Find the area of the region which contains all the points satisfying condition* $|x-2y|+|x+2y|\le 8$ *and* $xy\ge 2$.

Sol. The line $y=\pm\frac{x}{2}$ divide the xy plane in four parts

Region I $2y-x\le 0$ and $2y+x\ge 0$

So that, $|x-2y|+|x+2y|\le 8$

$\Rightarrow\quad (x-2y)+(x+2y)\le 8\ \Rightarrow\ 0\le x\le 4$

Region II $2y - x \mid 0$ and $2y + x \geq 0$

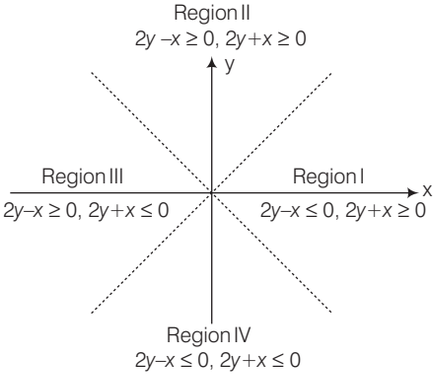
So that, $\quad | x - 2y | + | x + 2y | \leq 8$

$\Rightarrow \quad -(x - 2y) + (x + 2y) \leq 8 \Rightarrow 0 \leq y \leq 2$

Region III $2y + x \leq 0, 2y - x \geq 0$

So that, $\quad | x - 2y | + | x + 2y | \leq 8$

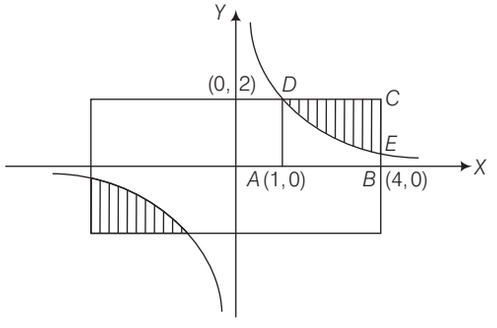
$\Rightarrow \quad -(x - 2y) - (x + 2y) \leq 8 \Rightarrow -4 \leq x \leq 0$



Region IV $2y + x \leq 0, 2y - x \leq 0$

So that, $\quad | x - 2y | + | x + 2y | \leq 8 \Rightarrow -2 \leq y \leq 0$

Here, all the points lie in the rectangle.



Also, the hyperbola $xy = 2$ meets the sides of the rectangle at the points (1, 2) and (4, 1 / 2) in the 1st quadrant graphically.

Hence, required area

$= 2$ (Area of rectangle $ABCD$ − Area of $ABEDA$)

$$= 2\left(3 \times 2 - \int_1^4 \frac{2}{x}\, dx \right) = 2 (6 - 2 \log 4) \text{ sq units}$$

● ***Ex. 48*** *Consider the function*

$$f(x) = \begin{cases} x - [x] - \dfrac{1}{2}, & \text{if } x \notin I \\ 0, & \text{if } x \in I \end{cases}$$

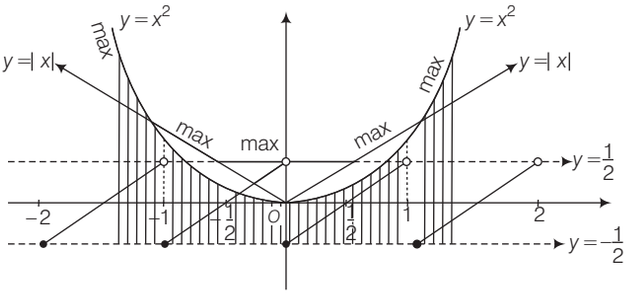
, where [.] denotes the greatest integer function and I is the set of integers. If $g(x) = \max \{x^2, f(x), | x |\}, -2 \leq x \leq 2$, *then find the area bounded by* $g(x)$ *when* $-2 \leq x \leq 2$.

Sol. Here, $\quad f(x) = \begin{cases} x - [x] - \dfrac{1}{2}, & \text{if } x \notin I \\ 0, & \text{if } x \in I \end{cases}$

$$= \begin{cases} \{x\} - \dfrac{1}{2}, & \text{if } x \notin I \\ 0, & \text{if } x \in I \end{cases}$$

Thus, $\quad g(x) = \max \{x^2, f(x), | x |\}$

which could be graphically expressed as



Clearly, $\quad g(x) = \begin{cases} x^2, & -2 \leq x \leq -1 \\ -x, & -1 \leq x \leq -1/4 \\ x + \dfrac{1}{2}, & -1/4 \leq x \leq 0 \\ x, & 0 \leq x \leq 1 \\ x^2, & 1 \leq x \leq 2 \end{cases}$

Hence, required area $= \int_{-2}^{2} g(x)\, dx$

$$= \int_{-2}^{-1} (x^2)\, dx + \int_{-1}^{-1/4} (-x)\, dx + \int_{-1/4}^{0} \left(x + \frac{1}{2} \right) dx + \int_0^1 x\, dx + \int_1^2 x^2\, dx$$

$$= \left(\frac{x^3}{3} \right)_{-2}^{-1} - \left(\frac{x^2}{2} \right)_{-1}^{-1/4} + \left(\frac{x^2}{2} + \frac{1}{2} x \right)_{-1/4}^{0} + \left(\frac{x^2}{2} \right)_0^1 + \left(\frac{x^3}{3} \right)_1^2 = \frac{275}{48} \text{ sq units}$$

● ***Ex. 49*** *Find the area of the region bounded by* $y = f(x), y = | g(x) |$ *and the lines* $x = 0, x = 2$, *where* f, g *are continuous functions satisfying*

$$f(x + y) = f(x) + f(y) - 8xy, \ \forall\, x, y \in R$$

and $\quad g(x + y) = g(x) + g(y) + 3xy\,(x + y), \ \forall\, x, y \in R$

Also, $f'(0) = 8$ and $g'(0) = -4$.

Sol. Here, $f(x + y) = f(x) + f(y) - 8xy$

Replacing $x, y \to 0$, we get $f(0) = 0$

Now, $\quad f'(x) = \lim_{h \to 0} \dfrac{f(x + h) - f(x)}{h} = \lim_{y \to 0} \dfrac{f(x + y) - f(x)}{y}$

$$= \lim_{y \to 0} \frac{f(x) + f(y) - 8xy - f(x)}{y}$$

$$= \lim_{y \to 0} \left\{ \frac{f(y)}{y} - \frac{8xy}{y} \right\}$$

$$= \lim_{y \to 0} \left(\frac{f'(y)}{1} \right) - 8x \text{ (using L'Hospital's rule)}$$

$$= f'(0) - 8x = 8 - 8x \qquad [\text{given, } f'(0) = 8]$$

$\Rightarrow \quad f'(x) = 8 - 8x$

Integrating both the sides, we get

$$f(x) = 8x - 4x^2 + c$$

As $\quad f(0) = 0 \Rightarrow c = 0$

$\Rightarrow \quad f(x) = 8x - 4x^2 \quad ...(i)$

Also, $\quad g(x + y) = g(x) + g(y) + 3xy\,(x + y)$

Replacing $x, y \Rightarrow 0$, we get $g(0) = 0$

Now, $\quad g'(x) = \lim\limits_{y \to 0} \dfrac{g(x+y) - g(x)}{y}$

$$= \lim_{y \to 0} \frac{g(x) + g(y) + 3x^2 y + 3xy^2 - g(x)}{y}$$

$$= \lim_{y \to 0} \left[\frac{g(y)}{y} + \frac{y(3x^2 + 3xy)}{y} \right]$$

$$= \frac{g'(0)}{1} + 3x^2 = -4 + 3x^2$$

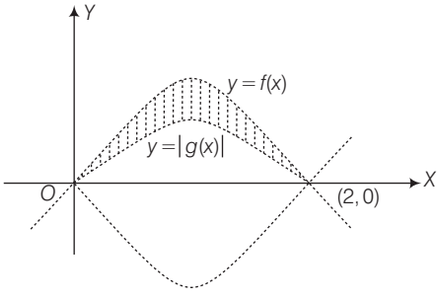
$\therefore \quad g'(x) = -4 + 3x^2$

$\Rightarrow \quad g(x) = x^3 - 4x \quad [\text{as } g(0) = 0] ...(ii)$

Points where $f(x)$ and $g(x)$ meets, we have

$$f(x) = g(x) \quad \text{or} \quad 8x - 4x^2 = x^3 - 4x$$

$\Rightarrow \quad x = 0, 2, -6$



Now, $\quad |g(x)| = \begin{cases} x^3 - 4x, & x \in [-2, 0] \cup (2, \infty) \\ 4x - x^3, & x \in [-\infty, -2] \cup (0, 2) \end{cases}$

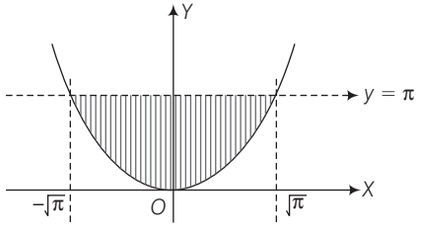
$\therefore$ Area bounded by $y = f(x)$ and $y = |g(x)|$ between $x = 0$ to $x = 2$

$$= \int_0^2 \{(8x - 4x^2) - (4x - x^3)\}\, dx$$

$$= \int_0^2 (x^3 - 4x^2 + 4x)\, dx = \frac{4}{3} \text{ sq units}$$

● ***Ex. 50*** *Find the area of the region bounded by the curve* $y = x^2$ *and* $y = \sec^{-1}[-\sin^2 x]$, *where [.] denotes the greatest integer function.*

Sol. As we know, $[-\sin^2 x] = 0$ or -1. But $\sec^{-1}(0)$ is not defined.



$\Rightarrow \quad \sec^{-1}[-\sin^2 x] = \sec^{-1}(-1) = \pi$

Thus, to find the area bounded between

$$y = x^2 \quad \text{and} \quad y = \pi$$

i.e. when $x^2 = \pi$ or $(x = -\sqrt{\pi}$ to $x = \sqrt{\pi})$

$\therefore$ Required area $= \int_{-\sqrt{\pi}}^{\sqrt{\pi}} (\pi - x^2)\, dx = \left(\pi x - \dfrac{x^3}{3} \right)_{-\sqrt{\pi}}^{\sqrt{\pi}}$

$$= \pi(\sqrt{\pi} + \sqrt{\pi}) - \frac{1}{3}(\pi\sqrt{\pi} + \pi\sqrt{\pi}) = \frac{4\pi}{3}\sqrt{\pi}$$

● ***Ex. 51*** *Sketch the graph of* $\cos^{-1}(4x^3 - 3x)$ *and find the area enclosed between* $y = 0$, $y = f(x)$ *and* $x \geq -1/2$.

Sol. Here, $\quad f(x) = \cos^{-1}(4x^3 - 3x)$

Let $\quad x = \cos\theta \quad$ and $\quad 0 \leq \theta \leq \pi$

$\Rightarrow \quad f(x) = \cos^{-1}(4\cos^3\theta - 3\cos\theta)$

$$= \cos^{-1}(\cos 3\theta);\ 0 \leq 3\theta \leq 3\pi$$

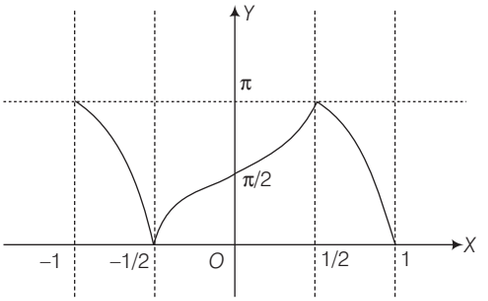
$\Rightarrow \quad f(x) = \begin{cases} 3\theta, & 0 \leq 3\theta \leq \pi \\ 2\pi - 3\theta, & \pi < 3\theta \leq 2\pi \\ 3\theta - 2\pi, & 2\pi < 3\theta \leq 3\pi \end{cases}$

$$= \begin{cases} 3\cos^{-1} x, & 1/2 \leq x \leq 1 \\ 2\pi - 3\cos^{-1} x, & -1/2 \leq x < 1 \\ 3\cos^{-1} x - 2\pi, & -1 \leq x < -1/2 \end{cases}$$

$\therefore \quad f'(x) = \begin{cases} -3/\sqrt{1 - x^2}, & 1/2 < x < 1 \\ 3/\sqrt{1 - x^2}, & -1/2 < x < 1/2 \\ -3/\sqrt{1 - x^2}, & -1 < x < -1/2 \end{cases}$

and $\quad f''(x) = \begin{cases} \dfrac{-3x}{(1 - x^2)^{3/2}}, & 1/2 < x < 1 \\ \dfrac{3x}{(1 - x^2)^{3/2}}, & -1/2 < x < 1/2 \\ \dfrac{-3x}{(1 - x^2)^{3/2}}, & -1 < x < -1/2 \end{cases}$

Thus, the graph for $f(x) = \cos^{-1}(4x^3 - 3x)$ is



Thus, required area $= \int_{-1/2}^{1} f(x)\, dx$

$$= \int_{-1/2}^{1/2} (2\pi - 3\cos^{-1} x)\, dx + \int_{1/2}^{1} (3\cos^{-1} x)\, dx$$

$$= 2\pi - 3\int_{-1/2}^{1/2}\left(\frac{\pi}{2} - \sin^{-1} x\right)dx + 3\int_{1/2}^{1}(\cos^{-1} x)\,dx$$

$$= \frac{\pi}{2} + 3\int_{1/2}^{1}\cos^{-1} x\,dx \qquad \left[\text{as}\int_{-1/2}^{1/2}\sin^{-1} x\,dx = 0\right]$$

$$= \frac{\pi}{2} + 3\left\{(x\cos^{-1} x)_{1/2}^{1} + \int_{1/2}^{1}\frac{x}{\sqrt{1-x^2}}\,dx\right\}$$

On solving, we get $= \frac{3\sqrt{3}}{2}$ sq units

● ***Ex. 52*** *Consider two curves $y^2 = 4a(x-\lambda)$ and $x^2 = 4a(y-\lambda)$, where $a > 0$ and λ is a parameter. Show that*

(i) there is a single positive value of λ for which the two curves have exactly one point of intersection in the 1st quadrant find it.

(ii) there are infinitely many negative values of λ for which the two curves have exactly one point of intersection in the 1st quadrant.

(iii) if $\lambda = -a$, then find the area of the bounded by the two curves and the axes in the 1st quadrant.

Sol. The two curves are inverse of each other. Hence, the two curves always meet along the line $y = x$.

Consider, $y^2 = 4a(x-\lambda)$ and put $x = y$

$\Rightarrow \quad y^2 - 4ay + 4a\lambda = 0$

$$\Rightarrow \quad y = \frac{4a \pm 4\sqrt{a^2 - a\lambda}}{2} = 2a \pm \sqrt{a^2 - a\lambda}$$

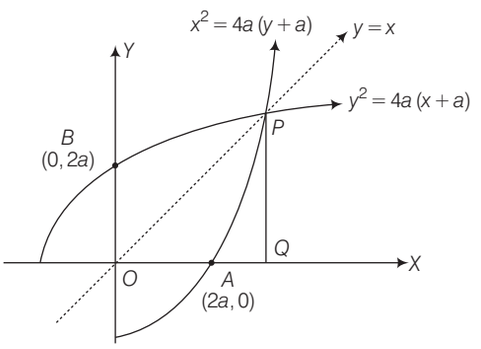
Since, y is real $\Rightarrow a^2 - a\lambda \mid 0$ or $\lambda \le a$

(i) If $0 < \lambda < a$, then there are two distinct values of y and both $2(a + \sqrt{a^2 - a\lambda})$ and $2(a - \sqrt{a^2 - a\lambda})$ are positive, i.e. both points lie in the first quadrant.

If $\lambda = a$, then $y = 2a$ only, i.e. only one point of intersection $(2a, 2a)$.

Hence, there is exactly one point of intersection in 1st quadrant for $\lambda = a$. It is infact the points of tangency of the two curves.

(ii) If $\lambda < 0$, then $y = 2(a + \sqrt{a^2 - a\lambda}) > 0$ and $y = 2(a - \sqrt{a^2 - a\lambda}) < 0$. i.e. the only point of intersection is in the first quadrant, the other in the 3rd quadrant. Hence, there are infinitely many such values.



(iii) For $\lambda = -a$, we have $y^2 = 4a(x+a)$

$$x^2 = 4a(y+a)$$

The point of intersection in the 1st quadrant $P = ((2+2\sqrt{2})\,a, (2+2\sqrt{2})\,a)$

Required area = 2 (area of ΔOPQ − area $\overline{APQA}$)

of $\Delta OPQ = \frac{1}{2}\cdot(2+2\sqrt{2})^2\,a^2 = 2(1+\sqrt{2})^2\,a^2$

Area of $APQA = \int_{2a}^{(2+2\sqrt{2})a} y\,dx = \int_{2a}^{(2+2\sqrt{2})a}\left(\frac{x^2}{4a} - a\right)dx$

$$= \frac{1}{4a}\left[\frac{x^3}{3}\right]_{2a}^{(2+2\sqrt{2})a} - a\,(x)_{2a}^{(2+2\sqrt{2})a}$$

$$= \frac{1}{12a}[(2+2\sqrt{2})^3\cdot a^3 - 8a^3] - 2\sqrt{2}\,a^2$$

$$= \left(\frac{4\sqrt{2}+12}{3}\right)a^2$$

$\therefore$ Required area $= 2\left(2(1+\sqrt{2})^2 + \frac{4\sqrt{2}+12}{3}\right)a^2$

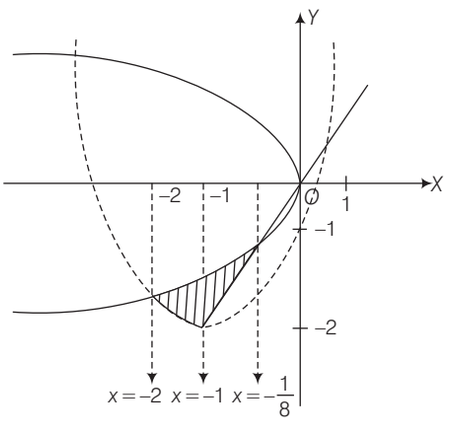
$$= \frac{4}{3}(15 + 8\sqrt{2})\,a^2$$

● ***Ex. 53*** *Let $f(x)$ be continuous function given by*

$$f(x) = \begin{cases} 2x, & |x| \le 1 \\ x^2 + ax + b, & |x| > 1 \end{cases}$$

Find the area of the region in the third quadrant bounded by the curves $x = -2y^2$ and $y = f(x)$ lying on the left of the line $8x + 1 = 0$. ***[IIT JEE 1999]***

Sol. Given, a continuous function $f(x)$, given by



$$f(x) = \begin{cases} 2x, & |x| \le 1 \\ x^2 + ax + b, & |x| > 1 \end{cases}$$

i.e. $$f(x) = \begin{cases} x^2 + ax + b, & -\infty < x < -1 \\ 2x, & -1 \le x \le 1 \\ x^2 + ax + b, & 1 < x < \infty \end{cases}$$

$\because$ f is continuous.

$\therefore$ It is continuous at $x = -1$ and $x = 1$.

$\therefore \quad (-1)^2 + a(-1) + b = 2(-1)$

and $\quad (1)^2 + a(1) + b = 2(1)$

$\Rightarrow \quad 1 - a + b = -2$

and $\quad 1 + a + b = 2$

$\Rightarrow \quad -a + b = -3$

and $\quad a + b = 1$

$\Rightarrow \quad b = -1$ and $a = 2$

$\therefore \quad f(x) = \begin{cases} x^2 + 2x - 1, & \text{when } -\infty < x < -1 \\ 2x, & \text{when } -1 \le x \le 1 \end{cases}$

Now, $\quad y = x^2 + 2x - 1 = (x+1)^2 - 2$

or $\quad (y+2) = (x+1)^2$

We need the area of the region in third quadrant bounded by the curves $a = -2y^2$, $y = f(x)$ lying on the left of the line $8x + 1 = 0$.

$\Rightarrow \quad (y+2) = (x+1)^2$

Cuts the Y-axis at $(0, -1)$ and the X-axis at $(-1-\sqrt{2}, 0)$ and $(-1+\sqrt{2}, 0)$.

When $x = 1$ and $y = 2$

Solving $x = -2y^2$ and $(y+2) = (x+1)^2$, we get

$$(y+2) = (-2y^2 + 1)^2$$

$\Rightarrow \quad 4y^4 - 4y^2 + 1 - y - 2 = 0$

$\Rightarrow \quad 4y^4 - 4y^2 - y - 1 = 0$

For $\quad y = -1,\ 4y^4 - 4y^2 - y - 1 = 0$

At $\quad y = -1,\ x = -2$

$\therefore \quad$ Required area $= \int_{-2}^{-1} \left\{ -\sqrt{-\frac{x}{2}} - (x+1)^2 + 2 \right\} dx + \int_{-1}^{-1/8} \left\{ -\sqrt{-\frac{x}{2}} - 2x \right\} dx$

$$= \left\{ \frac{(-x/2)^{3/2}}{\frac{3}{2}(1/2)} - \frac{(x+1)^3}{3} + 2x \right\}_{-2}^{-1} + \left\{ \frac{(-x/2)^{3/2}}{\frac{3}{2}(1/2)} - \frac{2x^2}{2} \right\}_{-1}^{-1/8}$$

$$= \left\{ \frac{4}{3}\left(-\frac{x}{2}\right)^{3/2} - \frac{(x+1)^3}{3} + 2x \right\}_{-2}^{-1} + \left\{ \frac{4}{3}\left(-\frac{x}{2}\right)^{3/2} - x^2 \right\}_{-1}^{-1/8}$$

$$= \left\{ \frac{4}{3}\left(\frac{1}{2}\right)^{3/2} - 0 - 2 \right\} - \left\{ \frac{4}{3}(1)^{3/2} - \frac{(-1)^3}{3} - 4 \right\} - \left\{ \frac{4}{3}\left(\frac{1}{2}\right)^{3/2} - (-1)^2 \right\} + \left\{ \frac{4}{3}\left(\frac{1}{16}\right)^{3/2} - \frac{1}{64} \right\}$$

$$= \left\{ \frac{4}{3\cdot 2\sqrt{2}} - 2 - \frac{4}{3} - \frac{1}{3} + 4 - \frac{4}{3\cdot 2\sqrt{2}} + 1 + \frac{4}{3(64)} - \frac{1}{64} \right\}$$

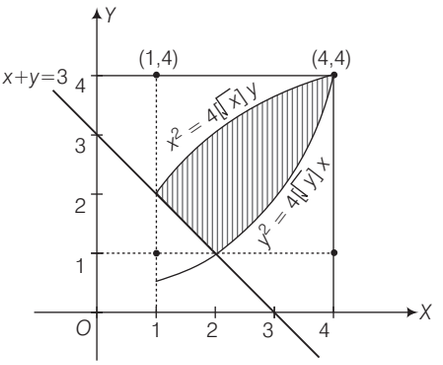
$$= \frac{4}{3} + \frac{1}{3(64)} = \frac{257}{192} \text{ sq units}$$

● ***Ex. 54*** *Let $[x]$ denotes the greatest integer function. Draw a rough sketch of the portions of the curves $x^2 = 4[\sqrt{x}]\,y$ and $y^2 = 4[\sqrt{y}]\,x$ that lie within the square $\{(x, y) \mid 1 \le x \le 4, 1 \le y \le 4\}$. Find the area of the part of the square that is enclosed by the two curves and the line $x + y = 3$.*

Sol. We have, $\quad 1 \le x \le 4$ and $1 \le y \le 4$

$\Rightarrow \quad 1 \le \sqrt{x} \le 2$ and $1 \le \sqrt{y} \le 2$

$\Rightarrow [\sqrt{x}] = 1$ and $[\sqrt{y}] = 1$ for all (x, y) lying with in the square.



Thus, $\quad x^2 = 4[\sqrt{x}]\,y$ and $y^2 = 4[\sqrt{y}]\,x$

$\Rightarrow \quad x^2 = 4y$ and $y^2 = 4x$ when $1 \le x, y \le 4$ which could be plotted as;

Thus, required area

$$= \int_1^2 (2\sqrt{x} - 3 + x)\,dx + \int_2^4 \left(2\sqrt{x} - \frac{x^2}{4} \right) dx$$

$$= \left(\frac{4}{3}x^{3/2} - 3x + \frac{x^2}{2} \right)_1^2 + \left(\frac{4}{3}x^{3/2} - \frac{x^3}{12} \right)_2^4$$

$$= \left(\frac{8\sqrt{2}}{3} - 6 + 2 \right) - \left(\frac{4}{3} - 3 + \frac{1}{2} \right) + \left(\frac{32}{3} - \frac{64}{12} \right) - \left(\frac{8\sqrt{2}}{3} - \frac{8}{12} \right)$$

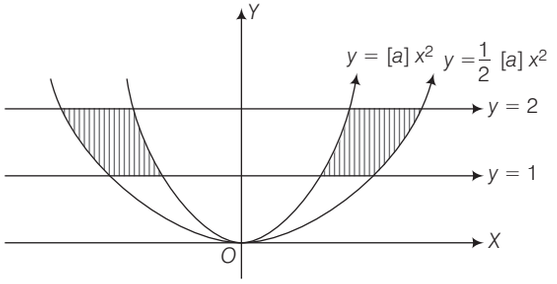
$$= \frac{19}{6} \text{ sq units}$$

● ***Ex. 55*** *Find all the values of the parameter a $(a \ge 1)$ for which the area of the figure bounded by pair of straight lines $y^2 - 3y + 2 = 0$ and the curves $y = [a]\,x^2, y = \frac{1}{2}[a]\,x^2$ is greatest, where [.] denotes the greatest integer function.*

Sol. The curves $y = [a]\,x^2$ and $y = \frac{1}{2}[a]\,x^2$ represent parabolas which are symmetric about Y-axis.

The equation $y^2 - 3y + 2 = 0$ gives a pair of straight lines $y = 1$, $y = 2$ which are parallel to X-axis.

Thus, the area bounded is shown as



From the above figure,

$$\text{Required area} = 2\int_{y=1}^{y=2} (x_2 - x_1)\, dy$$

$$= 2\int_1^2 \left(\sqrt{\frac{2y}{[a]}} - \sqrt{\frac{y}{[a]}} \right) dy$$

$$= \frac{2(\sqrt{2}-1)}{[a]} \int_1^2 \sqrt{y}\, dy = \frac{2(\sqrt{2}-1)}{[a]} \frac{2}{3} (y^{3/2})_1^2$$

$$= \frac{4}{3} \frac{(\sqrt{2}-1)}{[a]} \cdot (2^{3/2} - 1)$$

$$= \frac{4}{3} \frac{(5 - \sqrt{2} - 2\sqrt{2})}{[a]} = \frac{4}{3} \frac{(5 - 3\sqrt{2})}{[a]}$$

$\therefore$ Area is the greatest when $[a]$ is least, i.e. 1.

$\therefore$ Area is the greatest when $[a] = 1$

Hence, $a \in [1, 2)$

● ***Ex. 56*** *Find the area in the first quadrant bounded by* $[x] + [y] = n$, *where* $n \in N$ *and* $y = i$ *(where,* $i \in N\ \forall\ i \le n+1$*),* $[\cdot]$ *denotes the greatest integer less than or equal to* x.

Sol. As we know, $[x] + [y] = n \Rightarrow [x] = n - [y]$

When $y = 0$, $[x] = n \Rightarrow n \le x < n + 1$

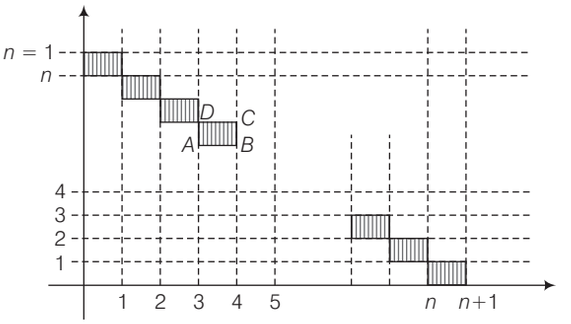
When $y = 1$, $[x] = n - 1 \Rightarrow n - 1 \le x < n - 2$

When $y = 2$, $[x] = n - 2$

$\Rightarrow$ $n - 2 \le x < n - 3$. ... and so on.

When $y = n$, $[x] = 0 \Rightarrow 0 \le x < 1$

which could be shown as



From the above figure,

$= (n + 1)$ area of square $ABCD = (n + 1) \cdot 1$

Required area $= (n + 1)$ sq units

Area of Bounded Regions Exercise 1 :
Single Option Correct Type Questions

1. A Point $P(x, y)$ moves such that $[x + y + 1] = [x]$. (where $[\cdot]$ denotes greatest integer function) and $x \in (0, 2)$, then the area represented by all the possible positions of P, is
(a) $\sqrt{2}$ (b) $2\sqrt{2}$
(c) $4\sqrt{2}$ (d) 2

2. If $f: [-1, 1] \to \left[-\frac{1}{2}, \frac{1}{2}\right]$, $f(x) = \frac{x}{1 + x^2}$. The area bounded by $y = f^{-1}(x)$, X-axis, $x = \frac{1}{2}$, $x = -\frac{1}{2}$ is
(a) $\frac{1}{2}\log e$ (b) $\log\left(\frac{e}{2}\right)$
(c) $\frac{1}{2}\log\frac{e}{3}$ (d) $\frac{1}{2}\log\left(\frac{e}{2}\right)$

3. If the length of latusrectum of ellipse
$E_1 : 4(x + y - 1)^2 + 2(x - y + 3)^2 = 8$
and $E_2 : \frac{x^2}{p} + \frac{y^2}{p^2} = 1, (0 < p < 1)$ are equal, then area of ellipse E_2, is
(a) $\frac{\pi}{2}$ (b) $\frac{\pi}{\sqrt{2}}$
(c) $\frac{\pi}{2\sqrt{2}}$ (d) $\frac{\pi}{4}$

4. The area of bounded by the curve
$4\,|\,x - 2017^{2017}\,| + 5\,|\,y - 2017^{2017}\,| \le 20$, is
(a) 60 (b) 50
(c) 40 (d) 30

5. If the area bounded by the corve $y = x^2 + 1$, $y = x$ and the pair of lines $x^2 + y^2 + 2xy - 4x - 4y + 3 = 0$ is K units, then the area of the region bounded by the curve $y = x^2 + 1, y = \sqrt{x - 1}$ and the pair of lines $(x + y - 1)(x + y - 3) = 0$, is
(a) K (b) $2K$
(c) $\frac{K}{2}$ (d) None of these

6. Suppose $y = f(x)$ and $y = g(x)$ are two functions whose graphs intersect at the three points (0, 4), (2, 2) and (4, 0) with $f(x) > g(x)$ for $0 < x < 2$ and $f(x) < g(x)$ for $2 < x < 4$. If $\int_0^4 [f(x) - g(x)]\,dx = 10$
and $\int_2^4 [g(x) - f(x)]\,dx = 5$, then the area between two curves for $0 < x < 2$, is
(a) 5 (b) 10
(c) 15 (d) 20

7. Let 'a' be a positive constant number. Consider two curves $C_1 : y = e^x$, $C_2 : y = e^{a-x}$. Let S be the area of the part surrounding by C_1, C_2 and the Y-axis, then $\lim_{a \to 0} \frac{S}{a^2}$ equals
(a) 4 (b) 1/2
(c) 0 (d) 1/4

8. 3 points $O(0,0), P(a, a^2)$, $Q(-b, b^2)(a > 0, b > 0)$ are on the parabola $y = x^2$. Let S_1 be the area bounded by the line PQ and the parabola and let S_2 be the area of the ΔOPQ, the minimum value of S_1/S_2 is
(a) 4/3 (b) 5/3
(c) 2 (d) 7/3

9. Area enclosed by the graph of the function $y = \ln^2 x - 1$ lying in the 4th quadrant is
(a) $\frac{2}{e}$ (b) $\frac{4}{e}$
(c) $2\left(e + \frac{1}{e}\right)$ (d) $4\left(e - \frac{1}{e}\right)$

10. The area bounded by $y = 2 - |2 - x|$ and $y = \frac{3}{|x|}$ is
(a) $\frac{4 + 3\ln 3}{2}$ (b) $\frac{19}{8} - 3\ln 2$
(c) $\frac{3}{2} + \ln 3$ (d) $\frac{1}{2} + \ln 3$

11. Suppose $g(x) = 2x + 1$ and $h(x) = 4x^2 + 4x + 5$ and $h(x) = (fog)(x)$. The area enclosed by the graph of the function $y = f(x)$ and the pair of tangents drawn to it from the origin, is
(a) 8/3 (b) 16/3
(c) 32/3 (d) None of these

12. The area bounded by the curves $y = -\sqrt{-x}$ and $x = -\sqrt{-y}$ where $x, y \le 0$
(a) cannot be determined
(b) is 1/3
(c) is 2/3
(d) is same as that of the figure bounded by the curves $y = \sqrt{-x}$; $x \le 0$ and $x = \sqrt{-y}$; $y \le 0$

13. $y = f(x)$ is a function which satisfies
(i) $f(0) = 0$ (ii) $f''(x) = f'(x)$ and (iii) $f'(0) = 1$
Then, the area bounded by the graph of $y = f(x)$, the lines $x = 0, x - 1 = 0$ and $y + 1 = 0$, is
(a) e (b) $e - 2$
(c) $e - 1$ (d) $e + 1$

14. Area of the region enclosed between the curves $x = y^2 - 1$ and $x = |y|\sqrt{1-y^2}$ is

(a) 1 (b) 4/3
(c) 2/3 (d) 2

15. The area bounded by the curve $y = x e^{-x}$; $xy = 0$ and $x = c$ where c is the x-coordinate of the curve's inflection point, is

(a) $1-3e^{-2}$ (b) $1-2e^{-2}$
(c) $1-e^{-2}$ (d) 1

16. If $(a,0); a>0$ is the point where the curve $y = \sin 2x - \sqrt{3}\sin x$ cuts the X-axis first, A is the area bounded by this part of the curve, the origin and the positive X-axis, then

(a) $4A + 8\cos a = 7$ (b) $4A + 8\sin a = 7$
(c) $4A - 8\sin a = 7$ (d) $4A - 8\cos a = 7$

17. The curve $y = ax^2 + bx + c$ passes through the point $(1,2)$ and its tangent at origin is the line $y = x$. The area bounded by the curve, the ordinate of the curve at minima and the tangent line is

(a) $\frac{1}{24}$ (b) $\frac{1}{12}$ (c) $\frac{1}{8}$ (d) $\frac{1}{6}$

18. A function $y = f(x)$ satisfies the differential equation $\frac{dy}{dx} - y = \cos x - \sin x$, with initial condition that y is bounded when $x \to \infty$. The area enclosed by $y = f(x), y = \cos x$ and the Y-axis in the 1st quadrant

(a) $\sqrt{2}-1$ (b) $\sqrt{2}$
(c) 1 (d) $1/\sqrt{2}$

19. If the area bounded between X-axis and the graph of $y = 6x - 3x^2$ between the ordinates $x = 1$ and $x = a$ is 19 sq units, then 'a' can take the value

(a) 4 or -2
(b) two values are in $(2,3)$ and one in $(-1,0)$
(c) two values one in $(3,4)$ and one in $(-2,-1)$
(d) None of the above

20. Area bounded by $y = f^{-1}(x)$ and tangent and normal drawn to it at the points with abscissae π and 2π, where $f(x) = \sin x - x$ is

(a) $\frac{\pi^2}{2} - 1$ (b) $\frac{\pi^2}{2} - 2$
(c) $\frac{\pi^2}{2} - 4$ (d) $\frac{\pi^2}{2}$

21. If $f(x) = x - 1$ and $g(x) = |f(|x|) - 2|$, then the area bounded by $y = g(x)$ and the curve $x^2 - 4y + 8 = 0$ is equal to

(a) $\frac{4}{3}(4\sqrt{2} - 5)$ (b) $\frac{4}{3}(4\sqrt{2} - 3)$
(c) $\frac{8}{3}(4\sqrt{2} - 3)$ (d) $\frac{8}{3}(4\sqrt{2} - 5)$

22. Let $S = \left\{(x,y): \frac{y(3x-1)}{x(3x-2)} < 0\right\}$,
$S' = \{(x,y) \in A \times B: -1 \le A \le 1, -1 \le B \le 1\}$,
then the area of the region enclosed by all points in $S \cap S'$ is

(a) 1 (b) 2
(c) 3 (d) 4

23. The area of the region bounded between the curves $y = e^{||x|\ln|x||}$, $x^2 + y^2 - 2(|x| + |y|) + 1 \ge 0$ and X-axis where $|x| \le 1$, if α is the x-coordinate of the point of intersection of curves in 1st quadrant, is

(a) $4\left[\int_0^{\alpha} ex\ln x\,dx + \int_{\alpha}^{1}(1 - \sqrt{1-(x-1)^2})\,dx\right]$
(b) $4\left[\int_0^{\alpha} ex\ln x\,dx + \int_{1}^{\alpha}(1 - \sqrt{1-(x-1)^2})\,dx\right]$
(c) $4\left[-\int_0^{\alpha} ex\ln x\,dx + \int_{\alpha}^{1}(1 - \sqrt{1-(x-1)^2})\,dx\right]$
(d) $2\left[\int_0^{\alpha} ex\ln x\,dx + \int_{1}^{\alpha}(1 - \sqrt{1-(x-1)^2})\,dx\right]$

24. A point P lying inside the curve $y = \sqrt{2ax - x^2}$ is moving such that its shortest distance from the curve at any position is greater than its distance from X-axis. The point P enclose a region whose area is equal to

(a) $\frac{\pi a^2}{2}$ (b) $\frac{a^2}{3}$
(c) $\frac{2a^2}{3}$ (d) $\left(\frac{3\pi - 4}{6}\right)a^2$

Area of Bounded Regions Exercise 2 :
More than One Option Correct Type Questions

25. The triangle formed by the normal to the curve $f(x) = x^2 - ax + 2a$ at the point (2, 4) and the coordinate axes lies in second quadrant, if its area is 2 sq units, then a can be
(a) 2
(b) 17/4
(c) 5
(d) 19/4

26. Let f and g be continuous function on $a \le x \le b$ and set $p(x) = \max\{f(x),\ g(x)\}$ and $q(x) = \min\{f(x), g(x)\}$, then the area bounded by the curves $y = p(x)$, $y = q(x)$ and the ordinates $x = a$ and $x = b$ is given by

(a) $\int_a^b |f(x) - g(x)|\, dx$ (b) $\int_a^b |p(x) - q(x)|\, dx$

(c) $\int_a^b \{f(x) - g(x)\}\, dx$ (d) $\int_a^b \{p(x) - q(x)\}\, dx$

27. The area bounded by the parabola $y = x^2 - 7x + 10$ and X-axis equals
(a) area bounded by $y = -x^2 + 7x - 10$ and X-axis
(b) 1/6 sq units
(c) 5/6 sq units
(d) 9/2 sq units

28. Area bounded by the ellipse $\frac{x^2}{4} + \frac{y^2}{9} = 1$ is equal to
(a) 6π sq units
(b) 3π sq units
(c) 12π sq units
(d) area bounded by the ellipse $\frac{x^2}{9} + \frac{y^2}{4} = 1$

29. There is a curve in which the length of the perpendicular from the origin to tangent at any point is equal to abscissa of that point. Then,
(a) $x^2 + y^2 = 2$ is one such curve
(b) $y^2 = 4x$ is one such curve
(c) $x^2 + y^2 = 2cx$ (c parameters) are such curves
(d) there are no such curves

Area of Bounded Regions Exercise 3 :
Statement I and II Type Questions

■ **Direction** (Q. No. 30-34) *For the following questions, choose the correct answers from the codes* (*a*), (*b*), (*c*) *and* (*d*) *defined as follows* :

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I
(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I
(c) Statement I is true, Statement II is false
(d) Statement I is false, Statement II is true

30. **Statement I** The area of the curve $y = \sin^2 x$ from 0 to π will be more than that of the curve $y = \sin x$ from 0 to π.

Statement II $x^2 > x$, if $x > 1$.

31. **Statement I** The area bounded by the curves $y = x^2 - 3$ and $y = kx + 2$ is least if $k = 0$.

Statement II The area bounded by the curves $y = x^2 - 3$ and $y = kx + 2$ is $\sqrt{k^2 + 20}$.

32. **Statement I** The area of region bounded parabola $y^2 = 4x$ and $x^2 = 4y$ is $\frac{32}{3}$ sq units.

Statement II The area of region bounded by parabola $y^2 = 4ax$ and $x^2 = 4by$ is $\frac{16}{3}ab$.

33. **Statement I** The area by region $|x + y| + |x - y| \le 2$ is 8 sq units.

Statement II Area enclosed by region $|x + y| + |x - y| \le 2$ is symmetric about X-axis.

34. **Statement I** Area bounded by $y = x(x - 1)$ and $y = x(1 - x)$ is $\frac{1}{3}$.

Statement II Area bounded by $y = f(x)$ and $y = g(x)$ is $\left| \int_a^b (f(x) - g(x))\, dx \right|$ is true when $f(x)$ and $g(x)$ lies above X-axis. (Where a and b are intersection of $y = f(x)$ and $y = g(x)$).

Area of Bounded Regions Exercise 4 : Passage Based Questions

Passage I

(Q. Nos. 35 to 37)

Let $f(x)=\dfrac{ax^2+bx+c}{x^2+1}$ *such that* $y=-2$ *is an asymptote of the curve* $y=f(x)$. *The curve* $y=f(x)$ *is symmetric about Y-axis and its maximum values is 4. Let* $h(x)=f(x)-g(x)$, *where* $f(x)=\sin^4 \pi x$ *and* $g(x)=\log_e x$. *Let* $x_0, x_1, x_2, \ldots . x_{n+1}$ *be the roots of* $f(x)=g(x)$ *in increasing order.*

35. Then, the absolute area enclosed by $y=f(x)$ and $y=g(x)$ is given by

(a) $\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^r \cdot h(x)dx$

(b) $\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^{r+1} \cdot h(x)dx$

(c) $2\sum_{r=0}^{n} \int_{x_r}^{x_{r-r+1}} (-1)^r \cdot h(x)dx$

(d) $\frac{1}{2}\cdot\sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^{r+1} h(x)dx$

36. In above inquestion the value of *n*, is

(a) 1 (b) 2
(c) 3 (d) 4

37. The whole area bounded by $y=f(x), y=g(x)\ x=0$ is

(a) 11/8 (b) 8/3
(c) 2 (d) 13/3

Passage II

(Q. Nos. 38 to 40)

Consider the function $f:(-\infty,\infty)\to(-\infty,\infty)$ *defined by* $f(x)=\dfrac{x^2-ax+1}{x^2+ax+1}, 0<a<2.$

38. Which of the following is true?

(a) $(2+a)^2 f''(1)+(2-a)^2 f''(-1)=0$

(b) $(2-a)^2 f''(1)-(2+a)^2 f''(-1)=0$

(c) $f'(1)f'(-1)=(2-a)^2$

(d) $f'(1)f'(-1)=-(2+a)^2$

39. Which of the following is true?

(a) $f(x)$ is decreasing on $(-1,1)$ and has a local minimum at $x=1$

(b) $f(x)$ is increasing on $(-1,1)$ and has a local maximum at $x=1$

(c) $f(x)$ is increasing on $(-1,1)$ but has neither a local maximum nor a local minimum at $x=1$

(d) $f(x)$ is decreasing on $(-1,1)$ but has neither a local maximum nor a local minimum at $x=1$

40. Let $g(x)=\int_0^{e^x} \dfrac{f'(t)}{1+t^2}\,dt$. Which of the following is true?

(a) $g'(x)$ is positive on $(-\infty,0)$ and negative on $(0,\infty)$

(b) $g'(x)$ is negative on $(-\infty,0)$ and positive on $(0,\infty)$

(c) $g'(x)$ change sign on both $(-\infty,0)$ and $(0,\infty)$

(d) $g'(x)$ does not change sign on $(-\infty,\infty)$

Passage III

(Q. Nos. 41 to 43)

Computing areas with parametrically represented boundaries : *If the boundary of a figure is represented by parametric equations* i.e. $x=x(t)$, $y=y(t)$, *then the area of the figure is evaluated by one of the three formulas*

$$S=-\int_\alpha^\beta y(t)\cdot x'(t)\,dt$$

$$S=\int_\alpha^\beta x(t)\cdot y'(t)\,dt$$

$$S=\frac{1}{2}\int_\alpha^\beta (xy'-yx')\,dt$$

where α *and* β *are the values of the parameter '*t*' corresponding, respectively to the beginning and the end of the traversal of the curve corresponding to increasing '*t*'.*

41. The area enclosed by the asteroid $\left(\dfrac{x}{a}\right)^{2/3}+\left(\dfrac{y}{a}\right)^{2/3}=1$ is

(a) $\frac{3}{4}a^2\pi$ (b) $\frac{3}{18}\pi a^2$
(c) $\frac{3}{8}\pi a^2$ (d) $\frac{3}{4}a\pi$

42. The area of the region bounded by an arc of the cycloid $x=a(t-\sin t), y=a(1-\cos t)$ and the *X*-axis is

(a) $6\pi a^2$ (b) $3\pi a^2$
(c) $4\pi a^2$ (d) None of these

43. Area of the loop described as $x=\dfrac{t}{3}(6-t), y=\dfrac{t^2}{8}(6-t)$ is

(a) $\frac{27}{5}$ (b) $\frac{24}{5}$
(c) $\frac{27}{6}$ (d) $\frac{21}{5}$

Area of Bounded Regions Exercise 5 : Matching Type Questions

44. Match the statements of Column I with values of Column II.

	Column I		Column II
(A)	The area bounded by the curve $y = x + \sin x$ and its inverse function between the ordinates $x = 0$ to $x = 2\pi$ is 4s. Then, the value of s is	(p)	2
(B)	The area bounded by $y = x e^{\lvert x\rvert}$ and lies $\lvert x\rvert = 1$, $y = 0$ is	(q)	1
(C)	The area bounded by the curves $y^2 = x^3$ and $\lvert y\rvert = 2x$ is	(r)	$\frac{16}{5}$
(D)	The smaller are included between the curves $\sqrt{\lvert x\rvert} + \sqrt{\lvert y\rvert} = 1$ and $\lvert x\rvert + \lvert y\rvert = 1$ is	(s)	$\frac{1}{3}$

45. Match the following :

	Column I		Column II
(A)	Area enclosed by $y = \lvert x\rvert$, $\lvert x\rvert = 1$ and $y = 0$ is	(p)	2
(B)	Area enclosed by the curve $y = \sin x$, $x = 0$, $x = \pi$ and $y = 0$ is	(q)	4
(C)	If the area of the region bounded by $x^2 \le y$ and $y \le x + 2$ is $\frac{k}{4}$, then k is equal to	(r)	27
(D)	Area of the quadrilateral formed by tangents at the ends of latusrectum of ellipse of ellipse $\frac{x^2}{9} + \frac{y^2}{5} = 1$ is	(s)	18

Area of Bounded Regions Exercise 6 : Single Integer Answer Type Questions

46. Consider $f(x) = x^2 - 3x + 2$. The area bounded by $\lvert y\rvert = \lvert f(\lvert x\rvert)\rvert$, $x \ge 1$ is A, then find the value of $3A + 2$.

47. The value of $c + 2$ for which the area of the figure bounded by the curve $y = 8x^2 - x^5$; the straight lines $x = 1$ and $x = c$ and X-axis is equal to $\frac{16}{3}$, is .....

48. The area bounded by $y = 2 - \lvert 2 - x\rvert$; $y = \frac{3}{\lvert x\rvert}$ is $\frac{k - 3\ln 3}{2}$, then k is equal to .....

49. The area of the ΔABC, coordinates of whose vertices are $A(2, 0)$, $B(4, 5)$ and $C(6, 3)$ is .....

50. A point P moves in XY-plane in such a way that $[\lvert x\rvert] + [\lvert y\rvert] = 1$, where $[\cdot]$ denotes the greatest integer function. Area of the region representing all possible of the point P is equal to ..... .

51. Let $f : [0, 1] \to \left[0, \frac{1}{2}\right]$ be a function such that $f(x)$ is a polynomial of 2nd degree, satisfy the following condition :
(a) $f(0) = 0$
(b) has a maximum value of $\frac{1}{2}$ at $x = 1$.
If A is the area bounded by $y = f(x)$; $y = f^{-1}(x)$ and the line $2x + 2y - 3 = 0$ in 1st quadrant, then the value of $24A$ is equal to ..... .

52. Let $f(x) = \min\left\{\sin^{-1} x, \cos^{-1} x, \frac{\pi}{6}\right\}$, $x \in [0, 1]$. If area bounded by $y = f(x)$ and X-axis, between the lines $x = 0$ and $x = 1$ is $\frac{a - X}{b(\sqrt{3} + 1)}$. Then, $(a - b)$ is ..... .

53. Let f be a real valued function satisfying $f\left(\frac{x}{y}\right) = f(x) - f(y)$ and $\lim\limits_{x \to 0} \frac{f(1 + x)}{x} = 3$. Find the area bounded by the curve $y = f(x)$, the Y-axis and the line $y = 3$, where $x, y \in R^+$.

Area of Bounded Regions Exercise 7 :
Subjective Type Questions

54. Find a continuous function 'f', $(x^4 - 4x^2) \le f(x) \le (2x^2 - x^3)$ such that the area bounded by $y = f(x)$, $y = x^4 - 4x^2$, the Y-axis and the line $x = t, (0 \le t \le 2)$ is k times the area bounded by $y = f(x)$, $y = 2x^2 - x^3$, Y-axis and line $x = t, (0 \le t \le 2)$.

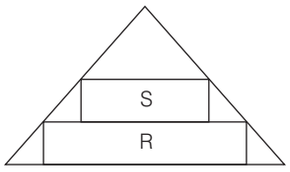
55. Let $f(t) = |t-1| - |t| + |t+1|, \forall\, t \in R$ and $g(x) = \max\{f(t) : x+1 \le t \le x+2\}; \forall\, x \in R$. Find $g(x)$ and the area bounded by the curve $y = g(x)$, the X-axis and the lines $x = -3/2$ and $x = 5$.

56. Let $f(x) = \text{minimum}\{e^x, 3/2, 1 + e^{-x}\}, 0 \le x \le 1$. Find the area bounded by $y = f(x)$, X-axis, Y-axis and the line $x = 1$.

57. Find the area bounded by $y = f(x)$ and the curve $y = \dfrac{2}{1+x^2}$, where f is a continuous function satisfying the conditions $f(x) \cdot f(y) = f(xy), \forall\, x, y \in R$ and $f'(1) = 2$, $f(1) = 1$.

58. Find out the area bounded by the curve $y = \int_{1/8}^{\sin^2 x} (\sin^{-1}\sqrt{t})\, dt + \int_{1/8}^{\cos^2 x} (\cos^{-1}\sqrt{t})\, dt \; (0 \le x \le \pi/2)$ and the curve satisfying the differential equation $y(x + y^3)\, dx = x(y^3 - x)\, dy$ passing through $(4, -2)$.

59. Let T be an acute triangle. Inscribe a pair R, S of rectangles in T as shown :

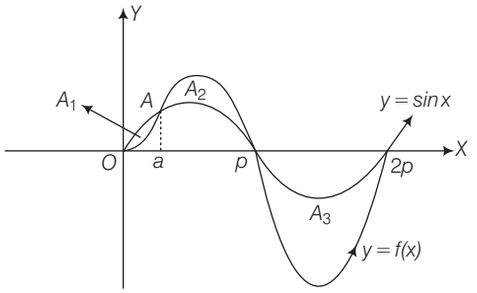


Let $A(x)$ denote the area of polygon X find the maximum value (or show that no maximum exists), of $\dfrac{A(R) + A(S)}{A(T)}$, where T ranges over all triangles and R, S over all rectangles as above.

60. Find the maximum area of the ellipse that can be inscribed in an isosceles triangles of area A and having one axis lying along the perpendicular from the vertex of the triangles to its base.

61. In the adjacent figure the graphs of two function $y = f(x)$ and $y = \sin x$ are given. $y = \sin x$ intersects, $y = f(x)$ at $A(a, f(a))$; $B(\pi, 0)$ and $C(2\pi, 0)$.

A_i $(i = 1, 2, 3)$ is the area bounded by the curves $y = f(x)$ and $y = \sin x$. between $x = 0$ and $x = a$; $i = 1$



between $x = a$ and $x = \pi$; $i = 2$ between $x = \pi$ and $x = 2\pi$; $i = 3$.

If $A_1 = 1 - \sin a + (a-1)\cos a$, determine the function $f(x)$. Hence, determine a and A_1. Also, calculate A_2 and A_3.

62. Find the area of the region bounded by curve $y = 25^x + 16$ and the curve $y = b \cdot 5^x + 4$, whose tangent at the point $x = 1$ make an angle $\tan^{-1}(40 \ln 5)$ with the X-axis.

63. If the circles of the maximum area inscribed in the region bounded by the curves $y = x^2 - x - 3$ and $y = 3 + 2x - x^2$, then the area of region $y - x^2 + 2x + 3 \le 0, y + x^2 - 2x - 3 \le 0$ and $s \le 0$.

64. Find limit of the ratio of the area of the triangle formed by the origin and intersection points of the parabola $y = 4x^2$ and the line $y = a^2$, to the area between the parabola and the line as a approaches to zero.

65. Find the area of curve enclosed by : $|x + y| + |x - y| \le 4, |x| \le 1, y \ge \sqrt{x^2 - 2x + 1}$.

66. Calculate the area enclosed by the curve $4 \le x^2 + y^2 \le 2(|x| + |y|)$.

67. Find the area enclosed by the curve $[x] + [y] = 4$ in 1st quadrant (where [.] denotes greatest integer function).

68. Sketch the region and find the area bounded by the curves $|y + x| \le 1, |y - x| \le 1$ and $2x^2 + 2y^2 = 1$.

69. Find the area of the region bounded by the curve, $2^{|x|}|y| + 2^{|x|-1} \le 1$, with in the square formed by the lines $|x| \le 1/2, |y| \le 1/2$.

70. Find all the values of the parameter $a\,(a \le 1)$ for which the area of the figure bounded by the pair of straight lines $y^2 - 3y + 2 = 0$ and the curves $y = [a]x^2$, $y = \dfrac{1}{2}[a]x^2$ is the greatest, where [.] denotes greatest integer function.

71. If $f(x)$ is positive for all positive values of X and $f'(x) < 0, f''(x) > 0, \forall\, x \in R^+$, prove that $\dfrac{1}{2}f(1) + \int_1^n f(x)\, dx < \sum_{r=1}^{n} f(r) < \int_1^n f(x)\, dx + f(1)$.

Area of Bounded Regions Exercise 8 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

72. Area of the region $\{(x, y)\} \in R^2 : y \geq \sqrt{|x+3|}$, $5y \leq (x+9) \leq 15\}$ is equal to **[Single Correct Option 2016]**

(a) $\frac{1}{6}$ (b) $\frac{4}{3}$ (c) $\frac{3}{2}$ (d) $\frac{5}{3}$

73. Let $F(x) = \int_x^{x^2 + \frac{\pi}{6}} 2\cos^2 t \, dt$ for all $x \in R$ and $f : \left[0, \frac{1}{2}\right] \to [0, \infty)$ be a continuous function. For $a \in \left[0, \frac{1}{2}\right]$, if $F'(a) + 2$ is the area of the region bounded by $x = 0$, $y = 0$, $y = f(x)$ and $x = a$, then $f(0)$ is **[Integer Answer Type 2015]**

74. The common tangents to the circle $x^2 + y^2 = 2$ and the parabola $y^2 = 8x$ touch the circle at the points P, Q and the parabola at the points R, S. Then, the area (in sq units) of the quadrilateral $PQRS$ is **[Single Correct Option 2014]**

(a) 3 (b) 6 (c) 9 (d) 15

75. The area enclosed by the curves $y = \sin x + \cos x$ and $y = |\cos x - \sin x|$ over the interval $\left[0, \frac{\pi}{2}\right]$ is **[Single Correct Option 2014]**

(a) $4(\sqrt{2} - 1)$ (b) $2\sqrt{2}(\sqrt{2} - 1)$

(c) $2(\sqrt{2} + 1)$ (d) $2\sqrt{2}(\sqrt{2} + 1)$

76. If S be the area of the region enclosed by $y = e^{-x^2}$, $y = 0$, $x = 0$ and $x = 1$. Then, **[More than One Option Correct 2012]**

(a) $S \geq \frac{1}{e}$ (b) $S \geq 1 - \frac{1}{e}$

(c) $S \leq \frac{1}{4}\left(1 + \frac{1}{\sqrt{e}}\right)$ (d) $S \leq \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{e}}\left(1 - \frac{1}{\sqrt{2}}\right)$

77. Let $f : [-1, 2] \to [0, \infty)$ be a continuous function such that $f(x) = f(1-x), \forall x \in [-1, 2]$. If $R_1 = \int_{-1}^{2} x f(x)\, dx$ and R_2 are the area of the region bounded by $y = f(x)$, $x = -1$, $x = 2$ and the X-axis. Then, **[Single Correct Option 2011]**

(a) $R_1 = 2R_2$ (b) $R_1 = 3R_2$ (c) $2R_1 = R_2$ (d) $3R_1 = R_2$

78. If the straight line $x = b$ divide the area enclosed by $y = (1-x)^2$, $y = 0$ and $x = 0$ into two parts $R_1 (0 \leq x \leq b)$ and $R_2 (b \leq x \leq 1)$ such that $R_1 - R_2 = \frac{1}{4}$. Then, b equals to **[Single Correct Option 2011]**

(a) $\frac{3}{4}$ (b) $\frac{1}{2}$ (c) $\frac{1}{3}$ (d) $\frac{1}{4}$

79. Area of the region bounded by the curve $y = e^x$ and lines $x = 0$ and $y = e$ is **[More than One Option Correct 2009]**

(a) $e - 1$ (b) $\int_1^e \ln(e + 1 - y)\, dy$

(c) $e - \int_0^1 e^x\, dx$ (d) $\int_1^e \ln y\, dy$

80. The area of the region between the curves $y = \sqrt{\frac{1+\sin x}{\cos x}}$ and $y = \sqrt{\frac{1-\sin x}{\cos x}}$ and bounded by the lines $x = 0$ and $x = \frac{\pi}{4}$ is **[Single Correct Option 2008]**

(a) $\int_0^{\sqrt{2}-1} \frac{t}{(1+t^2)\sqrt{1-t^2}}\, dt$ (b) $\int_0^{\sqrt{2}-1} \frac{4t}{(1+t^2)\sqrt{1-t^2}}\, dt$

(c) $\int_0^{\sqrt{2}+1} \frac{4t}{(1+t^2)\sqrt{1-t^2}}\, dt$ (d) $\int_0^{\sqrt{2}+1} \frac{t}{(1+t^2)\sqrt{1-t^2}}\, dt$

■ **Directions** (Q. Nos. 81 to 83) Consider the functions defined implicity by the equation $y^3 - 3y + x = 0$ on various intervals in the real line. If $x \in (-\infty, -2) \cup (2, \infty)$, the equation implicitly defines a unique real-valued differentiable function $y = f(x)$. If $x \in (-2, 2)$, the equation implicitly defines a unique real-valued differentiable function $y = g(x)$, satisfying $g(0) = 0$. **[Passage Based Questions 2008]**

81. If $f(-10\sqrt{2}) = 2\sqrt{2}$, then $f''(-10\sqrt{2})$ is equal to

(a) $\frac{4\sqrt{2}}{7^3 3^2}$ (b) $-\frac{4\sqrt{2}}{7^3 3^2}$

(c) $\frac{4\sqrt{2}}{7^3 3}$ (d) $-\frac{4\sqrt{2}}{7^3 3}$

82. The area of the region bounded by the curve $y = f(x)$, the X-axis and the lines $x = a$ and $x = b$, where $-\infty < a < b < -2$, is

(a) $\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}\, dx + bf(b) - af(a)$

(b) $-\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}\, dx + bf(b) - af(a)$

(c) $\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}\, dx - bf(b) + af(a)$

(d) $-\int_a^b \frac{x}{3[\{f(x)\}^2 - 1]}\, dx - bf(b) + af(a)$

83. $\int_{-1}^{1} g'(x)\, dx$ is equal to

(a) $2g(-1)$ (b) 0 (c) $-2g(1)$ (d) $2g(1)$

(ii) JEE Main & AIEEE

84. The area (in sq. units) of the region **[2017 JEE Main]**
$\{(x, y): x \geq 0, x + y \leq 3, x^2 \leq 4y\}$ and $y \leq 1 + \sqrt{x}\}$ is
(a) $\frac{5}{2}$ (b) $\frac{59}{12}$ (c) $\frac{3}{2}$ (d) $\frac{7}{3}$

85. The area (in sq units) of the region $\{(x, y): y^2 \geq 2x$ and $x^2 + y^2 \leq 4x, x \geq 0, y \geq 0\}$ is **[2016 JEE Main]**
(a) $\pi - \frac{4}{3}$ (b) $\pi - \frac{8}{3}$
(c) $\pi - \frac{4\sqrt{2}}{3}$ (d) $\frac{\pi}{2} - \frac{2\sqrt{2}}{3}$

86. The area (in sq units) of the region described by $\{(x, y): y^2 \leq 2x$ and $y \geq 4x - 1\}$ is **[2015 JEE Main]**
(a) $\frac{7}{32}$ (b) $\frac{5}{64}$
(c) $\frac{15}{64}$ (d) $\frac{9}{32}$

87. The area (in sq units) of the quadrilateral formed by the tangents at the end points of the latusrectum to the ellipse $\frac{x^2}{9} + \frac{y^2}{5} = 1$ is **[2015 JEE Main]**
(a) $\frac{27}{4}$ (b) 18
(c) $\frac{27}{2}$ (d) 27

88. The area of the region described by $A = \{(x, y): x^2 + y^2 \leq 1$ and $y^2 \leq 1 - x\}$ is **[2014 JEE Main]**
(a) $\frac{\pi}{2} + \frac{4}{3}$ (b) $\frac{\pi}{2} - \frac{4}{3}$
(c) $\frac{\pi}{2} - \frac{2}{3}$ (d) $\frac{\pi}{2} + \frac{2}{3}$

89. The area (in sq units) bounded by the curves $y = \sqrt{x}$, $2y - x + 3 = 0$, X-axis and lying in the first quadrant is **[2013 JEE Main]**
(a) 9 (b) 36
(c) 18 (d) $\frac{27}{4}$

90. The area bounded between the parabolas $x^2 = \frac{y}{4}$ and $x^2 = 9y$ and the straight line $y = 2$ is **[2012 AIEEE]**
(a) $20\sqrt{2}$ (b) $\frac{10\sqrt{2}}{3}$
(c) $\frac{20\sqrt{2}}{3}$ (d) $10\sqrt{2}$

91. The area of the region enclosed by the curves $y = x$, $x = e$, $y = \frac{1}{x}$ and the positive X-axis is **[2011 AIEEE]**
(a) 1 sq unit (b) $\frac{3}{2}$ sq units
(c) $\frac{5}{2}$ sq units (d) $\frac{1}{2}$ sq unit

92. The area bounded by the curves $y = \cos x$ and $y = \sin x$ between the ordinates $x = 0$ and $x = \frac{3\pi}{2}$ is **[2010 AIEEE]**
(a) $(4\sqrt{2} - 2)$ sq units (b) $(4\sqrt{2} + 2)$ sq units
(c) $(4\sqrt{2} - 1)$ sq units (d) $(4\sqrt{2} + 1)$ sq units

93. The area of the region bounded by the parabola $(y - 2)^2 = x - 1$, the tangent to the parabola at the point $(2, 3)$ and the X-axis is **[2009 AIEEE]**
(a) 6 sq units (b) 9 sq units
(c) 12 sq units (d) 3 sq units

94. The area of the plane region bounded by the curves $x + 2y^2 = 0$ and $x + 3y^2 = 1$ is equal to **[2008 AIEEE]**
(a) $\frac{5}{3}$ sq units (b) $\frac{1}{3}$ sq unit
(c) $\frac{2}{3}$ sq unit (d) $\frac{4}{3}$ sq units

Solutions

1. Here, $[x+y]=[x]-1$

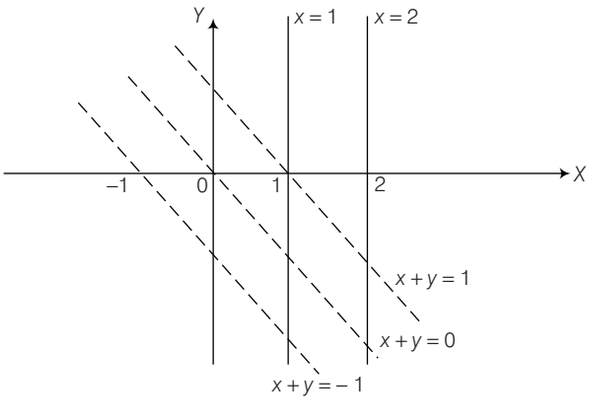
when $x \in [0,1) \Rightarrow [x+y]=-1$

$$-1 \le x+y<0 \quad \text{...(i)}$$

when $x \in [1,2) \Rightarrow [x+y]=0$

$$\therefore \quad 0 \le x+y<1 \quad \text{...(ii)}$$

which can be shown, as



$\therefore$ Required area $= 2$

2. Required area $= 2\int_0^{1/2} f^{-1}(x)\,dx$

Let, $f^{-1}(x)=t \Rightarrow x=f(t)$

$$dx=f'(t)dt$$

$$\therefore \quad A=2\int_0^1 (t\cdot f'(t)dt$$

$$=2\left[\left(t\cdot f\ (t)\right)_0^1-\int_0^1 1\cdot f(t)dt\right]$$

$$=2\left[f(1)-\int_0^1 \frac{t}{1+t^2}\,dt\right]$$

$$=2\left[f(1)-\frac{1}{2}\left(\log(1+t^2)\right)_0^1\right]$$

$$=2\left[f(1)-\frac{1}{2}\log 2\right]$$

$$=2\left[\frac{1}{2}-\frac{1}{2}\log 2\right]=1-\log 2=\log\left(\frac{e}{2}\right)$$

3. Here, $E_1:\dfrac{\left(\frac{x+y-1}{\sqrt{2}}\right)^2}{12}+\dfrac{\left(\frac{x-y+3}{\sqrt{2}}\right)^2}{(\sqrt{2})^2}=1$

Length of latusrectum $= 2\dfrac{a^2}{b}=\dfrac{2}{\sqrt{2}}=\sqrt{2}$

Now, $\dfrac{2p^2}{\sqrt{p}}=\sqrt{2} \Rightarrow p^{3/2}=2^{-1//2}$

$\Rightarrow \quad P=2^{-1/3}$

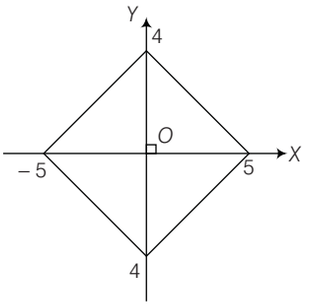
$\therefore \quad E_2:\dfrac{x^2}{2^{-1/3}}+\dfrac{y^2}{4^{-1/3}}=1$

Area of ellipse E_2, is

$$\pi\cdot\sqrt{p}\cdot p=\pi\ p^{3/2}=\frac{\pi}{\sqrt{2}}$$

4. Area of bounded region by $4\,|x-2017^{2017}|+5\,|y-2017^{2017}|\le 20$, is same as area of the region bounded by $4|x|+5|y|\le 20$.

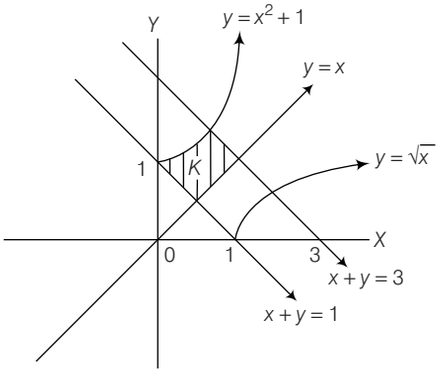
$\Rightarrow \quad 4\times\dfrac{1}{2}\times 4\times 5=40$



5. Here, $y=x^2+1$ and $y=\sqrt{x-1}$ are inverse of each other.

The shaded area is given K units

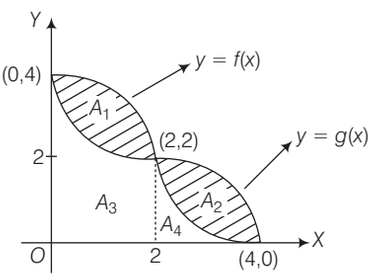
$\Rightarrow$ Area of the region bounded by $y=x^2+1, y=\sqrt{x-1}$ and $(x+y-1)(x+y-3)=0$, is $2K$ units.



6. Given, $\int_0^4 f(x)\,dx-\int_0^4 g(x)\,dx=10$

$$(A_1+A_3+A_4)-(A_2+A_3+A_4)=10$$

$$A_1-A_2=10 \quad \text{...(i)}$$



Again, $\int_2^4 g(x)\,dx-\int_2^4 f(x)\,dx=5$

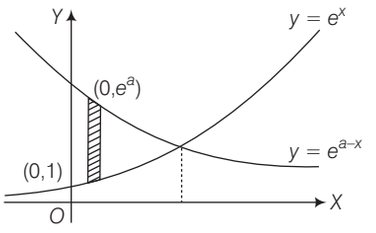
$$(A_2+A_4)-A_4=5$$

$$A_2=5 \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii),

$$A_1=15$$

7. Solving, $e^x = e^{a-x}$, we get $e^{2x} = e^a \Rightarrow x = \frac{a}{2}$



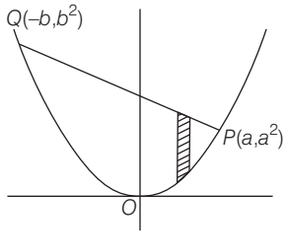
$$S = \int_0^{a/2} (e^a \cdot e^{-x} - e^x)\, dx = [-(e^a \cdot e^{-x} + e^x)]_0^{a/2}$$

$$= (e^a + 1) - (e^{a/2} + e^{a/2}) = e^a - 2e^{a/2} + 1 = (e^{a/2} - 1)^2$$

$$\therefore \quad \frac{S}{a^2} = \left(\frac{e^{a/2}-1}{a}\right)^2 = \frac{1}{4}\left(\frac{e^{a/2}-1}{a/2}\right)^2$$

$$\therefore \quad \lim_{a\to 0} \frac{S}{a^2} = \frac{1}{4}$$

8. $m_{PQ} = \frac{a^2 - b^2}{a+b} = a - b$ equation of PQ



$$y - a^2 = \frac{a^2 - b^2}{a+b}(x - a) \quad \text{or} \quad y - a^2 = (a-b)(x-a)$$

$$y = a^2 + x(a-b) - a^2 + ab$$

$$y = (a-b)x + ab$$

$$\therefore \quad S_1 = \int_{-b}^{a} ((a-b)x + ab - x^2)\, dx$$

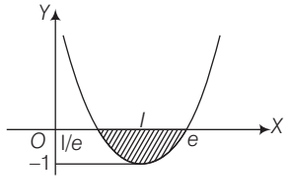
which simplifies to $\frac{(a+b)^3}{6}$. ...(i)

Also, $S_2 = \frac{1}{2}\begin{vmatrix} a & a^2 & 1 \\ -b & b^2 & 1 \\ 0 & 0 & 1 \end{vmatrix} = \frac{1}{2}[ab^2 + a^2 b] = \frac{1}{2}ab\,(a+b)$ ...(ii)

$$\therefore \quad \frac{S_1}{S_2} = \frac{(a+b)^3}{6} \cdot \frac{2}{ab\,(a+b)} = \frac{(a+b)^2}{3ab} = \frac{1}{3}\left[\frac{a}{b} + \frac{b}{a} + 2\right]$$

$$\therefore \quad \left.\frac{S_1}{S_2}\right|_{\min} = \frac{4}{3}$$

9. $y = \ln^2 x - 1 \Rightarrow y' = \frac{2\ln x}{x} = 0 \quad \Rightarrow \quad x = 1$



$x > 1$, y increasing and $0 < x < 1$, y is decreasing

$$A = \left| \int_{1/e}^{e} (\ln^2 x - 1)\, dx \right|$$

$$= \left| \int_{1/e}^{e} \ln^2 x\, dx - \int_{1/e}^{e} dx \right|$$

$$= \left| [x \ln^2 x]_{1/e}^{e} - 2\int_{1/e}^{e} \left(\frac{\ln x}{x}\right) \cdot x\, dx - \left(e - \frac{1}{e}\right) \right|$$

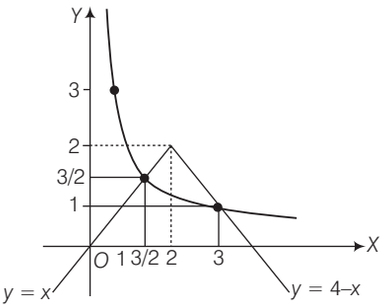
$$= \left| \left(e - \frac{1}{e}\right) - 2\int_{1/e}^{e} \left(\frac{\ln x}{x}\right) \cdot x\, dx - \left(e - \frac{1}{e}\right) \right|$$

$$= \left| -2\left[[x \ln x]_{1/e}^{e} - \int_{1/e}^{e} dx \right] \right|$$

$$= \left| -2\left[\left(e + \frac{1}{e}\right) - \left(e - \frac{1}{e}\right) \right] \right| = \left|\frac{4}{e}\right| = \frac{4}{e}$$

10. $y = \begin{cases} 2 - (2 - x), & \text{if } x \le 2 = x \\ 2 - (x - 2), & \text{if } x \ge 2 = 4 - x \end{cases} = \begin{cases} x, & \text{if } x \le 2 \\ 4 - x, & \text{if } x \ge 2 \end{cases}$

Also, $y = \begin{cases} \frac{3}{x}, & \text{if } x > 0 \\ -\frac{3}{x}, & \text{if } x < 0 \end{cases}$



$$A = \int_{3/2}^{2} \left(x - \frac{3}{x}\right) dx + \int_{2}^{3} \left((4 - x) - \frac{3}{x}\right) dx$$

$$= \left[\frac{x^2}{2} - 3\ln x\right]_{3/2}^{2} + \left[4x - \frac{x^2}{2} - 3\ln x\right]_{2}^{3}$$

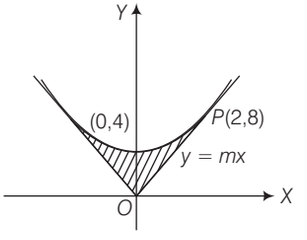
$$= \left[2 - 3\ln 2 - \left(\frac{9}{8} - 3\ln\frac{3}{2}\right)\right] + \left[12 - \frac{9}{2} - 3\ln 3 - (8 - 2 - \ln 2)\right]$$

$$= \frac{7}{8} - 3\ln 2 + 3\ln 3 - 3\ln 2 + \frac{3}{2} - 3\ln 3 + 3\ln 2 = \frac{19}{8} - 3\ln 2$$

11. Given, $g(x) = 2x + 1$; $h(x) = (2x+1)^2 + 4$

Now, $h(x) = f[g(x)]$

$$(2x+1)^2 + 4 = f(2x+1)$$



Let $2x+1=t \Rightarrow f(t)=t^2+4$

$\therefore$ $f(x)=x^2+4$ ...(i)

Solving, $y=mx$ and $y=x^2+4$

$x^2-mx+4=0$

Put $D=0$; $m^2=16 \Rightarrow m=\pm 4$

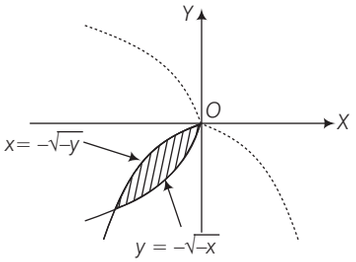
Tangents are $y=4x$ and $y=-4x$

$$A=2\int_0^2[(x^2+4)-4x]\,dx=2\int_0^2(x-2)^2dx$$

$$=\left[\frac{2}{3}(x-2)^3\right]_0^2=\frac{16}{3}\text{ sq units}$$

12. $y=-\sqrt{-x} \Rightarrow y^2=-x$, where x and y both negative

$x=-\sqrt{-y} \Rightarrow x^2=-y$, where x and y both negative

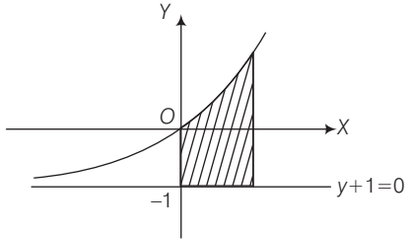


Since, $A=\frac{16ab}{3}$ where, $a=b=\frac{1}{4}$

$\therefore$ $A=\frac{1}{3}$

13. $\frac{f''(x)}{f'(x)}=1.$

Integrating, $\ln f'(x)=x+C$, $f'(0)=1 \Rightarrow C=0$

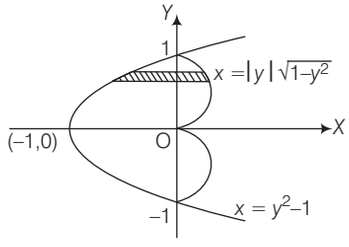


$f'(x)=e^x f(x)=e^x+k$, $f(0)=0 \Rightarrow k=-1$

$f(x)=e^x-1$

Area $=\int_0^1(e^x-1+1)\,dx=[e^x]_0^1=e-1$

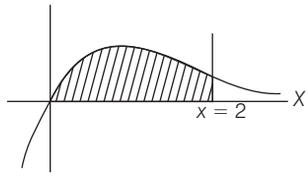
14. $A=2\int_0^1[y\sqrt{1-y^2}-(y^2-1)]\,dy=2$



15. $y=xe^{-x}$

$y'=e^{-x}-xe^{-x}=(1-x)e^{-x}$ increasing for $x<1$

$y''=-e^{-x}-[e^{-x}-xe^{-x}]=e^{-x}[-1-1+x]=(x-2)e^{-x}$



For point of inflection $y''=0 \Rightarrow x=2$

$$A=\int_0^2 xe^{-x}dx=[-xe^{-x}]_0^2+\int_0^2 e^{-x}=(-2e^{-2})-(e^{-x})_0^2$$

$$=-2e^{-2}-(e^{-2}-1)=1-e^{-2}-2e^{-2}=1-3e^{-2}$$

16. $(a, 0)$ lies on the given curve

$\therefore$ $0=\sin 2a-\sqrt{3}\sin a \Rightarrow \sin a=0$ or $\cos a=\sqrt{3}/2$

$\Rightarrow$ $a=\frac{\pi}{6}$ (as $a>0$ and the first point of intersection with positive X-axis)

and $A=\int_0^{\pi/6}(\sin 2x-\sqrt{3}\sin x)\,dx=\left(-\frac{\cos 2x}{2}+\sqrt{3}\cos x\right)_0^{\pi/6}$

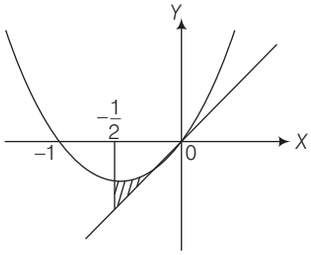
$$=\left(-\frac{1}{4}+\frac{3}{2}\right)-\left(-\frac{1}{2}+\sqrt{3}\right)=\frac{7}{4}-\sqrt{3}=\frac{7}{4}-2\cos a$$

$\Rightarrow$ $4A+8\cos a=7$

17. $x=1; y=2$

$2=a+b+c$ ...(i)

$x=0, y=0 \Rightarrow c=0 \Rightarrow a+b=2$



Now, $\left.\frac{dy}{dx}\right|_{(0,0)}=2a\ x+b=1$

$\therefore$ $b=1, a=1$

Hence, the curve is $y=x^2+x$

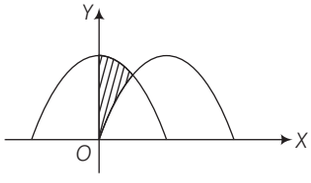
$$A=\int_{-\frac{1}{2}}^0(x^2+x-x)\,dx=\int_{-\frac{1}{2}}^0(x^2)\,dx=\frac{1}{24}\text{ sq units}$$

18. IF $=e^{-x}$

$\therefore$ $ye^{-x}=\int e^{-x}(\cos x-\sin x)\,dx$. Put $-x=t$

$$=-\int e^t(\cos t+\sin t)\,dt=-e^t\sin t+C$$

$ye^{-x}=e^{-x}\sin x+C$



Since, y is bounded when $x\to\infty \Rightarrow C=0$

$\therefore \quad y = \sin x$

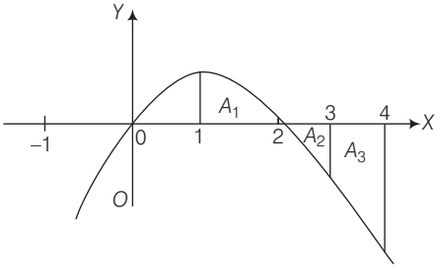
$$\text{Area} = \int_0^{\pi/4} (\cos x - \sin x)\, dx = \sqrt{2} - 1$$

19. $I = \int (6x - 3x^2)\, dx = \dfrac{6x^2}{2} - \dfrac{3x^3}{3} = 3x^2 - x^3 = x^2(3 - x)$

$A_1 = I(2) - I(1) = 4 - 2 = 2$ units

$A_2 = I(2) - I(3) = 4 - 0 = 4$ units

$A_3 = I(3) - I(4) = 0 - (-16) = 16$ units



$\Rightarrow$ One value of a will lie in (3, 4).

Using symmetry, other will lie in (−2, −1).

20. Required area, $A = \int_{\pi}^{2\pi} ((\sin x - x) + 2\pi)\, dx$

$$= \frac{\pi^2}{2} - 2 \text{ sq units}$$

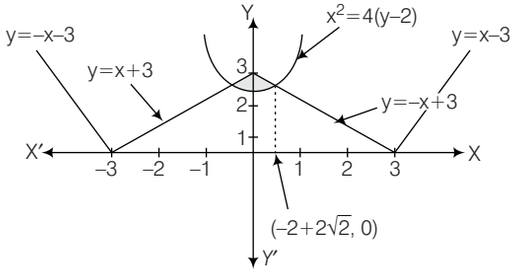
21. $g(x) = |\, f(|\, x\,|) - 2\,| = |\,|\, x\,| - 1 - 2\,| = |\,|\, x\,| - 3\,|$

$$= \begin{cases} (|\,x\,| - 3), & x < -3 \\ -(|\,x\,| - 3), & -3 \le x < 3 \\ |\,x\,| - 3 & x \ge 3 \end{cases} = \begin{cases} -x - 3, & x < -3 \\ -(-x - 3), & -3 \le x < 0 \\ -(x - 3), & 0 \le x < 3 \\ x - 3, & x \ge 3 \end{cases}$$

$$= \begin{cases} -x - 3, & x < -3 \\ x + 3, & -3 \le x < 0 \\ -x + 3, & 0 \le x < 3 \\ x - 3, & x \ge 3 \end{cases}$$

Now, $\quad x^2 - 4y + 8 = 0$

$\Rightarrow \quad x^2 = 4(y - 2)$



For point of intersection,

$$x^2 - 4(-x + 3) + 8 = 0$$

$\Rightarrow \quad x^2 + 4x - 4 = 0$

$\Rightarrow \quad x = \dfrac{-4 \pm \sqrt{16 + 16}}{2} = -2 \pm 2\sqrt{2}$

$\therefore$ Point of intersection is at $x = -2 + 2\sqrt{2}$

$\therefore$ Required area $= 2\int_0^{-2+2\sqrt{2}} \left[(-x + 3) - \left(\dfrac{x^2 + 8}{4}\right)\right] dx$

$$= \frac{2}{4}\int_0^{-2+2\sqrt{2}} (4 - 4x - x^2)\, dx = \frac{1}{2}\left[4x - 2x^2 - \frac{x^3}{3}\right]_0^{-2+2\sqrt{2}}$$

$$= \frac{1}{6}\,[12x - 6\,x^2 - x^3]_0^{-2+2\sqrt{2}}$$

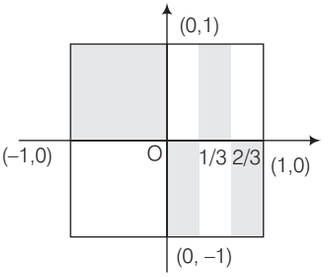
$$= \frac{1}{6}[12(-2 + 2\sqrt{2}) - 6(-2 + 2\sqrt{2})^2 - (-2 + 2\sqrt{2})^3]$$

$$= \frac{1}{6}\,[-24 + 24\sqrt{2} - 6(4 + 8 - 8\sqrt{2}) - (-8 + 16\sqrt{2}) + 24\sqrt{2} - 48]$$

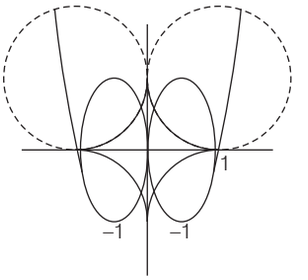
$$= \frac{1}{6}\,[-24 + 24\sqrt{2} - 72 + 48\sqrt{2} + 56 - 40\sqrt{2}]$$

$$= \frac{1}{6}\,[32\sqrt{2} - 40] = \frac{8}{6}(4\sqrt{2} - 5) = \frac{4}{3}(4\sqrt{2} - 5)$$

22. Shaded region represents $S \cap S'$ clearly area enclosed is 2 sq units.



23. Required area is $2\left[\int_0^{\alpha} ex \ln x\, dx + \int_1^{\alpha} (1 - \sqrt{1 - (x-1)^2})\, dx\right]$



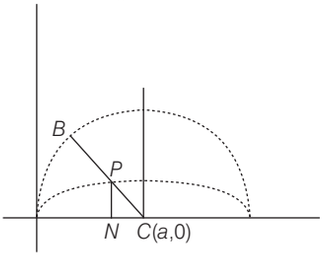
24. $y = \sqrt{2ax - x^2} \Rightarrow (x - a)^2 + y^2 = a^2$

Let $P(h,k)$ be a point, then $BP > PN$

For the bounded condition $BP = PN = k$

Now, $\quad AP = a - k = \sqrt{(h - a)^2 + k^2}$

$\Rightarrow \quad k = h - \dfrac{h^2}{2a}$



$\therefore$ Boundary of the region is $y = x - \frac{x^2}{2a}$

Required area $= 2\int_0^a \left(x - \frac{x^2}{2a}\right) dx = \frac{2a^2}{3}$

25. $f'(x) = 2x - a$. At (2, 4), $f'(x) = 4 - a$

Equation of normal at (2, 4) is $(y-4) = -\frac{1}{(4-a)}(x-2)$

Let point of intersection with X and Y-axes be A and B respectively, then

$$A \equiv (-4a + 18, 0)\ B \equiv \left(0, \frac{4a-18}{a-4}\right)$$

Since, $a > \frac{9}{2}$ as

$\therefore$ Area of triangle $= \frac{1}{2}(4a-18)\frac{(4a-18)}{(a-4)} = 2$

$\Rightarrow$ $(4a-17)(a-5) = 0$

$\Rightarrow$ $a = 5$ or $\frac{17}{4}$

26. Max $\{f(x), g(x)\} = \frac{1}{2}[|f(x)+g(x)|+|f(x)-g(x)|]$

Min $\{f(x), g(x)\} = \frac{1}{2}[|f(x)+g(x)|-|f(x)-g(x)|]$

$\therefore$ Area $= \int_a^b [\max\{f(x), g(x)\} - \min\{f(x), g(x)\}]\, dx$

27. Area bounded by parabola $y = x^2 - 7x + 10$ and X-axis is given by

$$\int_2^5 |x^2 - 7x + 10|\, dx = \int_2^5 |-x^2 + 7x - 10|\, dx = \frac{9}{2} \text{ sq units}$$

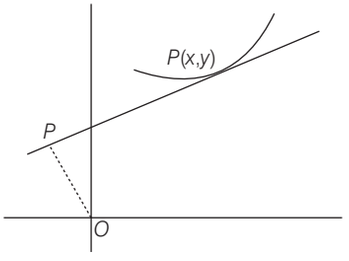
28. Area bounded by the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ will be the same as the area bounded by the ellipse $\frac{x^2}{b^2} + \frac{y^2}{a^2} = 1$ and πab

$\therefore$ Required area $= \pi(2)(3) = 6\pi$ sq units

29. $OP = x$

If slope is $\frac{dy}{dx}$, then equation of tangent is

$$Y - t = \frac{dy}{dx}(X - x)$$



Length of perpendicular from origin to this tangent is

$$x = \frac{Y - x\frac{dy}{dx}}{\sqrt{1 + \left(\frac{dy}{x}\right)^2}}$$

$$x^2\left\{1 + \left(\frac{dy}{dx}\right)^2\right\} = y^2 + x^2\left(\frac{dy}{dx}\right)^2 = 2xy\frac{dy}{dx}$$

$\Rightarrow$ $\frac{dy}{dx} = -\frac{x^2 - y^2}{2xy}$ [homogeneous form]

$$\frac{dy}{dx} = \frac{1-x}{y} = \frac{x - x^2}{xy} = \frac{\left[\frac{x^2+y^2}{2}\right] - x^2}{xy} = \frac{y^2 - x^2}{2xy}$$

Since, option (a) is true (equation of circle).

If option (a) is true (b) can't be (It is parabola).

If option (a) is true, option (c) is also true where $c = 1$.

30. $\therefore$ $\sin^2 x \le \sin x$, $\forall\ x \in (0, \pi)$

Therefore, area of $y = \sin^2 x$ will be lesser from area of $y = \sin x$.

Statement II is obviously true.

Hence, (d) is the correct answer.

31. Let the line $y = kx + 2$ cuts $y = x^2 - 3$ at $x = \alpha$ and $\alpha = \beta$, area bounded by the curves $= \int_\alpha^\beta (y_1 - y_2) = \int_\alpha^\beta \{(kx+2) - (x^2 - 3)\}\, dx$

$\Rightarrow$ $f(x) = \frac{(k^2+20)^{3/2}}{6}$

which clearly, shows the Statement II is false but $f(k)$ is least when $k = 0$.

Hence, (c) is the correct answer.

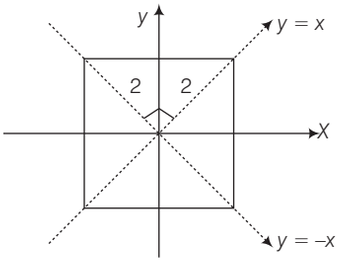
32. As of region bounded by parabola $y^2 = 4x$ and $x^2 = 4y$ is

$$\int_0^4 \left(2\sqrt{x} - \frac{x^2}{4}\right) dx = \left[\frac{4}{3}x^{3/2} - \frac{x^3}{12}\right]_0^4 = \frac{32}{3} - \frac{16}{3} = \frac{16}{3} \text{ sq units}$$

Hence, Statement I is false.

33. As the area enclosed by $|x| + |y| \le a$ is the area of square (i.e., $2a^2$).

$\therefore$Area enclosed by $|x+y| + |x-y| \le 2$ is area of square shown as



$\therefore$ Area $= 4\left(\frac{1}{2} \times 2 \times 2\right) = 8$ sq units

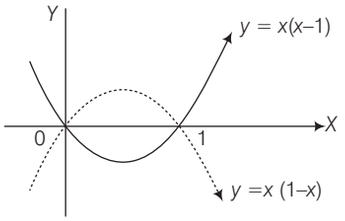
Also, the area enclosed by $|x+y| + |x-y| \le 2$ is symmetric about X-axis, Y-axis, $y = x$ and $y = -x$.

$\therefore$Both the Statements are true but Statement II is not the correct explanation of Statement I.

34. $\left|\int_a^b \{f(x) - g(x)\}\, dx\right|$ is true for all quadrants.

$\therefore$ Statement II is false.

The area bounded by $y = x(x-1)$ and $y = x(1-x)$.



$\therefore$ Area enclosed $= 2\int_0^1 x(1-x)\,dx = 2\left\{\frac{x^2}{2}-\frac{x^3}{3}\right\}_0^1$

$= 2\left(\frac{1}{2}-\frac{1}{3}\right) = 2\left(\frac{3-2}{6}\right) = \frac{1}{3}$

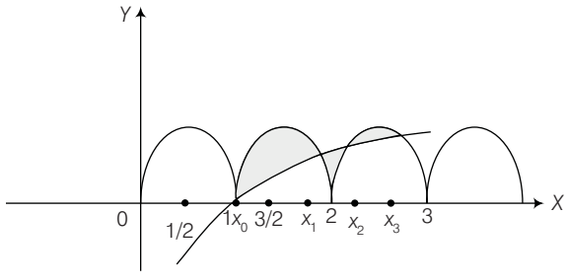
35. Since, absolute area

$= \int_{x_0}^{x_1} h(x)\,dx + \int_{x_1}^{x_2} -h(x)\,dx + \int_{x_2}^{x_3} h(x)\,dx$

$= \sum_{r=0}^{n} \int_{x_r}^{x_{r+1}} (-1)^r \cdot h(x)\,dx$

36. Also, $x_{n+1} = x_3 \Rightarrow n = 2$

37. Required area $= \int_0^1 \sin^4 \pi x\,dx - \int_0^1 \log_e x\,dx = \frac{11}{8}$



38. $f(x) = \frac{x^2-ax+1}{x^2+ax+1}$

For differentiation, better write $f(x)$ as

$$f(x) = 1 - \frac{2ax}{x^2+ax+1}$$

Now, on differentiation $f(x) = \frac{2a(x^2-1)}{(x^2+ax+1)^2}$ ...(i)

$$f'(1) = 0 = f'(-1)$$

Then, the options (b) and (d) are eliminated.

Again, for the differentiating Eq. (i) gives

$$(x^2+ax+1)^2 \cdot 2x - (x^2-1)$$

$$f''(x) = 2a \cdot \frac{2(x^2+ax+1)(2x+a)}{(x^2+ax+1)^4}$$

$$f''(-1) = -\frac{4a}{(2-a)^2},\ f''(1) = -\frac{4a}{(2+a)^2}$$

Combining both $f''(1)(2+a)^2 + f''(-1)(2-a)^2 = 0$

39. $f'(x) = 2a\frac{(x^2-1)}{(x^2+ax+1)^2} = 2a\frac{(x-1)(x+1)}{(x^2+ax+1)^2}$

If is easily seen that $f(x)$ decreases on $(-1,1)$ and has a local minimum at $x = 1$, because the derivatives changes its sign from negative to positive.

40. $\because$ $g'(x) = \frac{f'(e^x)e^x}{1+e^{2x}}$

Now, $f'(e^x) = \frac{2a\cdot(e^{2x}-1)}{(e^{2x}+ae^x+1)^2}$

It is seen from the above that $f'(e^x)$ and so $g'(x)$ is positive on $(0,\infty)$ and negative on $(-\infty,0)$.

41. Clearly, $x = a\sin^3 t, y = a\cos^3 t, (0 \le t \le 2\pi)$

$$S = \int_0^{2\pi} a\sin^3 t \cdot a \cdot 3\sin^2 t(-\sin t)\,dt$$

$$= -3a^2 \times \int_0^{\pi/2} \sin^4 t\cos^2 t\,dt$$

$$= -3a^2 \times \frac{\sqrt{\frac{5}{2}}\sqrt{\frac{3}{2}}}{2\sqrt{\frac{4+2+2}{2}}} = -3a^2\frac{\frac{3}{2}\times\frac{1}{2}\sqrt{\pi}\times\frac{1}{2}\sqrt{\pi}}{2\times3\times2\times1}$$

$$= -\frac{3}{8}\pi a^2 = \frac{3}{8}\pi a^2 \qquad \text{[absolute value]}$$

42. $S = -\int_0^{2\pi} a(1-\cos t)a(1-\cos t)\,dt$

$$= -a^2\int_0^{2\pi}(1-2\cos t+\cos^2 t)\,dt$$

$$= -a^2\int_0^{2\pi}\left(1-2\cos t+\left(\frac{1+\cos 2t}{2}\right)\right)dt$$

$$= -\frac{a^2}{2}\int_0^{2\pi}[3-4\cos t+\cos 2t]_0^{2\pi}$$

$$= -3\pi a^2 = 3\pi a^2 \qquad \text{[absolute value]}$$

43. $x = \frac{t}{3}(6-t) = \frac{1}{3}(6t-t^2),\ \ y = \frac{t^2}{8}(6-t) = \frac{1}{8}(6t^2-t^3)$

$\therefore$ Area $= \int_0^6 \frac{t}{3}(6-t)\cdot\frac{1}{8}(12t-13t^2)dt$

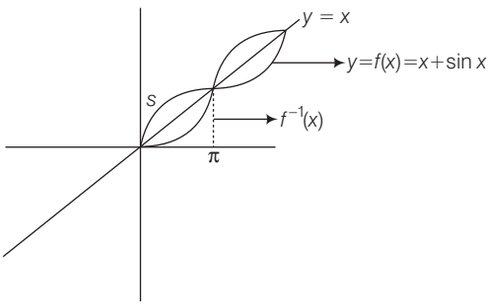
$$= \frac{1}{8}\int_0^6 (t^4+24t^2-10t^3)\,dt = \frac{1}{8}\left[\frac{t^5}{5}+8t^3-\frac{5}{2}t^4\right]_0^6$$

$$= \frac{1}{8}\left[\frac{7776}{5}+1728-3240\right] = \frac{216}{5\times8} = \frac{27}{5} \text{ sq units}$$

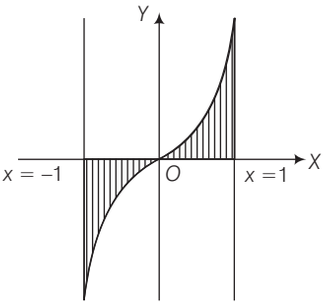
44. (A) Required area = 4s

$$s = \int_0^{\pi}(x+\sin x)\,dx - \int_0^{\pi} x\,dx$$

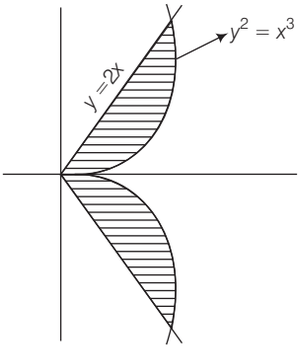
$$= \frac{\pi^2}{2} - \cos\pi + \cos 0 - \frac{\pi^2}{2} = 2 \text{ sq units}$$



(B) Required area $= 2\int_0^1 xe^x\,dx = 2[xe^x - e^x]_0^1 = 2$



(C) $y^2 = x^3$ and $|y| = 2x$ both the curve are symmetric about Y-axis

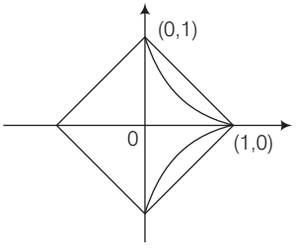


$4x^2 = x^3 \Rightarrow x = 0, 4$

Required area $= 2\int_0^4 (2x - x^{3/2})\,dx = \frac{16}{5}$

(D) $\sqrt{x} + \sqrt{|y|} = 1$

Above curve is symmetric about X-axis



$\sqrt{|y|} = 1 - \sqrt{x}$ and $\sqrt{x} = 1 - \sqrt{|y|}$

$\Rightarrow$ for $x > 0, y > 0, \sqrt{y} = 1 - \sqrt{x}$

$$\frac{1}{2\sqrt{y}}\frac{dy}{dx} = -\frac{1}{2\sqrt{x}}$$

$$\frac{dy}{dx} = -\sqrt{\frac{x}{y}}$$

$$\frac{dy}{dx} < 0$$

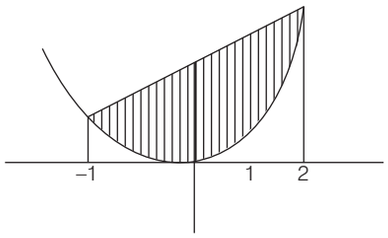
Function is decreasing required area $= \int_0^1 (2\sqrt{x} - 2x) = \frac{1}{3}$.

45. (A) The area = 2 unit

(B) Area enclosed $= \int_0^{\pi} \sin x\,dx = 2$

(C) The line $y = x + 2$ intersects $y = x^2$ at $x = -1$ and $x = 2$

The given region is shaded region area

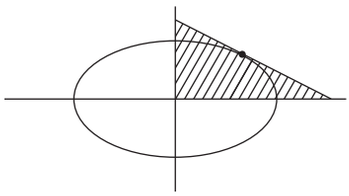


$$= \frac{15}{2} - \int_{-1}^{2} x^2\,dx = \frac{9}{2}$$

(D) Here, $a^2 = 9, b^2 = 5, b^2 = a^2(1 - e^2)$

$\Rightarrow \quad e^2 = \frac{4}{9} \Rightarrow = \frac{2}{3}$

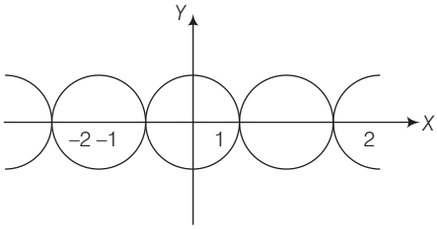
Equation of tangent at $\left(2, \frac{5}{3}\right)$ is $\frac{2x}{9} + \frac{y}{3} = 1$



x-intercept $= \frac{9}{2}$, y-intercept = 3

Area $= 4 \times \frac{9}{2} \times 3 \times \frac{1}{2} = 27$ sq units

46.



Area is given by $A = 2\int_0^1 (x^2 - 3x + 2)\,dx = \frac{5}{3}$

$\Rightarrow \quad 3A + 2 = 3 \cdot \frac{5}{3} + 2 = 7$

47. For $c < 1; \int_c^1 (8x^2 - x^5)\,dx = \frac{1}{3}$

$\Rightarrow \quad \frac{8}{3} - \frac{1}{6} - \frac{8c^3}{3} - \frac{c^6}{6} = \frac{16}{6}$

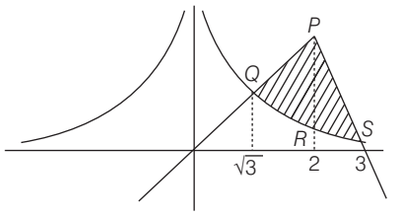
$\Rightarrow \quad c^3\left[-\frac{8}{3} + \frac{c^3}{6}\right] = \frac{16}{3} - \frac{8}{3} + \frac{1}{6} = \frac{17}{6}$

$\Rightarrow \quad c = -1$

Again, for $c \geq 1$ none of the values of c satisfy the required condition that

$\int_1^c (8x^2 - x^5)\,dx = \frac{16}{3} \Rightarrow c + 2 = 1$

48. $y=\begin{cases} x; & x<2 \\ 4-x; & x\geq 2 \end{cases}$ and $y=\begin{cases} 3/x; & x>0 \\ -3/x & x<2 \end{cases}$



Required area = $PQRSP$ = Area $PQRP$ + Area $PRSP$

$$=\left|\int_{\sqrt{3}}^{2}\left(x-\frac{3}{x}\right)dx\right|+\left|\int_{2}^{3}\left((4-x)-\frac{3}{x}\right)dx\right|$$

$$=\frac{4-3\ln 3}{2}\text{ sq units}$$

49. Equation of AB $y=\frac{5}{2}(x-2)$

Equation of BC $y-5=\frac{3-5}{6-4}(x-4)\Rightarrow y=-x+9$

Equation of CA $y-3=\frac{0-3}{2-6}(x-6)\Rightarrow y=\frac{3}{4}(x-2)$

Required area

$$=\frac{5}{2}\int_{2}^{4}(x-2)\,dx+\int_{4}^{6}-(x-9)\,dx-\frac{3}{4}\int_{2}^{6}(x-2)\,dx$$

$$=\frac{5}{2}\left[\frac{(x-2)^2}{2}\right]_2^4-\left[\frac{(x-9)^2}{2}\right]_4^6-\frac{3}{4}\left[\frac{(x-2)^2}{2}\right]_2^6$$

$$=\frac{5}{2}[2^2-0]-\frac{1}{2}[(-3)^2-(-5)^2]-\frac{3}{8}[4^2-0]$$

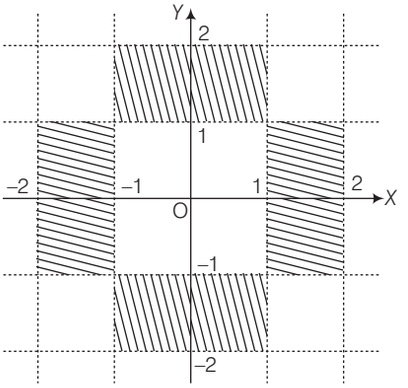
$$=\frac{5}{4}\times 4-\frac{1}{2}[9-25]-\frac{3}{8}[16-0]$$

$$=5-\frac{1}{2}[-16]-\frac{3}{8}\times 16=5+8-6=7\text{ sq units}$$

50. If $[|x|]=1$ and $[|y|]=0$, then $1\leq|x|<2, 0\leq|y|<1$

$\Rightarrow$ $x\in(-2,-1]\cup[1,2),\ y\in(-1,1)$

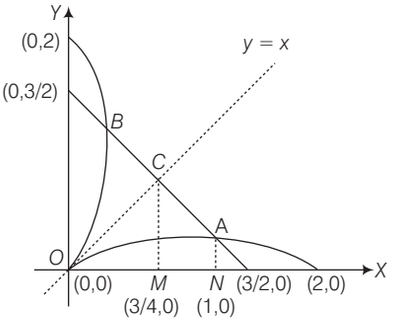
If $[|x|]=0, [|y|]=1$



Then, $x\in(-1,1),\ y\in(-2,-1]\cup[1,2]$

Area of required region $=4(2-1)(1-(-1))=8$ sq units

51. Clearly, $f(x)=\frac{2x-x^2}{2}$



Since, $2x+2y=3$; passes through $A\left(1,\frac{1}{2}\right)$ and $B\left(\frac{1}{2},1\right)$

so bounded area A

= Area OAB = 2 [Area OCM + Area $CMNA$ − Area ONA]

$$=2\left[\frac{1}{2}\times\frac{3}{4}\times\frac{3}{4}+\frac{1}{2}\left(\frac{3}{4}+\frac{1}{2}\right)\times\frac{1}{4}-\frac{1}{2}\int_0^1(2x-x^2)\,dx\right]=\frac{5}{24}$$

$\Rightarrow$ $24A=5$

52. $f(x)=\min\left\{\sin^{-1}x,\cos^{-1},x\frac{\pi}{6}\right\},\ x\in[0,1]$

$$\therefore\ \text{Area}=\int_0^{1/2}\sin^{-1}x,dx+\frac{1}{2}\left(\frac{\sqrt{3}}{2}-\frac{1}{2}\right)+\int_{\sqrt{3}/2}^{1}\cos^{-1}x\,dx$$

$$=(x\sin^{-1}x+\sqrt{1-x^2})_0^{1/2}+\frac{\sqrt{3}-1}{4}$$
$$+(x\cos^{-1}x-\sqrt{1-x^2})_{\sqrt{3}/2}$$

$$=\frac{\pi}{2}(1-\sqrt{3})+\frac{\sqrt{3}-1}{2}+\frac{\sqrt{3}-1}{2}$$

$$=(\sqrt{3}-1)\left(\frac{3}{4}-\frac{\pi}{12}\right)=\frac{9-\pi}{6(\sqrt{3}+1)}=\frac{a-\pi}{b(\sqrt{3}+1)}$$

$\therefore$ $a=9, b=6\ \Rightarrow\ a-b=3$

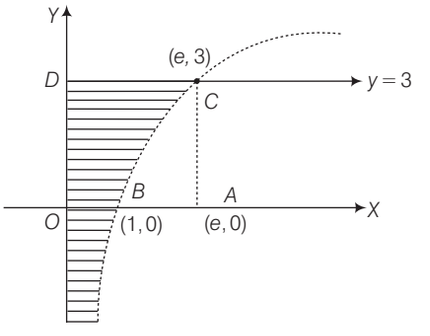
53. Given, $f\left(\frac{x}{y}\right)=f(x)-f(y)$ ...(i)

Putting, $x=y=1$, $f(1)=0$

Now, $f'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}=\lim_{h\to 0}\frac{f\left(1+\frac{h}{x}\right)}{h}$ [from Eq. (i)]

$$=\lim_{h\to 0}\frac{f\left(1+\frac{h}{x}\right)}{\frac{h}{x}\cdot x}$$

$\Rightarrow$ $f'(x)=\frac{3}{x}$ $\left[\text{since, }\lim_{x\to 0}\frac{f(1+x)}{x}=3\right]$



$\Rightarrow \quad f(x) = 3 \log x + c$

Putting $\quad x = 1 \Rightarrow c = 0$

$\Rightarrow \quad f(x) = 3 \log x = y$ [say]

$\therefore$ Required area $= \int_{-\infty}^{3} x\, dy = \int_{-\infty}^{3} e^{y/3}\, dy = 3\,[e^{y/3}]_{-\infty}^{3}$

$= 3(e - 0) = 3e$ sq units

54. According to given conditions,

$$\int_0^t [f(x) - (x^4 - 4x^2)]\, dx = k \int_0^t [(2x^2 - x^3) - f(x)]\, dx$$

Differentiable both the sides w.r.t. t, we get

$$f(t) - (t^4 - 4t^2) = k((2t^2 - t^3) - f(t))$$

or $\quad (1 + k) f(t) = 2kt^2 - kt^3 + t^4 - 4t^2.$

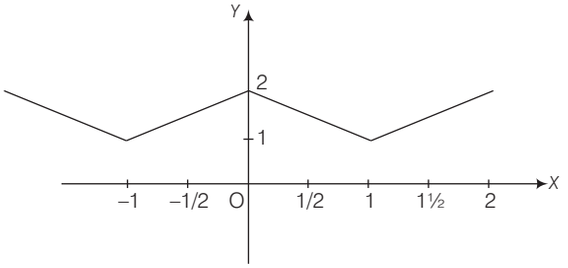
$$\Rightarrow \quad f(t) = \frac{1}{k+1}\{t^4 - kt^3 + (2k - 4)t^2\}$$

Hence, required f is given by;

$$f(x) = \frac{1}{k+1}[x^4 - kx^3 + (2k - 4)x^2]$$

55. $f(t) = |t - 1| = |t| + |t + 1|$

$$\Rightarrow \quad f(t) = \begin{cases} -t, & 1 \le -1 \\ 2 + t, & -1 < t \le 0 \\ 2 - t, & 0 < t \le 1 \\ t, & t > 1 \end{cases}$$



***Case* I** $\quad x + 2 \le -\frac{1}{2} \Rightarrow x \le -\frac{5}{2}$

$g(x) = \max\{f(t) : x + 1 \le t \le x + 2\}$

$= f(x + 1) = -x - 1,\ x \le -5/2$

***Case* II** $\quad -\frac{1}{2} < x + 2 \le 0 \Rightarrow -\frac{5}{2} < x \le -2$

$g(x) = f(x + 2) = 4 + x, -\frac{5}{2} < x \le -2$

***Case* III** $\quad 0 < x + 2 \le 1 \Rightarrow -2 < x \le -1$

$g(x) = 2$

***Case* IV** $\quad 1 < x + 2 \le 3/2 \Rightarrow -1 < x \le -1/2$

$g(x) = f(x + 1) = 1 - x$

***Case* V** $\quad x + 2 > 3/2 \Rightarrow x > -1/2$

$g(x) = f(x + 2) = 2 + x$

Hence, $\quad g(x) = \begin{cases} -x - 1, & x \le -5/2 \\ 4 + x, & -5/2 < x \le -2 \\ 2, & -2 < x \le -1 \\ 1 - x, & -1 < x \le -1/2 \\ 2 + x, & x > -1/2 \end{cases}$

Now, required area $= \int_{-3/2}^{5} g(x)\, dx$

$= \int_{-3/2}^{-1} (2)\, dx + \int_{-1}^{-1/2} (1 - x)\, dx + \int_{-1/2}^{5} (2 + x)\, dx$

$= 2\left(-1 + \frac{3}{2}\right) + \left(-\frac{1}{2} - \frac{1}{8}\right) - \left(-1 - \frac{1}{2}\right) + 2\left(5 + \frac{1}{2}\right) + \frac{1}{2}\left(25 - \frac{1}{4}\right)$

$= \frac{101}{4}$ sq units

56. It is easy to see that,

$$f(x) = \begin{cases} e^x, & 0 \le x < \log(3/2) \\ 3/2, & \log(3/2) \le x < \log(2) \\ 1 + e^x, & \log(2) \le x \le 1 \end{cases}$$

Let A be the required area. Then,

$$A = \int_0^{(\log 3/2)} e^x\, dx + \int_{\log 3/2}^{\log 2} \frac{3}{2}\, dx + \int_{\log 2}^{1} (1 + e^{-x})\, dx$$

$$= (e^x)_0^{\log 3/2} + \frac{3}{2}(x)_{\log 3/2}^{\log 2} + (x - e^{-x})_{\log 2}^{1}$$

$$= \left(\frac{3}{2} - 1\right) + \frac{3}{2}\left(\log 2 - \log\frac{3}{2}\right) + \left(1 - \frac{1}{e} - \log 2 + \frac{1}{2}\right)$$

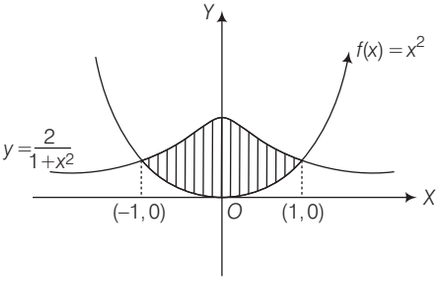
$$= \left[2 + \log\left(\frac{4}{3\sqrt{3}}\right) - \frac{1}{e}\right] \text{sq units}$$

57. $f'(x) = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h}$

$$= \lim_{h \to 0} \frac{f(x(1 + h/x)) - f(x)}{h}$$

$$= \frac{f(x)}{x} \lim_{h \to 0} \frac{f(1 + h/x) - f(1)}{h/x} = \frac{f(x)}{x} \cdot f'(1)$$

$\therefore f'(x) = \frac{2f(x)}{x}$ or $\frac{f'(x)}{f(x)} = \frac{2}{x}$



Integrating both the sides, we get $f(x) = Cx^2$, since $f(1) = 1 \Rightarrow C = 1$.

So, $\quad f(x) = x^2$

Now, $\quad \frac{2}{1 + x^2} = x^2 \Rightarrow x^4 + x^2 - 2 = 0$

$\Rightarrow \quad x^2 = 1 \Rightarrow x = \pm 1$

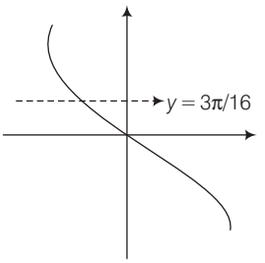
Required area $= 2\left[\int_0^1 \left(\frac{2}{1 + x^2} - x^2\right) dx\right]$

$$= 2\left[2\tan^{-1}x - \frac{x^3}{3}\right]_0^1 = 2\left[\frac{\pi}{2} - \frac{1}{3}\right]$$

$$= \left(\pi - \frac{2}{3}\right) \text{sq units}$$

58. $y(x+y^3)\,dx = x(y^3-x)\,dy$

$\Rightarrow\ xy\,dx + y^2\,dx = xy^3\,dy - x^2\,dy$



$$\Rightarrow \qquad xd(xy) = x^2y^3\left(\frac{1}{x}\,dy - \frac{y}{x^2}\,dx\right)$$

$$\Rightarrow \qquad \frac{d(xy)}{(xy)^2} = \frac{y}{x}\cdot d\left(\frac{y}{x}\right) \Rightarrow -\frac{1}{xy} = \frac{1}{2}\left(\frac{y}{x}\right)^2 + C$$

At, $x = 4,\ y = -2$

So, $$\frac{1}{8} = \frac{1}{2}\left(-\frac{1}{2}\right)^2 + C \Rightarrow C = 0$$

Hence, $$y^3 + 2x = 0$$

So, $$f(x) = (-2x)^{1/3}$$

The second equation given is

$$y = \int_{1/8}^{\sin^2 x} \sin^{-1}\sqrt{t}\,dt + \int_{1/8}^{\cos^2 x} \cos^{-1}\sqrt{t}\,dt$$

$\Rightarrow\ y' = x\cdot 2\sin x\cos x + x\cdot 2\cos x(-\sin x) = 0$

So, y is constant.

Put $\sin x = \cos x = \dfrac{1}{\sqrt{2}}$

Hence, $y = \displaystyle\int_{1/8}^{1/2} (\sin^{-1}\sqrt{t} + \cos^{-1}\sqrt{t})\,dt$

$$= \int_{1/8}^{1/2}\left(\frac{\pi}{2}\right)dt = \frac{\pi}{2}\cdot\frac{3}{8} = \frac{3\pi}{16},\ \text{and}\ g(x) = \frac{3\pi}{16}$$

So, we must find the area between $y = f(x), y = \dfrac{3\pi}{16}$

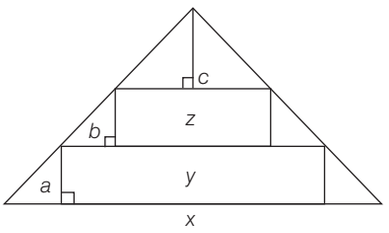
At $y = \dfrac{3\pi}{16}$; $x = -\dfrac{1}{2}\left(\dfrac{3\pi}{16}\right)^3 = P$ (say)

Hence, $$\text{area} = \int_P^0 \left(\frac{3\pi}{16} + (2x)^{1/3}\right)dx$$

$$= \left(\frac{3\pi}{16}x + 2^{1/3}\cdot\frac{x^{4/3}}{4/3}\right)_P^0 = \frac{1}{8}\left(\frac{3\pi}{16}\right)^4 \text{ sq units}$$

59. As in the figure $\dfrac{A(R)+A(S)}{A(T)} = \dfrac{ay+bz}{h\,x/2}$

where $h = a + b + c$, the altitude of T.



By similar triangles $\dfrac{x}{h} = \dfrac{y}{b+c} = \dfrac{z}{c}$,

So, $$\frac{A(R)+A(S)}{A(T)} = \frac{\frac{a(b+c)\,x}{h} + b\cdot\frac{cx}{h}}{hx/2}$$

$$= \frac{2}{h^2}(ab + ac + bc)$$

We need to maximize $(ab + bc + ca)$ subject to $a + b + c = h$. One way to do this is first to fix a, so $b + c = h - a$.

Then, $$(ab + bc + ac) = a(h - a) + bc$$

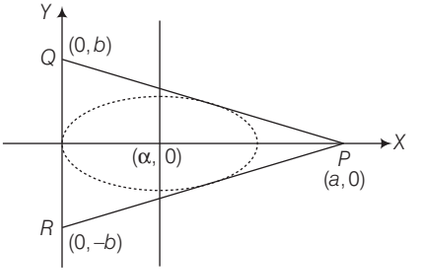
and bc is maximized when $b = c$. We now wish to maximize $2ab + b^2$ subject to $a + 2b = h$. This is a straight forward calculus problem giving $a = b = c = 1/3$. Hence, the maximum ratio is 2/3 (independent of T).

60. Consider a coordinate system with vertex P of the isosceles ΔPQR at $(a, 0)$ and Q and R at $(0, b)$ and $(0, -b)$ respectively.

$$A = \frac{1}{2}\,a\cdot 2b = ab \qquad \ldots(i)$$

Let the centre of ellipse be $(\alpha, 0)$ and the axes be of lengths, 2α and 2β.

So, the equation of ellipse is $\dfrac{(x-\alpha)^2}{\alpha^2} + \dfrac{(y)^2}{\beta^2} = 1$



Now, the line PQ is tangent to the ellipse. To apply condition of tangency, let us take a new system $x'y'$ whose origin is at $(\alpha, 0)$.

Then, $x = x' + \alpha$ and $y = y'$.

So, the ellipse becomes $\dfrac{x'^2}{\alpha^2} + \dfrac{y'^2}{\beta^2} = 1$

and the line PQ becomes $\dfrac{x'+\alpha}{a} + \dfrac{y'}{b} = 1$

which can be written as $y' = -\dfrac{b}{a}x' + b\left(1 - \dfrac{\alpha}{a}\right)$

So, $$b^2\left(1-\frac{\alpha}{a}\right)^2 = \alpha^2\left(-\frac{b}{a}\right)^2 + \beta^2$$

$$\Rightarrow \qquad \beta^2 = b^2\left(1 - \frac{2\alpha}{a}\right) \qquad \ldots(ii)$$

Now, area of ellipse $= \pi\alpha\beta \Rightarrow A^2 = \pi^2\alpha^2\beta^2$

Using Eq. (ii), $A^2 = \pi^2\alpha^2 b^2\left(1 - \dfrac{2\alpha}{a}\right) = f(x)$ (say)

$$f'(x) = \pi^2 b^2\left(2\alpha - \frac{6\alpha^2}{a}\right)$$

$$f'(\alpha) = 0 \Rightarrow 2\alpha = \frac{6\alpha^2}{a} \Rightarrow \alpha = \frac{a}{3}\,(\alpha \neq 0)$$

Since, $f''(\alpha) = \pi^2 b^2\left(2 - \frac{12\alpha}{a}\right) = -2\pi^2 b^2 = (-\text{ve})$

$(\text{at}\ \alpha = a/3)$

So, $f\left(\frac{a}{3}\right) = \pi^2 \cdot \frac{a^2}{9} \cdot b^2\left(1 - \frac{2}{3}\right) = \frac{\pi^2 A^2}{27}$ [using Eq. (i)]

Hence, $(A)_{\max} = \frac{\pi A}{3\sqrt{3}} = \frac{\sqrt{3}\pi A}{9}$ sq units

61. $A_1 = \int_0^a \{\sin x - f(x)\}\, dx = -[\cos x]_0^a - \int_0^a f(x)\, dx$

$= -(\cos a - 1) - \int_0^a f(x)\, dx = 1 - \sin a + (a-1)\cos a$ (given)

$\Rightarrow -\cos a - \int_0^a f(x)\, dx = -\sin a + (a-1)\cos a$

$\Rightarrow -\int_0^a f(x)\, dx = -\sin a + a\cos a$

$\Rightarrow \int_0^a f(x)\, dx = \sin a - a\cos a$

Differentiating w.r.t. a.

$f(a) = \cos a - (\cos a - a\sin a) = a\sin a$

$\therefore\ f(x) = x\sin x$

Now, $y = \sin x$ and $y = f(x)$ intersects at

$\Rightarrow\ a\sin a = \sin a \Rightarrow (a-1)\sin a = 0$

$\Rightarrow\ a = 1$ [as $\sin a = 0$]

Hence, $A_1 = 1 - \sin 1$

$A_2 = \int_1^{\pi} (x\sin x - \sin x)\, dx = \pi - 1 - \sin 1$

$A_3 = \int_{\pi}^{2\pi} |x\sin x - \sin x|\, dx = 3\pi - 2$

62. For $x = 1$, $y = b\cdot 5^x + 4 = 5b + 4$

and $\frac{dy}{dx} = b\cdot 5^x \log 5 \Rightarrow 5b\log 5 = 40\log 5 \Rightarrow b = 8$

The two curves intersects at points where

$8\cdot 5^x + 4 = 25^x + 16$

$\Rightarrow\ 5^{2x} - 8\cdot 5 + 12 = 0 \Rightarrow x = \log_5 2,\ x = \log_5 6$

Hence, the area of the given region;

$= \int_{\log_5 2}^{\log_5 6} \{8\cdot 5^x + 4 - (25^x + 16)\}\, dx$

$= \int_{\log_5 2}^{\log_5 6} (8\cdot 5^x - 25^x - 12)\, dx$

$= \left[\frac{8\cdot 5^x}{\log_e 5} - 12x - \frac{25^x}{\log_e 25}\right]_{\log_5 2}^{\log_5 6}$

$= \frac{-5^{\log_5 36}}{\log_e 25} + \frac{8\cdot 5^{\log_5 6}}{\log_e 5} - 12(\log_5 6 - \log_5 2) + \frac{5^{\log_5 4}}{\log_e 25} - \frac{8\cdot 5^{\log_5 2}}{\log_e 5}$

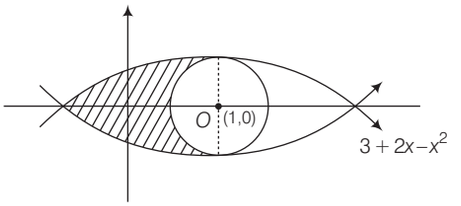
$= \frac{-36}{2\log_e 5} + \frac{48}{\log_e 5} - 12[\log_5 3] + \frac{4}{2(\log_e 5)} - \frac{16}{(\log_e 5)}$

$= \frac{16}{\log_e 5} - 12\log_5 3 = 4\log_5 e^4 - 4\log_5 25$

$= 4\log_5\left[\frac{e^4}{27}\right]$ sq units

63. By the symmetry of the figure circle(s) of maximum area will have the end point of diameter at the vertex of the two parabola.

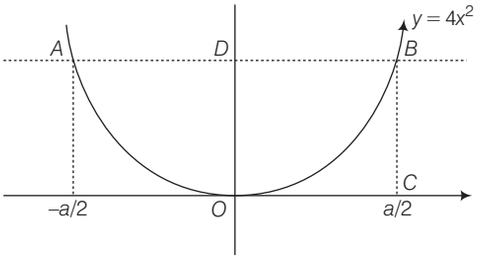
$\Rightarrow$ Radius of circle $= \frac{1}{2}\times AB = \frac{1}{2}\times 8 = 4$ units



So, the area of shaded region $= 4\times\left[\int_1^3 (3 + 2x - x^2)\, dx - \frac{1}{4}\right.$

area of circle $= 4\left(\frac{16}{3} - 4\pi\right)$ sq units

64. Area of $\Delta AOB = 2\times\left(\frac{1}{2}\times\frac{a}{2}\times a^2\right) = \frac{a^3}{2}$

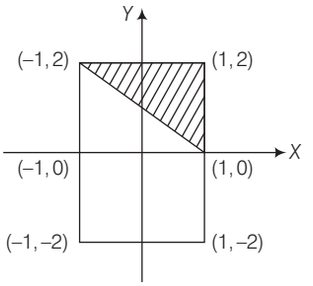


Area = Area $OCBD - \int_0^{a/2} 4x^2\, dx = \frac{a^3}{2} - \frac{a^3}{6} = \frac{a^3}{3}$

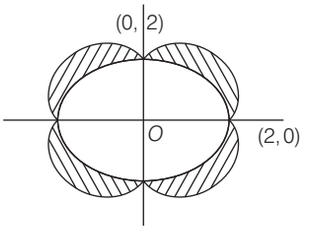
$= \lim_{x\to 0} \frac{\text{Area of triangle}}{\text{Area between the line and parabola}}$

$= \lim_{x\to 0} \frac{a^3/2}{a^3/3} = \frac{3}{2}$

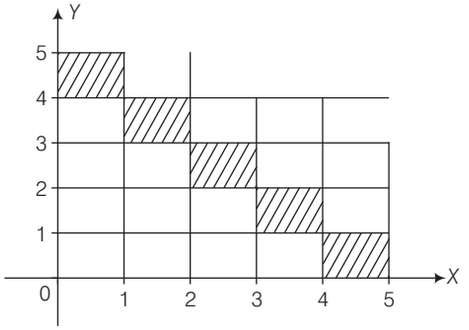
65. Required area $= \frac{1}{2}\times 2\times 2 = 2$ sq units



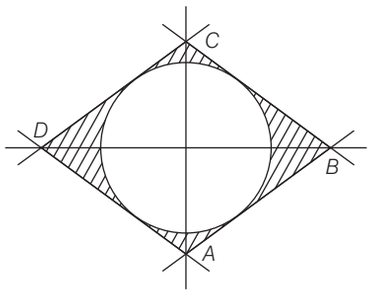
66. Required area $= 4\times\left[\frac{\pi(\sqrt{2})^2}{2} - (\pi - 2)\right] = 8$ sq units



67. 5 sq units



68. Area of the square $ABCD = 2$ sq units



Area of the circle $= \pi \times \frac{1}{2} = \frac{\pi}{2}$ sq units.

Required area $= \left(2 - \frac{\pi}{2}\right)$ sq units

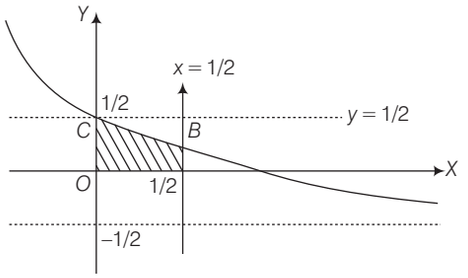
69. $2^{|x|} \cdot |y| + 2^{|x|-1} \le 1$ ...(i)

Clearly, this region is symmetrical about X and Y-axes.

Let $x < 0$, Eq. (i) gives,

$$2^{x} - y + 2^{x-1} \le 1$$

$$\Rightarrow \quad y \le \frac{1 - 2^{x-1}}{2^{x}} = 2^{-x} - \frac{1}{2}$$



Clearly, bounded region in the first quadrant is $OABC$. The required area is 4 times the area of the region $OABC$.

$$\text{Required area} = 4\int_0^{1/2}\left(2^{-x} - \frac{1}{2}\right)dx = 4\left(-\frac{2^{-x}}{\ln 2} - \frac{x}{2}\right)_0^{1/2}$$

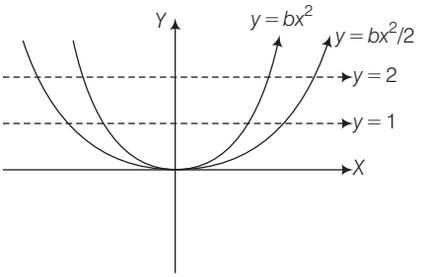
$$= \left[\frac{4}{\ln 2}(1 - 2^{-1/2}) - 1\right] \text{sq units}$$

70. Pair of lines $y^2 - 3y + 2 = 0$

$\Rightarrow$ Lines are $y = 2$, $y = 1$.

Let $[a] = b$

Now, curves are $y = bx^2$ and $y = \frac{b}{2}x^2$



$$\text{Bounded area} = 2\left[\int_1^2 (x_2 - x_1)\,dy\right]$$

$$= 2\left[\int_1^2 \left(\sqrt{\frac{2y}{b}} - \sqrt{\frac{y}{b}}\right)dy\right]$$

$$= 2\left[\sqrt{\frac{2}{b}} \cdot \frac{y^{3/2}}{3/2} - \frac{1}{\sqrt{b}} \cdot \frac{y^{3/2}}{3/2}\right]_1^2$$

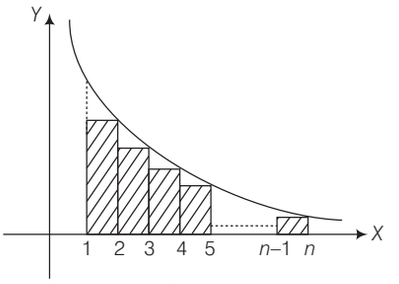
$$= \frac{4}{3\sqrt{b}}\left((\sqrt{2} - 1)\,y^{3/2}\right)_1^2 = \frac{4}{3\sqrt{b}}(\sqrt{2} - 1)(2\sqrt{2} - 1)$$

Area will be maximum when $b = [a]$ is least.

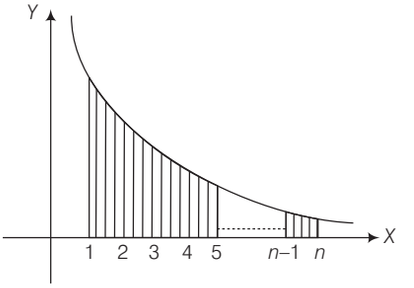
As $a \ge 2 \Rightarrow [a]_{\text{least}} = 1 \Rightarrow 1 \le a < 2$

71. Since, $f'(x) < 0 \Rightarrow f(x)$ is a decreasing function and also $f''(x) > 0 \Rightarrow f(x)$ is concave upwards.

Hence, the graph of the function $y = f(x)$ is as follows :



(i)



(ii)

Let S_L denotes the shaded area in figure (i).

$$\Rightarrow \quad S_L = f(2) + f(3) + \ldots + f(n) = \sum_{r=1}^{n} f(r) - f(1)$$

From the figure (i) it is clear that, $S_L < \int_1^n f(x)\,dx$

$$\Rightarrow \quad \sum_{r=1}^{n} f(r) - f(1) < \int_1^n f(x)\,dx$$

$$\Rightarrow \quad \sum_{r=1}^{n} f(r) < \int_1^n f(x)\,dx + f(1) \qquad \ldots(i)$$

Let S_u denotes the area of the shaded region in figure (ii).

$$\Rightarrow \quad S_u = \left(\frac{1}{2}f(1) + f(2)\right) + \frac{1}{2}(f(2) + f(3)) + \ldots + \frac{1}{2}(f(n-1) + f(n))$$

$$= [(f(1) + f(2) + f(3)) + \ldots + f(n-1) + f(n)] - \frac{1}{2}(f(1) + f(n))$$

$$= \sum_{r=1}^{n} f(r) - \frac{1}{2}f(1) - \frac{1}{2}f(n)$$

From figure (ii) it is clear that;

$$S_u > \int_1^n f(x)\,dx$$

$$\Rightarrow \quad \sum_{r=1}^{n} f(r) - \frac{1}{2}(f(1) + f(n)) > \int_1^n f(x)\,dx$$

$$\Rightarrow \quad \sum_{r=1}^{n} f(r) > \int_1^n f(x)\,dx + \frac{1}{2}(f(1) + f(n))$$

$$> \int_1^n f(x)\,dx + 4\cdot\frac{1}{2}f(1) \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$\frac{1}{2}f(1) + \int_1^n f(x)\,dx < \sum_{r=1}^{n} f(r) < \int_1^n f(x)\,dx + f(1).$$

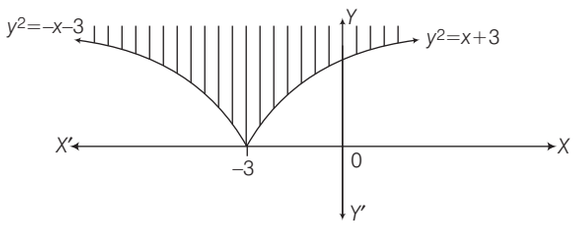
72. Here, $\{(x, y) \in R^2 : y \geq \sqrt{|x+3|}, 5y \leq (x+9) \leq 15\}$

$$\therefore \quad y \geq \sqrt{|x+3|}$$

$$\Rightarrow \quad y \geq \begin{cases} \sqrt{x+3}, \text{ when } x \geq -3 \\ \sqrt{-x-3}, \text{ when } x \leq -3 \end{cases}$$

or $$y^2 \geq \begin{cases} x+3, \text{ when } x \geq -3 \\ -3-x, \text{ when } x \leq -3 \end{cases}$$

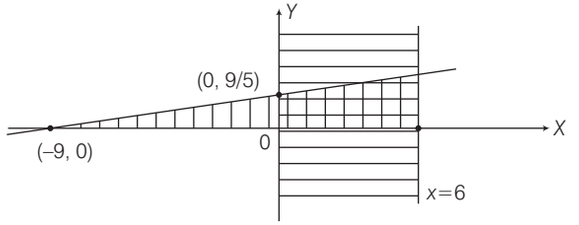
Shown as



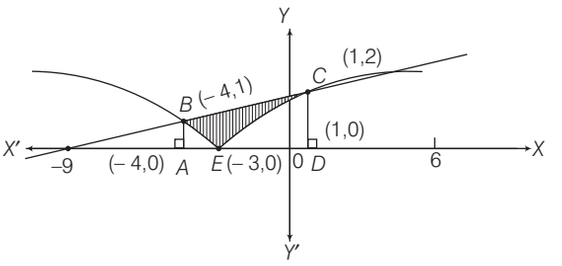
Also, $5y \leq (x+9) \leq 15$

$\Rightarrow \quad (x+9) \geq 5y$ and $x \leq 6$

Shown as



$\therefore \quad \{(x, y) \in R^2 : y \geq \sqrt{|x+3|}, 5y \leq (x+9) \leq 15\}$



$\therefore$ Required area = Area of trapezium $ABCD$ − Area of ABE under parabola − Area of CDE under parabola

$$= \frac{1}{2}(1+2)(5) - \int_{-4}^{-3}\sqrt{-(x+3)}\,dx - \int_{-3}^{1}\sqrt{(x+3)}\,dx$$

$$= \frac{15}{2} - \left[\frac{(-3-x)^{3/2}}{-\frac{3}{2}}\right]_{-4}^{-3} - \left[\frac{(x+3)^{3/2}}{\frac{3}{2}}\right]_{-3}^{1}$$

$$= \frac{15}{2} + \frac{2}{3}[0-1] - \frac{2}{3}[8-0] = \frac{15}{2} - \frac{2}{3} - \frac{16}{3} = \frac{15}{2} - \frac{18}{3} = \frac{3}{2}$$

73. Since, $F'(a) + 2$ is the area bounded by $x = 0$, $y = 0$, $y = f(x)$ and $x = a$.

$$\therefore \quad \int_0^a f(x)dx = F'(a) + 2$$

Using Newton-Leibnitz formula,

$$f(a) = F''(a) \quad \text{and} \quad f(0) = F''(0) \qquad \ldots(i)$$

Given, $$F(x) = \int_x^{x^2 + \pi/6} 2\cos^2 t\,dt$$

On differentiating,

$$F'(x) = 2\cos^2\left(x^2 + \frac{\pi}{6}\right)\cdot 2x - 2\cos^2 x \cdot 1$$

Again differentiating,

$$F''(x) = 4\left\{\cos^2\left(x^2+\frac{\pi}{6}\right) - 2x\cos\left(x^2+\frac{\pi}{6}\right)\sin\left(x^2+\frac{\pi}{6}\right)2x\right\} + \{4\cos x \cdot \sin x\}$$

$$= 4\left\{\cos^2\left(x^2 + \frac{\pi}{6}\right) - 4x^2\cos\left(x^2 + \frac{\pi}{6}\right)\sin\left(x^2 + \frac{\pi}{6}\right)\right\} + 2\sin 2x$$

$$\therefore \quad F''(0) = 4\left\{\cos^2\left(\frac{\pi}{6}\right)\right\} = 3$$

$$\therefore \quad f(0) = 3$$

74. Let equation of tangent to parabola be $y = mx + \frac{2}{m}$

It also touches the circle $x^2 + y^2 = 2$.

$$\therefore \quad \left|\frac{2}{m\sqrt{1+m^2}}\right| = \sqrt{2}$$

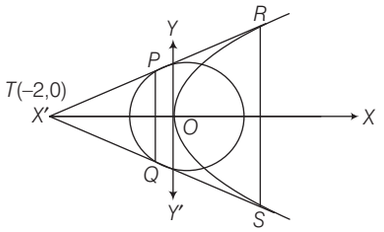
$$\Rightarrow \quad m^4 + m^2 = 2 \quad \Rightarrow \quad m^4 + m^2 - 2 = 0$$

$$\Rightarrow \quad (m^2 - 1)(m^2 + 2) = 0$$

$$\Rightarrow \quad m = \pm 1, m^2 = -2 \qquad [\text{rejected } m^2 = -2]$$

So, tangents are $y = x + 2$, $y = -x - 2$.

They intersect at $(-2, 0)$.



Equation of chord PQ is $-2x = 2 \Rightarrow x = -1$

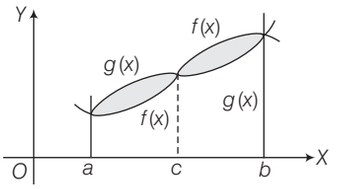
Equation of chord RS is $0 = 4(x-2) \Rightarrow x = 2$

$\therefore$ Coordinates of P, Q, R, S are

$$P(-1, 1),\ Q(-1, -1),\ R(2, 4),\ S(2, -4)$$

$\therefore$ Area of quadrilateral $= \dfrac{(2+8)\times 3}{2} = 15$ sq units

75. To find the bounded area between $y = f(x)$ and $y = g(x)$ between $x = a$ to $x = b$.



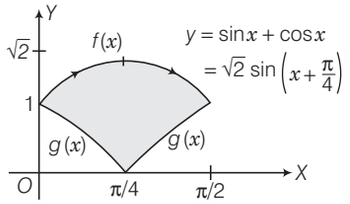
$\therefore$ Area bounded $= \int_a^c [g(x) - f(x)]dx + \int_c^b [f(x) - g(x)]dx$

$$= \int_a^b |f(x) - g(x)|dx$$

Here, $f(x) = y = \sin x + \cos x$, when $0 \le x \le \dfrac{\pi}{2}$

and $g(x) = y = |\cos x - \sin x| = \begin{cases} \cos x - \sin x, & 0 \le x \le \dfrac{\pi}{4} \\ \sin x - \cos x, & \dfrac{\pi}{4} \le x \le \dfrac{\pi}{2} \end{cases}$

could be shown as



$\therefore$ Area bounded $= \int_0^{\pi/4} \{(\sin x + \cos x) - (\cos x - \sin x)\}dx$

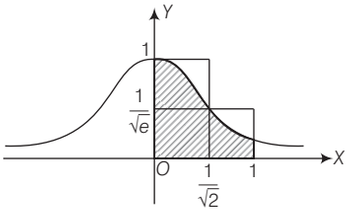
$$+ \int_{\pi/4}^{\pi/2} \{(\sin x + \cos x) - (\sin x - \cos x)\}dx$$

$$= \int_0^{\pi/4} 2\sin x\,dx + \int_{\pi/4}^{\pi/2} 2\cos x\,dx$$

$$= -2[\cos x]_0^{\pi/4} + 2[\sin x]_{\pi/4}^{\pi/2}$$

$$= 4 - 2\sqrt{2} = 2\sqrt{2}(\sqrt{2} - 1) \text{ sq units}$$

76. Graph for $y = e^{-x^2}$



Since, $x^2 \le x$ when $x \in [0, 1]$

$$\Rightarrow \quad -x^2 \ge -x \quad \text{or} \quad e^{-x^2} \ge e^{-x}$$

$$\therefore \quad \int_0^1 e^{-x^2}dx \ge \int_0^1 e^{-x}dx$$

$$\Rightarrow \quad S \ge -(e^{-x})_0^1 = 1 - \frac{1}{e} \qquad \ldots(i)$$

Also, $\int_0^1 e^{-x^2}dx \le$ Area of two rectangles

$$\le \left(1\times\frac{1}{\sqrt{2}}\right) + \left(1 - \frac{1}{\sqrt{2}}\right)\times\frac{1}{\sqrt{e}}$$

$$\le \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{e}}\left(1 - \frac{1}{\sqrt{2}}\right) \qquad \ldots(ii)$$

$$\therefore \quad \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{e}}\left(1 - \frac{1}{\sqrt{2}}\right) \ge S \ge 1 - \frac{1}{e} \qquad \text{[from Eqs. (i) and (ii)]}$$

77. $R_1 = \int_{-1}^{2} x\,f(x)\,dx \qquad \ldots(i)$

Using $\int_a^b f(x)\,dx = \int_a^b f(a + b - x)\,dx$

$$R_1 = \int_{-1}^{2} (1 - x)\,f(1 - x)\,dx$$

$$\therefore \quad R_1 = \int_{-1}^{2} (1 - x)\,f(x)\,dx \qquad \ldots(ii)$$

$[f(x) = f(1 - x)$, given$]$

Given, R_2 is area bounded by $f(x)$, $x = -1$ and $x = 2$.

$$\therefore \quad R_2 = \int_{-1}^{2} f(x)\,dx \qquad \ldots(iii)$$

On adding Eqs. (i) and (ii), we get

$$2R_1 = \int_{-1}^{2} f(x)\,dx \qquad \ldots(iv)$$

From Eqs. (iii) and (iv), we get

$$2R_1 = R_2$$

78. Here, area between 0 to b is R_1 and b to 1 is R_2.

$$\therefore \quad \int_0^b (1 - x)^2\,dx - \int_b^1 (1 - x)^2\,dx = \frac{1}{4}$$

$$\Rightarrow \quad \left[\frac{(1-x)^3}{-3}\right]_0^b - \left[\frac{(1-x)^3}{-3}\right]_b^1 = \frac{1}{4}$$

$$\Rightarrow -\frac{1}{3}[(1-b)^3 - 1] + \frac{1}{3}[0 - (1-b)^3] = \frac{1}{4}$$

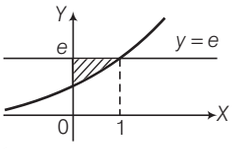
$$\Rightarrow \quad -\frac{2}{3}(1-b)^3 = -\frac{1}{3} + \frac{1}{4} = -\frac{1}{12}$$

$$\Rightarrow \quad (1-b)^3 = \frac{1}{8}$$

$$\Rightarrow \quad (1-b) = \frac{1}{2} \Rightarrow b = \frac{1}{2}$$

79. Shaded area $= e - \left(\int_0^1 e^x\,dx\right) = 1$

Also, $\int_1^e \ln(e + 1 - y)\,dy$ [put $e + 1 - y = t \Rightarrow -dy = dt$]



$$= \int_e^1 \ln\ t(-dt) = \int_1^e \ln t\,dt = \int_1^e \ln y\,dy = 1$$

80. Required area $= \int_0^{\pi/4}\left(\sqrt{\frac{1+\sin x}{\cos x}}-\sqrt{\frac{1-\sin x}{\cos x}}\right)dx$

$\left[\because \frac{1+\sin x}{\cos x} > \frac{1-\sin x}{\cos x} > 0\right]$

$$= \int_0^{\pi/4}\left(\sqrt{\frac{1+\frac{2\tan\frac{x}{2}}{1+\tan^2\frac{x}{2}}}{\frac{1-\tan^2\frac{x}{2}}{1+\tan^2\frac{x}{2}}}}-\sqrt{\frac{1-\frac{2\tan\frac{x}{2}}{1+\tan^2\frac{x}{2}}}{\frac{1-\tan^2\frac{x}{2}}{1+\tan^2\frac{x}{2}}}}\right)dx$$

$$= \int_0^{\pi/4}\left(\sqrt{\frac{1+\tan\frac{x}{2}}{1-\tan\frac{x}{2}}}-\sqrt{\frac{1-\tan\frac{x}{2}}{1+\tan\frac{x}{2}}}\right)dx$$

$$= \int_0^{\pi/4}\frac{1+\tan\frac{x}{2}-1+\tan\frac{x}{2}}{\sqrt{1-\tan^2\frac{x}{2}}}dx = \int_0^{\pi/4}\frac{2\tan\frac{x}{2}}{\sqrt{1-\tan^2\frac{x}{2}}}dx$$

Put $\tan\frac{x}{2} = t \Rightarrow \frac{1}{2}\sec^2\frac{x}{2}\,dx = dt$

$$= \int_0^{\tan\frac{\pi}{8}}\frac{4t\,dt}{(1+t^2)\sqrt{1-t^2}}$$

As $\int_0^{\sqrt{2}-1}\frac{4t\,dt}{(1+t^2)\sqrt{1-t^2}}$ $\left[\because \tan\frac{\pi}{8} = \sqrt{2}-1\right]$

81. Given, $y^3 - 3y + x = 0$

$$\Rightarrow 3y^2\frac{dy}{dx} - 3\frac{dy}{dx} + 1 = 0 \quad \text{...(i)}$$

$$\Rightarrow 3y^2\left(\frac{d^2y}{dx^2}\right) + 6y\left(\frac{dy}{dx}\right)^2 - 3\frac{d^2y}{dx^2} = 0 \quad \text{...(ii)}$$

At $x = -10\sqrt{2},\ y = 2\sqrt{2}$

On substituting in Eq. (i) we get

$$3(2\sqrt{2})^2\cdot\frac{dy}{dx} - 3\cdot\frac{dy}{dx} + 1 = 0 \Rightarrow \frac{dy}{dx} = -\frac{1}{21}$$

Again, substituting in Eq. (ii), we get

$$3(2\sqrt{2})^2\frac{d^2y}{dx^2} + 6(2\sqrt{2})\cdot\left(-\frac{1}{21}\right)^2 - 3\cdot\frac{d^2y}{dx^2} = 0$$

$$\Rightarrow 21\cdot\frac{d^2y}{dx^2} = -\frac{12\sqrt{2}}{(21)^2}$$

$$\Rightarrow \frac{d^2y}{dx^2} = \frac{-12\sqrt{2}}{(21)^3} = \frac{-4\sqrt{2}}{7^3\cdot 3^2}$$

82. Required area $= \int_a^b y\,dx = \int_a^b f(x)\,dx = [f(x)\cdot x]_a^b - \int_a^b f'(x)x\,dx$

$$= bf(b) - af(a) - \int_a^b f'(x)x\,dx$$

$$= bf(b) - af(a) + \int_a^b \frac{x\,dx}{3[\{f(x)\}^2 - 1]}$$

$$\left[\because f'(x) = \frac{dy}{dx} = \frac{-1}{3(y^2-1)} = \frac{-1}{3[\{f(x)\}^2-1]}\right]$$

83. Let $I = \int_{-1}^{1} g'(x)\,dx = [g(x)]_{-1}^{1} = g(1) - g(-1)$

Since, $y^3 - 3y + x = 0$ ...(i)

and $y = g(x)$

$\therefore$ $\{g(x)\}^3 - 3g(x) + x = 0$ [from Eq. (i)]

At $x = 1$, $\{g(1)\}^3 - 3g(1) + 1 = 0$ ...(ii)

At $x = -1$, $\{g(-1)\}^3 - 3g(-1) - 1 = 0$ ...(iii)

On adding Eqs. (i) and (ii), we get

$\{g(1)\}^3 + \{g(-1)\}^3 - 3\{g(1) + g(-1)\} = 0$

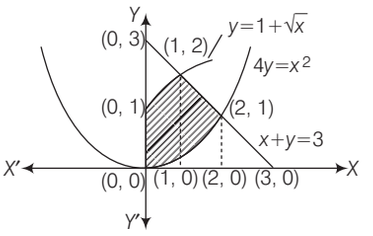
$\Rightarrow [g(1) + g(-1)][\{g(1)\}^2 + \{g(-1)\}^2 - g(1)g(-1) - 3] = 0$

$\Rightarrow g(1) + g(-1) = 0$

$\Rightarrow g(1) = -g(-1)$

$\therefore I = g(1) - g(-1) = g(1) - \{-g(1)\} = 2g(1)$

84. Required area $= \int_0^1 (1+\sqrt{x})dx + \int_1^2 (3-x)dx - \int_0^2 \frac{x^2}{4}dx$



$$= \left[x + \frac{x^{3/2}}{3/2}\right]_0^1 + \left[3x - \frac{x^2}{2}\right]_1^2 - \left[\frac{x^3}{12}\right]_0^2$$

$$= \left(1 + \frac{2}{3}\right) + \left(6 - 2 - 3 + \frac{1}{2}\right) - \left(\frac{8}{12}\right)$$

$$= \frac{5}{3} + \frac{3}{2} - \frac{2}{3} = 1 + \frac{3}{2} = \frac{5}{2} \text{ sq units}$$

85. Given equations of curves are $y^2 = 2x$, ...(i)

which is a parabola with vertex (0, 0) and axis parallel to X-axis.

And $x^2 + y^2 = 4x$ ...(ii)

which is a circle with centre (2, 0) and radius = 2

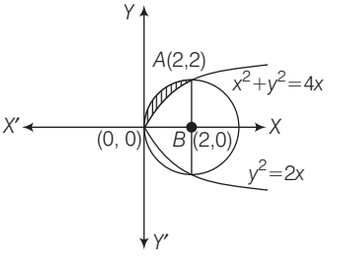
On substituting $y^2 = 2x$ in Eq. (ii), we get

$$x^2 + 2x = 4x \Rightarrow x^2 = 2x$$

$\Rightarrow x = 0$ or $x = 2$

$\Rightarrow y = 0$ or $y = \pm 2$ [using Eq. (i)]

Now, the required area is the area of shaded region, i.e.



Required area $= \frac{\text{Area of a circle}}{4} - \int_0^2 \sqrt{2x}\,dx$

$$= \frac{\pi(2)^2}{4} - \sqrt{2}\int_0^2 x^{1/2}dx = \pi - \sqrt{2}\left[\frac{x^{3/2}}{3/2}\right]_0^2$$

$$= \pi - \frac{2\sqrt{2}}{3}[2\sqrt{2} - 0] = \left(\pi - \frac{8}{3}\right) \text{ sq units}$$

86. Given region is $\{(x, y) : y^2 \le 2x \text{ and } y \ge 4x - 1\}$

$y^2 \le 2x$ represents a region inside the parabola

$$y^2 = 2x \quad \ldots(i)$$

and $y \ge 4x - 1$ represents a region to the left of the line

$$y = 4x - 1 \quad \ldots(ii)$$

The point of intersection of the curve (i) and (ii) is

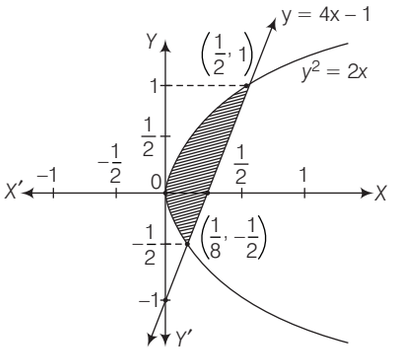
$$(4x - 1)^2 = 2x$$

$$\Rightarrow \quad 16x^2 + 1 - 8x = 2x$$

$$\Rightarrow \quad 16x^2 - 10x + 1 = 0$$

$$\Rightarrow \quad x = \frac{1}{2}, \frac{1}{8}$$

$\therefore$ The points where these curves intersect, are $\left(\frac{1}{2}, 1\right)$ and $\left(\frac{1}{8}, -\frac{1}{2}\right)$.



Hence, required area $= \int_{-1/2}^{1}\left(\frac{y+1}{4} - \frac{y^2}{2}\right)dy$

$$= \frac{1}{4}\left(\frac{y^2}{2} + y\right)_{-1/2}^{1} - \frac{1}{6}(y^3)_{-1/2}^{1}$$

$$= \frac{1}{4}\left\{\left(\frac{1}{2} + 1\right) - \left(\frac{1}{8} - \frac{1}{2}\right)\right\} - \frac{1}{6}\left\{1 + \frac{1}{8}\right\}$$

$$= \frac{1}{4}\left\{\frac{3}{2} + \frac{3}{8}\right\} - \frac{1}{6}\left\{\frac{9}{8}\right\} = \frac{1}{4} \times \frac{15}{8} - \frac{3}{16} = \frac{9}{32}$$

87. Given equation of ellipse is

$$\frac{x^2}{9} + \frac{y^2}{5} = 1 \quad \ldots(i)$$

$\therefore \quad a^2 = 9, b^2 = 5 \quad \Rightarrow \quad a = 3, b = \sqrt{5}$

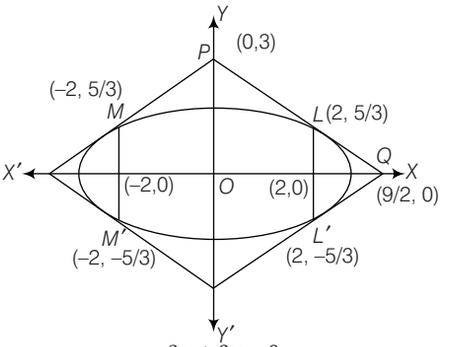
Now, $\quad e = \sqrt{1 - \frac{b^2}{a^2}} = \sqrt{1 - \frac{5}{9}} = \frac{2}{3}$

Foci $= (\pm ae, 0) = (\pm 2, 0)$ and $\frac{b^2}{a} = \frac{5}{3}$

$\therefore$ Extremities of one of latusrectum are $\left(2, \frac{5}{3}\right)$ and $\left(2, \frac{-5}{3}\right)$.

$\therefore$ Equation of tangent at $\left(2, \frac{5}{3}\right)$ is,

$$\frac{x(2)}{9} + \frac{y(5/3)}{5} = 1$$



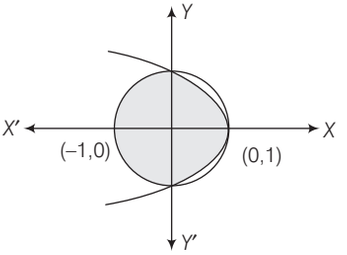
or $\quad 2x + 3y = 9 \quad \ldots(ii)$

Eq.(ii) intersects X and Y-axes at $\left(\frac{9}{2}, 0\right)$ and $(0, 3)$, respectively.

$\therefore$ Area of quadrilateral $= 4 \times$ Area of ΔPOQ

$$= 4 \times \left(\frac{1}{2} \times \frac{9}{2} \times 3\right) = 27 \text{ sq units}$$

88. Given, $A = \{(x, y) : x^2 + y^2 \le 1 \text{ and } y^2 \le 1 - x\}$

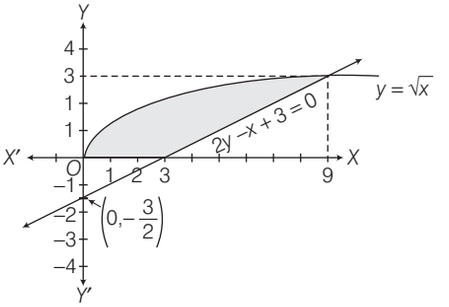


Required area $= \frac{1}{2}\pi r^2 + 2\int_0^1 (1 - y^2)dy = \frac{1}{2}\pi(1)^2 + 2\left(y - \frac{y^3}{3}\right)_0^1$

$$= \frac{\pi}{2} + \frac{4}{3}$$

89. Given curves are $y = \sqrt{x} \quad \ldots(i)$

and $\quad 2y - x + 3 = 0 \quad \ldots(ii)$



On solving Eqs. (i) and (ii), we get $2\sqrt{x} - (\sqrt{x})^2 + 3 = 0$

$$\Rightarrow \quad (\sqrt{x})^2 - 2\sqrt{x} - 3 = 0$$

$$\Rightarrow \quad (\sqrt{x} - 3)(\sqrt{x} + 1) = 0$$

$$\Rightarrow \quad \sqrt{x} = 3 \quad [\because \sqrt{x} = -1 \text{ is not possible}]$$

$$\Rightarrow \quad y = 3$$

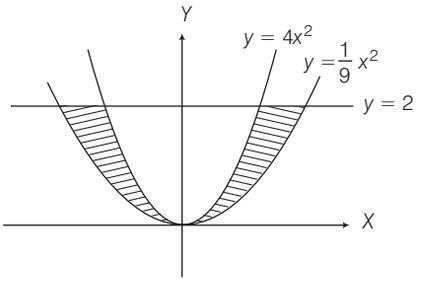
$\therefore$ Required area $= \int_0^3 (\text{line} - \text{curve})\, dy = \int_0^3 \{(2y + 3) - y^2\}\, dy$

$$= \left[y^2 + 3y - \frac{y^3}{3}\right]_0^3 = 9 + 9 - 9 = 9$$

90. **Given** Two parabolas $x^2 = \frac{y}{4}$ and $x^2 = 9y$

To find The area bounded between the parabolas and the straight line $y = 2$.

The required area is equal to the shaded region in the drawn figure.



The area of the shaded region (which can be very easily found by using integration) is twice the area shaded in first quadrant.

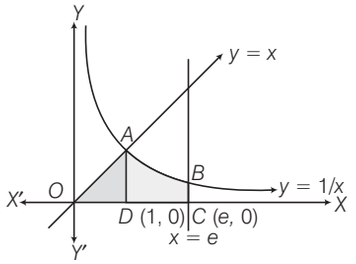
$$\text{Required area} = 2\int_0^2 \left(3\sqrt{y} - \frac{\sqrt{y}}{2}\right) dy = 2\int_0^2 \left(\frac{5}{2}\sqrt{y}\right) dy$$

$$= 5\left[\frac{y^{3/2}}{3/2}\right]_{y=0}^{y=2} = \frac{10}{3}(2^{3/2} - 0) = \frac{20\sqrt{2}}{3}$$

91. Given, $y = x$, $x = e$ and $y = \frac{1}{x}$, $x \geq 0$

Since, $y = x$ and $x \geq 0 \quad \Rightarrow \quad y \geq 0$

$\therefore$ Area to be calculated in I quadrant shown as



$\therefore$ Area = Area of ΔODA + Area of $DABCD$

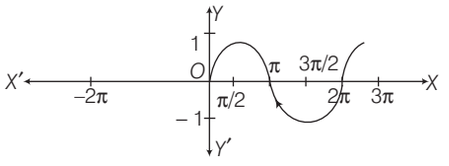
$$= \frac{1}{2}(1 \times 1) + \int_1^e \frac{1}{x}\, dx$$

$$= \frac{1}{2} + (\log|x|)_1^e$$

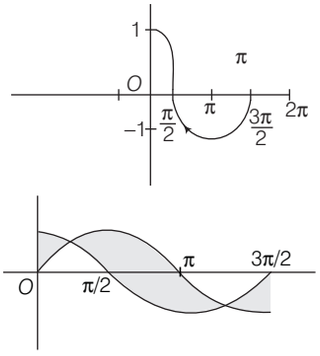
$$= \frac{1}{2} + \{\log|e| - \log 1\} \qquad [\because \log|e| = 1]$$

$$= \frac{1}{2} + 1 = \frac{3}{2} \text{ sq units}$$

92. Graph of $y = \sin x$ is



and graph of $y = \cos x$ is

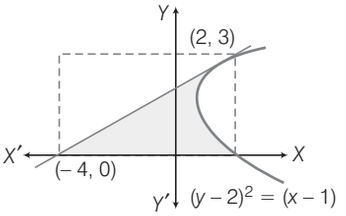


$$\text{Required area} = \int_0^{\pi/4} (\cos x - \sin x)\, dx + \int_{\pi/4}^{5\pi/4} (\sin x - \cos x)\, dx + \int_{5\pi/4}^{3\pi/2} (\cos x - \sin x)\, dx$$

$$= [\sin x + \cos x]_0^{\pi/4} + [-\cos x - \sin x]_{\pi/4}^{5\pi/4} + [\sin x + \cos x]_{5\pi/4}^{3\pi/2}$$

$$= (4\sqrt{2} - 2) \text{ sq units}$$

93. The equation of tangent at (2, 3) to the given parabola is $x = 2y - 4$



$\therefore$ Required area $= \int_0^3 \{(y-2)^2 + 1 - 2y + 4\} dy$

$$= \left[\frac{(y-2)^3}{3} - y^2 + 5y\right]_0^3$$

$$= \frac{1}{3} - 9 + 15 + \frac{8}{3} = 9 \text{ sq units}$$

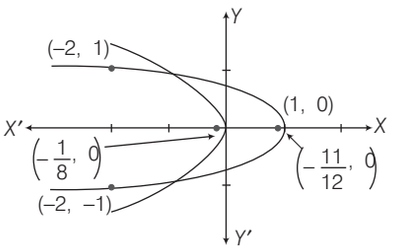
94. Given, equations of curves are $x + 3y^2 = 1$ ... (i)

and $x + 2y^2 = 0$ ... (ii)

On solving Eqs. (i) and (ii), we get

$$y = \pm 1 \text{ and } x = -2$$

$\therefore$ Required area $= \left|\int_{-1}^{1} (x_1 - x_2) dy\right|$



$$= \left|\int_{-1}^{1} (1 - 3y^2 + 2y^2) dy\right| = \left|\int_{-1}^{1} (1 - y^2) dy\right|$$

$$= \left|2\int_0^1 (1 - y^2) dy\right| = \left|2\left[y - \frac{y^3}{3}\right]_0^1\right| = \left|2\left(1 - \frac{1}{3}\right)\right| = \frac{4}{3} \text{ sq units}$$

A differential equation can simply be said to be an equation involving derivatives of an unknown function. For example, consider the equation

$$\frac{dy}{dx} + xy = x^2$$

This is a differential equation since it involves the derivative of the funtion $y(x)$ which we may wish to determine. We must first understand why and how differnetial equations arise and why we need them at all. In general, we can say that a differential equation describes the behaviour of some continuously varying quantity.

Scenario 1 : A Freely Falling Body

A body is release at rest from a heigh h. How do we described the motion of this body?

The height x of the body is a function of time. Since the acceleration of the body is g, we have $\frac{d^2x}{dt^2} = g$

This is the differential equation describing the motion of the body. Along with the initial condition $x(0) = h$, it completely describes the motion of the body at all instants after the body starts falling.

Scenario 2 : Radioactive disintegration

Experimental evidence shows that the rate of decay of any ratioactive substance is proportional to the amount of the substance present,

i.e. $$\frac{dm}{dt} = -\lambda m$$

where m is the mass of the radioactive substance and a function of t. If we know $m(0)$, the initial mass, we can use this differential equation to determine the mass of the substance remaining at any later time instant.

Scenario 3 : Population Growth

The growth of population (of say, a biological culture) in a closed environment is dependent on the birth and death rates. The birth rate will contribute to increaseing the population while the death rate will contribute to its decrease. It has been found that for low populations, the birth rate is the dominant influence in population growth and the growth rate is linearly dependent on the current population. For high populations, there is a competition among the population for the limited resources available, and thus death rate becomes dominant. Also, the death rate shows a quadratic dependence on the current population.

Thus, if $N(t)$ represents the population at time t, the different equation describing the population variation is of the form

$$\frac{dN}{dt} = \lambda_1 N - \lambda_2 N^2$$

where λ_1 and λ_2 are constants.

Along with the initial population $N(0)$, this equation can tell us the population at any later time instant.

Session 1

Solution of a Differential Equation

These three examples should be sufficient for you to realise why and how differential equations arise and why they are important.

In all the three equations mentioned above, there is only independent variable (the time t in all the three cases). Such equations are termed **ordinary differential equations.** We might have equations involving more than one independent variable :

$$\frac{\partial f}{\partial x} + x\frac{\partial f}{\partial y} = x^2$$

where the notation $\frac{\partial}{\partial x}$ stands for the partial derivative, i.e. the term $\frac{\partial f}{\partial x}$ would imply that we differentiate the function f with respect to the independent variable x as the variable (while treating the other independent variable y as a constant). A similar interpretation can be attached to $\frac{\partial}{\partial y}$.

Such equations are termed **partial differential equations** but we shall not be concerned with them in this chapter.

Consider the ordinary differnetial equation

$$\frac{d^2y}{dx^2} + x\frac{dy}{dx} + x^2 = c$$

The order of the highest derivative present in this equation is two; thus we shall call it a second order differential equation (*DE*, for convenience).

The **order** of a *DE* is the order of the highest derivative that occurs in the equation

Again, consider the *DE*

$$\frac{d^2y}{dx^3}+\frac{dy}{dx}=x^2y^2$$

The degree of the highest order derivative in this DE is two, so this is a DE of degree two (and order three).

The degree of a DE is the degree of the highest order derivative that occurs in the equation, **when all the derivatives in the equation are made of free of fractional powers.**

$$\sqrt{\left(\frac{dy}{dx}\right)^2-1}+x\left(\frac{d^2y}{dx^2}\right)=k$$

is not of degree two. When we make this equation free of fractional powers, by the following rearrangement,

$$\left(\frac{dy}{dx}\right)^2-1+\left\{k-x\left(\frac{d^2y}{dx^2}\right)^2\right\}^2$$

we see that the degree of the highest order derivative will become four. Thus, this is a DE of degree four (and order two).

Finally, an n^{th} **linear DE** (degree one) is an equation of the form

$$a_0\frac{d^ny}{dx^n}+a_1\frac{d^{n-1}}{dx^{n-1}}+\ldots+a_{n-1}\frac{dy}{dx}+a_ny=b$$

where the $a_i's$ and b are functions of x.

Solving an n^{th} order DE to evaluate the unknown function will essentially consists of doing n integrations on the DE. Each integration step will introduce an arbitrary constant. Thus, you can expect in general that the **solution of an n^{th} order DE will contain n independnet arbitrary constants.**

By n independent constants, we mean to say that the most general solution of the DE cannot be expressed in fewer that n constants. As an example, the second order DE

$$\frac{d^y}{dx^2}+y=0$$

has its most general solution of the form

$$y=A\cos x+B\sin x. \qquad \ldots(1)$$

(verify that this is a solution by explicit substitution).

Thus, two arbitrary and independent constants must be included in the general solution. We cannot reduce (1) to a relation containing only one arbitrary constant. On the other hand, it can be verified that the function

$$y=ae^{x+b}$$

is a solution to the second-order DE

$$\frac{d^2y}{dx^2}=y$$

but even through it (seems to) contain two arbitrary constants, it is not the general solution to this DE. This is because it can be reduced to a relation involving only one arbitrary constant :

$$y=ae^{x+b}=ae^x.e^b=ce^x \quad (\text{where } c=a\cdot e^b)$$

Let us summarise what we have seen till now : the most general solution of an n^{th} order DE will consist of n orbitrary constants; conversely, from a functional relation involving n arbitrary constants, an n^{th} order DE can be generated (we shall soon see how to do this). We are generally interested in solutions of the DE satisfying some particular constraints (say, some initial values). Since the most general solution of the DE involves n arbitrary constant, we see that the maximum member of independent conditions which can be imposed on a solution of the DE is n. As a first example, consider the functional relation

$$y=x^2+c_1e^{2x}+c_2e^{3x} \qquad \ldots(i)$$

This curve's equation contains two arbitrary constants; as we vary c_1 and c_2, we obtain different curves; those curves constitute a family of curves. All members of this family will satisfy the DE that we can generate from this general relation; this DE will be second order since the relation contains two arbitrary constants.

We now see how to generate the DE. Differentiate the given relation twice to obtain

$$y'=2x+2c_1e^{2x}+3c_2e^{3x} \qquad \ldots(ii)$$

$$y''=2+4c_1e^{2x}+9c_2e^{3x} \qquad \ldots(iii)$$

From Eqs. (i), (ii) and (iii), c_1 and c_2 can be eliminated to obtain

$$\begin{vmatrix} e^{2x} & e^{3x} & x^2-y \\ 2e^{2x} & 3e^{3x} & 2x-y' \\ 4e^{2x} & 9e^{3x} & 2-y'' \end{vmatrix}$$

$$\Rightarrow \quad \begin{vmatrix} 1 & 1 & x^2-y \\ 2 & 3 & 2x-y' \\ 4 & 9 & 2-y'' \end{vmatrix}$$

$$\Rightarrow 6-3''-18x+9y'+8x-4y'-4+2y''+7x^2-6y=0$$

$$\Rightarrow \quad y''-5y'+6y=6x^2-10x+2 \qquad \ldots(iv)$$

This is the required DE; it corresponds to the family of curves given by Eq. (i). Differently put, the most general solution of this DE is given by Eq. (i).

As an exercise for the reader, show that the DE corrersponding to the general equation

$$y = Ae^{2x} + Be^{x} + C$$

where A, B, C are arbitrary constants, is

$$y''' - 3y'' + 2y' = 0$$

By expected, the three arbitrary constants cause the DE to the third order.

Example 1 Find the order and degree (if defined) of the following differential equations :

(i) $y = 1 + \left(\frac{dy}{dx}\right) + \frac{1}{2!}\left(\frac{dy}{dx}\right)^2 + \frac{1}{3!}\left(\frac{dy}{dx}\right)^3 + \ldots$

(ii) $\left(\frac{d^3y}{dx^3}\right)^{2/3} = \frac{dy}{dx} + 2$ (iii) $\frac{d^2y}{dx^2} = x \ln\left(\frac{dy}{dx}\right)$

Sol. (i) The given differential equation can be rewritten as

$$y = e^{dy/dx}$$

$$\Rightarrow \qquad \frac{dy}{dx} = \ln y.$$

Hence, its order is 1 and degree 1.

(ii) The given differential equation can be rewritten as

$$\left(\frac{d^3y}{dx^3}\right)^2 = \left(\frac{dy}{dx} + 2\right)^3.$$

Hence, its order is 3 and degree 2.

(iii) Its order is obviously 2.

Since, the given differential equation cannot be written as a polynomial in all the differential coefficients, the degree of the equation is not defined.

Example 2 Find the order and degree (if defined) of the following differential equations :

(i) $\sqrt{\frac{d^2y}{dx^2}} = \sqrt[3]{\frac{dy}{dx} + 3}$ (ii) $\frac{d^2y}{dx^2} = \sin\left(\frac{dy}{dx}\right)$

(iii) $\frac{dy}{dx} = \sqrt{3x + 5}$

Sol. (i) The given differential equation can be rewritten as

$$\left(\frac{d^2y}{dx^2}\right)^3 = \left(\frac{dy}{dx} + 3\right)^2$$

Hence, order is 2 and degree is 3.

(ii) The given differential equation has the order 2. Since, the given differential equation cannot be written as a polynomial in the differential coefficients, the degree of the equation is not defined.

(iii) Its order is obviously 1 and degree 1.

Linear and Non-linear Differential Equation

A differential equation is a linear differential equation if it is expressible in the form

$$a_0 \frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + a_2 \frac{d^{n-2} y}{dx^{n-2}} + \ldots + a_{n-1} \frac{dy}{dx} + any = Q$$

where $a_0, a_1, a_2, \ldots, a_n$ and Q are either constants or functions of independent variable x.

Thus, if a differential equation when expressed in the form of a polynomial involves the derivatives and dependent variable in the first power and there ae no product of these, and also the coefficient of the various terms are either constants or functions of the independent variable, then it is said to be linear differential equation. otherwise, it i a non-linear differential equation.

The differentiable equation $\left(\frac{d^3y}{dx^3}\right)^2 - 6\left(\frac{d^2y}{dx^2}\right) - 4y = 0$, is a non-linear differential equation, because its degree is 2, more than one.

e.g. The differential equation, $\left(\frac{d^3y}{dx^3}\right) + 2\left(\frac{dy}{dx}\right)^2 + 9y = x$, is non-linear differential equation, because differential coefficient $\frac{dy}{dx}$ has exponent 2.

e.g. The differential equation $(x^2 + y^2)\,dx - 2xydy = 0$ is a non-linear differential equation, because the exponent of dependent variable y is 2 and it involves the product of y and $\frac{dy}{dx}$. e.g. Consider the differential equation

$$\left(\frac{d^2y}{dx^2}\right) - 5\left(\frac{dy}{dx}\right) + 6y = \sin x$$

This is a linear differential equation of order 2 and degree.

Formation of Differential Equations

If an equation in independent and dependent variables involving some arbitrary constants is given, then a differential equation is obtained as follows :

(i) Differentiate the given equation w.r.t. the independent variable (say x) as many times as the number of arbitrary constants in it.

(ii) Eliminate the arbitrary constants.

(iii) The eliminant is the required differential equation. i.e. If we have an equation $f(x, y, c_1, c_2, \ldots, c_n) = 0$

Containing n arbitrary constants $c_1, c_2, c_3, \ldots, c_n$, then by differentiating this n times, we shall get n-equations.

Now, among these n-equations and the given equation, in all $(n+1)$ equations, if the n arbitrary constants $c_1, c_2, c_3, \ldots, c_n$ are eliminated, we shall evidently get a differential equation of the nth order. For there being n differentiation, the resulting equation must contain a derivative of the nth order.

Algorithm for Formation of Differential Equations

Step I Write the given equation involving independent variable x (say), dependent variable y (say) and the arbitrary constant.

Step II Obtain the number of arbitrary constants in Step I. Let there be n arbitrary constants.

Step III Differentiate the relation in step I, n times with respect to x.

Step IV Eliminate arbitrary consstants with the help of n equations involving differential coefficients obtained in step III and an equation in step I.

The equation so obtained is the desired differential equation. The following examples will illustrate the above procedure.

Example 3 Form the differential equation, if $y^2 = 4a(x+b)$, where a, b are arbitrary constants.

Sol. Differentiating $y^2 = 4a(x+b)$ w.r.t. x,

$$2y \cdot \frac{dy}{dx} = 4a \quad \text{i.e.} \quad y\frac{dy}{dx} = 2a$$

Again, differentiating w.r.t. x, we get

$$y\frac{d^2y}{dx^2} + \left(\frac{dy}{dx}\right)^2 = 0$$

which is the required differential equation. Thus, the elimination of arbitrary leads to the formation of a differential equation.

Example 4 Find the differential equation whose solution represents the family $xy = ae^x + be^{-x}$.

Sol.
$$xy = ae^x + be^{-x} \quad \ldots(i)$$

Differentiating Eq. (i) w.r.t. x, we get

$$x\frac{dy}{dx} + y = ae^x - be^{-x} \quad \ldots(ii)$$

Differentiating Eq. (ii) w.r.t. x, we get

$$x\frac{d^2y}{dx^2} + \frac{dy}{dx}\cdot 1 + \frac{dy}{dx} = ae^x + be^{-x} \quad \ldots(iii)$$

Using Eqs. (i) and (iii), we get

$$x\frac{d^2y}{dx^2} + 2\frac{dy}{dx} = xy$$

Which is the required differential equation.

Example 5 Find the differential equation whose solution represents the family $c(y+c)^2 = x^3$.

Sol. Differentiating $c(y+c)^2 = x^3$ ...(i)

We get $c[2(y+c)]\frac{dy}{dx} = 3x^2$ but from Eq. (i), we have

$$\frac{2x^3}{(y+c)^2}(y+c)\frac{dy}{dx} = 3x^2$$

$$\Rightarrow \quad \frac{2x^3}{y+c}\cdot\frac{dy}{dx} = 3x^2 \quad \text{i.e.} \quad \frac{2x}{y+c}\cdot\frac{dy}{dx} = 3$$

$$\Rightarrow \quad \frac{2x}{3}\left[\frac{dy}{dx}\right] = y + c \quad \therefore \quad c = \frac{2x}{3}\left[\frac{dy}{dx}\right] - y$$

Substituting c in Eq. (i), we get

$$\left[\frac{2x}{3}\left(\frac{dy}{dx}\right) - y\right]\left[\frac{2x}{3}\frac{dy}{dx}\right]^2 = x^3$$

Which is the required differential equation.

Example 6 ***Find the differential equation whose solution represents the family*** $y = ae^{3x} + be^x$.

Sol.
$$y = ae^{3x} + be^x \quad \ldots(i)$$

Differentiating the given equation twice, we get

$$\frac{dy}{dx} = 3ae^{3x} + be^x \quad \text{and} \quad \frac{d^2y}{dx^2} = 9ae^{3x} + be^x$$

From the three equations by eliminating a and b, we obtain

$$\frac{d^2y}{dx^2} - \frac{4dy}{dx} + 3y = 0$$

Remark

The order of the differential equation will be equal to number of independent parameters and is not equal to the number of all the parameters in the family of curves.

Example 7 ***Find the order of the family of curves*** $y = (c_1 + c_2)e^x + c_3 e^{x+c_4}$.

Sol. Here, the number of arbitrary parameters is 4 but the order of the corresponding differential equation will not be 4 as it can be rewritten as, $y = (c_1 + c_2 + c_3 e^{c_4})e^x$, which is of the form $y = Ae^x$. Hence, the corresponding differential equation will be of order 1.

Example 8 The differential equation of all non-horizontal lines in a plane is given by

(a) $\frac{d^2y}{dx^2} = 0$ (b) $\frac{d^2x}{dy^2} = 0$

(c) $\frac{d^2y}{dx^2} = 0$ and $\frac{d^2x}{dy^2} = 0$ (d) All of these

Sol. The equation of the family of all non-horizontal lines in a plane is given by,

$$ax + by = 1 \qquad \text{(where } a \neq 0\text{)} \quad \ldots(i)$$

Differentiating w.r.t. y, we get

$$a\frac{dx}{dy} + b = 0 \qquad (\text{as } a \neq 0 \text{ and } b \in R)$$

Again, differentiating w.r.t. y, we get

$$a\frac{d^2x}{dy^2} = 0 \qquad (\text{as } a \neq 0 \text{ and } b \in R)$$

$$\Rightarrow \qquad \frac{d^2x}{dy^2} = 0 \qquad (\text{as } a \neq 0)$$

$\therefore$ Differential equation of all non-horizontal lines in a plane is $\frac{d^2x}{dy^2} = 0$. Hence, (b) is the correct answer.

Example 9 The differential equation of all non-vertical lines in a plane is given by

(a) $\frac{d^2y}{dx^2} = 0$ (b) $\frac{d^2x}{dy^2} = 0$

(c) $\frac{d^2x}{dy^2} = 0$ and $\frac{d^2y}{dx^2} = 0$ (d) All of these

Sol. The equation of the family of all non-vertical lines in a plane is given by $ax + by = 1$, where $b \neq 0$ and $a \in R$.

Differentiating both the sides w.r.t. x, we get

$$a + b\frac{dy}{dx} = 0 \qquad (\text{as } b \neq 0 \text{ and } a \in R)$$

Again, differentiating both the sides w.r.t. x, we get

$$b\frac{d^2y}{dx^2} = 0 \qquad (\text{as } b \neq 0 \text{ and } a \in R)$$

$$\Rightarrow \qquad \frac{d^2y}{dx^2} = 0 \qquad (\text{as } b \neq 0)$$

$\therefore$ Differential equation of all non-vertical lines in a plane.

$$\Rightarrow \qquad \frac{d^2y}{dx^2} = 0$$

Hence, (a) is the correct answer.

Example 10 ***The differential equation of all straight lines which are at a constant distance*** p ***from the origin, is***

(a) $(y + xy_1)^2 = p^2(1 + y_1^2)$ (b) $(y - xy_1^2) = p^2(1 + y_1)^2$

(c) $(y - xy_1)^2 = p^2(1 + y_1^2)$ (d) None of these

Sol. As, we know $x\cos\alpha + y\sin\alpha = p$ ...(i)

Represents the family of straight lines which are at a constant distance p from origin. Differentiating Eq. (i) w.r.t. x, we get

$$\cos\alpha + \sin\alpha \cdot \frac{dy}{dx} = 0$$

$$\Rightarrow \qquad \tan\alpha = -\frac{1}{y_1} \quad \text{or} \quad \sin\alpha = \frac{1}{\sqrt{1 + y_1^2}}$$

and $$\cos\alpha = -\frac{y_1}{\sqrt{1 + y_1^2}} \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$\frac{-xy_1}{\sqrt{1 + y_1^2}} + \frac{y}{\sqrt{1 + y_1^2}} = p$$

$\Rightarrow (y - xy_1)^2 = p^2(1 + y_1^2)$ is required differential equations.

Hence, (c) is the correct answer.

Example 11 The differential equation of all circles of radius r, is given by

(a) $\{1 + (y_1)^2\}^2 = r^2 y_2^3$ (b) $\{1 + (y_1)^2\}^3 = r^2 y_2^3$

(c) $\{1 + (y_1)^2\}^3 = r^2 y_2^2$ (d) None of these

Sol. Equation of circle of radius r,

$$(x - a)^2 + (y - b)^2 = r^2 \qquad \ldots(i)$$

(Here, a, b are two arbitrary constants)

Differentiating Eq. (i), we get

$$2(x - a) + 2(y - b)y_1 = 0 \qquad \ldots(ii)$$

Again, differentiating Eq. (ii), we get

$$1 + (y - b)y_2 + y_1^2 = 0$$

$$\Rightarrow \qquad (y - b) = -\left(\frac{1 + y_1^2}{y_2}\right) \qquad \ldots(iii)$$

Putting $(y - b)$ in Eq. (ii), we get

$$(x - a) = \frac{(1 + y_1^2)y_1}{y_2} \qquad \ldots(iv)$$

From Eqs. (i), (iii) and (iv), we get

$$\frac{(1 + y_1^2)^2 \cdot y_1^2}{y_2^2} + \frac{(1 + y_1^2)^2}{y_2^2} = r^2$$

$$\Rightarrow \qquad (1 + (y_1)^2)^3 = r^2 y_2^2$$

Hence, (c) is the correct answer.

Example 12 The differential equations of all circles touching the x-axis at origin is

(a) $(y^2 - x^2) = 2xy\left(\frac{dy}{dx}\right)$

(b) $(x^2 - y^2)\frac{dy}{dx} = 2xy$

(c) $(x^2 - y^2) = 2xy\left(\frac{dy}{dx}\right)$

(d) None of the above

Sol. The equation of circle touches x-axis at origin.

$$\Rightarrow \qquad (x - 0)^2 + (y - a)^2 = a^2$$

$$\text{or} \qquad x^2 + y^2 - 2ay = 0 \qquad \ldots(i)$$

Differentiating w.r.t. x, we get

$$2x + 2y\frac{dy}{dx} - 2a\frac{dy}{dx} = 0$$

$$\Rightarrow \quad \frac{dy}{dx}(a - y) = x$$

$$\Rightarrow \quad a = \frac{x + y\left(\frac{dy}{dx}\right)}{\left(\frac{dy}{dx}\right)} \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$x^2 + y^2 - 2y\left[\frac{x + y\left(\frac{dy}{dx}\right)}{\left(\frac{dy}{dx}\right)}\right] = 0$$

or $$(x^2 - y^2)\frac{dy}{dx} = 2xy$$

Hence, (b) is the correct answer.

Example 13 The differential equation of all circles in the first quadrant which touch the coordinate axes is

(a) $(x - y)^2\,(1 + (y')^2) = (x + yy')^2$

(b) $(x + y)^2\,(1 + (y')^2) = (x + y')^2$

(c) $(x - y)^2\,(1 + y') = (x + yy')^2$

(d) None of these

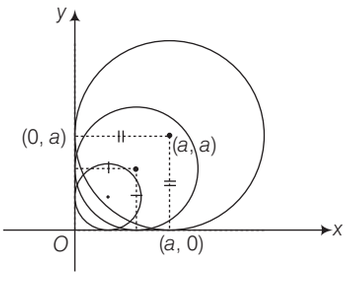
Sol. Equation of circles touching coordinate axes is

$$(x - a)^2 + (y - a)^2 = a^2 \quad \ldots(i)$$

Differentiating, we get

$$2(x - a) + 2(y - a)y' = 0$$

$$\Rightarrow \quad a = \frac{x + yy'}{1 + y'}; \quad \text{where } y' = \frac{dy}{dx} \quad \ldots(ii)$$



From Eqs. (i) and (ii),

$$\left(x - \frac{x + yy'}{1 + y'}\right)^2 + \left(y - \frac{x + yy'}{1 + y'}\right)^2 = \left(\frac{x + yy'}{1 + y'}\right)^2$$

$$\Rightarrow \quad \left(\frac{xy' - yy'}{1 + y'}\right)^2 + \left(\frac{y - x}{1 + y'}\right)^2 = \left(\frac{x + yy'}{1 + y'}\right)^2$$

$$\Rightarrow \quad (x - y)^2\,(y')^2 + (y - x)^2 = (x + yy')^2$$

$$\Rightarrow \quad (x - y)^2\,(1 + (y')^2) = (x + yy')^2$$

Hence, (a) is the correct answer.

Example 14 The differential equation satisfying the curve $\frac{x^2}{a^2 + \lambda} + \frac{y^2}{b^2 + \lambda} = 1$, where λ being arbitrary unknown, is

(a) $(x + yy_1)(xy_1 - y) = (a^2 - b^2)\,y_1$

(b) $(x + yy_1)(x - yy_1) = y_1$

(c) $(x - yy_1)(xy_1 + y) = (a^2 - b^2)\,y_1$

(d) None of these

Sol. Here, $$\frac{x^2}{a^2 + \lambda} + \frac{y^2}{b^2 + \lambda} = 1 \quad \ldots(i)$$

Differentiating both the sides, we get

$$\frac{2x}{a^2 + \lambda} + \frac{2y}{b^2 + \lambda}\cdot\frac{dy}{dx} = 0$$

$$\Rightarrow \quad x(b^2 + \lambda) + y(a^2 + \lambda)\,y_1 = 0$$

$$\Rightarrow \quad \lambda = -\left(\frac{xb^2 + a^2yy_1}{x + yy_1}\right)$$

$$\therefore \quad a^2 + \lambda = a^2 - \frac{xb^2 + a^2yy_1}{x + yy_1}$$

$$\Rightarrow \quad a^2 + \lambda = \frac{(a^2 - b^2)\,x}{x + yy_1} \quad \ldots(ii)$$

Also, $$b^2 + \lambda = \frac{(a^2 - b^2)\,yy_1}{x + yy_1} \quad \ldots(iii)$$

From Eqs. (i), (ii) and (iii), we get

$$\frac{x^2(x + yy_1)}{(a^2 - b^2)\,x} + \frac{y^2(x + yy_1)}{(a^2 - b^2)\,yy_1} = 1$$

$$\Rightarrow \quad (x + yy_1)(xy_1 - y) = (a^2 - b^2)\,y_1$$

Hence, (a) is the correct answer.

Example 15 The differential equation of all conics whose centre lies at origin, is given by

(a) $(3xy_2 + x^2y_3)(y - xy_1) = 3xy_2\,(y - xy_1 - x^2y_2)$

(b) $(3xy_1 + x^2y_2)(y_1 - xy_3) = 3xy_1\,(y - xy_2 - x^2y_3)$

(c) $(3xy_2 + x^2y_3)(y_1 - xy) = 3xy_1\,(y - xy_1 - x^2y_2)$

(d) None of the above

Sol. Equation of all conics whose centre lies at origin, is

$$ax^2 + 2hxy + by^2 = 1 \quad \ldots(i)$$

Differentiating Eq. (i) w.r.t. x, we get

$$2ax + 2hxy_1 + 2hy + 2byy_1 = 0$$

$$\Rightarrow \quad ax + h(y + xy_1) + byy_1 = 0$$

Multiplying by x equation becomes,

$$ax^2 + h(xy + x^2y_1) + bxyy_1 = 0 \quad \ldots(ii)$$

Subtracting Eqs. (i) and (ii), we get

$$h(xy - x^2y_1) + b(y^2 - xyy_1) = 1$$

$$\Rightarrow \quad (hx + by)\, y - xy_1\,(hx + by) = 1$$

$$\Rightarrow \quad (hx + by)\,(y - xy_1) = 1$$

$$\Rightarrow \quad hx + by = \frac{1}{y - xy_1} \qquad \ldots(\text{iii})$$

Again, differentiating w.r.t. x, we get

$$h + by_1 = -\frac{(y_1 - xy_2 - y_1)}{(y - xy_1)^2}$$

or
$$h + by_1 = \frac{xy_2}{(y - xy_1)^2} \qquad \ldots(\text{iv})$$

From Eqs. (iii) and (iv), we get

$$b\,(y - xy_1) = \frac{y - xy_1 - x^2y_2}{(y - xy_1)^2}$$

$$\Rightarrow \quad b = \frac{y - xy_1 - x^2y_2}{(y - xy_1)^3} \qquad \ldots(\text{v})$$

Again, differentiating both the sides w.r.t. x, we get

$$0 = \frac{y_1 - y_1 - 3xy_2 - x^2y_3}{(y - xy_1)^3} + \frac{3\,(y - xy_1 - x^2y_2)\,xy_2}{(y - xy_1)^4}$$

$$\Rightarrow \quad (3xy_2 + x^2y_3)\,(y - xy_1) = 3xy_2\,(y - xy_1 - x^2y_2)$$

Hence, (a) is the correct answer.

Exercise for Session 1

1. The differential equation of all parabolas whose axis of symmetry is along X-axis is of order.
(a) 2 (b) 3 (c) 1 (d) None of these

2. The order and degree of the differential equation of all tangent lines to the parabola $x^2 = 4y$ is
(a) 1, 2 (b) 2, 2 (c) 3, 1 (d) 4, 1

3. The degree of the differential equation $\frac{d^2y}{dx^2} + 3\left(\frac{dy}{dx}\right)^2 = x^2 \log\left(\frac{d^2y}{dx^2}\right)$ is
(a) 1 (b) 2 (c) 3 (d) Not defined

4. The degree of the defferential equation satisfying the relation $\sqrt{1+x^2} + \sqrt{1+y^2} = \lambda(x\sqrt{1+y^2} - y\sqrt{1+x^2})$ is
(a) 1 (b) 2 (c) 3 (d) 4

5. The degree of the differential equation $\left(\frac{d^2y}{dx^2}\right)^2 + \left(\frac{dy}{dx}\right)^2 = x \sin\left(\frac{d^2y}{dx^2}\right)$ is
(a) 1 (b) 2 (c) 3 (d) Not defined

6. The differential equation of all circles touching the y-axis at origin, is
(a) $y^2 - x^2 = 2xy\frac{dy}{dx}$ (b) $y^2 - x^2 = 2xy\frac{dx}{dy}$ (c) $x^2 - y^2 = 2xy\frac{dy}{dx}$ (d) $x^2 - y^2 = 2xy\frac{dx}{dy}$

7. The differential equation of all parabolas having their axes of symmetry coincident with the axes of x, is
(a) $yy_2 + y_1^2 = y + y_1$ (b) $yy_2 + y_1^2 = 0$ (c) $yy_2 + y_1^2 = y_1$ (d) None of these

8. The differential equation of all conics whose axes coincide with the coordinate axes, is
(a) $xyy_2 + xy_1^2 - yy_1 = 0$ (b) $yy_2 + y_1^2 - yy_1 = 0$
(c) $xyy_2 + (x - y)\,y_1 = 0$ (d) None of these

9. The differential equation having $y = (\sin^{-1} x)^2 + A(\cos^{-1} x) + B$, where A and B are arbitrary constant, is
(a) $(1 - x^2)\,y_2 - xy_1 = 2$ (b) $(1 - x^2)\,y_2 + yy_1 = 0$
(c) $(1 - x)\,y_2 + xy_1 = 0$ (d) None of these

10. The differential equation of circles passing through the points of intersection of unit circle with centre at the origin and the line bisecting the first quadrant, is
(a) $y_1(x^2 + y^2 - 1) + (x + yy_1) = 0$ (b) $(y_1 - 1)(x^2 + y^2 - 1) + (x + yy_1)\,2(x - y) = 0$
(c) $(x^2 + y^2 - 1) + yy_2 = 0$ (d) None of these

Session 2

Solving of Variable Seperable Form, Homogeneous Differential Equation

Solving of Variable Seperable Form

Solution of a Differential Equation

The solution of the differential equation is a relation between the variables of the equation not containing the derivatives, but satisfying the given differential equation (i.e from which the given differential equation can be derived).

Thus, the solution of $\frac{dy}{dx} = e^x$ could be obtained by simply integrating both the sides, i.e. $y = e^x + C$ and that of, $\frac{dy}{dx} = px + q$ is $y = p\frac{x^2}{2} + qx + C$, where C is arbitrary constant.

(i) **A general solution or an integral** of a differential equation is a relation between the variables (not involving the derivatives) which contains the same number of the arbitrary constants as the order of the differential equation. For example, a general solution of the differential equation $\frac{d^2x}{dt^2} = -4x$ is $x = A\cos 2t + B\sin 2t$, where A and B are the arbitrary constants.

(ii) **Particular solution or particular integral** is that solution of the differential equation obtained from the general solution by assigning particular values to the arbitrary constant in the general solution.

For example, $x = 10\cot 2t + 5\sin 2t$ is a particular solution of differential equation $\frac{d^2x}{dt^2} = -4x$.

Differential Equations of the First Order and First Degree

In this section we shall discuss the differential equations which are of first order and first degree only.

A differential equation of first order and first degree is of the form $\frac{dy}{dx} = f(x, y)$.

Remark

All the differential equations, even of first order and first degree, cannot be solved. However, if they belong to any of the standard forms which we are going to discuss, in the subsequent articles they can be solved.

Equations in Which the Variables are Separable

The equation $\frac{dy}{dx} = f(x, y)$ is said to be in variables separable form, if we can express it in the form $f(x)\,dx = g(y)\,dy$. By integrating this, solution of the equation is obtained which is, $\int f(x)\,dx = \int g(y)\,dy + C$

Example 16 ***Solve***

$$\sec^2 x \tan y\,dx + \sec^2 y \tan x\,dy = 0.$$

Sol. Dividing the given equation by $\tan x \tan y$, we get

$$\frac{\sec^2 x}{\tan x}dx + \frac{\sec^2 y}{\tan y}dy = 0$$

This is variable-separable type

Integrating, $\int \frac{\sec^2 x}{\tan x}dx + \int \frac{\sec^2 y}{\tan y}dy = C'$

$$\ln|\tan x| + \ln|\tan y| = \ln C;\ \text{where } C' = \ln C$$

or $$\ln|\tan x \cdot \tan y| = \ln C;\ (C > 0)$$

$\Rightarrow$ $$|\tan x \cdot \tan y| = C$$

This is the general solution.

Example 17 Solve $\frac{dy}{dx} = e^{x-y} + x^2 e^{-y}$.

Sol. Here, $\frac{dy}{dx} = \frac{e^x}{e^y} + \frac{x^2}{e^y} \Rightarrow e^y\,dy = (x^2 + e^x)\,dx$

This is variable-separable form,

$\therefore$ Integrating both the sides,

$$\int e^y\, dy = \int (x^2 + e^x)\, dx \Rightarrow e^y = \frac{x^3}{3} + e^x + C$$

Which is the general solution of the given differential equation, where C is an arbitrary constant.

Example 18 Solve $\sqrt{1+x^2+y^2+x^2y^2} + xy\dfrac{dy}{dx} = 0$.

Sol. The given differential equation can be written as

$$\sqrt{(1+y^2)(1+x^2)} = -xy\frac{dy}{dx}$$

$$\Rightarrow \quad -\frac{\sqrt{1+x^2}\,dx}{x} = \frac{y\,dy}{\sqrt{1+y^2}}$$

This is the variable-separable form.

$\therefore$ Integrating both the sides, we get

$$-\int \frac{\sqrt{1+x^2}}{x}\,dx = \int \frac{y}{\sqrt{1+y^2}}\,dy$$

$$\Rightarrow -\left[\sqrt{1+x^2} + \frac{1}{2}\log\left(\frac{\sqrt{1+x^2}-1}{\sqrt{1+x^2}+1}\right)\right] = \sqrt{1+y^2} + C$$

This is the general solution to the given differential equation.

Example 19 Solve $y - x\dfrac{dy}{dx} = a\left(y^2 + \dfrac{dy}{dx}\right)$.

Sol. Rewriting the given equation as

$$y - ay^2 = (x+a)\frac{dy}{dx}$$

$$\Rightarrow \quad \frac{dy}{y(1-ay)} = \frac{dx}{(x+a)}$$

This is the variable-separable form.

Integrating both the sides, we get

$$\int \frac{dy}{y(1-ay)} = \int \frac{dx}{(x+a)}$$

$$\Rightarrow \quad \int \left(\frac{1}{y} + \frac{a}{1-ay}\right)dy = \int \frac{dx}{x+a}$$

$$\Rightarrow \quad \ln y - \frac{a}{a}\ln(1-ay) + \ln C = \ln(a+x)$$

$$\Rightarrow \quad \ln\left(\frac{(a+x)(1-ay)}{y}\right) = \ln(C)$$

or $Cy = (a+x)(1-ay)$ is the general solution.

Example 20 Solve $e^{dy/dx} = x+1$, given that when $x = 0, y = 3$.

Sol. This is an Example of particular solution.

$$e^{(dy/dx)} = x+1$$

$\therefore \quad \dfrac{dy}{dx} = \ln(x+1)$

$\therefore \quad \int dy = \int \ln(x+1)\,dx$ (integration by parts)

i.e. $\quad y = x\ln(x+1) - \int \dfrac{x}{x+1}\,dx$

i.e. $\quad y = x\ln(x+1) - x + \ln(x+1) + C$

This is the general solution.

To find the particular solution, put $x = 0, y = 3$ in the general equation.

$\therefore \quad 3 = 0 - 0 + 0 + C$

$\therefore \quad C = 3$

$\therefore$ The required particular solution is,

$$y = (x+1)\ln(x+1) - x + 3$$

Differential Equations Reducible to the Separable Variable Type

Sometimes differential equation of the first order cannot be solved directly by variable separation but by some substitution we can reduce it to a differential equation with separable variable. ''A differential equation of the form $\dfrac{dy}{dx} = f(ax+by+c)$ is solved by writing $ax+by+c = t$.''

Example 21 Solve $\dfrac{dy}{dx} = \sin^2(x+3y) + 5$.

Sol. Let $x+3y = t$, so that $1 + \dfrac{3dy}{dx} = \dfrac{dt}{dx}$

The given differential equation becomes,

$$\frac{1}{3}\left(\frac{dt}{dx} - 1\right) = \sin^2(t) + 5 \Rightarrow \frac{dt}{dx} = 3\sin^2 t + 16$$

$$\Rightarrow \quad \int \frac{dt}{3\sin^2 t + 16} = \int dx$$

$$\Rightarrow \quad \int \frac{\sec^2 t\, dt}{3\tan^2 t + 16\sec^2 t} = x + C$$

$$\Rightarrow \quad \int \frac{\sec^2 t\, dt}{19\tan^2 t + 16} = x + C$$

$$\Rightarrow \quad \int \frac{du}{19u^2 + 16} = x + C;\ \text{where } \tan t = u$$

$$\Rightarrow \quad \sec^2 t\, dt = du$$

$$\Rightarrow \quad \frac{1}{19}\int \frac{du}{u^2 + \frac{16}{19}} \Rightarrow \frac{1}{19}\frac{\sqrt{19}}{4}\tan^{-1}\left(\frac{\sqrt{19}u}{4}\right) + C$$

$$\Rightarrow \quad \frac{1}{4\sqrt{19}}\left\{\tan^{-1}\left(\frac{\sqrt{19}}{4}\tan(3y+x)\right)\right\} + C$$

Example 22 Solve $(x+y)^2 \dfrac{dy}{dx} = a^2$.

Sol. $$(x+y)^2 \frac{dy}{dx} = a^2 \quad \ldots(i)$$

Put $x + y = t \Rightarrow 1 + \dfrac{dy}{dx} = \dfrac{dt}{dx}$ or $\dfrac{dy}{dx} = \left(\dfrac{dt}{dx} - 1\right)$

$\therefore$ Eq. (i) reduces to $t^2 \left\{\dfrac{dt}{dx} - 1\right\} = a^2$

i.e. $t^2 \dfrac{dt}{dx} = a^2 + t^2$, separating the variable and integrating.

$$\int dx = \int \frac{t^2}{a^2 + t^2}\, dt = \int \left(1 - \frac{a^2}{a^2 + t^2}\right) dt$$

$$\therefore \quad x = t - a \tan^{-1}\left(\frac{t}{a}\right) + C$$

i.e. $$x = x + y - a \tan^{-1}\left(\frac{x+y}{a}\right) + C$$

i.e. $y = a \tan^{-1}\left(\dfrac{x+y}{a}\right) - C$ is the required general solution.

Example 23 ***Solve***

$(2x + 3y - 1)\,dx + (4x + 6y - 5)\,dy = 0.$

Sol. $(2x + 3y - 1)\,dx + (4x + 6y - 5)\,dy = 0 \quad \ldots(i)$

Substitute $u = 2x + 3y - 1$

$$\therefore \quad \frac{du}{dx} = 2 + \frac{3dy}{dx} \quad \text{or} \quad \frac{dy}{dx} = \frac{1}{3}\left(\frac{du}{dx} - 2\right)$$

$\therefore$ Eq. (i) reduces to

$$u + (2u - 3)\frac{1}{3}\left(\frac{du}{dx} - 2\right) = 0$$

i.e. $$u - \frac{2}{3}(2u - 3) + \frac{1}{3}(2u - 3)\frac{du}{dx} = 0$$

i.e. $$\frac{-u + 6}{3} + \frac{1}{3}(2u - 3)\frac{du}{dx} = 0$$

Writing this in the variable-separable form

$$\left(\frac{2u - 3}{u - 6}\right) du = dx$$

$$\therefore \quad \int dx = \int \frac{2u - 3}{u - 6}\, du$$

$$\therefore \quad x + C = \int \frac{2(u-6) + 9}{(u-6)}\, du$$

$$\therefore \quad x + C = 2u + 9 \ln|u - 6|$$

$$\therefore \quad x + C = 2(2x + 3y - 1) + 9 \ln|2x + 3y - 7|$$

$3x + 6y - 2 + 9 \ln|2x + 3y - 7| = C$ is the general solution.

Remarks

Sometimes transformation to the polar coordinates facilitates separation of varibales. It is convenient to remember the following differentials.

1. $x\,dx + y\,dy = r\,dr$ **2.** $x\,dy - y\,dx = r^2\,d\theta$

3. $dx^2 + dy^2 = dr^2 + r^2 d\,\theta^2$

Example 24 Solve $\dfrac{x\,dx + y\,dy}{x\,dy - y\,dx} = \sqrt{\dfrac{a^2 - x^2 - y^2}{x^2 + y^2}}$.

Sol. Let $x = r\cos\theta, y = r\sin\theta$

So that $$x^2 + y^2 = r^2 \quad \ldots(i)$$

and $$\tan\theta = \frac{y}{x} \quad \ldots(ii)$$

From Eq. (i), we have $d(x^2 + y^2) = d(r^2)$

i.e. $$x\,dx + y\,dy = r\,dr \quad \ldots(iii)$$

From Eq. (ii), we have $d\left(\dfrac{y}{x}\right) = d(\tan\theta)$

i.e. $$\frac{x\,dy - y\,dx}{x^2} = \sec^2\theta\, d\theta$$

i.e. $x\,dy - y\,dx = x^2 \sec^2\theta\, d\theta = r^2 \cos^2\theta \sec^2\theta\, d\theta \ldots(iv)$

Using Eqs. (iii) and (iv) in the given equation, we get

$$\frac{r\,dr}{r^2\,d\theta} = \sqrt{\frac{a^2 - r^2}{r^2}} \text{ i.e. } \frac{dr}{\sqrt{a^2 - r^2}} = d\theta$$

i.e. $$\sin^{-1}\left(\frac{r}{a}\right) = \theta + C \quad \text{or} \quad r = a\sin(\theta + C)$$

or $$\sqrt{x^2 + y^2} = a\sin\{C + \tan^{-1}(y/x)\}$$

It is advised to remember the results (iii) and (iv).

Homogeneous Differential Equation

By definition, a homogeneouos function $f(x, y)$ of degree n satisfies the property

$$f(\lambda x, \lambda y) = \lambda^n f(x, y)$$

For example, the functions

$$f_1(x, y) = x^3 + y^3$$

$$f_2(x, y) = x^2 + xy + y^2$$

$$f_3(x, y) = x^3 e^{x/y} + xy^2$$

are all homogeneous functions, of degrees three, two and three respectively (verify this assertion).

Observe that any homogeneous function $f(x, y)$ of degree n can be equivalnetly written as follows :

$$f(x, y) = x^n f\left(\frac{y}{x}\right) = y^n f\left(\frac{x}{y}\right)$$

For example, $f_{(x,\ y)} = x^3 + y^3$

$$= x^3\left(1 + \left(\frac{y}{x}\right)^3\right) = y^3\left(1 + \left(\frac{x}{y}\right)^3\right)$$

Having seen homogeneous functions we define homogeneous DEs as follows :

Any DE of the form $M(x, y)\,dx + N(x, y)dy = 0$

or $\frac{dy}{dx} = -\frac{M(x,y)}{N(x,y)}$ is called homogeneous if $M(x, y)$ and $N(x, y)$ are homogeneous functions of the same degree.

What is so special about homogeneous DEs? Well, it turns out that they areextremely simple to solve. To see how, we express both $M(x, y)$ and $N(x, y)$ as, say $x^n M\left(\frac{y}{x}\right)$ and $x^n N\left(\frac{y}{x}\right)$. This can be done sicne $M(x, y)$ and $N(x, y)$ are both homogeneous function of degree n. Doing this reduces our DE to

$$\frac{dy}{dx} = -\frac{M(x,y)}{N(x,y)} = \frac{x^n M\left(\frac{y}{x}\right)}{x^n N\left(\frac{y}{x}\right)} = -\frac{M\left(\frac{y}{x}\right)}{N\left(\frac{y}{x}\right)} = P\left(\frac{y}{x}\right)$$

(The function $P(t)$ stands for $\frac{-M(t)}{N(t)}$)

Now, the simple substitution $y = vx$ reduces this DE to a VS form

$$y = vx$$

$$\Rightarrow \quad \frac{dy}{dx} = v + x\frac{dy}{dx}$$

Thus, $\frac{dy}{dx} = p\left(\frac{y}{x}\right)$ transforms to

$$v + x\frac{dv}{dx} = P(v)$$

$$\Rightarrow \quad \frac{dv}{P(v) - v} = \frac{dx}{x}$$

This can now be integraed directly since it is in VS form. Let us see some examples of solving homogeneous DEs.

Alogorithm for Solving Homogeneous Differential Equation

***Step* I** Put the differential equation in the form

$$\frac{dy}{dx} = \frac{\phi(x,y)}{\psi(x,y)}$$

***Step* II** Put $y = vx$ and $\frac{dy}{dx} = v + x\frac{dv}{dx}$ in the equation in step I and can out x from the right hand side. The equation reduces to the form $v + x\frac{dv}{dx} = f(v)$.

***Step* III** Shift v on R.H.S and seperate the variables in v and x.

***Step* IV** Integrate both sides to obtain the solution in terms of v and x.

***Step* V** Replace v by $\frac{y}{x}$ in the solution obtained in step IV to obtain the solution in terms of x and y.

Following examples illustrate the procedure.

Example 25 Solve $y\,dx + (2\sqrt{xy} - x)\,dy = 0$.

Sol. $$y\,dx + (2\sqrt{xy} - x)\,dy = 0 \qquad \ldots(i)$$

This is homogeneous type. Substitute $y = ux$

$$\therefore \quad \frac{dy}{dx} = u + \frac{x\,du}{dx}$$

$\therefore$ Equation $ux\,dx + (2\sqrt{x^2 u} - x)(u\,dx + x\,du) = 0$

i.e. $x \cdot \{udx + (2\sqrt{u} - 1)\,u\,dx + x\,du\,(2\sqrt{u} - 1)\} = 0$

i.e. $$dx\,(2u^{3/2} - u + u) + x\,du\,(2\sqrt{u} - 1) = 0$$

Separating the variables, $\frac{dx}{x} + \left(\frac{2\sqrt{u} - 1}{2u^{3/2}}\right)du = 0$

Integrating both the sides $\ln|x| + \ln|u| + \frac{1}{\sqrt{u}} = C$

or $\ln|xu| + \frac{1}{\sqrt{u}} = C$ or $\ln|y| + \sqrt{\frac{x}{y}} = C \quad \left(\because u = \frac{y}{x}\right)$

Which is the general solution.

Example 26 Solve $(x^2 + y^2)\,dx - 2xy\,dy = 0$.

Sol. Here, $\frac{dy}{dx} = \frac{x^2 + y^2}{2xy} = \frac{1}{2}\left[\frac{x}{y} + \frac{y}{x}\right]$

With $y = ux$, $\frac{dy}{dx} = u + x\frac{du}{dx}$, so that the differential equation becomes

$$u + x\frac{du}{dx} = \frac{1}{2}\left(\frac{1}{u} + u\right)$$

$$\Rightarrow \quad \frac{x\,du}{dx} = \frac{1 + u^2}{2u} - u$$

$$\Rightarrow \quad \frac{x\,du}{dx} = \frac{1 - u^2}{2u}$$

$$\Rightarrow \quad \int \frac{2u}{1 - u^2}\,du = \int \frac{dx}{x}$$

$$\Rightarrow \quad -\log|1 - u^2| = \log|x| - \log|C|$$

$$\Rightarrow \quad x(1 - u^2) = C$$

$$\Rightarrow \quad \frac{x^2 - y^2}{x} = C \qquad \left(\because u = \frac{y}{x}\right)$$

Hence, $x^2 - y^2 = xC$, is the required solution.

Example 27 Solve $\dfrac{2\,dy}{dx} = \dfrac{y}{x} + \dfrac{y^2}{x^2}$.

Sol. The above equation is homogeneous so that we put $y = ux$.

$$\Rightarrow \quad 2\left[u + x\frac{du}{dx}\right] = u + u^2 \;\Rightarrow\; 2u + 2x\frac{du}{dx} = u + u^2$$

$$\Rightarrow \quad 2x\frac{du}{dx} = u^2 - u \;\Rightarrow\; \frac{du}{u^2 - u} = \frac{dx}{2x}$$

$$\Rightarrow \quad \int \frac{du}{u(u-1)} = \frac{1}{2}\int \frac{dx}{x}$$

$$\Rightarrow \quad \int \frac{1}{u-1}\,du - \int \frac{1}{u}\,du = \frac{1}{2}\int \frac{dx}{x}$$

$$\Rightarrow \quad \log|u-1| - \log|u| = \frac{1}{2}\log|x| + \log|C|$$

$$\Rightarrow \quad \log\left|\frac{u-1}{u}\right| = \log|C\sqrt{x}|$$

$$\Rightarrow \quad \frac{u-1}{u} = C\sqrt{x} \;\Rightarrow\; \frac{y-x}{y} = C\sqrt{x}$$

$$\Rightarrow \quad y - x = C\sqrt{x}\cdot y$$

Which is the required solution.

Example 28 ***Solve***

$(1+2\,e^{x/y})\,dx + 2\,e^{x/y}\,(1 - x/y)\,dy = 0.$

Sol. The appearance of x/y in the equation suggests the substitution $x = vy$ or $dx = v\,dy + y\,dv$.

$\therefore$ The given equation is

$$(1+2e^v)(v\,dy + y\,dv) + 2e^v(1-v)\,dy = 0$$

i.e. $$y(1+2e^v)\,dv + (v + 2e^v)\,dy = 0$$

i.e. $$\frac{1+2e^v}{v+2e^v}\,dv + \frac{dy}{y} = 0$$

Integrating, $$\int \frac{1+2e^v}{v+2e^v}\,dv + \int \frac{dy}{y} = 0$$

$$\log|v + 2e^v| + \log|y| = \log|C|$$

$$\Rightarrow \quad (v + 2e^v)\,y = C \qquad \left(v = \frac{x}{y}\right)$$

$$\Rightarrow \quad \left(\frac{x}{y} + 2e^{x/y}\right)y = C$$

$$\Rightarrow \quad (x + 2ye^{x/y}) = C, \text{ is required solution.}$$

Example 29 ***Show that any equation of the form***

$$y\,f(xy)\,dx + x\,g(xy)\,dy = 0$$

can be converted to variable separable form by substituting $xy = v$.

Sol. Since, $xy = v$, $y = \dfrac{v}{x}$ and $d(x\,y) = d\,v$

i.e. $$x\,dy + y\,dx = dv$$

and $$dy = d\left(\frac{v}{x}\right) = \frac{x\,dv - v\,dx}{x^2}$$

i.e. $$x\,dy = dv - \frac{v}{x}\,dx$$

$\therefore$ $$\frac{v}{x}f(v)\,dx + g(v)\left\{dv - \frac{v}{x}\,dx\right\} = 0$$

$\therefore$ $$\frac{v\{f(v) - g(v)\}}{x}\,dx + g(v)\,dv = 0$$

i.e. $$\frac{dx}{x} + \frac{g(v)\,dv}{v\{f(v) - g(v)\}} = 0$$

Which is in variables separable form.

Reducible to Homogeneous Form

Type I

Many a times, the DE specified may not be homogeneous but some suibtale manipulation might reduce it to a homogeneous form. Generally, such equations involve a function of a rational expression whose numerator and denominator are linear functions of the variable, i.e., of the form

$$\frac{dy}{dx} = f\left(\frac{ax + by + c}{dx + cy + f}\right) \qquad \ldots(i)$$

Note that the presence of the constant c and f causes this DE to be non-homogeneous.

To make it homogeneous, we use the substitutions

$$x \to X + h$$
$$y \to Y + k$$

and select h and k so that

$$\left.\begin{aligned} ah + bk + c &= 0 \\ dh + ek + f &= 0 \end{aligned}\right\} \qquad \ldots(ii)$$

This can always be done $\left(\text{if } \dfrac{a}{b} \neq \dfrac{d}{e}\right)$. The RHS of the DE in (i) now reduces to $= f\left(\dfrac{a(X+h) + b(Y+k) + c}{d(X+h) + e(Y+k+f)}\right)$

$$= f\left(\frac{aX + bY}{dX + eY}\right) \qquad \text{(Using Eq. (ii))}$$

This expression is clearly homogeneous! The LHS of Eq. (i) is $\dfrac{dy}{dx}$ which equals $\dfrac{dy}{dY}\cdot\dfrac{dY}{dX}\cdot\dfrac{dX}{dx}$. Since $\dfrac{dy}{dY}\cdot\dfrac{dx}{dX} = 1$, the LHS $\dfrac{dy}{dx}$ equals $\dfrac{dY}{dX}$. Thus, our equation becomes

$$\frac{dY}{dX} = f\left(\frac{aX + bY}{dX + eY}\right) \quad \text{...(iii)}$$

We have thus succeeded in transforming the non-homogeneous DE in Eq. (i) to the homogeneous DE in Eq. (iii). This can now be solved as described earlier.

Example 30 Solve the DE $\frac{dy}{dx} = \frac{2y - x - 4}{y - 3x + 3}$.

Sol. We substitute $x \to X + h$ and $y \to Y + k$ where h, k need to be determined

$$\frac{dy}{dx} = \frac{dY}{dX} = \frac{(2Y - X) + (2k - h - 4)}{(Y - 3X) + (k - 3h + 3)}$$

h and k must be chosen so that

$$2k - h - 4 = 0$$
$$k - 3h + 3 = 0$$

This gives $h = 2$ and $k = 3$. Thus,

$$x = X + 2$$
$$y = Y + 3$$

Our DE now reduces to

$$\frac{dY}{dX} = \frac{2Y - X}{Y - 3X}$$

Using the substitution $Y = vX$, and simplifying, we have (verify),

$$\frac{v - 3}{v^2 \;\; 5v + 1} dv = \frac{-dX}{X}$$

We now integrate this DE which is VS; the left-hand side can be integrated by the techniques described in the unit of Indefinite Integration.

Finally, we substitute $v = \frac{Y}{X}$ and

$$X = x - 2$$
$$Y = y - 3$$

to obtain the general solution.

Type II

Suppose our DE is of the form

$$\frac{dy}{dx} = f\left(\frac{ax + by + c}{dx + ey + f}\right)$$

We try to find h, k so that

$$ah + bk + c = 0$$
$$dh + ek + f = 0$$

What if this system does not yield a solution? Recall that this will happen if $\frac{a}{b} = \frac{d}{e}$. How do we reduce the DE to a homogeneous one in such a case?

Let $\frac{a}{d} = \frac{b}{e} = \lambda$ (say).

Thus,

$$\frac{ax + by + c}{dx + ey + f} = \frac{\lambda(dx + ey) + c}{dx + ey + f}$$

This suggests the substitution $dx + ey = v$, which will give

$$d + e\frac{dy}{dx} = \frac{dv}{dx}$$

$$\Rightarrow \quad \frac{dy}{dx} = \frac{1}{e}\left(\frac{dv}{dx} - d\right)$$

Thus, our DE reduces to

$$\frac{1}{e}\left(\frac{dv}{dx} - d\right) = \frac{\lambda v + c}{v + f}$$

$$\Rightarrow \quad \frac{dv}{dx} = \frac{\lambda ev + ec}{v + f} + d$$

$$= \frac{(\lambda e + d)v + (ec + d)}{v + f}$$

$$\Rightarrow \quad \frac{(v + f)}{(\lambda e + d)\, v + ec + df} dv = dx$$

which is in VS form and hence can be solved.

Example 31 Solve the DE $\frac{dy}{dx} = \frac{x + 2y - 1}{x + 2y + 1}$.

Sol. Note that h, k do not exist in this case which can reduce this DE to homogeneous form. Thus, we use the substitution

$$x + 2y = v$$

$$\Rightarrow \quad 1 + 2\frac{dy}{dx} = \frac{dv}{dx}$$

Thus, our DE becomes

$$\frac{1}{2}\left(\frac{dv}{dx} - 1\right) = \frac{v - 1}{v + 1}$$

$$\Rightarrow \quad \frac{dv}{dx} = \frac{2v - 2}{v + 1} + 1 = \frac{3v - 1}{v + 1}$$

$$\Rightarrow \quad \frac{v + 1}{3v - 1} dv = dx$$

$$\Rightarrow \quad \frac{1}{3}\left(1 + \frac{4}{3v - 1}\right) dv = dx$$

Integrating, we have

$$\frac{1}{3}\left(v + \frac{4}{3}\ln(3v - 1)\right) = x + C_1$$

Substituting $v = x + 2y$, we have

$$x + 2y + \frac{4}{3}\ln(3x + 6y - 1) = 3x + C_2$$

$$\Rightarrow \quad y - x + \frac{2}{3}\ln(3x + 6y - 1) = C$$

Example 32 ***The solution of the differential equation*** $\frac{dy}{dx}=\frac{\sin y+x}{\sin 2y-x\cos y}$ ***is***

(a) $\sin^2 y = x\sin y+\frac{x^2}{2}+C$

(b) $\sin^2 y = x\sin y-\frac{x^2}{2}+C$

(c) $\sin^2 y = x+\sin y+\frac{x^2}{2}+C$

(d) $\sin^2 y = x-\sin y+\frac{x^2}{2}+C$

Sol. Here, $\frac{dy}{dx}=\frac{\sin y+x}{\sin 2y-x\cos y}$

$\Rightarrow \cos y\frac{dy}{dx}=\frac{\sin y+x}{2\sin y-x}$, put $\sin y=t$

$\Rightarrow \frac{dt}{dx}=\frac{t+x}{2t-x}$, put $t=vx$

$$\frac{x\,dv}{dx}+v=\frac{vx+x}{2vx-x}=\frac{v+1}{2v-1}$$

$\therefore \quad x\frac{dv}{dx}=\frac{v+1}{2v-1}-v=\frac{v+1-2v^2+v}{2v-1}$

or $\frac{2v^2-v}{-2v^2+2v+1}dv=\frac{dx}{x}$

On solving, we get

$$\sin^2 y = x\sin y+\frac{x^2}{2}+C$$

Hence, (a) is the correct answer.

Example 33 The equation of curve passing through (1, 0) and satisfying $\left(y\frac{dy}{dx}+2x\right)^2=(y^2+2x^2)\left(1+\left(\frac{dy}{dx}\right)^2\right)$, is given by

(a) $\sqrt{2}\,x^{\pm\frac{1}{\sqrt{2}}}=\frac{y+\sqrt{y^2+2x^2}}{x}$

(b) $\sqrt{2}x^{\pm\sqrt{2}}=\frac{y+\sqrt{y^2+\sqrt{2}\,x^2}}{x}$

(c) $\sqrt{2}\,y^{\pm\frac{1}{\sqrt{2}}}=\frac{y+\sqrt{x^2+2y^2}}{x}$

(d) None of the above

Sol. The given differential equation can be written as

$$y^2\left(\frac{dy}{dx}\right)^2+4x^2+4xy\cdot\frac{dy}{dx}=(y^2+2x^2)\left(1+\left(\frac{dy}{dx}\right)^2\right)$$

$$\Rightarrow \quad \frac{dy}{dx}=\frac{y}{x}\pm\sqrt{\frac{1}{2}\left(\frac{y}{x}\right)^2+1} \qquad \ldots(i)$$

Let $y=vx$

$$\Rightarrow \quad v+x\frac{dv}{dx}=\frac{dy}{dx}$$

$\therefore$ Eq. (i) becomes

$$v+x\frac{dv}{dx}=v\pm\sqrt{\frac{1}{2}v^2+1}$$

or $\int\frac{dv}{\sqrt{\frac{1}{2}v^2+1}}=\int\frac{dx}{x}$

$$\Rightarrow \quad \sqrt{2}\log|v+\sqrt{v^2+2}|=\log|xC|$$

$$\Rightarrow \sqrt{2}\log\left|\frac{y+\sqrt{y^2+2x^2}}{x}\right|=\log|xC|,$$

putting $x=1$ and $y=0$

$$\Rightarrow \quad C=(\sqrt{2})^{\sqrt{2}}$$

$\therefore$ Curves are given by $\frac{y+\sqrt{y^2+2x^2}}{x}=\sqrt{2}\,x^{\pm\frac{1}{\sqrt{2}}}$

Hence, (a) is the correct answer.

Exercise for Session 2

1. The solution of $\frac{dy}{dx} = \frac{(x+y)^2}{(x+2)(y-2)}$, is given by

(a) $(x+2)^4\left(1+\frac{2y}{x}\right) = ke^{2y/x}$ (b) $(x+2)^4\left(1+\frac{2(y-2)}{(x+2)}\right) = k\,e^{\frac{2(y-2)}{(x+2)}}$

(c) $(x+2)^3\left(1+2\frac{(y-2)}{x+2}\right) = ke^{\frac{2(y-2)}{x+2}}$ (d) None of these

2. If $(y^3 - 2x^2y)\,dx + (2xy^2 - x^3)\,dy = 0$, then the value of $xy\sqrt{y^2-x^2}$, is

(a) $y^2 + x$ (b) xy^2

(c) any constant (d) None of these

3. The solution of $dy/dx = \cos(x+y) + \sin(x+y)$, is given by

(a) $\log\left|1+\tan\left(\frac{x+y}{2}\right)\right| = x + C$ (b) $\log|1+\tan(x+y)| = x + C$

(c) $\log|1-\tan(x+y)| = x + C$ (d) None of these

4. The solution of $\frac{dy}{dx} = (x+y-1) + \frac{x+y}{\log(x+y)}$, is given by

(a) $\{1+\log(x+y)\} - \log\{1+\log(x+y)\} = x + C$ (b) $\{1-\log(x+y)\} - \log\{1-\log(x+y)\} = x + C$

(c) $\{1+\log(x+y)\}^2 - \log\{1+\log(x+y)\} = x + C$ (d) None of these

5. The solution of $(2x^2+3y^2-7)\,xdx - (3x^2+2y^2-8)\,ydy = 0$, is given by

(a) $(x^2+y^2-1) = (x^2+y^2-3)^5\,C$ (b) $(x^2+y^2-1)^2 = (x^2+y^2-3)^5\,C$

(c) $(x^2+y^2-3) = (x^2+y^2-1)^5\,C$ (d) None of these

6. The solution of $\frac{dy}{dx} = \frac{(x-1)^2 + (y-2)^2\tan^{-1}\left(\frac{y-2}{x-1}\right)}{(xy-2x-y+2)\tan^{-1}\left(\frac{y-2}{x-1}\right)}$, is equal to

(a) $\{(x-1)^2+(y-1)^2\}\tan^{-1}\left(\frac{y-2}{x-1}\right) - 2(x-1)(y-2) = 2(x-1)^2\log C(x-1)$

(b) $\{(x-1)^2+(y-1)^2\} - 2(x-1)(y-2)\tan^{-1}\left(\frac{y-2}{x-1}\right) = 2(x-1)^2\log C$

(c) $\{(x-1)^2+(y-1)^2\}\tan^{-1}\left(\frac{y-2}{x-1}\right) - 2(x-1)(y-2) = \log C(x-1)$

(d) None of the above

7. The solution of $\frac{dy}{dx} = \left(\frac{x+2y-3}{2x+y+3}\right)^2$, is

(a) $(x+3)^3 - (y-3)^3 = C(x-y+6)^4$ (b) $(x+3)^3 - (y-3)^3 = C$

(c) $(x+3)^4 + (y-3)^4 = C$ (d) None of these

8. The solution of $\frac{dy}{dx} = \frac{-\cos x(3\cos y - 7\sin x - 3)}{\sin y(3\sin x - 7\cos y + 7)}$, is

(a) $(\cos y - \sin x - 1)^2(\sin x + \cos y - 1)^5 = C$ (b) $(\cos y - \sin x - 1)^2(\sin x + \cos y - 1)^3 = C$

(c) $(\cos y - \sin x - 1)^2(\sin x + \cos y - 1)^7 = C$ (d) None of these

9. A curve C has the property that if the tangent drawn at any point P on C meets. The coordinate axes at A and B, then P is the mid point of AB. The curve passes through the point $(1, 1)$. Then the equation of curve is

(a) $xy = 1$ (b) $\frac{x}{y} = 1$

(c) $2x = xy - 1$ (d) None of these

10. The family of curves whose tangent form an angle $\frac{\pi}{4}$ with the hyperbola $xy = 1$, is

(a) $y = x - 2\tan^{-1}(x) + K$ (b) $y = x + 2\tan^{-1}(x) + K$

(c) $y = 2x - \tan^{-1}(x) + K$ (d) $y = 2x + \tan^{-1}(x) + K$

11. A and B are two separate reservoires of mater capacity of reservoir are filled completely with water their inlets are closed and then the water is released simultaneously from both the reservoirs. The rate of flow of water out of each reservoir at any instant of time is proportional to the quantity of water in the reservoir at that time. One hour after the water is released, the quantity of water in the reservoir A is $1\frac{1}{2}$ times the quantity of the water in reservoir B. The time after which do both the reservoirs have the same quantity of water, is

(a) $\log_{3/4}(2)$ (b) $\log_{3/4}\left(\frac{1}{2}\right)$

(c) $\log_{1/2}\left(\frac{1}{2}\right)$ (d) None of these

12. A curve passes through $(2, 1)$ and is such that the square of the ordinate is twice the rectangle contained by the abscissa and the intercept of the normal. Then the equation of curve is

(a) $x^2 + y^2 = 9x$ (b) $4x^2 + y^2 = 9x$

(c) $4x^2 + 2y^2 = 9x$ (d) None of these

13. A normal at $P(x, y)$ on a curve neets the X-axis at Q and N is the foot of the ordinate at P. If $NQ = \frac{x(1+y^2)}{(1+x^2)}$.

Then the equation of curve passing through (3, 1) is

(a) $5(1+y^2) = (1+x^2)$ (b) $(1+y^2) = 5(1+x^2)$

(c) $(1+x^2) = (1+y^2).x$ (d) None of these

14. The curve for which the ratio of the length of the segment intercepted by any tangent on the Y-axis to the length of the radius vector is constant (k), is

(a) $(y + \sqrt{x^2 - y^2})x^{k-1} = c$ (b) $(y + \sqrt{x^2 + y^2})x^{k-1} = c$

(c) $(y - \sqrt{x^2 - y^2})x^{k-1} = c$ (d) $(y - \sqrt{x^2 + y^2})x^{k-1} = c$

15. A point $P(x, y)$ nores on the curve $x^{2/3} + y^{2/3} = a^{2/3}, a > 0$ for each position (x, y) of p, perpendiculars are drawn from origin upon the tangent and normal at P, the length (absolute valve) of them being $P_1(x)$ and $P_2(x)$ brespectively, then

(a) $\frac{dp_1}{dx}.\frac{dp_2}{dx} < 0$ (b) $\frac{dp_1}{dx}.\frac{dp_2}{dx} \le 0$

(c) $\frac{dp_1}{dx}.\frac{dp_2}{dx} > 0$ (d) $\frac{dp_1}{dx}.\frac{dp_2}{dx} \ge 0$

Session 3

Solving of Linear Differential Equations, Bernoulli's Equation, Orthogonal Trajectory

Solving of Linear Differential Equations

First Order Linear Differential Equations

A differential equation is said to be linear if an unknown variable and its derivative occur only in the first degree.

An equation of the form

$$\frac{dy}{dx} + P(x) \cdot y = Q(x).$$

Where $P(x)$ and $Q(x)$ are functions of x only or constant is called a linear equation of the first order.

To get the general solution of the above equation we proceeds as follows. By multiplying both the sides of the above equation by $e^{\int Pdx}$, we get

$$e^{\int Pdx} \cdot \frac{dy}{dx} + yP \cdot e^{\int Pdx} = Q\, e^{\int Pdx}$$

i.e. $$e^{\int Pdx} \cdot \frac{dy}{dx} + y \frac{d}{dx}(e^{\int Pdx}) = Q\, e^{\int Pdx}$$

i.e. $$\frac{d}{dx}(y\, e^{\int Pdx}) = Q \cdot e^{\int Pdx}$$

$\therefore$ Integrating, we get $y\, e^{\int Pdx} = \int Q\, e^{\int Pdx} dx + C$

Here, the term $e^{\int Pdx}$ which converts the left hand expression of the equation into a perfect differential is called an Integrating factor. In short it is written as IF. Thus, we remember the solution of the above equation as

$$y\,(\text{IF}) = \int Q\,(\text{IF})\, dx + C.$$

Algoritm for Solving A Linear Differential Equation

Step I Write the differential equation in the form $dy / dx + Py = Q$ and obtain P and Q.

Step II Find integrating factor (I.F.) given by I.F. $= e^{\int Pdx}$.

Step III Multiply both sides of equation in Step I by I.F.

Step IV Integrate both sides of the equation obtained in step III. w.r.t x to obtain y (I.F.) $= \int Q.(\text{I.F.})\, dx + C$

This gives the required solution following examples illustrate the procedure.

Example 34 Solve $\frac{dy}{dx} + 2y = \cos x$.

Sol. It is a linear equation of the form

$$\frac{dy}{dx} + Py = Q(x)$$

where $P = 2$ and $Q = \cos x$

Then $$\text{IF} = e^{\int Pdx} = e^{\int 2dx} = e^{2x}$$

Hence, the general solution is $y\,(\text{IF}) = \int Q\,(\text{IF})\, dx$

i.e. $$y \cdot e^{2x} = \int e^{2x} \cos x\, dx + C$$

$$y \cdot e^{2x} = \frac{e^{2x}}{5}[2 \cos x + \sin x] + C$$

Example 35 Solve $\frac{dy}{dx} + \frac{y}{x} = \log x$.

Sol. It is a linear differential equation of the form

$$\frac{dy}{dx} + Py = Q(x)$$

Here, $$P = \frac{1}{x}, Q = \log x$$

Then $$\text{IF} = e^{\int Pdx} = e^{\int 1/x\, dx} = e^{\log x} = x$$

Hence, the general solution is

$$y\,(\text{IF}) = \int Q\,(\text{IF})\, dx + C$$

i.e. $$yx = \int (\log x)\, x\, dx + C$$

i.e. $$yx = (\log x) \cdot \frac{x^2}{2} - \int \frac{1}{x} \cdot \frac{x^2}{2} + C$$

i.e. $$yx = \frac{x^2}{2}(\log x) - \frac{x^2}{4} + C$$

Example 36 *Solve* $\dfrac{dy}{dx} = \dfrac{y}{2y \ln y + y - x}$.

Sol. The equation can be written as

$$\frac{dx}{dy} = \frac{2y \ln y + y - x}{y} = (2 \ln y + 1) - \frac{x}{y}$$

i.e. $$\frac{dx}{dy} + \frac{1}{y} \cdot x = (2 \ln y + 1)$$

In this equation it is clear that $P = \dfrac{1}{y}$ and $Q = (2 \ln y + 1)$.

Which are function of y only because equation contains derivatives of x with respect to y.

$$\text{IF} = e^{\int P dy} = e^{\int 1/y \, dy} = e^{\ln y} = y$$

$\therefore$ The solution is; $x \, (\text{IF}) = \int (2 \ln y + 1) \, (\text{IF}) \, dy$

i.e. $$xy = \int (2 \ln y + 1) \cdot y \, dy = y^2 \ln y + C$$

i.e. $$x = y \ln y + \frac{C}{y}$$

Note In some cases a linear differential equation may be of the form $\dfrac{dx}{dy} + P_1 x = Q_1$, where P_1 and Q_1 are function of y alone. In such a case the integrating factor is $e^{\int P_1 \, dy}$.

Example 37 Solve $\cos^2 x \dfrac{dy}{dx} - y \tan 2x = \cos^4 x$, where $|x| < \dfrac{\pi}{4}$ and $y\left(\dfrac{\pi}{6}\right) = \dfrac{3\sqrt{3}}{8}$.

Sol. The given equation can be written as

$$\frac{dy}{dx} - \sec^2 x \cdot \tan 2x \cdot y = \cos^2 x$$

$$\text{IF} = e^{\int -\tan 2x \cdot \sec^2 x \, dx} = e^{\int + \frac{2 \tan x}{\tan^2 x - 1} \sec^2 x \, dx}$$

$$= e^{\int \frac{dt}{t}}, \text{ where } t = \tan^2 x - 1$$

$$= e^{\ln |t|} = |t| = |\tan^2 x - 1|$$

It is given that $|x| < \dfrac{\pi}{4}$ and for this region $\tan^2 x < 1$.

$\therefore$ $$\text{IF} = (1 - \tan^2 x)$$

$\therefore$ The solution is

$$y (1 - \tan^2 x) = \int \cos^2 x \, (1 - \tan^2 x) \, dx$$

$$= \int (\cos^2 x - \sin^2 x) \, dx$$

$$= \int (\cos 2x) \, dx = \frac{\sin 2x}{2} + C$$

Now, when $x = \dfrac{\pi}{6}, y = \dfrac{3\sqrt{3}}{8}$

$\therefore$ $$\frac{3\sqrt{3}}{8}\left(1 - \frac{1}{3}\right) = \frac{1}{2} \cdot \frac{\sqrt{3}}{2} + C \implies C = 0$$

$\therefore$ $$y = \frac{\sin 2x}{2(1 - \tan^2 x)}$$

Example 38 Solve $\dfrac{dy}{dx} + y \, \phi'(x) = \phi(x) \cdot \phi'(x)$, where $\phi(x)$ is a given function.

Sol. Here, $P = \phi'(x)$ and $Q = \phi(x) \, \phi'(x)$

$$\text{IF} = e^{\int \phi'(x) \, dx} = e^{\phi(x)}$$

$\therefore$ The solution is

$$y \, e^{\phi(x)} = \int \phi(x) \cdot \phi'(x) \cdot e^{\phi(x)} \, dx = \int t \cdot e^t \, dt,$$

where $\phi(x) = t$

$$y \, e^{\phi(x)} = e^t (t - 1) + C$$

i.e. $$y e^{\phi(x)} = \{\phi(x) - 1\} e^{\phi(x)} + C$$

Bernoulli's Equation

Sometimes a differential equation is not linear but it can be converted into a linear differential equation by a suitable substitution. An equation of the form

$$\frac{dy}{dx} + Py = Q \, y^n. \qquad (n \neq 0, 1)$$

Where P and Q are functions of x only, is known as Bernoulli's equation (for $n = 0$ the equation is linear.)

It is easy to reduce the above equation into linear form as below :

Dividing both the sides by y^n, we get

$$y^{-n} \frac{dy}{dx} + P \, y^{1-n} = Q$$

Putting $y^{1-n} = z$ and hence, $(1-n) \, y^{-n} \dfrac{dy}{dx} = \dfrac{dz}{dx}$ the equation becomes $\dfrac{dz}{dx} + (1-n) \, Pz = (1-n) \, Q$ which is linear in z.

Here, $$\text{IF} = e^{\int (1-n) \, P \, dx}$$

$\therefore$ The solution is,

$$z \, e^{\int (1-n) \, P dx} = \int \{(1-n) \cdot Q \cdot e^{\int (1-n) \, P dx}\} \, dx$$

Example 39 Solve $(y \log x - 1)\, y\, dx = x\, dy$.

Sol. The given differential equation can be written as

$$x\frac{dy}{dx} + y = y^2 \log x \quad \text{...(i)}$$

Dividing by xy^2, hence

$$\frac{1}{y^2}\cdot\frac{dy}{dx} + \frac{1}{xy} = \frac{1}{x}\log x$$

Let $$\frac{1}{y} = v \Rightarrow -\frac{1}{y^2}\cdot\frac{dy}{dx} = \frac{dv}{dx}$$

So that $$\frac{dv}{dx} - \frac{1}{x}v = -\frac{1}{x}\log x$$

Which is the standard linear differential equations, with

$$P = -\frac{1}{x},\ Q = -\frac{1}{x}\log x$$

$$\text{IF} = e^{\int -1/x\, dx} = e^{-\ln x} = e^{\ln x^{-1}} = \frac{1}{x}$$

The solution is given by

$$v\cdot\frac{1}{x} = \int\frac{1}{x}\left(-\frac{1}{x}\log x\right)dx = -\int\frac{\log x}{x^2}\,dx$$

$$= \frac{\log x}{x} - \int\frac{1}{x}\cdot\frac{1}{x}\,dx = \frac{\log x}{x} + \frac{1}{x} + C$$

$$\Rightarrow \quad v = 1 + \log x + Cx = \log(ex) + Cx$$

or $$\frac{1}{y} = \log(ex) + Cx \quad \text{or} \quad y\{\log(ex) + Cx\} = 1$$

Example 40 Solve $\dfrac{dy}{dx} + xy = xy^2$.

Sol. Dividing by y^2, we get

$$y^{-2}\frac{dy}{dx} + \frac{1}{y}\cdot x = x$$

Let $$\frac{1}{y} = z$$

So that $$-\frac{1}{y^2}\cdot\frac{dy}{dx} = \frac{dz}{dx}$$

$\therefore$ The given equation reduces to

$$\frac{dz}{dx} - xz = -x$$

$$\text{IF} = e^{\int -x\, dx} = e^{-x^2/2}$$

$\therefore$ The solution is

$$z\, e^{-x^2/2} = \int -x\cdot e^{-x^2/2}\,dx = e^{-x^2/2} + C$$

i.e. $$\frac{1}{y} = 1 + Ce^{x^2/2}$$

Example 41 Solve $\dfrac{dy}{dx} = \dfrac{y\,\phi'(x) - y^2}{\phi(x)}$, where $\phi(x)$ is a given function.

Sol. The equation can be written as

$$\frac{dy}{dx} - \frac{\phi'(x)}{\phi(x)}y = -\frac{y^2}{\phi(x)}$$

i.e. $$-y^{-2}\frac{dy}{dx} + \frac{\phi'(x)}{\phi(x)}\cdot\frac{1}{y} = \frac{1}{\phi(x)}$$

Let $\dfrac{1}{y} = z$. So that, $-\dfrac{1}{y^2}\dfrac{dy}{dx} = \dfrac{dz}{dx}$

$\therefore$ $$\frac{dz}{dx} + \frac{\phi'(x)}{\phi(x)}\cdot z = \frac{1}{\phi(x)}$$

$$\text{IF} = e^{\int\frac{\phi'(x)}{\phi(x)}dx} = e^{\ln\phi(x)} = \phi(x)$$

$\therefore$ The solution is $z\cdot\phi(x) = \int\dfrac{1}{\phi(x)}\cdot\phi(x)\,dx = x + C$

i.e. $$\frac{\phi(x)}{y} = x + C \quad ie, \quad \frac{\phi(x)}{x + C} = y$$

Remark

Another type of equation which is reducible to the linear form is

$$f'(y)\frac{dy}{dx} + P(x)\cdot f(y) = Q(x)$$

An equation of this type can be easily reduced the linear form by taking $z = f(y)$.

Example 42 Solve $\sec^2 y\dfrac{dy}{dx} + 2x\tan y = x^3$.

Sol. Let $\tan y = z$ so that $\sec^2 y\cdot\dfrac{dy}{dx} = \dfrac{dz}{dx}$

Thus, the given equation reduces to

$$\frac{dz}{dx} + 2x\cdot z = x^3$$

$$\text{IF} = e^{\int 2x\,dx} = e^{x^2}$$

$\therefore$ The solution is, $z\cdot e^{x^2} = \int x^3\cdot e^{x^2}dx$

i.e. $$\tan y\cdot e^{x^2} = \frac{1}{2}\int x^2\, e^{x^2}\cdot(2x)\,dx = \frac{1}{2}\int t\cdot e^t\,dt,$$

where $t = x^2$

$$\tan y\cdot e^{x^2} = \frac{1}{2}(t\cdot e^t - e^t) + C$$

i.e. $$\tan y = Ce^{-x^2} + \frac{e^{-x^2}}{2}\cdot e^{x^2}(x^2 - 1)$$

$$\tan y = Ce^{-x^2} + \frac{1}{2}(x^2 - 1)$$

Example 43 Solve $\frac{dy}{dx} + x(x+y) = x^3(x+y)^3 - 1$.

Sol. The given equation can be written as

$$\left(\frac{dy}{dx} + 1\right) + x(x+y) = x^3(x+y)^3$$

i.e. $$\frac{d(x+y)}{dx} + x(x+y) = x^3(x+y)^3$$

i.e. $(x+y)^{-3} \cdot \frac{d(x+y)}{dx} + x(x+y)^{-2} = x^3$

Let $(x+y)^{-2} = z$ so that $-2(x+y)^{-3}\frac{d(x+y)}{dx} = \frac{dz}{dx}$

The given equation reduces to

$$-\frac{1}{2}\frac{dz}{dx} + xz = x^3$$

i.e. $$\frac{dz}{dx} - 2xz = -2x^3$$

$$\text{IF} = e^{\int -2x\,dx} = e^{-x^2}$$

$\therefore$ The solution is

$$z \cdot e^{-x^2} = \int -2x^3 \cdot e^{-x^2}\,dx = (x^2+1)e^{-x^2} + C$$

$$\frac{1}{(x+y)^2} = Ce^{x^2} + x^2 + 1$$

Example 44 Solve $\sin y \cdot \frac{dy}{dx} = \cos y(1 - x\cos y)$.

Sol. The given differential equation is

$$\sin y \frac{dy}{dx} = \cos y(1 - x\cos y)$$

or $$\sin y \frac{dy}{dx} - \cos y = -x\cos^2 y$$

Dividing by $\cos^2 y$, we get

$$\tan y \cdot \sec y \cdot \frac{dy}{dx} - \sec y = -x$$

Let $\sec y = v \Rightarrow \sec y \tan y \cdot \frac{dy}{dx} = \frac{dv}{dx}$

So that $$\frac{dv}{dx} - v = -x$$

Which is linear differential equation with $P = -1, Q = -x$

$$\text{IF} = e^{\int P dx} = e^{\int -1\,dx} = e^{-x}$$

The solution is given by

$$v \cdot e^{-x} = \int -x \cdot e^{-x}\,dx = xe^{-x} + e^{-x} + C$$

$$= e^{-x}(x+1) + C$$

or $$v = (1+x) + Ce^x$$

or $$\sec y = (1+x) + Ce^x$$

Orthogonal Trajectory

Any curve, which cuts every member of a given family of curves at right angles, is called an orthogonal trajectory of the family. For example, each straight line passing through the origin, *ie*, $y = kx$ is an orthogonal trajectory of the family of the circles $x^2 + y^2 = a^2$.

Procedure for Finding the Orthogonal Trajectory

(i) Let $f(x, y, c) = 0$ be the equation of the given family of curves, where c is an arbitrary parameter.

(ii) Differentiate $f = 0$; w.r.t. 'x' and eliminate 'c', i.e. form a differential equation.

(iii) Substitute $-\frac{dx}{dy}$ for $\frac{dy}{dx}$ in the above differential equation. This will give the differential equation of the orthogonal trajectories.

(iv) By solving this differential equation, we get the required orthogonal trajectories.

Example 45 Find the orthogonal trajectories of the hyperbola $xy = C$.

Sol. The equation of the given family of curves is $xy = c$ ...(i)

Differentiating Eq. (i) w.r.t. x, we get

$$\frac{x\,dy}{dx} + y = 0 \quad \text{...(ii)}$$

Substitute $-\frac{dx}{dy}$ for $\frac{dy}{dx}$ in Eq. (ii), we get

$$-\frac{x\,dx}{dy} + y = 0 \quad \text{...(iii)}$$

This is the differential equation for the orthogonal trajectory of given family of hyperbola. Eq. (iii) can be rewritten as $x\,dx = y\,dy$, which on integration gives

$$x^2 - y^2 = C.$$

This is the family of required orthogonal trajectories.

Example 46 Find the orthogonal trajectories of the curves $y = cx^2$.

Sol. Here, $$y = cx^2 \quad \text{...(i)}$$

Differentiating w.r.t. x, we get

$$\frac{dy}{dx} = 2cx \quad \text{...(ii)}$$

Eliminating c from Eqs. (i) and (ii),

$$y = \left(\frac{1}{2x}\frac{dy}{dx}\right)x^2$$

$$\Rightarrow \quad 2y = x\frac{dy}{dx} \qquad \text{...(iii)}$$

This is the differential equation of the family of curves given in Eq. (i).

Now, to obtain orthogonal trajectory replace $\frac{dy}{dx}$ by $-\frac{dx}{dy}$ in Eq. (iii).

$$\Rightarrow \quad 2y = -x\frac{dx}{dy}$$

or $\quad 2y\,dy = -x\,dx$

Integrating both the sides, we get

$$y^2 = -\frac{x^2}{2} + C_1$$

$\Rightarrow x^2 + 2y^2 = C_1$, is the required family of orthogonal trajectory.

Example 47 Find the equation of all possible curves that will cut each member of the family of circles $x^2 + y^2 - 2cx = 0$ at right angle.

Sol. Here, $\quad x^2 + y^2 - 2cx = 0 \qquad \text{...(i)}$

Differentiating w.r.t. x, we get

$$2x + 2yy_1 - 2c = 0$$

$$\Rightarrow \quad c = x + yy_1 \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we eliminate c

$$\Rightarrow \quad x^2 + y^2 - 2(x + yy_1)\,x = 0$$

or $\quad -x^2 + y^2 - 2xy\frac{dy}{dx} = 0$

This is the differential equation representing the given family of circles. To find differential equation of the orthogonal trajectories, we replace $\frac{dy}{dx}$ by $-\frac{dx}{dy}$.

$$\Rightarrow \quad y^2 - x^2 = -2xy\frac{dx}{dy}$$

$$\Rightarrow \quad y^2\,dy = x^2\,dy - 2xy\,dx$$

$$\Rightarrow \quad -dy = \frac{yd(x^2) - x^2\,dy}{y^2}$$

$$\Rightarrow \quad -dy = d\left(\frac{x^2}{y}\right)$$

Integrating both the sides, we get

$$-y = \frac{x^2}{y} + C \;\Rightarrow\; x^2 + y^2 + Cy = 0$$

Represents family of orthogonal trajectory.

Example 48 ***Find the orthogonal trajectory of the circles***

$$x^2 + y^2 - ay = 0.$$

Sol. Here, $\quad x^2 + y^2 - ay = 0 \qquad \text{...(i)}$

Differentiating, we get

$$2x + 2yy_1 - ay_1 = 0$$

$$\Rightarrow \quad a = \frac{2(x + yy_1)}{y_1} \qquad \text{...(ii)}$$

Substituting 'a' in Eq. (i), we get

$$x^2 + y^2 - \frac{2(x + yy_1)}{y_1}y = 0$$

$$\Rightarrow \quad (x^2 - y^2)\,y_1 - 2xy = 0$$

This is the differential equation of the family of circles given in Eq. (i).

$\therefore$ The differential representing the orthogonal trajectory is obtained by replacing $\frac{dy}{dx}$ by $-\frac{dy}{dx}$.

i.e. $\quad -(x^2 - y^2)\frac{dx}{dy} - 2xy = 0$

$$\Rightarrow \quad 2xy\,dy - y^2\,dx = -x^2\,dx$$

$$\Rightarrow \quad \frac{x\,d(y^2) - y^2\,dx}{x^2} = -dx$$

$$\Rightarrow \quad d\left(\frac{y^2}{x}\right) = -dx$$

Integrating both the sides, we get

$y^2 + x^2 = Cx$, is required family of orthogonal trajectories.

Exercise for Session 3

1. The solution of $(1+x^2)\frac{dy}{dx}+y=e^{\tan^{-1}x}$, is given by

(a) $2ye^{\tan^{-1}x}=e^{2\tan^{-1}x}+C$ (b) $ye^{\tan^{-1}y}=e^{2\tan^{-1}x}+C$

(c) $2ye^{\tan^{-1}y}=e^{2\tan^{-1}y}+C$ (d) None of these

2. The solution of $\frac{dy}{dx}+\frac{x}{1-x^2}y=x\sqrt{y}$, is given by

(a) $3\sqrt{y}+(1-x^2)=C(1-x^2)^{1/4}$ (b) $\frac{3}{2}\sqrt{y}+(1-x^2)=C(1-x^2)^{3/2}$

(c) $3\sqrt{y}-(1-x^2)=C(1-x^2)^{3/2}$ (d) None of these

3. The solution of $\frac{dy}{dx}+x\sin 2y=x^3\cos^2 y$, is

(a) $e^{x^2}=(x^2-1)e^{x^2}\tan y+C$ (b) $e^{x^2}\tan y=\frac{1}{2}(x^2-1)e^{x^2}+C$

(c) $e^{x^2}\tan y=(x^2-1)\tan y+C$ (d) None of these

4. The solution of $3x(1-x^2)y^2\,dy/dx+(2x^2-1)y^3=ax^3$ is

(a) $y^3=ax+C\sqrt{1-x^2}$ (b) $y^3=ax+Cx\sqrt{1-x^2}$

(c) $y^2=ax+C\sqrt{1-x^2}$ (d) None of these

5. The solution of $\frac{dy}{dx}+\frac{y}{x}\log y=\frac{y}{x^2}(\log y)^2$, is

(a) $x=\frac{1}{2x}\log y+C$ (b) $x^2+\log y=C$ (c) $\frac{1}{x\log y}=\frac{1}{2x^2}+C$ (d) None of these

6. The solution of $\frac{dy}{dx}+yf'(x)-f(x)\cdot f'(x)=0, y\neq f(x)$ is

(a) $y=f(x)+1+ce^{-f(x)}$ (b) $y-ce^{-f(x)}$

(c) $y=f(x)-1+ce^{-f(x)}$ (d) None of these

7. The solution of $(x^{2-1})\,dy/dx\cdot\sin y-2x\cdot\cos y=2x-2x^3$, is

(a) $(x^2-1)\cos y=\frac{x^4}{2}-x^2+C$ (b) $(x^2-1)\sin y=\frac{x^4}{2}-x^2+C$

(c) $(x^2-1)\cos y=\frac{x^4}{4}-\frac{x^2}{2}+C$ (d) $(x^2-1)\sin y=\frac{x^4}{4}-\frac{x^2}{2}+C$

8. The Curve possessing the property text the intercept made by the tangent at any point of the curve on the y-axis is equal to square of the abscissa of the point of tangency, is given by

(a) $y^2=x+C$ (b) $y=2x^2+cx$

(c) $y=-x^2+cx$ (d) None of these

9. The tangent at a point P of a curve meets the y-axis at A, and the line parallel to y-axis at A, and the line parallel to y-axis through P meets the x-axis at B. If area of ΔOAB is constant (O being the origin), Then the curve is

(a) $cx^2-xy+k=0$ (b) $x^2+y^2=cx$

(c) $3x^2+4y^2=k$ (d) $xy-x^2y^2+kx=0$

10. The value of k such that the family of parabolas $y=cx^2+k$ is the orthogonal trajectory of the family of ellipse $x^2+2y^2-y=C$, is

(a) y_2 (b) y_3 (c) y_4 (d) y_5

Session 4

Exact Differential Equations

Exact Differential Equations

A differential equation of the form $M(x, y)\,dx + N(x, y)\,dy = 0$ is said to be exact (or total) if its left hand expression is the exact differential of some function $u(x, y)$.

i.e. $$du = M \cdot dx + N \cdot dy$$

Hence, its solution is $u(x, y) = c$ (where c is an arbitrary constant). But then there is a question that how do we confirm whether the above mentioned equation is exact. The answer to this question is the following theorem.

Theorem The necessary and sufficient condition for the differential equation $M\,dx + N\,dy = 0$ to be exact is $\dfrac{\partial M}{\partial y} = \dfrac{\partial N}{\partial x}$.

The solution of $M\,dx + N\,dy = 0$ is ,

$$\int_{y-\text{constant}} M\,dx + \int(\text{terms of } N \text{ not containing } x)\,dy = C$$

provided $\dfrac{\partial M}{\partial y} = \dfrac{\partial N}{\partial x}$.

Example 49 Solve $(x^2 - ay)\,dx + (y^2 - ax)\,dy = 0$.

Sol. Here, we have $M = x^2 - ay$ and $N = y^2 - ax$

$$\therefore \quad \frac{\partial M}{\partial y} = -a = \frac{\partial N}{\partial x}$$

Thus, the equation is exact.

$\therefore$ The solution is, $\int_{y-\text{constant}} (x^2 - ay)\,dx + \int y^2\,dy = C$

$$\Rightarrow \quad \frac{x^3}{3} - axy + \frac{y^3}{3} = C$$

Example 50 Solve $(2x \log y)\,dx + \left(\dfrac{x^2}{y} + 3y^2\right)dy = 0$.

Sol. Here, we have $M = 2x \log y$ and $N = \dfrac{x^2}{y} + 3y^2$

$$\therefore \quad \frac{\partial M}{\partial y} = \frac{2x}{y}$$

and $\dfrac{\partial N}{\partial x} = \dfrac{2x}{y}$ and hence the equation is exact.

$\therefore$ The solution is,

$$\int_{y-\text{constant}} (2x \log y)\,dx + \int 3y^2\,dy = C$$

$$\Rightarrow \quad x^2 \log y + y^3 = C$$

Equations Reducible to the Exact Form

Sometimes a differential equation of the form $M\,dx + N\,dy = 0$ which is not exact can be reduced to an exact form by multiplying by a suitable function $f(x, y)$ which is not identically zero. This function $f(x, y)$ which then multiplied to a non-exact differential equation makes it exact is known as integrating factor.

One can find integrating factors by inspection but for that some experience and practice is required.

For finding the integrating factors by inspection, the following identities must be remembered.

1. $x\,dy + y\,dx = d(xy)$
2. $x\,dx + y\,dy = \dfrac{1}{2}\,d(x^2 + y^2)$
3. $\dfrac{x\,dy - y\,dx}{x^2} = d\left(\dfrac{y}{x}\right)$
4. $\dfrac{y\,dx - x\,dy}{y^2} = d\left(\dfrac{x}{y}\right)$
5. $\dfrac{x\,dy - y\,dx}{xy} = \dfrac{dy}{y} - \dfrac{dx}{x} = d\left[\log\left(\dfrac{y}{x}\right)\right]$
6. $\dfrac{y\,dx - x\,dy}{xy} = d\left[\log\left(\dfrac{x}{y}\right)\right]$
7. $\dfrac{x\,dy - y\,dx}{x^2 + y^2} = \dfrac{\dfrac{x\,dy - y\,dx}{x^2}}{1 + \dfrac{y^2}{x^2}} = \dfrac{d\left(\dfrac{y}{x}\right)}{1 + \left(\dfrac{y}{x}\right)^2} = d\left[\tan^{-1}\left(\dfrac{y}{x}\right)\right]$
8. $\dfrac{dx + dy}{x + y} = d[\ln(x + y)]$
9. $d(\ln(xy)) = \dfrac{x\,dy + y\,dx}{xy}$
10. $d\left(\dfrac{1}{2}\ln(x^2 + y^2)\right) = \dfrac{x\,dx + y\,dy}{x^2 + y^2}$

11. $d\left(-\frac{1}{xy}\right)=\frac{x\,dy+y\,dx}{x^2\,y^2}$

12. $d\left(\frac{e^y}{x}\right)=\frac{x\,e^y\,dy-e^y\,dx}{x^2}$

13. $d\left(\frac{e^x}{y}\right)=\frac{ye^x dx-e^x dy}{y^2}$

14. $d(x^m\,y^n)=x^{m-1}\,y^{n-1}\,(my\,dx+nx\,dy)$

15. $\frac{d[f(x,y)]^{1-n}}{1-n}=\frac{f'(x,y)}{(f(x,y))^n}$

Example 51 Solve $(x^2-ay)\,dx+(y^2-ax)\,dy=0$.

Sol. The given differential equation is

$$x^2dx+y^2dy-a(y\,dx+x\,dy)=0$$

$$\Rightarrow\quad d\left(\frac{x^3}{3}\right)+d\left(\frac{y^3}{3}\right)-ad(xy)=0$$

Integrating, we get $\frac{x^3}{3}+\frac{y^3}{3}-a\,xy=k$

$$\Rightarrow\quad x^3+y^3-3axy=3k=C$$

Example 52 Solve $(2x\log y)\,dx+\left(\frac{x^2}{y}+3y^2\right)dy=0$.

Sol. The given differential equation is

$$(\log y)\,2x\,dx+\frac{x^2}{y}\,dy+3y^2\,dy=0$$

$$\Rightarrow\quad (\log y)\,d(x^2)+x^2\,d(\log y)+d(y^3)=0$$

$$\Rightarrow\quad d(x^2\log y)+d(y^3)=0$$

$$\Rightarrow\quad x^2\log y+y^3=C$$

(integrating both the sides)

Example 53 Solve $x\,dx+y\,dy=x\,dy-y\,dx$.

Sol. The given equation can be written as

$$\frac{1}{2}d(x^2+y^2)=x^2\,d\left(\frac{y}{x}\right)$$

$$\Rightarrow\quad \frac{d(x^2+y^2)}{x^2+y^2}=\frac{2x^2\,d\left(\frac{y}{x}\right)}{x^2+y^2}$$

$$\Rightarrow\quad \frac{d(x^2+y^2)}{x^2+y^2}=\frac{2d(y/x)}{1+(y/x)^2}$$

$$\Rightarrow\quad \log(x^2+y^2)=2\tan^{-1}\left(\frac{y}{x}\right)+C$$

Example 54 ***Solve***

$$\frac{y+\sin x\cos^2(xy)}{\cos^2(xy)}\,dx+\left(\frac{x}{\cos^2(xy)}+\sin y\right)dy=0.$$

Sol. The given differential equation can be written as

$$\frac{y\,dx+x\,dy}{\cos^2(xy)}+\sin x\,dx+\sin y\,dy=0$$

$$\Rightarrow\quad \sec^2(xy)\,d(xy)+\sin x\,dx+\sin y\,dy=0$$

$$d(\tan(xy))+d(-\cos x)+d(-\cos y)=0$$

$$\Rightarrow\quad \tan(xy)-\cos x-\cos y=C$$

Example 55 Solve $\frac{x+y\frac{dy}{dx}}{y-x\frac{dy}{dx}}=x^2+2y^2+\frac{y^4}{x^2}$.

Sol. The given equation can be written as

$$\frac{x\,dx+y\,dy}{(x^2+y^2)^2}=\frac{y\,dx-x\,dy}{y^2}\cdot\frac{y^2}{x^2}$$

$$\Rightarrow\quad \int\frac{d(x^2+y^2)}{(x^2+y^2)^2}=2\int\frac{1}{x^2/y^2}\,d\left(\frac{x}{y}\right)$$

Integrating both the sides, we get

$$-\frac{1}{(x^2+y^2)}=-\frac{1}{(x/y)}+C$$

$$\Rightarrow\quad \frac{y}{x}-\frac{1}{x^2+y^2}=C$$

Example 56 The solution of

$$e^{x\frac{(y^2-1)}{y}}\{xy^2\,dy+y^3dx\}+\{ydx-xdy\}=0,\text{ is}$$

(a) $e^{xy}+e^{x/y}+C=0$ (b) $e^{xy}-e^{x/y}+C=0$

(c) $e^{xy}+e^{y/x}+C=0$ (d) $e^{xy}-e^{y/x}+C=0$

Sol. Here, $e^{x\frac{(y^2-1)}{y}}\cdot y^2\{xdy+ydx\}+\{ydx-xdy\}=0$

$$\Rightarrow\quad e^{xy}\cdot y^2\cdot\{xdy+ydx\}+e^{x/y}\{ydx-xdy\}=0$$

or $$e^{xy}\cdot\{xdy+ydx\}+e^{x/y}\frac{\{ydx-xdy\}}{y^2}=0$$

or $$e^{xy}\cdot d(xy)+e^{x/y}\cdot d\left(\frac{x}{y}\right)=0$$

or $$d(e^{xy})+d(e^{x/y})=0$$

Integrating both the sides, we get

$$e^{xy}+e^{x/y}+C=0$$

Hence, (a) is the correct answer.

Example 57 *The solution of* $x^2dy - y^2dx + xy^2(x-y)\,dy = 0$, *is*

(a) $\log\left|\frac{x-y}{xy}\right| = \frac{y^2}{2} + C$ (b) $\log\left|\frac{xy}{x-y}\right| = \frac{x^2}{2} + C$

(c) $\log\left|\frac{x-y}{xy}\right| = \frac{x^2}{2} + C$ (d) $\log\left|\frac{x-y}{xy}\right| = x + C$

Sol. Here, $x^2y^2\left(\frac{dy}{y^2} - \frac{dx}{x^2}\right) + x^2y^3\left(\frac{1}{y} - \frac{1}{x}\right)dy = 0$

$$\Rightarrow \quad -d\left(\frac{1}{y} - \frac{1}{x}\right) + y\left(\frac{1}{y} - \frac{1}{x}\right)dy = 0$$

$$\Rightarrow \quad -\frac{d\left(\frac{1}{y} - \frac{1}{x}\right)}{\left(\frac{1}{y} - \frac{1}{x}\right)} + ydy = 0 \text{ or } \frac{d\left(\frac{1}{y} - \frac{1}{x}\right)}{\left(\frac{1}{y} - \frac{1}{x}\right)} = d\left(\frac{y^2}{2}\right)$$

Integrating both the sides, we get

$$\log\left|\frac{1}{x} - \frac{1}{y}\right| = \frac{y^2}{2} + C$$

Hence, (a) is the correct answer.

Example 58 *The solution of the differential equation* $ydx - xdy + xy^2\,dx = 0$, is

(a) $\frac{x}{y} + x^2 = \lambda$ (b) $\frac{x}{y} + \frac{x^2}{2} = \lambda$

(c) $\frac{x}{2y^2} + \frac{x^2}{4} = \lambda$ (d) None of these

Sol. Given equation is, $ydx - xdy + xy^2\,dx = 0$

Which could be converted into exact form

i.e. $$\frac{ydx - xdy}{y^2} + xdx = 0$$

$$\Rightarrow \quad d\left(\frac{x}{y}\right) + d\left(\frac{x^2}{2}\right) = 0$$

Integrating both the sides, we get

$$\frac{x}{y} + \frac{x^2}{2} = \text{constant}$$

or $$\frac{x}{y} + \frac{x^2}{2} = \lambda$$

Hence, (b) is the correct answer.

Example 59 The solution of differential equation $xdy\,(y^2e^{xy} + e^{x/y}) = ydx\,(e^{x/y} - y^2e^{xy})$, is

(a) $xy = \log(e^x + \lambda)$ (b) $x^2/y = \log(e^{x/y} + \lambda)$

(c) $xy = \log(e^{x/y} + \lambda)$ (d) $xy^2 = \log(e^{x/y} + \lambda)$

Sol. The given equation is

$$(xy^2e^{xy})\,dy + (xe^{x/y})\,dy = (ye^{x/y})\,dx - (y^3e^{xy})\,dx$$

$$\Rightarrow \quad y^2e^{xy}(xdy + ydx) = e^{x/y}(ydx - xdy)$$

$$\Rightarrow \quad e^{xy}(d(xy)) = e^{x/y}\cdot\left(\frac{ydx - xdy}{y^2}\right)$$

$$\Rightarrow \quad e^{xy}(d(xy)) = e^{x/y}\cdot d\left(\frac{x}{y}\right)$$

$$\Rightarrow \quad d(e^{xy}) = d(e^{x/y})$$

Integrating both the sides, we get

$$e^{xy} = e^{x/y} + \lambda$$

$$\Rightarrow \quad xy = \log(e^{x/y} + \lambda)$$

Hence, (c) is the correct answer.

Example 60 *The solution of the differential equation*

$(y + x\sqrt{xy}\,(x+y))\,dx + (y\sqrt{xy}\,(x+y) - x)\,dy = 0$, is

(a) $\frac{x^2+y^2}{2} + 2\tan^{-1}\sqrt{\frac{x}{2y}} = C$

(b) $\frac{x^2+y^2}{2} + 2\tan^{-1}\sqrt{\frac{x}{y}} = C$

(c) $\frac{x^2+y^2}{\sqrt{2}} + 2\tan^{-1}\sqrt{\frac{x}{y}} = C$

(d) None of these

Sol. The given equation can be written as

$$(ydx - xdy) + x\sqrt{xy}\,(x+y)\,dx + y\sqrt{xy}\,(x+y)\,dy = 0$$

$$\Rightarrow \quad (ydx - xdy) + (x+y)\sqrt{xy}\,(xdx + ydy) = 0$$

$$\Rightarrow \quad \frac{ydx - xdy}{y^2} + \left(\frac{x}{y} + 1\right)\cdot\sqrt{\frac{x}{y}}\,d\left(\frac{x^2+y^2}{2}\right) = 0$$

$$\Rightarrow \quad d\left(\frac{x}{y}\right) + d\left(\frac{x^2+y^2}{2}\right)\left(\frac{x}{y} + 1\right)\sqrt{\frac{x}{y}} = 0$$

$$\Rightarrow \quad d\left(\frac{x^2+y^2}{2}\right) + \frac{d\left(\frac{x}{y}\right)}{\left(\frac{x}{y} + 1\right)\cdot\sqrt{\frac{x}{y}}} = 0$$

or $$d\left(\frac{x^2+y^2}{2}\right) + 2d\left(\tan^{-1}\left(\sqrt{\frac{x}{y}}\right)\right) = 0$$

Integrating both the sides, we get

$$\Rightarrow \quad \frac{x^2+y^2}{2} + 2\tan^{-1}\sqrt{\frac{x}{y}} = C$$

Hence, (b) is the correct answer.

Exercise for Session 4

1. The solution of $xdy + ydx + 2x^3dx = 0$, is

(a) $xy + x^4 = C$ (b) $xy + \frac{1}{2}x^4 = C$ (c) $\frac{x^2}{y} + \frac{x^4}{4} = C$ (d) None of these

2. The solution of, $ydx - xdy + (1 + x^2)\,dx + x^2 \sin y\, dy = 0$, is given by

(a) $x + 1 - y^2 + \cos y + C = 0$ (b) $y + 1 - x^2 + x \cos y + C = 0$

(c) $\frac{x}{y} + \frac{1}{y} - y + \cos y + C = 0$ (d) $\frac{y}{x} + \frac{1}{x} - x + \cos y + C = 0$

3. The solution of $(1 + x\sqrt{x^2 + y^2})\,dx + (-1 + \sqrt{x^2 + y^2})\,ydy = 0$, is

(a) $2x - y^2 + \frac{2}{3}(x^2 + y^2)^{3/2} = C$ (b) $2x - y + \frac{2}{3}(x^2 + y^2)^{3/2} = C$

(c) $2y - x^2 + \frac{2}{3}(x^2 + y^2)^{3/2} = C$ (d) None of these

4. The solution of, $\frac{xdy}{x^2 + y^2} = \left(\frac{y}{x^2 + y^2} - 1\right)dx$, is given by

(a) $\tan^{-1}\left(\frac{x}{y}\right) + x = C$ (b) $\tan^{-1}\left(\frac{y}{x}\right) + x = C$ (c) $\tan^{-1}\left(\frac{y}{x}\right) + xy = C$ (d) $\tan^{-1}\left(\frac{y}{x}\right) + x^2 = C$

5. The solution of $ye^{x/y}\,dx = (xe^{x/y} + y^2 \sin y)\,dy$, is given by

(a) $e^{x/y} = -\cos y + C$ (b) $e^{x/y} + 2\cos y = C$ (c) $e^{x/y} = x \cos y + C$ (d) $e^{x/y} = 2\cos y\, e^{x/y} + C$

6. The solution of $x \sin\left(\frac{y}{x}\right)dy = \left\{ y \sin\left(\frac{y}{x}\right) - x \right\}dx$, is given by

(a) $\log x - \cos\left(\frac{y}{x}\right) = \log C$ (b) $\log x - \sin\left(\frac{y}{x}\right) = C$ (c) $\log\left(\frac{x}{y}\right) - \cos\left(\frac{y}{x}\right) = \log C$ (d) None of these

7. The solution of $\frac{xdx + ydy}{xdy - ydx} = \sqrt{\frac{a^2 - x^2 - y^2}{x^2 + y^2}}$, is given by

(a) $\sin^{-1}(\sqrt{x^2 + y^2}) = a\,\tan^{-1}\left(\frac{y}{x}\right) + C$ (b) $\sin^{-1}(\sqrt{x^2 + y^2}) = \frac{1}{a}\tan^{-1}\left(\frac{y}{x}\right) + C$

(c) $\sin^{-1}\left(\frac{\sqrt{x^2 + y^2}}{a}\right) = \tan^{-1}\left(\frac{y}{x}\right) + C$ (d) None of the above

8. The solution of $(1 + e^{x/y})\,dx + e^{x/y}\left(1 - \frac{x}{y}\right)dy = 0$, is given by

(a) $x - ye^{x/y} = C$ (b) $x + ye^{x/y} = C$ (c) $y - \frac{x}{y}e^{x/y} = C$ (d) None of these

9. The solution of $\frac{x + y\,dy/dx}{y - x\,dy/dx} = \frac{x \sin^2(x^2 + y^2)}{y^3}$, is given by

(a) $-\cot(x^2 + y^2) = \left(\frac{x}{y}\right)^2 + C$ (b) $\tan(x^2 + y^2) = x^2y^2 + C$

(c) $\cot(x^2 + y^2) = \frac{x}{y} + C$ (d) None of these

10. The solution of $\frac{dy}{dx} + \frac{y}{x} = \frac{1}{(1 + \log x + \log y)^2}$, is given by

(a) $xy\,(1 + \log(xy)) = C$ (b) $xy^2\,(1 + \log(xy)) = C$ (c) $xy\,(1 + \log(xy))^2 = C$ (d) $xy\,(1 + (\log xy)^2) = C$

Session 5

Solving of First Order and Higher Degrees, Application of Differential Equations, Application of First Order Differential Equations

Solving of First Order and Higher Degrees

Differential Equation of First Order and Higher Degrees

A differential equation of first order is of the form $f(x, y, P)$ where $P = dy / dx$. If in the equation degree of P is greater than one, then the equation is of first order and higher degree.

The differential equation of first order and higher degree can be written in the form

$$P^n + F_1(x, y)\, P^{n-1} + \ldots + F_{n-1}(x, y)\, P + F_n(x, y) = 0$$

The differential equations of these category can be solved by one or more of the following methods :

(i) Equations solvable for P.

(ii) Equations solvable for y.

(iii) Equations solvable for x.

(iv) Clairaut's equations.

Now, we shall discuss these cases.

(i) Equations Solvable For P

If the equation

$$P^n + F_1(x, y)\, P^{n-1} + \ldots + F_{n-1}(x, y)\, P + F_n(x, y) = 0,$$

is solvable for P, then LHS expression can be resolved into n linear factors and hence can be put in the form

$$(P - f_1(x, y))\,(P - f_2(x, y)) \ldots (P - f_n(x, y)) = 0.$$

Equating each of these factors to zero, we get n differential equations of the first order and first degree.

$$\frac{dy}{dx} = f_1(x, y), \frac{dy}{dx} = f_2(x, y), \ldots, \frac{dy}{dx} = f_n(x, y)$$

Let the solutions of these obtained equations are

$$\phi_1(x, y, c_1) = 0, \phi_2(x, y, c_2) = 0, \ldots, \phi_n(x, y, c_n) = 0$$

respectively.

Hence, the general solution is given by

$$\phi_1(x, y, c), \phi_2(x, y, c), \ldots, \phi_n(x, y, c) = 0$$

Here, the arbitrary constant $c_1, c_2, \ldots, c_n$ are replaced by a single arbitrary constant c because every first order equation has only one arbitrary constant in its solution.

Example 61 Solve $(p - x)(p - e^x)(p - 1/y) = 0$; where $p = \dfrac{dy}{dx}$.

Sol. The component linear equations are $p = x$, $p = e^x$, $p = \dfrac{1}{y}$

If $\dfrac{dy}{dx} = x$, then $dy = x\, dx \Rightarrow y = \dfrac{x^2}{2} + C_1$

If $\dfrac{dy}{dx} = e^x$, then $dy = e^x\, dx \Rightarrow y = e^x + C_2$

If $\dfrac{dy}{dx} = \dfrac{1}{y}$, then $y\, dy = dx \Rightarrow \dfrac{y^2}{2} = x + C_3$

$\therefore$ The required solution is

$$\left(y - \frac{x^2}{2} + C\right)(y - e^x + C)\left(\frac{y^2}{2} - x + C\right) = 0$$

Example 62 Solve $x^2p^2 + xyp - 6y^2 = 0$.

Sol. The given equation is

$$x^2p^2 + xyp - 6y^2 = 0$$

Solving as a quadratic in p, we get

$$p = \frac{(-xy \pm \sqrt{x^2y^2 + 24x^2y^2})}{2x^2} = \frac{2y}{x}, -\frac{3y}{x}$$

If $p = \dfrac{2y}{x}$, then $\dfrac{dy}{dx} = \dfrac{2y}{x} \Rightarrow \dfrac{dy}{y} = \dfrac{2dx}{x}$

$$\Rightarrow \quad \log\left|\frac{y}{x^2}\right| = k \Rightarrow y = C_1 x^2$$

If $p = -\dfrac{3y}{x}$, then $\dfrac{dy}{dx} = -\dfrac{3y}{x} \Rightarrow \dfrac{dy}{y} = -\dfrac{3dx}{x}$

$$\Rightarrow \quad x^3y = C_2$$

$\therefore$ The required solution is $(y - Cx^2)(x^3y - C) = 0$.

Example 63 Solve $xy^2(p^2+2)=2py^3+x^3$.

Sol. The given equation can be written as

$$(xy^2p^2-x^3)+2(xy^2-py^3)=0$$

$$\Rightarrow \quad x(y^2p^2-x^2)+2y^2(x-py)=0$$

$$\Rightarrow \quad (py-x)\{x(py+x)-2y^2\}=0$$

If $py-x=0$, then $y\,dy-x\,dx=0 \Rightarrow y^2-x^2=C_1$

If $xyp+x^2-2y^2=0$, then $2y\dfrac{dy}{dx}-\dfrac{4y^2}{x}=-2x$

$$\Rightarrow \quad \frac{dt}{dx}-\frac{4}{x}t=-2x,$$

where $t=y^2$ IF $=e^{-\int \frac{4}{x}dx}=e^{-4\ln x}=\dfrac{1}{x^4}$

Its solution is $t\left(\dfrac{1}{x^4}\right)=\int -2x\cdot\dfrac{1}{x^4}\,dx$

i.e. $\dfrac{t}{x^4}=\dfrac{1}{x^2}+C_2$ i.e. $y^2=x^2+C_2x^4$

Hence, the required solution is

$$(y^2-x^2-C)(y^2-x^2-Cx^4)=0$$

(ii) Equations Solvable For y

Equation that comes under this category, can be expressed in the form

$$y=g(x,p)$$

(i.e. an explicit function y in term of x and p) ...(i)

Differentiating Eq. (i) w.r.t. x, we get

$$\frac{dy}{dx}=p=F\left(x,p,\frac{dp}{dx}\right)$$

Which is a differential equation of the first order containing x and p. Let us suppose that its solution is

$$\phi(x,p,c)=0 \qquad \text{...(ii)}$$

Then, the solution is obtained by eliminating p between $y=g(x,p)$ and $\phi(x,p,c)=0$. However, if eliminating of p is difficult express x and y as a function of the parameter p.

Example 64 Solve $xp^2-2yp+ax=0$.

Sol. The given equation can be written as,

$$y=\frac{xp}{2}+\frac{ax}{2p} \qquad \text{...(i)}$$

$$\frac{dy}{dx}=\frac{p}{2}+\frac{x}{2}\cdot\frac{dp}{dx}+\frac{a}{2p}-\frac{ax}{2p^2}\cdot\frac{dp}{dx}$$

$$\Rightarrow \quad p(p^2-a)=x(p^2-a)\cdot\frac{dp}{dx}$$

$$\Rightarrow \quad \frac{dp}{dx}=\frac{p}{x}\Rightarrow p=Cx$$

(The equation $p^2-a=0$ gives us singular solution in which we are not interested).

The substitute p in Eq. (i), we get the required solution

$$2y=Cx^2+\frac{a}{C}$$

Example 65 Solve $y=2px-p^2$.

Sol. Differentiating the given equation w.r.t. x, we get

$$\frac{dy}{dx}=2p+2x\frac{dp}{dx}-2p\frac{dp}{dx}$$

or $\quad 2(x-p)\dfrac{dp}{dx}+p=0$

or $\quad \dfrac{dx}{dp}+\dfrac{2}{p}x=2$

It is a linear equation in x and p.

$$\text{IF}=e^{\int \frac{2}{p}dx}=e^{2\log p}=p^2$$

$\therefore$ The solution is $xp^2=\int p^2\cdot 2\,dp=\dfrac{2}{3}p^3+C$

Thus, the solution of the given equation is

$$x=\frac{2}{3}p+Cp^{-2}\text{, where } p \text{ is parameter.}$$

(iii) Equations Solvable For x

This type of equation can be put in the form

$$x=g(y,p) \qquad \text{...(i)}$$

Differentiating w.r.t. y, we get

$$\frac{1}{p}=\frac{dx}{dy}=G\left(x,p,\frac{dp}{dx}\right)$$

which is a differential equation of 1st order containing y and p and its solution is

$$\phi(y,p,c)=0$$

Then, the solution is obtained by eliminating p between $x=g(y,p)$ and $\phi(y,p,c)=0$. However, if eliminating of p is difficult express x and y as a function of the parameter p.

Example 66 Solve $y=2px+y^2p^3$.

Sol. Solving for x, we get

$$x=\frac{y}{2p}-\frac{y^2p^2}{2} \qquad \text{...(i)}$$

Differentiating Eq. (i) w.r.t. y, we get

$$\frac{dx}{dy}=\frac{1}{2p}-\frac{y}{2p^2}\cdot\frac{dp}{dy}-yp^2-y^2p\cdot\frac{dp}{dy}$$

or $$\frac{1}{p}-\frac{1}{2p}+yp^2=-y\left(\frac{1}{2p^2}+yp\right)\cdot\frac{dp}{dy}$$

or $$(1+2yp^3)\,p=-y\,(1+2p^3y)\cdot\frac{dp}{dy}$$

or $$\frac{dp}{p}+\frac{dy}{y}=0\Rightarrow py=C\Rightarrow p=\frac{C}{y}$$

Substituting this in the Eq. (i), we get

$$x=\frac{y^2}{2C}-\frac{C^2}{2}\;\Rightarrow\;y^2=2Cx+C^2$$

(iv) Clairaut's Equation

The differential equation $y=px+f(p)$ is known as Clairaut's equation. The solution of equation of this type is given by $y=cx+f(c)$.

Which is obtained by replacing p by c in the given equation.

Remark

Some equations can be reduced to Clairaut's form by suitable substitution.

Example 67 Solve $y=px+\dfrac{p}{\sqrt{1+p^2}}$.

Sol. Its solution is, $y=cx+\dfrac{c}{\sqrt{1+c^2}}$

Example 68 Solve $\sqrt{1+p^2}=\tan(px-y)$.

Sol. The given equation is

$$\sqrt{1+p^2}=\tan(px-y)$$

or $$px-y=\tan^{-1}(\sqrt{1+p^2})$$

or $$y=px-\tan^{-1}(\sqrt{1+p^2})$$

Its solution is, $$y=cx-\tan^{-1}(\sqrt{1+c^2})$$

Example 69 Solve $y^2\log y=pxy+p^2$.

Sol. Let $\log y=t$. Then $\dfrac{1}{y}\dfrac{dy}{dx}=\dfrac{dt}{dx}$

So, if $\dfrac{dt}{dx}=p$, then $\dfrac{p}{y}=p$

Substituting these in the given equation, we have

$$y^2t=y\cdot p\;xy+p^2y^2\quad\text{or}\quad t=px+p^2$$

Which is in Clairaut's form.

Thus, the required solution is

$$t=cx+c^2\quad\text{or}\quad\log y=cx+c^2$$

(c being an arbitrary constant.)

Application of Differential Equations

Differential Equation of First Order But not of First Degree

1. The most general form of a first order and higher degree differential equation is $p^n+P_1\,p^{n-1}+P_2\,p^{n-2}+\ldots\ldots+P_n=0$ where $P_1, P_2,$ ....., P_n are function of x, y and $p=dy/dx$. If a 1st order any degree equation can be resolved into differential equation (involving p) of first degree and 1st order, in such case we say that the equation is solvable for p.

   Let their solution be $g_1(x,y,c_1)\times g_2(x,y,c_2)\times\ldots\times g_n(x,y,c_n)=0$, (where $c_1, c_2,$ ....., c_n, are arbitrary constant) we take $c_1=c_2=\ldots\ldots=c_n=c$ because the differential equation of 1st order 1st degree contain only one arbitrary constant. So solution is

   $$g_1(x,y,c)\times g_2(x,y,c)\times\ldots\times g_n(x,y,c)=0$$

2. The most general form of a first order and higher degree differential equation is $p^n+P_1\,p^{n-1}+P_2\,p^{n-2}+\ldots+P_n=0$, where $P_1, P_2,$ ....., P_n are function of x, y and $p=dy/dx$. If differential equation is expressible in the form $y=f(x,p)$, then

   ***Step* 1** Differentiate w.r.t. x, we get $p\dfrac{dy}{dx}=f\left(x,p,\dfrac{dp}{dx}\right)$.

   ***Step* 2** Solving this we obtain $\phi(x,p,c)=0$.

   ***Step* 3** The solution of differential equation is obtained by eliminating p.

Application of First Order Differential Equations

Growth and Decay Problems

Let $N(t)$ denotes the amount of substance (or population) that is either growing or decaying. If we assume that dN/dt, the time rate of change of this amount of substance, is proportional to the amount of substance present, then

$$\frac{dN}{dt}=kN\quad\text{or}\quad\frac{dN}{dt}-kN=0\qquad\ldots(i)$$

Where k is the constant of proportionality. We are assuming that $N(t)$ is a differentiable, hence continuous, function of time.

Example 70 The population of a certain country is known to increase at a rate proportional to the number of people presently living in the country. If after two years the population has doubled and after three years the population is 20000, estimate the number of people initially living in the country.

Sol. Let N denotes the number of people living in the country at any time t, and let N_0 denote the number of people initially living in the country. Then, from Eq. (i)

$$\frac{dN}{dt} - kN = 0$$

Which has the solution $N = Ce^{kt}$ ...(i)

At $t = 0$, $N = N_0$; hence, it follows from Eq. (i) that $N_0 = Ce^{k(0)}$ or that $C = N_0$.

Thus, $N = N_0 e^{kt}$ ...(ii)

At $t = 2$, $N = 2N_0$. Substituting these values into Eq. (ii), we have

$$2N_0 = N_0 e^{2k} \text{ from which } k = \frac{1}{2}\ln 2 = 0.347$$

Substituting this value into Eq. (i) gives

$$N = N_0 e^{(0.347)\,t} \quad \text{...(iii)}$$

At $t = 3$, $N = 20000$. Substituting these values into Eq. (iii), we obtain

$$20000 = N_0 e^{(0.347)(3)}$$

Example 71 ***A certain radioactive material is known to decay at a rate proportional to the amount present. If initially there is 50 mg of the material present and after two hours it is observed that the material has lost 10% of its original mass, find (a) and expression for the mass of the material remaining at any time t, (b) the mass of the material after four hours, and (c) the time at which the material has decayed to one half of its initial mass.***

Sol. (a) Let N denotes the amount of material present at time t. Then, from Eq. (i)

$$\frac{dN}{dt} - kN = 0$$

This differential equation is separable and linear, its solution is

$$N = Ce^{kt} \quad \text{...(i)}$$

At $t = 0$, we are given that $N = 50$. Therefore, from Eq. (i), $50 = Ce^{k(0)}$ or $C = 50$.

Thus, $N = 50\, e^{kt}$ ...(ii)

At $t = 2$, 10% of the original mass of 50 mg or 5 mg has decayed. Hence, at $t = 2$, $N = 50 - 5 = 45$. Substituting these values into Eq. (ii) and solving for k, we have

$$45 = 50e^{2k} \quad \text{or} \quad k = \frac{1}{2}\ln\frac{45}{50} = -0.053$$

Substituting this value into Eq. (ii), we obtain the amount of mass present at any time t as

$$N = 50e^{-0.053\,t} \quad \text{...(iii)}$$

Where t is measured in hours.

(b) We require N at $t = 4$. Substituting $t = 4$ into Eq. (iii) and then solving for N, we find $N = 50e^{(-0.053)\,(4)}$

(c) We require t when $N = 50/2 = 25$. Substituting $N = 25$ into Eq. (iii) and solving for t, we find $25 = 50e^{-0.053t}$

or $-0.053\ t = \ln\frac{1}{2}$ or $t = 13$ h

Example 72 Five mice in a stable population of 500 are intentionally infected with a contagious disease to test a theory of epidemic spread that postulates the rate of change in the infected population is proportional to the product of the number of mice who have the disease with the number that are disease free. Assuming the theory is correct, how long will it take half the population to contract the disease?

Sol. Let $N(t)$ denotes the number of mice with the disease at time t. We are given that $N(0) = 5$, and it follows that $500 - N(t)$ is the number of mice without the disease at time t. The theory predicts that

$$\frac{dN}{dt} = kN\,(500 - N) \quad \text{...(i)}$$

Where k is a constant of proportionality. This equation is different from Eq. (i) because the rate of change is no longer proportional to just the number of mice who have the disease. Eq. (i) has the differential form

$$\frac{dN}{N(500 - N)} - kdt = 0 \quad \text{...(ii)}$$

Which is separable. Using partial fraction decomposition, we have

$$\frac{1}{N(500 - N)} = \frac{1/500}{N} + \frac{1/500}{500 - N}$$

Hence, Eq. (ii) may be rewritten as

$$\frac{1}{500}\left(\frac{1}{N} + \frac{1}{500 - N}\right)dN - kdt = 0$$

It solution is $\frac{1}{500}\int\left(\frac{1}{N} + \frac{1}{500 - N}\right)dN - \int kdt = C$

or $\frac{1}{500}(\ln|N| - \ln|500 - N|) - kt = C$

Which may be rewritten as

$$\ln\left|\frac{N}{500 - N}\right| = 500\,(C + kt)$$

$$\frac{N}{500-N} = e^{500(C+kt)} \qquad \ldots(iii)$$

But $e^{500(C+kt)} = e^{500}\ e^{kt}$. Setting $C_1 = e^{500C}$, we can write Eq. (iii) as

$$\frac{N}{500-N} = C_1 e^{500kt} \qquad \ldots(iv)$$

At $t = 0$, $N = 5$. Substituting these values into Eq. (iv), we find

$$\frac{4}{495} = C_1\, e^{500k(0)} = C_1$$

So, $C_1 = 1/99$ and Eq. (iv) becomes

$$\frac{N}{500-N} = \frac{1}{99}\, e^{500kt} \qquad \ldots(v)$$

We could solve Eq. (v) for N, but this is not necessary. We seek a value of t when $N = 250$, one half the population. Substituting $N = 250$ into Eq. (v) and solving for t, we obtain

$$1 = \frac{1}{99}\, e^{500kt}; \qquad \ln 99 = 500kt$$

or $t = 0.0091/k$ time units. Without additional information, we cannot obtain a numerical value for the constant of proportionality k or be more definitive about t.

Geometrical Applications

Let $P(x_1, y_1)$ be any point on the curve $y = f(x)$, then slope of the tangent at $P\ (= \tan\psi) = \left(\frac{dy}{dx}\right)_{(x_1, y_1)}$ and hence we find the following facts.

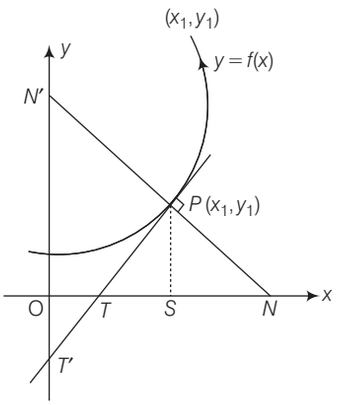


Fig. 4.2

(i) The equation of the tangent at P is,

$y - y_1 = \frac{dy}{dx}(x - x_1)$ when it cuts x-axis, $y = 0$.

$\therefore$ x-intercept of the tangent $= x_1 - y_1\left(\frac{dx}{dy}\right)$

y-intercept of the tangent $= y_1 - x_1\frac{dy}{dx}$

(ii) The equation of normal at P is,

$y - y_1 = -\frac{1}{(dy/dx)}(x - x_1)$ x and y-intercepts of normal are; $x_1 + y_1\frac{dy}{dx}$ and $y_1 + x_1\frac{dx}{dy}$

(iii) Length of tangent $= PT = |y_1|\sqrt{1 + (dx/dy)^2_{(x_1, y_1)}}$

(iv) Length of normal $= PN = |y_1|\sqrt{1 + (dy/dx)^2_{(x_1, y_1)}}$

(v) Length of subtangent $= ST = \left|y_1\left(\frac{dx}{dy}\right)_{(x_1, y_1)}\right|$

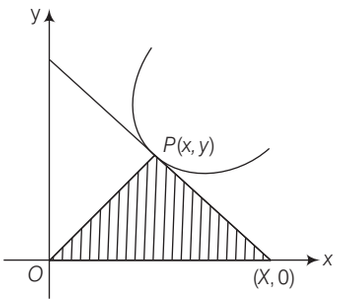
(vi) Length of subnormal $= SN = \left|y_1\left(\frac{dy}{dx}\right)_{(x_1, y_1)}\right|$

(vii) Length of radius vector $= \sqrt{x_1^2 + y_1^2}$

Example 73 Find the curve for which the area of the triangle formed by the x-axis tangent drawn at any point on the curve and radius vector of the point of tangency is constant equal to a^2.

Sol. Tangent drawn at any point (x, y) is

$$Y - y = \frac{dy}{dx}(X - x)$$



When $Y = 0$, $X = x - y\frac{dx}{dy}$

Area of $\Delta = 2a^2$ (given)

i.e. $\left|\frac{1}{2}\cdot X \cdot Y\right| = 2a^2$

i.e. $\left|xy - y^2\frac{dx}{dy}\right| = 2a^2$

i.e. $xy - y^2\frac{dx}{dy} = \pm 2a^2$

i.e. $\frac{dx}{dy} - \frac{x}{y} = \pm\frac{2a^2}{y^2}$

$$\text{IF} = e^{\int -\frac{1}{y}\,dy} = \frac{1}{y}$$

$\therefore$ The solution is $x \cdot \frac{1}{y} = \int \pm \frac{2a^2}{y^2} \cdot \frac{1}{y}\,dy$

$$\frac{x}{y} = \pm \frac{2a^2 \cdot y^{-2}}{-2} + C, \text{ i.e. } x = Cy + \frac{a^2}{y}$$

Example 74 Find the curve for which the intercept cut off by any tangent on y-axis is proportional to the square of the ordinate of the point of tangency.

Sol. The equation of tangent at any point (x, y) is

$$Y - y = \frac{dy}{dx}(X - x)$$

When $X = 0; Y = y - x\frac{dy}{dx} = y$-intercept

It is given $Y \propto y^2$. i.e. $Y = ky^2$

(k being constant of proportionality)

i.e. $$y - x\frac{dy}{dx} = ky^2$$

i.e. $$\frac{dy}{dx} - \frac{1}{x}y = -\frac{ky^2}{x}$$

i.e. $$-y^{-2}\frac{dy}{dx} + \frac{1}{x}\cdot\frac{1}{y} = \frac{k}{x}$$

Let $\frac{1}{y} = z$ so that, $-\frac{1}{y^2}\cdot\frac{dy}{dx} = \frac{dz}{dx}$ $\therefore$ $\frac{dz}{dx} + \frac{z}{x} = \frac{k}{x}$

$$\text{IF} = e^{\int \frac{1}{x}dx} = e^{\log x} = x$$

$\therefore$ The solution is $zx = \int \frac{kx}{x}\,dx = kx + C$

$\Rightarrow$ $$\frac{x}{y} = kx + C$$

$\Rightarrow$ $$x = kxy + Cy$$

$\Rightarrow$ $x - Cy = kxy \Rightarrow \frac{1}{ky} + \frac{-C}{k}\cdot\frac{1}{x} = 1$

$\Rightarrow$ $\frac{C_1}{x} + \frac{C_2}{y} = 1$ $\left(\text{where } \frac{1}{k} = C_2 \text{ and } -\frac{C}{k} = C_1\right)$

Example 75 For any differential function $y = f(x)$, the value of $\frac{d^2y}{dx^2} + \left(\frac{dy}{dx}\right)^3 \cdot \frac{d^2x}{dy^2}$ is equal to

(a) $2y\frac{dy}{dx}$ (b) $y^2\frac{dy}{dx}$

(c) $y\frac{dy}{dx} + \left(\frac{d^2x}{dy^2}\right)^2$ (d) None of these

Sol. We know, $\frac{dy}{dx} = \left(\frac{dx}{dy}\right)^{-1}$, differentiating both the sides

or $$\frac{d^2y}{dx^2} = -\left(\frac{dx}{dy}\right)^{-2}\cdot\frac{d}{dy}\left(\frac{dx}{dy}\right)\cdot\frac{dy}{dx}$$

$$= -\left(\frac{dx}{dy}\right)^{-2}\cdot\frac{d^2x}{dy^2}\cdot\frac{dy}{dx}$$

$\Rightarrow$ $$\frac{d^2y}{dx^2} = -\frac{d^2x}{dy^2}\cdot\left(\frac{dy}{dx}\right)^3$$

or $$\frac{d^2y}{dx^2} + \left(\frac{dy}{dx}\right)^3\cdot\frac{d^2x}{dy^2} = 0$$

Hence, (d) is the correct answer.

Example 76 ***The solution of*** $y = x\frac{dy}{dx} + \frac{dy}{dx} - \left(\frac{dy}{dx}\right)^2$, ***is***

(a) $y = (x-1)^2$ (b) $4y = (x+1)^2$

(c) $(y-1)^2 = 4x$ (d) None of these

Sol. The given equation can be written as

$$y = xp + p - p^2; \quad \text{where } p = \frac{dy}{dx} \quad \ldots(i)$$

Differentiating both the sides w.r.t. x, we get

$$p = p + \frac{xdp}{dx} + \frac{dp}{dx} - 2p\frac{dp}{dx}$$

$\therefore$ $$\frac{dp}{dx}(x + 1 - 2p) = 0$$

$\therefore$ Either $\frac{dp}{dx} = 0$ i.e. $p = C$ ...(ii)

or $x + 1 - 2p = 0$ *ie*, $p = \frac{1}{2}(x+1)$ ...(iii)

Eliminating p between Eqs. (i) and (ii), we get

$$y = Cx + C - C^2$$

As the complete solution and eliminating p between Eqs. (i) and (iii)

$$y = \frac{1}{2}(x+1)\,x + \frac{1}{2}(x+1) - \frac{1}{4}(x+1)^2$$

ie, $4y = (x+1)^2$ as the singular solution.

Hence, (b) is the correct answer.

Example 77 The solution of $\left(\frac{dy}{dx}\right)^2 + (2x + y)\frac{dy}{dx} + 2xy = 0$, is

(a) $(y + x^2 - C_1)(x + \log y + y^2 + C_2) = 0$

(b) $(y + x^2 - C_1)(x - \log y - C_2) = 0$

(c) $(y + x^2 - C_1)(x + \log y - C_2) = 0$

(d) None of the above

Sol. The given equation can be written as

$$p^2 + (2x + y)\, p + 2xy = 0, \text{ where } p = \frac{dy}{dx}$$

i.e. $(p + 2x)(p + y) = 0$

$\therefore$ $p + 2x = 0$, otherwise $p + y = 0$

$\Rightarrow$ $\frac{dy}{dx} + 2x = 0$ or $\frac{dy}{dx} + y = 0$

$\Rightarrow$ $\int dy + 2\int x\, dx = C_1$ or $\int \frac{dy}{y} + \int dx = C_2$

$\Rightarrow$ $y + x^2 = C_1$ or $\log y + x = C_2$

$\therefore$ $(y + x^2 - C_1) = 0$

or $(x + \log y - C_2) = 0$

$\Rightarrow$ $(y + x^2 - C_1)(x + \log y - C_2) = 0$

is the required solution.

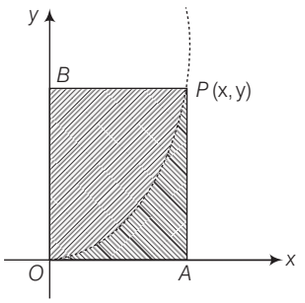
Hence, (c) is the correct answer.

Example 78 A curve $y = f(x)$ passes through the origin. Through any point (x, y) on the curve, lines are drawn parallel to the coordinate axes. If the curve divides the area formed by these lines and coordinate axes in the ratio $m : n$. Then the equation of curve is

(a) $y = Cx^{m/n}$ (b) $my^2 = Cx^{m/n}$

(c) $y^3 = Cx^{m/n}$ (d) None of these

Sol. $\frac{\text{Area of } OBPO}{\text{Area of } OPAO} = \frac{m}{n}$



$\Rightarrow$ $\frac{xy - \int_0^x y\, dx}{\int_0^x y\, dx} = \frac{m}{n} \Rightarrow nxy = (m + n)\int_0^x y\, dx$

Differentiating w.r.t. x, we get

$$n\left(x\frac{dy}{dx} + y\right) = (m + n)\, y$$

$\Rightarrow$ $nx\frac{dy}{dx} = my$

$\Rightarrow$ $\frac{m}{n}\cdot\frac{dx}{x} = \frac{dy}{y}$, integrating both the sides

$$y = Cx^{m/n}$$

Hence, (a) is the correct answer.

Example 79 The equation of the curve passing through the points $(3a, a)\,(a > 0)$ in the form $x = f(y)$ which satisfy the differential equation;

$\frac{a^2}{xy}\cdot\frac{dx}{dy} = \frac{x}{y} + \frac{y}{x} - 2$, is

(a) $x = y + a\left(\frac{1 + e^{y-k}}{1 - 2e^{y-k}}\right)$ (b) $x = y + a\left(\frac{1 + e^{y-k}}{1 - e^{y-k}}\right)$

(c) $y = x + a\left(\frac{1 + e^{y-k}}{1 - e^{y-k}}\right)$ (d) None of these

Sol. Here, $\frac{a^2}{xy}\cdot\frac{dx}{dy} = \frac{x}{y} + \frac{y}{x} - 2$

$\Rightarrow$ $a^2 = \frac{dy}{dx}(x^2 + y^2 - 2xy)$

$\Rightarrow$ $(x - y)^2\cdot\frac{dy}{dx} = a^2$, put $x - y = v$ $\therefore 1 - \frac{dy}{dx} = \frac{dv}{dx}$

$\Rightarrow$ $v^2\left(1 - \frac{dv}{dx}\right) = a^2$

$\Rightarrow$ $v^2 - a^2 = v^2\frac{dv}{dx} \Rightarrow \frac{v^2 dv}{v^2 - a^2} = dx$

$\Rightarrow$ $\left(1 + \frac{a^2}{v^2 - a^2}\right)dv = dx$

Integrating both the sides, we get

$$v + \frac{a}{2}\log\left|\frac{v - a}{v + a}\right| = x + C$$

$\Rightarrow$ $(x - y) + \frac{a}{2}\log\left(\frac{x - y - a}{x - y + a}\right) = x + C$

$\Rightarrow$ $y + C = \frac{a}{2}\log\left(\frac{x - y - a}{x - y + a}\right)$ ...(i)

It passes through $(3a, a)$

$\Rightarrow$ $a + C = \frac{a}{2}\log\left(\frac{1}{3}\right)$

$\Rightarrow$ $C = -a + \frac{a}{2}\log\left(\frac{1}{3}\right)$

$\Rightarrow$ $C = -a\left(\frac{2 + \log 3}{2}\right)$

$\therefore$ $y = \frac{a}{2}(2 + \log 3) + \log\left(\frac{x - y - a}{x - y + a}\right)$

$\Rightarrow$ $\frac{x - y - a}{x - y + a} = e^{y-k}$, where $k = \frac{a}{2}(2 + \log 3)$

$\therefore$ $\frac{x - y}{a} = \frac{1 + e^{y-k}}{1 - e^{y-k}}$

$\Rightarrow$ $x = y + a\left(\frac{1 + e^{y-k}}{1 - e^{y-k}}\right)$, where $k = \frac{a}{2}(2 + \log 3)$

Which is required equation of curve.

Hence, (b) is the correct answer.

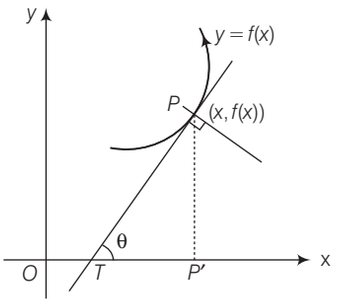
Example 80 ***The family of curves, the subtangent at any point of which is the arithmetic mean of the coordinates of the point of tangency, is given by***

(a) $(x-y)^2 = Cy$ (b) $(y-x)^2 = Cx$

(c) $(x-y)^2 = Cxy$ (d) None of these

Sol. Let the family of curves be $y = f(x)$

$$\tan\theta = \frac{l(PP')}{l(TP')}$$



$$\tan\theta = \frac{l(PP')}{l(TP')}$$

$$\therefore \quad l(\text{subtangent}) = \frac{f(x)}{f'(x)}$$

$$\therefore \quad \frac{y}{y'} = \frac{x+y}{2} \text{ (given)}$$

$$\therefore \quad y' = \frac{2y}{x+y}$$

$$\Rightarrow \quad \frac{dy}{dx} = \frac{2y}{x+y} \quad \therefore \quad \frac{dx}{dy} = \frac{x+y}{2xy} \qquad \ldots(i)$$

It is a homogeneous differential equation.

$\therefore$ Put $x = vy$

Differentiating w.r.t. y, we get

$$\frac{dx}{dy} = v + y\frac{dv}{dy} \qquad \ldots(ii)$$

In Eq. (i) replacing $\frac{dx}{dy}$ by Eq. (ii), we get

$$v + y\frac{dv}{dy} = \frac{vy+y}{2y} = \frac{1+v}{2}$$

$$\Rightarrow \quad y\frac{dv}{dy} = \frac{1+v}{2} - v = \frac{1+v-2v}{2} = \frac{1-v}{2}$$

$$\Rightarrow \quad \frac{2}{1-v}dv = \frac{dy}{y}$$

Integrating, $\frac{2\log|1-v|}{-1} = \log|y| + \log C_1 (C_1 > 0)$

$$\therefore \quad -2\log|y-x| + 2\log|y| = \log|y| + \log C_1$$

$$\Rightarrow \quad \log|y-x|^2 = \log|y| - \log C_1$$

$$\Rightarrow \quad \log|y-x|^2 = \log|y| + \log C,$$

where $\log C = -\log C_1$

$$\Rightarrow \quad \log|y-x|^2 = \log|yC|$$

$\Rightarrow (x-y)^2 = Cy$, is the required equation of family of curves.

Hence, (a) is the correct answer.

Exercise for Session 5

1. The equation of curve for which the normal at every point passes through a fixed point, is

(a) a circle
(b) an ellipse
(c) a hyperbola
(d) None of these

2. If the tangent at any point P of a curve meets the axis of x in T. Then the curve for which $OP = PT$, O being the origin is

(a) $x = Cy^2$
(b) $x = Cy^2$ or $x = C / y^2$
(c) $x = Cy$ or $x = C / y$
(d) None of these

3. According to Newton's law, the rate of cooling is proportional to the difference between the temperature of the body and the temperature of the air. If the temperature of the air is 20°C and body cools for 20 min from 100°C to 60°C, then the time it will take for it temperature to drop to 30°C, is

(a) 30 min
(b) 40 min
(c) 60 min
(d) 80 min

4. Let $f(x, y)$ be a curve in the x-y plane having the property that distance from the origin of any tangent to the curve is equal to distance of point of contact from the y-axis. If $f(1, 2) = 0$, then all such possible curves are

(a) $x^2 + y^2 = 5x$
(b) $x^2 - y^2 = 5x$
(c) $x^2y^2 = 5x$
(d) All of these

5. Given the curves $y = f(x)$ passing through the point $(0, 1)$ and $y = \int_{-\infty}^{x} f(t)$ passing through the point $\left(0, \frac{1}{2}\right)$. The tangents drawn to both the curves at the points with equal abscissae intersect on the x-axis. Then the curve $y = f(x)$, is

(a) $f(x) = x^2 + x + 1$
(b) $f(x) = \frac{x^2}{e^x}$
(c) $f(x) = e^{2x}$
(d) $f(x) = x - e^x$

6. A curve passing through (1, 0) is such that the ratio of the square of the intercept cut by any tangent on the y-axis to the Sub-normal is equal to the ratio of the product of the Coordinates of the point of tangency to the product of square of the slope of the tangent and the subtangent at the same point, is given by

(a) $x = e^{\pm 2\sqrt{y/x}}$
(b) $x = e^{\pm \sqrt{y/x}}$
(c) $y = e^{\pm \sqrt{y/x}} - 1$
(d) $xy + e^{y/x} - 1 = 0$

7. Consider a curve $y = f(x)$ in xy-plane. The curve passes through (0, 0) and has the property that a segment of tangent drawn at any point $P(x, f(x))$ and the line $y = 3$ gets bisected by the line $x + y = 1$. then the equation of curve, is

(a) $y^2 = 9(x - y)$
(b) $(y - 3)^2 = 9(1 - x - y)$
(c) $(y + 3)^2 = 9(1 - x - y)$
(d) $(y - 3)^2 - 9(1 + x + y)$

8. Consider the curved mirror $y = f(x)$ passing through (0, 6) having the property that all light rays emerging from origin, after getting reflected from the mirror becomes parallel to x-axis, then the equation of curve, is

(a) $y^2 = 4(x - y)$ or $y^2 = 36(9 + x)$
(b) $y^2 = 4(1 - x)$ or $y^2 = 36(9 - x)$
(c) $y^2 = 4(1 + x)$ or $y^2 = 36(9 - x)$
(d) None of these

JEE Type Solved Examples :
Single Option Correct Type Questions

● **Ex. 1** *The order of the differential equation of family of curves* $y = C_1 \sin^{-1}x + C_2 \cos^{-1}x + C_3 \tan^{-1}x + C_4 \cot^{-1}x$ *(where* C_1, C_2, C_3 *and* C_4 *are arbitrary constants) is*

(a) 2 (b) 3

(c) 4 (d) None of these

Sol. Here, $y = C_1\sin^{-1}x + C_2\cos^{-1}x + C_3\tan^{-1}x + C_4\cot^{-1}x$

$$\Rightarrow y = C_1\sin^{-1}x + C_2\left(\frac{\pi}{2} - \sin^{-1}x\right) + C_3\tan^{-1}x + C_4\left(\frac{\pi}{2} - \tan^{-1}x\right)$$

$$= (C_1 - C_2)\sin^{-1}x + (C_3 - C_4)\tan^{-1}x + (C_3 - C_4)\frac{\pi}{2}$$

There are only two independent arbitrary constant order of the differential equation is 2.

Hence, (c) is the correct answer.

● **Ex. 2** *The solution of the differential equation* $\frac{dy}{dx} = \frac{1}{xy(x^2\sin y^2 + 1)}$ *is*

(a) $x^2(\cos y^2 - \sin y^2 - 2ce^{-y^2}) = 2$

(b) $y^2(\sin x^2 - \cos y^2 - 2ce^{-y^2}) = 2$

(c) $x^2(\cos y^2 - \sin y^2 - e^{-y^2}) = 4c$

(d) None of the above

Sol. Here, $\frac{dx}{dy} = xy(x^2\sin y^2 + 1)$

$$\Rightarrow \quad \frac{1}{x^3}\frac{dx}{dy} - \frac{1}{x^2}y = y\sin y^2$$

Let, $\quad -\frac{1}{x^2} = t \;\Rightarrow\; \frac{2}{x^3}\frac{dx}{dy} = \frac{dt}{dy}$

$$\Rightarrow \quad \frac{dt}{dy} + 2t\cdot y = y\cdot\sin y^2, I.F. = e^{\int +2y\,dy = e^{+y^2}}$$

So, required solution is

$$t\cdot e^{y^2} = \int 2y\sin y^2 \times e^{y^2}dy = \frac{1}{2}e^{y^2}(\sin y^2 - \cos y^2) + C$$

$$\Rightarrow \quad 2t = (\sin y^2 - \cos y^2) + 2C\,e^{-y^2}$$

$$\Rightarrow \quad 2 = -x^2(\sin y^2 - \cos y^2 + 2ce^{-y^2})$$

$$\Rightarrow \quad x^2(\cos y^2 - \sin y^2 - 2ce^{-y^2}) = 2$$

● **Ex. 3** *The curve satisfying the differential equation* $\frac{dy}{dx} = \frac{y(x+y^3)}{x(y^3 - x)}$ *and passing through* $(4, -2)$ *is*

(a) $y^2 = -2x$ (b) $y = -2x$

(c) $y^3 = -2x$ (d) None of these

Sol. Here, $(xy^3 - x^2)dy = (xy + y^4)dx$

$$\Rightarrow \quad y^3(xdy - ydx) - x(xdy + ydx = 0)$$

$$\Rightarrow \quad x^2y^3d\left(\frac{y}{x}\right) - x\,d(xy) = 0$$

dividing by x^3y^2, we get

$$\Rightarrow \quad \frac{y}{x}d\left(\frac{y}{x}\right) - \frac{1}{x^2y^2}\cdot d\left(\frac{x}{y}\right) = 0$$

$$\Rightarrow \quad \frac{1}{2}d\left(\frac{y}{x}\right)^2 + d\left(\frac{1}{xy}\right) = 0$$

Now integrating, we get

$$\frac{1}{2}\left(\frac{y}{x}\right)^2 + \frac{1}{xy} = c$$

It passes through $(4, -2)$

$$\Rightarrow \quad \frac{1}{8} - \frac{1}{8} = c \;\Rightarrow\; C = 0$$

$\therefore\ y^3 = -2x$ is required curve.

● **Ex. 4** *Spherical rain drop evaporates at a rate proportional to its surface area. The differential equation corresponding to the rate of change of the radius of the rain drop, if the constant of proportionality is* $K > 0$*, is*

(a) $\frac{dr}{dt} + K = 0$ (b) $\frac{dr}{dt} - K = 0$

(c) $\frac{dr}{dt} = Kr$ (d) None of these

Sol. $$\frac{dV}{dt} = -k4\pi r^2 \qquad ...(i)$$

But $$V = \frac{4}{3}\pi r^3$$

$$\Rightarrow \quad \frac{dV}{dt} = 4\pi r^2\frac{dr}{dt} \qquad ...(ii)$$

Therefore, $$\frac{dr}{dt} = -K$$

Hence, (a) is the correct answer.

● **Ex. 5** *A function* $y = f(x)$ *satisfies the differential equation* $f(x)\cdot\sin 2x - \cos x + (1 + \sin^2 x)\,f'(x) = 0$ *with initial condition* $y(0) = 0$*. The value of* $f(\pi/6)$ *is equal to*

(a) 1/5 (b) 3/5

(c) 4/5 (d) 2/5

Sol. $y\sin 2x - \cos x + (1 + \sin^2 x)\frac{dy}{dx} = 0$ where $y = f(x)$

$$\frac{dy}{dx} + \left(\frac{\sin 2x}{1 + \sin^2 x}\right)y = \frac{\cos x}{1 + \sin^2 x}$$

$$\text{IF} = e^{\int \frac{\sin 2x}{1+\sin^2 x}\,dx} = e^{\int \frac{dt}{t}} = e^{\ln(1+\sin^2 x)}$$

$$= 1 + \sin^2 x \quad (\text{by putting } 1 + \sin^2 x = t)$$

$$y(1 + \sin^2 x) = \int \cos x\, dx$$

$$y(1 + \sin^2 x) = \sin x + C;\ y(0) = 0 \Rightarrow C = 0$$

Therefore, $$y = \frac{\sin x}{1 + \sin^2 x};\ y\left(\frac{\pi}{6}\right) = \frac{2}{5}$$

Hence, (d) is the correct answer.

● **Ex. 6** *The general solution of the differential equation* $\frac{dy}{dx} = \frac{1-x}{y}$ *is a family of curves which looks most like which of the following?*

(a) (b) (c)  (d) 
Sol. $$\int y\,dy = \int (1 - x)\,dx$$

$$\frac{y^2}{2} = x - \frac{x^2}{2} + C$$

$$x^2 + y^2 - 2x = C$$

$$(x-1)^2 + y^2 = C + 1 = C$$

Hence, (b) is the correct answer.

Remark

Family of concentric circles with (1, 0) as the centre and variable radius.

● **Ex. 7** *Water is drained from a vertical cylindrical tank by opening a valve at the base of the tank. It is known that the rate at which the water level drops is proportional to the square root of water depth y, where the constant of proportionality* $k > 0$ *depends on the acceleration due to gravity and the geometry of the hole. If t is measured in minutes and* $k = \frac{1}{15}$*, then the time to drain the tank, if the water is 4 m deep to start with is*

(a) 30 min (b) 45 min (c) 60 min (d) 80 min

Sol. $\frac{dy}{dt} = -k\sqrt{y}$; when $t = 0$; $y = 4$

$$\int_4^0 \frac{dy}{\sqrt{y}} = -k\int_0^t dt$$

$$[2\sqrt{y}]_4^0 = -kt = -\frac{t}{15}$$

$$0 - 4 = -\frac{t}{15}$$

$$\Rightarrow \quad t = 60 \text{ min}$$

Hence, (c) is the correct answer.

● **Ex. 8** *Number of straight lines which satisfy the differential equation* $\frac{dy}{dx} + x\left(\frac{dy}{dx}\right)^2 - y = 0$ *is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. $y = kx + b;\ \frac{dy}{dx} = k$

$$\Rightarrow \quad kx + b \equiv k + xk^2 \quad \Rightarrow\ k = k^2 \text{ and } b = k$$

$$k = 0 \text{ or } k = 1$$

Hence, (b) is the correct answer.

● **Ex. 9** *Consider the two statements :*

Statement I $y = \sin kt$ *satisfy the differential equation* $y'' + 9y = 0$.

Statement II $y = e^{kt}$ *satisfy the differential equation* $y'' + y' - 6y = 0$.

The value of k for which both the statements are correct is

(a) −3 (b) 0 (c) 2 (d) 3

Sol. **Statement I** $y = \sin kt,\ y' = k\cos kt;\ y'' = -k^2 \sin kt$

$$\therefore \quad -k^2 \sin kt + 9\sin kt = 0$$

$$\sin kt\,[9 - k^2] = 0 \ \Rightarrow\ k = 0, k = 3, k = -3$$

Statement II $y = e^{kt},\ y' = ke^{kt};\ y'' = k^2 e^{kt}$

$$\therefore \quad k^2 e^{kt} + ke^{kt} - 6e^{kt} = 0$$

$$e^{kt}[k^2 + k - 6] = 0$$

$$(k + 3)(k - 2) = 0$$

$$k = -3 \text{ or } 2$$

Common value is $k = -3$.

Hence, (a) is the correct answer.

● **Ex. 10** *If* $y = \frac{x}{\ln|cx|}$ *(where c is an arbitrary constant) is the general solution of the differential equation* $\frac{dy}{dx} = \frac{y}{x} + \phi\left(\frac{x}{y}\right)$*, then the function* $\phi\left(\frac{x}{y}\right)$ *is*

(a) $\frac{x^2}{y^2}$ (b) $-\frac{x^2}{y^2}$ (c) $\frac{y^2}{x^2}$ (d) $-\frac{y^2}{x^2}$

Sol. $\ln c + \ln|x| = \frac{x}{y}$

Differentiating w.r.t. x, $\frac{1}{x} = \frac{y - xy_1}{y^2}$

$$\frac{y^2}{x} = y - x\frac{dy}{dx}$$

$$\frac{dy}{dx} = \frac{y}{x} - \frac{y^2}{x^2} \ \Rightarrow\ \phi\left(\frac{x}{y}\right) = -\frac{y^2}{x^2}$$

Hence, (d) is the correct answer.

● **Ex. 11** *If* $\int_a^x ty(t)\,dt = x^2 + y(x)$, *then* y *as a function of* x *is*

(a) $y = 2 - (2 + a^2)\,e^{\frac{x^2 - a^2}{2}}$ (b) $y = 1 - (2 + a^2)\,e^{\frac{x^2 - a^2}{2}}$

(c) $y = 2 - (1 + a^2)\,e^{\frac{x^2 - a^2}{2}}$ (d) None of these

Sol. Differentiating both the sides, we get

$$xy\,(x) = 2x - y'(x)$$

Hence, $\dfrac{dy}{dx} - xy = -2x \qquad \left[y'(x) = \dfrac{dy}{dx};\ y(x) = y\right]$

$$\text{IF} = e^{\int -x\,dx} = e^{\frac{-x^2}{2}}$$

$$ye^{\frac{-x^2}{2}} = \int -2xe^{\frac{-x^2}{2}}\,dx$$

Let $e^{-\frac{x^2}{2}} = t \implies -xe^{-\frac{x^2}{2}}\,dx = dt$

$$I = \int 2dt$$

$$ye^{-\frac{x^2}{2}} = 2e^{-\frac{x^2}{2}} + C$$

$$y = 2 + Ce^{\frac{x^2}{2}}$$

If $x = a \implies a^2 + y = 0 \implies y = -a^2$ (from the given equation)

Hence, $-a^2 = 2 + Ce^{\frac{a^2}{2}};\ Ce^{\frac{a^2}{2}} = -(2 + a^2)$

$$C = -(2 + a^2)\,e^{-\frac{a^2}{2}};\ y = 2 - (2 + a^2)\,e^{\frac{x^2 - a^2}{2}}$$

Hence, (a) is the correct answer.

● **Ex. 12** *The differential equation* $\dfrac{dy}{dx} = \dfrac{\sqrt{1 - y^2}}{y}$ *determines a family of circles with* ***[IIT JEE 2007]***

(a) variable radii and a fixed centre at (0, 1)

(b) variable radii and fixed centre at (0, −1)

(c) fixed radius 1 and variable centres along the x-axis

(d) fixed radius 1 and variable centres along the y-axis

Sol. $\because \quad \dfrac{dy}{dx} = \dfrac{\sqrt{1 - y^2}}{y}$

$$\Rightarrow \quad \int \frac{y}{\sqrt{1 - y^2}}\,dy = \int dx \implies -\frac{1}{2} \cdot 2\sqrt{1 - y^2} = x + C$$

$$\Rightarrow \quad -\sqrt{1 - y^2} = x + C \implies 1 - y^2 = (x + C)^2$$

$$\Rightarrow \quad (x + C)^2 + y^2 = 1$$

Therefore, the differential equation represents a circle of fixed radius 1 and variable centres along the x-axis. Hence, (c) is the correct answer.

JEE Type Solved Examples :
More than One Correct Option Type Questions

● **Ex. 13** *A curve* $y = f(x)$ *has the property that the perpendicular distance of the origin from the normal at any point P of the curve is equal to the distance of the point P from the x-axis. Then the differential equation of the curve*

(a) is homogeneous

(b) can be converted into linear differential equation with some suitable substitution

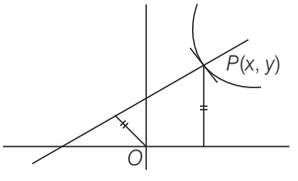
(c) is the family of circles touching the x-axis at the origin

(d) the family of circles touching the y-axis at the origin

Sol. Equation of normal

$$Y - y = -\frac{1}{m}(X - x) \implies -my + my = X - x$$

$$X + my - (x + my) = 0$$



$$\text{Perpendicular from } (0, 0) = \left|\frac{x + my}{\sqrt{1 + m^2}}\right| = y \implies x^2 + 2xym = y^2$$

$$\frac{dy}{dx} = \frac{y^2 - x^2}{2xy} \implies \text{homogeneous}$$

Also, $x \cdot 2y \cdot \dfrac{dy}{dx} - x^2 = y^2$

Put $y^2 = t$; $\quad 2y\dfrac{dy}{dx} = \dfrac{dt}{dx};\ x \cdot \dfrac{dt}{dx} + x^2 = t$

$\dfrac{dt}{dx} - \dfrac{1}{x}t = -x$ which is linear differential equation.

Hence, (a), (b) and (d) are the correct answers.

● **Ex. 14** *A differentiable function satisfies* $f(x) = \int_0^x \{f(t)\cos t - \cos(t - x)\}\,dt$. *Which is of the following hold good?*

(a) $f(x)$ has a minimum value $1 - e$

(b) $f(x)$ has a maximum value $1 - e^{-1}$

(c) $f''\left(\dfrac{\pi}{2}\right) = e$ (d) $f'(0) = 1$

Sol. $f(x) = \int_0^x \{f(t)\cos t - \cos(t - x)\}\,dx$

$$= \int_0^x f(t)\cos t\,dt - \int_0^x \cos(-t)\,dt \left[\int_0^a f(x)dx = \int_0^a f(a - x)\,dx\right]$$

$$f(x) = \int_0^x f(t)\cos t\,dt - \sin x$$

Differentiating both the sides, we get

$$f'(x) = f(x)\cos x - \cos x$$

Let $f(x) = y;\ f'(x) = \dfrac{dy}{dx}$

$$\frac{dy}{dx} - y\cos x = -\cos x \qquad \text{(L.D.E.)}$$

$$\text{IF} = e^{-\int \cos x\,dx} = e^{-\sin x}$$

Therefore, $y \cdot e^{-\sin x} = -\int e^{-\sin x}\cos x\,dx;$

$$y \cdot e^{-\sin x} = C + e^{-\sin x};\ y = Ce^{\sin x} + 1$$

If $x = 0;$ $y = 0$ (from the given relation)

$\Rightarrow$ $C = -1$

Therefore, $f(x) = 1 - e^{\sin x}$

Now, minimum value $= 1 - e$ (when $x = \pi/2$)

Maximum value $= 1 - e^{-1}$ (when $x = -\pi/2$)

$$f'(x) = -e^{\sin x}\cos x$$

Therefore, $f'(0) = -1$

$$f''(x) = -[\cos^2 x \cdot e^{\sin x} - e^{\sin x}\cdot\sin x]$$

$$f''\left(\frac{\pi}{2}\right) = e$$

Hence, (a), (b) and (c) are the correct answers.

● ***Ex. 15*** *Let* $\dfrac{dy}{dx} + y = f(x)$ *where* y *is a continuous function of* x *with* $y(0) = 1$ *and* $f(x) = \begin{cases} e^{-x}, & \text{if } 0 \le x \le 2 \\ e^{-2}, & \text{if } x > 2 \end{cases}$. *Which is of the following hold(s) good?*

(a) $y(1) = 2e^{-1}$ (b) $y'(1) = -e^{-1}$

(c) $y(3) = -2e^{-3}$ (d) $y'(3) = -2e^{-3}$

Sol. $\dfrac{dy}{dx} + y = f(x) \Rightarrow \text{IF} = e^x$

$$ye^x = \int e^x f(x)\,dx + C$$

Now, if $0 \le x \le 2$, then $ye^x = \int e^x e^{-x}\,dx + C$

$\Rightarrow$ $ye^x = x + C$

$x = 0,\ y(0) = 1,\ C = 1$

$\therefore$ $ye^x = x + 1$ ...(i)

$$y = \frac{x+1}{e^x};\ y(1) = \frac{2}{e} \Rightarrow y' = \frac{e^x - (x+1)e^x}{e^{2x}}$$

$$y'(1) = \frac{e - 2e}{e^2} = \frac{-e}{e^2} = -\frac{1}{e}$$

If $x > 2$, $ye^x = \int e^{x-2}\,dx$

$$ye^x = e^{x-2} + C$$

$$y = e^{-2} + Ce^{-x}$$

As y is continuous.

$\therefore$ $\lim\limits_{x\to 2} \dfrac{x+1}{e^x} = \lim\limits_{x\to 2}(e^{-2} + Ce^{-x})$

$$3e^{-2} = e^{-2} + Ce^{-2} \Rightarrow C = 2$$

$\therefore$ for $x > 2$

$$y = e^{-2} + 2e^{-x}$$

Hence, $y(3) = 2e^{-3} + e^{-2} = e^{-2}(2e^{-1} + 1)$

$$y' = -2e^{-x}$$

$$y'(3) = -2e^{-3}$$

Hence, (a), (b) and (d) are the correct answers.

● ***Ex. 16*** *A curve* $y = f(x)$ *passes through (1, 1) and tangent at* $P(x, y)$ *cuts the x-axis and y-axis at A and B respectively such that* $BP : AP = 3 : 1$, *then* ***[IIT JEE 2006]***

(a) equation of curve is $xy' - 3y = 0$

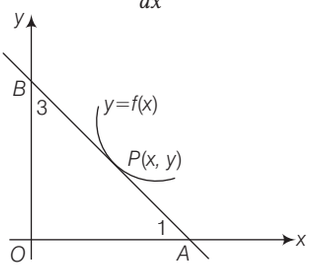
(b) normal at (1, 1) is $x + 3y = 4$

(c) curve passes through $\left(2, \dfrac{1}{8}\right)$

(d) equation of curve is $xy' + 3y = 0$

Sol. Equation of the tangent to the curve $y = f(x)$ at (x, y) is

$$Y - y = \frac{dy}{dx}(X - x)$$



$\because$ Thus, cuts the x-axis at A and y-axis at B.

$$\therefore \quad A\left(\frac{x\frac{dy}{dx} - y}{\frac{dy}{dx}}, 0\right) \text{ and } B\left(0, -x\frac{dy}{dx} + y\right)$$

$\because$ $BP : PA = 3 : 1$

$$\Rightarrow \quad x = \frac{3\left(x\frac{dy}{dx} - y\right)}{(dy/dx)} + 1 \times 0}{4}$$

$$\Rightarrow \quad x\frac{dy}{dx} + 3y = 0$$

$$\Rightarrow \quad \int \frac{dy}{y} = \int -3\frac{dx}{x}$$

$$\Rightarrow \quad \log y = -3\log x + \log C$$

$$\Rightarrow \quad y = \frac{C}{x^3}$$

$\because$ Curve passes through (1, 1) $\therefore$ $C = 1$

$\therefore$ Curve is $x^3y = 1$ which also passes through $\left(2, \dfrac{1}{8}\right)$.

Hence, (c) and (d) are the correct answers.

JEE Type Solved Examples :
Statement I and II Type Questions

● **Ex. 17** *Let a solution $y = y(x)$ of the differential equation $x\sqrt{x^2-1}\,dy - y\sqrt{y^2-1}\,dx = 0$ satisfy $y(2) = \frac{2}{\sqrt{3}}$.* ***[IIT JEE 2008]***

Statement I $y(x) = \sec\left(\sec^{-1} x - \frac{\pi}{6}\right)$.

Statement II $y(x)$ *is given by* $\frac{1}{y} = \frac{2\sqrt{3}}{x} - \sqrt{1-\frac{1}{x^2}}$.

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I.
(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I.
(c) Statement I is true, Statement II is false.
(d) Statement I is false, Statement II is true.

Sol. $\because \quad x\sqrt{x^2-1}\,dy - y\sqrt{y^2-1}\,dx = 0$

Which can be rewritten as $\frac{dx}{x\sqrt{x^2-1}} = \frac{dy}{y\sqrt{y^2-1}}$

Integration yields, $\int \frac{dx}{x\sqrt{x^2-1}} = \int \frac{dy}{y\sqrt{y^2-1}}$

$\Rightarrow \quad \sec^{-1} x = \sec^{-1} y + C$

$\Rightarrow \quad \sec^{-1}(2) = \sec^{-1}(2/\sqrt{3}) + C$

$\Rightarrow \quad \frac{\pi}{3} = \frac{\pi}{6} + C \;\Rightarrow\; C = \frac{\pi}{6}$

Thus, $\quad \sec^{-1} x = \sec^{-1} y + \frac{\pi}{6}$

$\Rightarrow \quad y = \sec\left(\sec^{-1} x - \frac{\pi}{6}\right)$

$$= \frac{1}{\cos\left(\cos^{-1}\frac{1}{x} - \frac{\pi}{6}\right)} = \frac{1}{\frac{1}{x}\cdot\frac{\sqrt{3}}{2} + \sqrt{1-\frac{1}{x^2}}\cdot\frac{1}{2}}$$

$\Rightarrow \quad \frac{1}{y} = \frac{\sqrt{3}}{2x} + \frac{\sqrt{1-\frac{1}{x^2}}}{2}$

Hence, (c) is the correct answer.

JEE Type Solved Examples :
Passage Based Questions

Passage
(Q. Nos. 18 to 20)

A curve $y = f(x)$ satisfies the differential equation $(1+x^2)\frac{dy}{dx} + 2yx = 4x^2$ and passes through the origin.

18 The function $y = f(x)$
(a) is strictly increasing, $\forall\, x \in R$
(b) is such that it has a minima but no maxima
(c) is such that it has a maxima but no minima
(d) has no inflection point

19 The area enclosed by $y = f^{-1}(x)$, the x-axis and the ordinate at $x = 2/3$ is
(a) $2\ln 2$ (b) $\frac{4}{3}\ln 2$ (c) $\frac{2}{3}\ln 2$ (d) $\frac{1}{3}\ln 2$

20 For the function $y = f(x)$ which one of the following does not hold good?
(a) $f(x)$ is a rational function
(b) $f(x)$ has the same domain and same rage
(c) $f(x)$ is a transcendental function
(d) $y = f(x)$ is a bijective mapping

Sol. (Q. Nos. 18 to 20)

$$\frac{dy}{dx} + \left(\frac{2x}{1+x^2}\right)y = \frac{4x^2}{1+x^2}$$

$$\text{IF} = e^{\int \frac{2x}{1+x^2}dx}$$

$$= e^{\ln(1+x^2)} = (1+x^2)$$

$\therefore \quad y(1+x^2) = \int 4x^2\,dx = \frac{4x^3}{3} + C$

Passing through $(0, 0) \Rightarrow C = 0$

$\therefore \quad y = \frac{4x^3}{3(1+x^2)}$

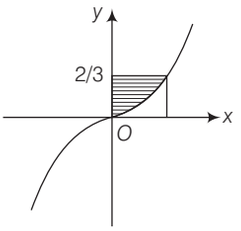
$$\frac{dy}{dx} = \frac{4}{3}\left[\frac{(1+x^2)3x^2 - x^3\cdot 2x}{(1+x^2)^2}\right]$$

$$= \frac{4}{3}\left[\frac{3x^2+x^4}{(1+x^2)^2}\right] = \frac{4x^2(3+x^2)}{3(1+x^2)^2}$$

Hence, $\frac{dy}{dx} > 0, \forall\, x \neq 0; \frac{dy}{dx} = 0$ at $x = 0$

and it does not change sign $\Rightarrow x = 0$ is the point of inflection
$y = f(x)$ is increasing for all $x \in R$.

$x \to \infty;\ y \to \infty;\ x \to -\infty;\ y \to -\infty$



Area enclosed by $y = f^{-1}(x)$, x-axis and ordinate at $x = \frac{2}{3}$

$$A = \frac{2}{3} - \frac{4}{3}\int_0^1 \frac{x^3}{1+x^2}\,dx$$

Put $1 + x^2 = t \implies 2x\,dx = dt$

$$A = \frac{2}{3} - \frac{2}{3}\int_1^2 \frac{(t-1)}{t}\,dt$$

$$= \frac{2}{3} - \frac{2}{3}\int_1^2 \left(1 - \frac{1}{t}\right)dt$$

$$= \frac{2}{3} - \frac{2}{3}[t - \ln t]_1^2 = \frac{2}{3} - \frac{2}{3}[(2 - \ln 2) - 1]$$

$$= \frac{2}{3} - \frac{2}{3}[1 - \ln 2] = \frac{2}{3}\ln 2$$

JEE Type Solved Examples :
Single Integer Answer Type Questions

● ***Ex. 21*** *Let $y = f(x)$ be a curve passing through (4, 3) such that slope of normal at any point lying in the first quadrant is negative and the normal and tangent at any point P cuts the Y-axis at A and B respectively such that the mid-point of AB is origin, then the number of solutions of $y = f(x)$ and $y = |5 - |x||$, is*

Sol. Equation of tangent at any point (x_1, y_1) of curve $y = f(x)$ is $(y - y_1) = f'(x_1)(x - x_1)$, so $B\,(0, y_1 - x_1 f'(x_1))$

Equation of normal at (x_1, y_1) is $(y, y_1) = -\frac{1}{f'(x_1)}(x, x_1)$ so,

$A = \left(0, y_1 + \frac{x_1}{f'(x_1)}\right)$ mid point of AB is origin, so

$$2y_1 - x_1\left(f'(x_1) - \frac{1}{f'(x_1)}\right) = 0$$

Thus differential equation of curve $y = f(x)$, is

$$x\left(\frac{dy}{dx}\right)^2 - 2y\frac{dy}{dx} - x = 0$$

Thus, $$\frac{dy}{dx} = \frac{y \pm \sqrt{x^2 + y^2}}{x}$$

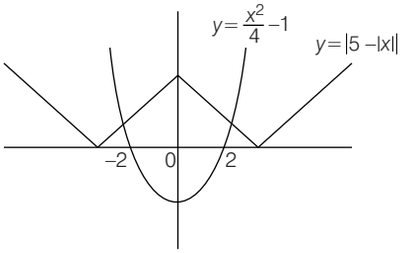
In first quadrant, $x > 0, y > 0, \frac{dy}{dx} > 0$,

So $$\frac{dy}{dx} = \frac{y + \sqrt{x^2 + y^2}}{x}, \text{ put } y = vx$$

$$\Rightarrow \quad v + x\frac{dv}{dx} = \frac{vx + x\sqrt{1 + v^2}}{x}$$

$$\Rightarrow \quad \int \frac{dv}{\sqrt{1 + v^2}} = \int \frac{dx}{x}$$

on solving we get $y = \frac{x^2}{4} - 1$



$\therefore$ number of solutions for $y = f(x)$ and $y = |5 - |x||$

$\therefore$ number of solutions are 2.

● ***Ex. 22*** *A real valued function, $f(x)$, $f : \left(0, \frac{\pi}{2}\right) \to R^+$ satisfies the differential equation $xf'(x) = 1 + f(x)\{x^2 f(x)^{-1}\}$ and $f\left(\frac{\pi}{4}\right) = \frac{4}{\pi}$, then $\lim_{x\to 0} f(x)$, is*

Sol. Here, $xf'(x) = 1 + x^2 f^2(x) - f(x)$

$$\Rightarrow \quad \frac{x\,f'(x) + f(x)}{1 + x^2 f^2(x)} = 1$$

Integrating both sides

$$\int \frac{(x\,f'(x) + f(x))dx}{1 + (x\,f(x))^2} = x + C$$

$$\Rightarrow \quad \tan^{-1}(xf(x) = x + C, \text{ as } f\left(\frac{\pi}{4}\right) = \frac{4}{\pi}.$$

$$\Rightarrow \quad \tan^{-1}1 = \frac{\pi}{4} + C$$

$$\Rightarrow \quad C = 0$$

$$\therefore \quad x\,f(x) = \tan x$$

$$\Rightarrow \quad f(x) = \frac{\tan x}{x}$$

and $$\lim_{x\to 0} f(x) = \lim_{x\to 0}\frac{\tan x}{x} = 1$$

● ***Ex. 23*** *If the area bounded by* $y = f(x), x = \frac{1}{2}, x = \frac{\sqrt{3}}{2}$ *and the X-axis is A sq units where* $f(x) = x + \frac{2}{3}x^3 + \frac{2}{3}\cdot\frac{4}{5}x^5 + \frac{2}{3}\cdot\frac{4}{5}\cdot\frac{6}{7}x^7 + \ldots\infty, |x|<1$, *Then the value of* $[4A]$ *is (where* $[\cdot]$ *is G.I.F)*

Sol. Here, $f'(x) = 1 + 2x^2 + \frac{2}{3}\cdot 4x^4 + \frac{2}{3}\cdot\frac{4}{5}\cdot 6x^6 + \ldots\infty$

$= 1 + x\left(\frac{d}{dx}(xf(x))\right)$

$\Rightarrow \quad f'(x) = 1 + x\,|xf'(x) + f(x)|$

$\Rightarrow (1 - x^2)f'(x) = 1 + xf(x)$

$\Rightarrow \quad \frac{dy}{dx} - \frac{x}{1-x^2}\cdot y = \frac{1}{x^2}$, I.F. $= e^{\int \frac{-x}{1-x^2}dx} = e^{\frac{1}{2}\log|1-x^2|} = \sqrt{1-x^2}$

$\therefore \quad y\cdot\sqrt{1-x^2} = \int \frac{1}{1-x^2}\cdot\sqrt{1-x^2} + C$

$\Rightarrow \quad y\sqrt{1-x^2} = \sin^{-1}x + C$, as $f(0) = 0 \Rightarrow C = 0$

$\Rightarrow \quad y = \frac{\sin^{-1}x}{\sqrt{1-x^2}}$

$\Rightarrow \quad A = \int_{1/2}^{\sqrt{3}/2} \frac{\sin^{-1}x}{\sqrt{1-x^2}}dx = \int_{\pi/6}^{\pi/3} t\,dt = \left(\frac{t^2}{2}\right)_{\frac{\pi}{6}}^{\frac{\pi}{2}} = \frac{1}{2}\left[\frac{\pi^2}{4} - \frac{\pi^2}{36}\right]$

$\therefore \quad [4A] = 1$

Subjective Type Questions

● ***Ex. 24*** *For a certain curve* $y = f(x)$ *satisfying* $\frac{d^2y}{dx^2} = 6x - 4$; $f(x)$ *has a local minimum value 5 when* $x = 1$. *Find the equation of the curve and also the global maximum and global minimum values of* $f(x)$ *given that* $0 \le x \le 2$.

Sol. Integrating, $\frac{d^2y}{dx^2} = 6x - 4$, we get $\frac{dy}{dx} = 3x^2 - 4x + C$

when $x = 1, \frac{dy}{dx} = 0$. So that $C = 1$

Hence, $\frac{dy}{dx} = 3x^2 - 4x + 1$ ...(i)

Integrating, we get

$y = x^3 - 2x^2 + x + C_1$, when $x = 1, y = 5$,

so that $C_1 = 5$

Thus, we have $y = x^3 - 2x^2 + x + 5$

Form Eq. (i), we get the critical points $x = \frac{1}{3}, x = 1$

At the critical point $x = \frac{1}{3}, \frac{d^2y}{dx^2}$ is (–ve).

Therefore, at $x = \frac{1}{3}$, y has a local maximum.

At $x = 1, \frac{d^2y}{dx^2}$ is (+ ve).

Therefore, at $x = 1$, y has a local minimum.

Also, $f(1) = 5$

$\Rightarrow \quad f\left(\frac{1}{3}\right) = \frac{139}{27}$

$f(0) = 5, f(2) = 7$

Hence, the global maximum value = 7, the global minimum value = 5.

● ***Ex. 25*** *If* $\phi(x)$ *is a differentiable real-valued function satisfying* $\phi'(x) + 2\,\phi(x) \le 1$, *prove that* $\phi(x) - \frac{1}{2}$ *is a non-increasing function of x.*

Sol. $\phi'(x) + 2\,\phi(x) \le 1$

$\Rightarrow \quad e^{2x}\,\phi'(x) + 2\,\phi(x)\,e^{2x} \le e^{2x}$

$\Rightarrow \quad \frac{d}{dx}\left(e^{2x}\,\phi(x) - \frac{1}{2}e^{2x}\right) \le 0$

$\Rightarrow \quad e^{2x}\left(\phi(x) - \frac{1}{2}\right)$ is a non-increasing function of x.

$\Rightarrow \quad \phi(x) - \frac{1}{2}$ is a non-increasing function of x.

● ***Ex. 26*** *Determine all curve for which the ratios of the length of the segment intercepted by any tangent on the y-axis to the length of the radius vector is a constant.*

Sol. Let $y = f(x)$ be the equation of the required curve.

Given that $\frac{\left|y - x\frac{dy}{dx}\right|}{\sqrt{x^2+y^2}} = k$ (a constant)

$\Rightarrow \quad \frac{dy}{dx} = \frac{y}{x} \pm k\sqrt{1 + \left(\frac{y}{x}\right)^2}$

Let $y = vx$, then $v + x\frac{dv}{dx} = v \pm k\sqrt{1+v^2}$

$\Rightarrow \quad \frac{dv}{\sqrt{1+v^2}} = \pm k\frac{dx}{x}$, integrating we get

$\Rightarrow \quad \log\left|v + \sqrt{1+v^2}\right| = \pm k\ln x + C$

$\Rightarrow \quad \log\left|\frac{xy + \sqrt{x^2+y^2}}{x}\right| = \pm k\ln x + C$

Which are the equations of the required curves.

● **Ex. 27** *Let $u(x)$ and $v(x)$ satisfy the differential equations $\frac{du}{dx} + p(x)\,u = f(x)$ and $\frac{dv}{dx} + p(x)\,v = g(x)$, where $p(x)$, $f(x)$ and $g(x)$ are continuous functions. If $u(x_1) > v(x_1)$ for some x_1 and $f(x) > g(x)$, for all $x > x_1$, prove that any point (x, y), where $x > x_1$, does not satisfy the equation $y = u(x)$ and $y = v(x)$.* **[IIT JEE 1997]**

Sol. Given that

$$\frac{du}{dx} + p(x)\cdot u = f(x) \quad \text{and} \quad \frac{dv}{dx} + p(x)\cdot v = g(x)$$

Subtracting, we get

$$\frac{d(u-v)}{dx} + p(x)\cdot(u-v) = f(x) - g(x)$$

Multiplying by $e^{\int p(x)\,dx}$, we get

$$e^{\int p(x)\,dx}\cdot\frac{d(u-v)}{dx} + (u-v)\cdot p(x)\cdot e^{\int p(x)\,dx} = \{f(x)-g(x)\}\cdot e^{\int p(x)\,dx}$$

i.e. $$\frac{d}{dx}\{(u-v)\,e^{\int p\,dx}\} = \{f(x)-g(x)\}\,e^{\int p(x)\,dx}$$

Since, exponential function takes only positive values and

$f(x) > g(x)$ for all $x > x_1$, RHS is + ve; $x > x_1$

$$\therefore \quad \frac{d}{dx}\{(u-v)\cdot e^{\int p(x)\,dx}\} = 0$$

ie, $(u-v)\cdot e^{\int p(x)\,dx}$ is increasing function.

Hence, if $e^{\int p(x)\,dx} = \phi(x)$, then for $x > x_1$

We have, $\{u(x)-v(x)\}\,\phi(x) > \{u(x_1)-v(x_1)\}\,\phi(x_1)$

i.e. $$u(x)-v(x) > \frac{\{u(x_1)-v(x_1)\}\cdot\phi(x_1)}{\phi(x)} > 0 \quad [\because u(x_1) > v(x_1)]$$

Thus, $u(x) > v(x),\ \forall\ x > x_1$

i.e. $u(x) \neq v(x),\ \forall\ x > x_1$

Hence, no point (x, y) such that $x > x_1$ can satisfy the equations $y = u(x)$ and $y = v(x)$.

● **Ex. 28** *A normal is drawn at a point $P(x, y)$ of a curve. It meets the x-axis at Q. If PQ is of constant length k, then show that the differential equation describing such curves is, $y\frac{dy}{dx} = \pm\sqrt{k^2 - y^2}$ and the equation of such a curve passing through $(0, k)$.* **[IIT JEE 1994]**

Sol. Let $y = f(x)$ be the curve such that the normal at $P(x, y)$ to this curve meets x-axis at Q. Then,

PQ = length of the normal at P

$$= y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}$$

But $PQ = k$

$$\therefore \quad y\sqrt{1 + \left(\frac{dy}{dx}\right)^2} = k$$

$$\Rightarrow \quad y^2 + y^2\left(\frac{dy}{dx}\right)^2 = k^2 \quad \text{or} \quad y\frac{dy}{dx} = \pm\sqrt{k^2 - y^2}$$

$$\Rightarrow \quad \frac{y\ dy}{\sqrt{k^2 - y^2}} = \pm\,dx$$

Integrating both the sides, we get

$-\sqrt{k^2 - y^2} = \pm\ x + C$, since it passes through $(0, k) \to C = 0$.

$$\therefore \quad -\sqrt{k^2 - y^2} = \pm\ x$$

or $$k^2 - y^2 = x^2$$

$\Rightarrow$ $x^2 + y^2 = k^2$, is required equation of the curve.

● **Ex. 29** *A curve passing through the point (1, 1) has the property that the perpendicular distance of the normal at any point P on the curve from the origin is equal to the distance of P from x-axis. Determine the equation of the curve.* **[IIT JEE 1999]**

Sol. Let $P(x, y)$ be any point on the curve $y = f(x)$. Then, the equation of the normal at P is,

$$Y - y = -\frac{1}{(dy/dx)}(X - x)$$

or $$X + Y\frac{dy}{dx} - \left(y\frac{dy}{dx} + x\right) = 0 \qquad \text{...(i)}$$

It is given that distance of Eq. (i) from origin = Distance from x-axis (i.e. y)

i.e. $$\left|\frac{0 - \left(y\frac{dy}{dx} + x\right)}{\sqrt{1 + \left(\frac{dy}{dx}\right)^2}}\right| = y$$

$$\Rightarrow \quad \left(y\frac{dy}{dx} + x\right)^2 = y^2\left[1 + \left(\frac{dy}{dx}\right)^2\right]$$

$$\Rightarrow \quad x^2 + 2xy\frac{dy}{dx} = y^2$$

or $$\frac{dy}{dx} = \frac{y^2 - x^2}{2xy}$$

which is homogeneous differential equation and we can solve by homogeneous or by total differential.

Here, using total differential,

$$2xy\,dy - y^2\,dx = -x^2\,dx$$

$$\Rightarrow \quad \frac{x\,d(y^2) - y^2\,dx}{x^2} = -\,dx$$

$$\Rightarrow \quad d\left(\frac{y^2}{x}\right) = -\,dx$$

Integrating both the sides, we get

$$\Rightarrow \quad \frac{y^2}{x} = -\,x + C \qquad \text{...(ii)}$$

It passes through $(1, 1) \Rightarrow C = 2$

$$\therefore \quad \frac{y^2}{x} = -\,x + 2 \ \text{ or } \ y^2 = -\,x^2 + 2x$$

$\Rightarrow$ $x^2 + y^2 - 2x = 0$, is required equation of curve.

● ***Ex. 30*** *A country has a food deficit of 10%. Its population grows continuously at a rate of 3% per year. Its annual food production every year is 4% more than that of the last year. Assuming that the average food requirement per person remains constant, prove that the country will become self-sufficient in food after n years, where n is the smallest integer bigger than or equal to* $\frac{\log_e 10 - \log_e 9}{(\log_e 1.04) - 0.03}$ ***[IIT JEE 2000]***

Sol. Let P_0 be the initial population, Q_0 be its initial food production.

Let P be the population of the country in year t and Q be its food production in year t.

$$\Rightarrow \quad \frac{dP}{dt} = \frac{3P}{100} \quad \text{or} \quad \frac{dP}{P} = \frac{3}{100}\,dt$$

Integrating, we get

$$\log P = \frac{3}{100}\,t + C$$

At $t = 0$, we have $P = P_0$

$$\Rightarrow \quad C = \log P_0$$

$$\Rightarrow \quad P = P_0\, e^{0.03\,t} \qquad \text{...(i)}$$

It is given that the annual food production every year is 4% more than that of last year.

$$\Rightarrow \quad Q = Q_0\left(1 + \frac{4}{100}\right)^t$$

Let the average consumption per person be k units.

$$\Rightarrow \quad Q_0 = kP_0\left(\frac{90}{100}\right) = 0.9\,kP_0$$

$$\therefore \quad Q = 0.9\,kP_0\,(1.04)^t \qquad \text{...(ii)}$$

This gives quantity of food available in year t. The population in year t is,

$$P = P_0\, e^{0.03\,t} \qquad \text{[from Eq. (i)]}$$

$\therefore$ Consumption in year, $t = kP_0 e^{0.03\,t}$ ...(iii)

The country will be self sufficient, if

$$Q \geq P$$

$$\Rightarrow \quad 0.9k\,P_0\,(1.04)^t \geq kP_0 e^{0.03\,t}$$

$$\Rightarrow \quad \frac{9}{10}\,(1.04)^t \geq e^{0.03\,t}$$

$$\Rightarrow \quad (1.04)^t\, e^{-0.03\,t} \geq \frac{10}{9}$$

$$\Rightarrow \quad t\log(1.04) - 0.03\,t \geq \log\left(\frac{10}{9}\right)$$

$$\Rightarrow \quad t\{\log(1.04) - 0.03\} \geq \log\left(\frac{10}{9}\right)$$

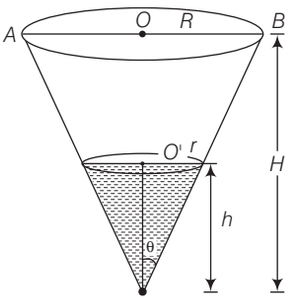
$$\Rightarrow \quad t \geq \frac{\log 10 - \log 9}{\log(1.04) - 0.03}$$

Thus, the least number of year in which country becomes self sufficient.

$$\Rightarrow \quad t = \frac{\log 10 - \log 9}{\log(1.04) - 0.03}$$

● ***Ex. 31*** *A right circular cone with radius R and height H contains a liquid which evaporates at a rate proportional to its surface area in contact with air (proportionality constant = k > 0), find the time after which the cone is empty.* ***[IIT JEE 2003]***

Sol. Let the semi-vertical angle of the cone be θ and let the height of the liquid at time 't' be 'h' from the vertex V and radius of the liquid cone be r. Let V be the volume at time t. Then,



$$V = \frac{1}{3}\,\pi r^2 h$$

$$\Rightarrow \quad V = \frac{1}{3}\,\pi r^3 \cot\theta \qquad \left(\because \tan\theta = \frac{r}{h}\right)$$

Let S be the surface area of the liquid in contact with air at time t.

Then, $\quad S = \pi r^2$

$$\Rightarrow \quad \frac{dV}{dt} \propto S$$

$$\Rightarrow \quad \frac{dV}{dt} = -kS,\ k \text{ is constant of proportionality.}$$

$$\Rightarrow \quad \frac{d}{dt}\left(\frac{1}{3}\,\pi r^3 \cot\theta\right) = -k\pi r^2$$

$$\Rightarrow \quad \pi r^2 \frac{dr}{dt}\cot\theta = -k\pi r^2 \Rightarrow \cot\theta\,dr = -k\,dt$$

On integrating, we get $\cot\theta \int_R^0 dr = -k\int_0^T dt$

$\Rightarrow$ $R\cot\theta = +kT$, where T is required time.

$\Rightarrow$ $T = H/k$ (as $\tan\theta = R/H$)

● ***Ex. 32*** *Solve the equation*

$$x\int_0^x y(t)\,dt = (x+1)\int_0^x t\,y(t)\,dt,\ x > 0.$$

Sol. Differentiating the equation w.r.t. x, we get

$$xy(x) + 1\cdot\int_0^x y(t)\,dt = (x+1)\,xy(x) + 1\cdot\int_0^x t\,y(t)\,dt$$

i.e. $$\int_0^x y(t)\,dt = x^2\,y(x) + \int_0^x t\,y(t)\,dt$$

Again, differentiating w.r.t. x, we get

$$y(x) = x^2\,y'(x) + 2xy(x) + xy(x)$$

i.e. $$(1-3x)\,y(x) = \frac{x^2\,dy(x)}{dx}$$

i.e. $$\frac{(1-3x)\,dx}{x^2} = \frac{dy(x)}{y(x)}$$

Integrating, we get $y = \frac{C}{x^3}\,e^{-1/x}$

● **Ex. 33** *If (y_1, y_2) are two solutions of the differential equation* $\dfrac{dy}{dx} + P(x) \cdot y = Q(x)$

Then prove that $y = y_1 + C(y_1 - y_2)$ is the general solution of the equation where C is any constant. For what relation between the constant α, β will the linear combination $\alpha y_1 + \beta y_2$ also be a solution.

Sol. As y_1, y_2 are the solutions of the differential equation;

$$\frac{dy}{dx} + P(x) \cdot y = Q(x) \quad \ldots(i)$$

$$\therefore \quad \frac{dy_1}{dx} + P(x) \cdot y_1 = Q(x) \quad \ldots(ii)$$

and $$\frac{dy_2}{dx} + P(x) \cdot y_2 = Q(x) \quad \ldots(iii)$$

From Eqs. (i) and (ii), $\left(\dfrac{dy}{dx} - \dfrac{dy_1}{dx}\right) + P(x)(y - y_1) = 0$

$$\therefore \quad \frac{d}{dx}(y - y_1) + P(x) \cdot (y - y_1) = 0 \quad \ldots(iv)$$

From Eqs. (ii) and (iii), $\dfrac{d}{dx}(y_1 - y_2) + P(x)(y_1 - y_2) = 0$ ...(v)

From Eqs. (iv) and (v), $\dfrac{\frac{d}{dx}(y - y_1)}{\frac{d}{dx}(y_1 - y_2)} = \dfrac{y - y_1}{y_1 - y_2}$

$$\Rightarrow \quad \frac{\frac{d}{dx}(y - y_1)}{y - y_1} = \frac{\frac{d}{dx}(y_1 - y_2)}{y_1 - y_2}$$

Integrating both the sides, we get

$$\log(y - y_1) = \log(y_1 - y_2)$$

$$\therefore \quad y = y_1 + C(y_1 - y_2)$$

Now, $y = \alpha y_1 + \beta y_2$ will be a solutions, if

$$\frac{d}{dx}(\alpha y_1 + \beta y_2) + P(x)(\alpha y_1 + \beta y_2) = Q(x)$$

or $$\alpha\left(\frac{dy_1}{dx} + P(x)\, y_1\right) + \beta\left(\frac{dy_2}{dx} + P(x)\, y_2\right) = Q(x)$$

or $\alpha Q(x) + \beta Q(x) = Q(x)$ [using Eqs. (ii) and (iii)]

$\therefore \quad (\alpha + \beta) Q(x) = Q(x)$

Hence, $\alpha + \beta = 1$

● **Ex. 34** *Find a pair of curves such that*

(a) the tangents drawn at points with equal abscissae intersect on the y-axis.

(b) the normal drawn at points with equal abscissae intersect on x-axis.

(c) one curve passes through (1, 1) and other passes through (2, 3).

Sol. Let the curve be $y = f_1(x)$ and $y = f_2(x)$ equation of tangents with equal abscissa, x are

$$(y - f_1(x)) = f'_1(x)(X - x)$$

and $$Y - f_2(x) = f'_2(x)(X - x)$$

These tangent intersect at y-axis,

$$\Rightarrow \quad -x f'_1(x) + f_1(x) = -x f'_2(x) + f_2(x)$$

$$\Rightarrow \quad f_1(x) - f_2(x) = x(f'_1(x) - f'_2(x))$$

Integrating both the sides, we get

$$\Rightarrow \quad \ln|f_1(x) - f_2(x)| = \ln|x| + C$$

$$\Rightarrow \quad f_1(x) - f_2(x) = \pm C_1 x \quad \ldots(i)$$

Now, equations of normal with equal abscissa x, are

$$y - f_1(x) = -\frac{1}{f'_1(x)}(X - x)$$

and $$(y - f_2(x)) = -\frac{1}{f'_2(x)}(X - x)$$

As these normal intersect on the x-axis,

$$x + f_1(x) \cdot f'_1(x) = x + f_2(x) \cdot f'_2(x)$$

$$\Rightarrow \quad f_1(x) \cdot f_1'(x) = f_2(x) \cdot f_2'(x) \text{ Integrating}$$

$$\Rightarrow \quad f'^2_1(x) - f_2^2(x) = C_2$$

$$\Rightarrow \quad f_1(x) + f_2(x) = \frac{C_2}{f_1(x) - f_2(x)} = \pm\frac{C_2}{C_1 x} = \pm\frac{\lambda_2}{x}$$

[using Eq. (i)] ...(ii)

From Eqs. (i) and (ii), we get

$$2f_1(x) = \pm\left(\frac{\lambda_2}{x} + C_1 x\right), 2f_2(x) = \pm\left(\frac{\lambda_2}{x} - C_1 x\right)$$

We have, $f_1(1) = 1$ and $f_2(2) = 3$

$$\Rightarrow \quad f_1(x) = \frac{2}{x} - x \quad \text{and} \quad f_2(x) = \frac{2}{x} + x$$

● **Ex. 35** *Given two curves $y = f(x)$ passing through (0, 1) and $y = \int_{-\infty}^{x} f(t)\, dt$ passing through $(0, 1/n)$. The tangents drawn to both the curves at the points with equal abscissae intersect on the x-axis find the curve $y = f(x)$.*

Sol. Equation of the tangent to the curve; $y = f(x)$ is

$$(Y - y) = f'(x)(X - x)$$

Equation of tangent to the curve $g(x) = y_1 = \int_{-\infty}^{x} f(t)\, dt$ is

$$(Y - y_1) = g'(x)(X - x) = f(x)(X - x)$$

Given that tangent with equal abscissas intersect on the x-axis.

$$\Rightarrow \quad x - \frac{y}{f'(x)} = x - \frac{y_1}{f(x)}$$

$$\Rightarrow \quad \frac{f(x)}{f'(x)} = \frac{y_1}{f(x)} \qquad [\because y = f(x)]$$

$$\Rightarrow \quad \frac{f(x)}{y_1} = \frac{f'(x)}{f(x)} \Rightarrow \frac{g'(x)}{g(x)} = \frac{f'(x)}{f(x)}$$

$$\Rightarrow \quad \frac{g'(x)}{g(x)} = k \quad \Rightarrow \quad g(x) = Ce^{kx}$$

$$\Rightarrow \quad g'(x) = k\, Ce^{kx} \Rightarrow f(x) = k\, Ce^{kx}$$

$y = f(x)$ passes through $(0, 1) \Rightarrow kC = 1$

$y_1 = g(x)$ passes through

$(0, 1/n) \Rightarrow C = \dfrac{1}{n} \Rightarrow k = n$

$$\Rightarrow \quad f(x) = e^{nx}$$

● ***Ex. 36*** *A normal is drawn at a point $P(x, y)$ of a curve. It meets the x-axis and the y-axis in point A and B, respectively, such that $\frac{1}{OA}+\frac{1}{OB}=1$, where O is the origin, find the equation of such a curve passing through (5, 4).*

Sol. The equation of the normal at (x, y) is

$$(X-x)+(Y-y)\frac{dy}{dx}=0$$

$$\Rightarrow \quad \frac{X}{x+y\frac{dy}{dx}}+\frac{Y}{\frac{(x+y\,dy/dx)}{dy/dx}}=1$$

$$\Rightarrow \quad OA=x+y\frac{dy}{dx},\ OB=\frac{\left(x+y\frac{dy}{dx}\right)}{\frac{dy}{dx}}$$

Also, $\frac{1}{OA}+\frac{1}{OB}=1 \Rightarrow 1+\frac{dy}{dx}=x+y\frac{dy}{dx}$

$$\Rightarrow \quad (y-1)\frac{dy}{dx}+(x-1)=0$$

Integrating, we get

$$(y-1)^2+(x-1)^2=C$$

Since, the curve passes through (5, 4), $C = 25$.

Hence, the curve is $(x-1)^2+(y-1)^2=25$.

● ***Ex. 37*** *A line is drawn from a point $P(x, y)$ on curve $y = f(x)$, making an angle with the x-axis which is supplementary to the one made by the tangent to the curve at $P(x, y)$. The line meets the x-axis at A. Another line perpendicular to the first, is drawn from $P(x, y)$ meeting the y-axis at B. If OA = OB, where O is origin, find all curve which passes through (1, 1).*

Sol. The equation of the line through $P(x, y)$ making an angle with the x-axis which is supplementary to the angle made by the tangent at $P(x, y)$ is

$$Y-y=-\frac{dy}{dx}(X-x) \qquad ...(i)$$

where it meets the x-axis.

$$Y=0, \quad X=x+\frac{y}{dy/dx} \Rightarrow OA=x+y\frac{dx}{dy} \qquad ...(ii)$$

The line through $P(x, y)$ and perpendicular to Eq. (i) is

$$Y-y=\frac{dx}{dy}(X-x)$$

where it meets the y-axis.

$$X=0,\ Y=y-x\frac{dx}{dy} \Rightarrow OB=y-x\frac{dx}{dy} \qquad ...(iii)$$

Since, $OA = OB$

$$\Rightarrow \quad x+y\frac{dx}{dy}=y-x\frac{dx}{dy}$$

or $$(y-x)=(y+x)\frac{dx}{dy}$$

or $$\frac{dy}{dx}=\frac{y+x}{y-x},\ \text{put } y=vx$$

$$\Rightarrow \quad x\frac{dv}{dx}=\frac{1+2v-v^2}{v-1}$$

$$\Rightarrow \quad \frac{(1-v)\,dv}{1+2v-v^2}+\frac{dx}{x}=0$$

$$\Rightarrow \quad \log(1+2v-v^2)+\log x=C_1$$

$$\Rightarrow \quad x^2+2xy-y^2=C$$

where $C_1=\log\sqrt{C}$

Since, curve passes through $(1, 1) \rightarrow C = 2$

$\therefore$ Required curve, $x^2-y^2+2xy=2$

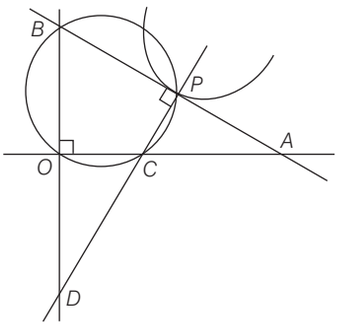
● ***Ex. 38*** *The tangent and a normal to a curve at any point P meet the x and y axes at A, B, C and D respectively. Find the equation of the curve passing through (1, 0) if the centre of circle through O, C, P and B lies on the line y = x (where O is origin).*

Sol. Let $P(x, y)$ be a point on the curve.

$$\Rightarrow \quad C\equiv\left(x+y\frac{dy}{dx},\ 0\right)$$

$$B\equiv\left(0,\ y-x\frac{dy}{dx}\right)$$

Circle passing through O, C, P and B has its centre at mid-point of BC.



Let the centre of the circle be (α, β).

$$\Rightarrow \quad 2\alpha=x+y\frac{dy}{dx}$$

and $$2\beta=y-x\frac{dy}{dx}$$

and since $\beta=\alpha,\ y-x\frac{dy}{dx}=x+y\frac{dy}{dx}$

$$\Rightarrow \quad \frac{dy}{dx}=\frac{y-x}{y+x}$$

Let $y = vx \Rightarrow x\frac{dv}{dx}=-\frac{(1+v^2)}{1+v}$

$$\Rightarrow \quad \frac{1+v}{v^2+1}\,dv=-\frac{dx}{x}$$

Integrating both the sides, we get

$$\int \frac{1+v}{v^2+1}\,dv = -\int \frac{dx}{x}$$

$$\Rightarrow \quad \frac{1}{2}\int \frac{2v}{v^2+1}\,dv + \int \frac{dv}{v^2+1} = -\int \frac{dx}{x}$$

$$\Rightarrow \quad \frac{1}{2}\log|v^2+1| + \tan^{-1}|v| = -\log x + C$$

$$\Rightarrow \quad \log\{(\sqrt{v^2+1})\,x\} + \tan^{-1} v = C$$

$$\Rightarrow \quad \log\sqrt{x^2+y^2} + \tan^{-1}\frac{y}{x} = C$$

As $x = 1$ and $y = 0$,

$$\log 1 + \tan^{-1} 0 = C \Rightarrow C = 0$$

$\therefore$ Required curve, $(\log\sqrt{x^2+y^2}) + \tan^{-1}\left(\frac{y}{x}\right) = 0$

● ***Ex. 39*** *If $f(x)$ be a positive, continuous and differentiable on the interval (a, b). If $\lim_{x\to a^+} f(x) = 1$ and $\lim_{x\to b^-} f(x) = 3^{1/4}$. Also, $f'(x) \geq f^3(x) + \frac{1}{f(x)}$, then*

(a) $b - a \geq \pi/4$ (b) $b - a \leq \pi/4$

(c) $b - a \leq \pi/24$ (d) None of these

Sol. Since,

$$f'(x) \geq f^3(x) + \frac{1}{f(x)}$$

$$\Rightarrow \quad f'(x)\,f(x) \geq 1 + f^4(x)$$

$$\Rightarrow \quad \frac{f(x)\,f'(x)}{1+f^4(x)} \geq 1$$

On integrating w.r.t. 'x' from $x = a$ to $x = b$.

$$\frac{1}{2}(\tan^{-1}(f^2(x)))_a^b \geq (b-a)$$

or $$(b-a) \leq \frac{1}{2}\left\{\lim_{x\to b^-}(\tan^{-1}(f^2(x))) - \lim_{x\to a^+}(\tan^{-1}(f^2(x)))\right\}$$

or $$(b-a) \leq \pi/24$$

Hence, (c) is the correct answer.

Differential Equations Exercise 1 :
Single Option Correct Type Questions

1. If the differential equation of the family of curve given by $y = Ax + Be^{2x}$, where A and B are arbitrary constants, is of the form $(1-2x)\frac{d}{dx}\left(\frac{dy}{dx}+ly\right)+k\left(\frac{dy}{dx}+ly\right)=0$, then the ordered pair (k, l) is

(a) $(2, -2)$ (b) $(-2, 2)$
(c) $(2, 2)$ (d) $(-2, -2)$

2. A curve passes through the point $\left(1, \frac{\pi}{4}\right)$ and its slope at any point is given by $\frac{y}{x} - \cos^2\left(\frac{y}{x}\right)$. Then, the curve has the equation

(a) $y = x\tan^{-1}\left(\ln\frac{e}{x}\right)$ (b) $y = x\tan^{-1}(\ln 2)$
(c) $y = \frac{1}{x}\tan^{-1}\left(\ln\frac{e}{x}\right)$ (d) None of these

3. The x-intercept of the tangent to a curve is equal to the ordinate of the point of contact. The equation of the curve through the point (1, 1) is

(a) $ye^{\frac{x}{y}} = e$ (b) $xe^{\frac{x}{y}} = e$
(c) $xe^{\frac{y}{x}} = e$ (d) $ye^{\frac{y}{x}} = e$

4. A function $y = f(x)$ satisfies the condition $f'(x)\sin x + f(x)\cos x = 1$, $f(x)$ being bounded when $x \to 0$. If $I = \int_0^{\pi/2} f(x)\,dx$, then

(a) $\frac{\pi}{2} < I < \frac{\pi^2}{4}$ (b) $\frac{\pi}{4} < I < \frac{\pi^2}{2}$
(c) $1 < I < \frac{\pi}{2}$ (d) $0 < I < 1$

5. A curve is such that the area of the region bounded by the coordinate axes, the curve and the ordinate of any point on it is equal to the cube of that ordinate. The curve represents

(a) a pair of straight lines (b) a circle
(c) a parabola (d) an ellipse

6. The value of the constant 'm' and 'c' for which $y = mx + c$ is a solution of the differential equation $D^2y - 3Dy - 4y = -4x$.

(a) is $m = -1; c = 3/4$ (b) is $m = 1; c = -3/4$
(c) no such real m, c (d) is $m = 1; c = 3/4$

7. The real value of m for which the substitution, $y = u^m$ will transform the differential equation, $2x^4y\frac{dy}{dx} + y^4 = 4x^6$ into a homogeneous equation is

(a) $m = 0$ (b) $m = 1$
(c) $m = 3/2$ (d) No value of m

8. The solution of the differential equation,

$$x^2\frac{dy}{dx}\cdot\cos\frac{1}{x} - y\sin\frac{1}{x} = -1,$$

where $y \to -1$ as $x \to \infty$ is

(a) $y = \sin\frac{1}{x} - \cos\frac{1}{x}$ (b) $y = \frac{x+1}{x\sin\frac{1}{x}}$
(c) $y = \sin\frac{1}{x} + \cos\frac{1}{x}$ (d) $y = \frac{x+1}{x\cos\frac{1}{x}}$

9. A wet porous substance in the open air loses its moisture at a rate proportional to the moisture content. If a sheet hung in the wind loses half its moisture during the first hour, then the time when it would have lost 99.9% of its moisture is (weather conditions remaining same)

(a) more than 100 h
(b) more than 10 h
(c) approximately 10 h
(d) approximately 9 h

10. A curve C passes through origin and has the property that at each point (x, y) on it, the normal line at that point passes through (1, 0). The equation of a common tangent to the curve C and the parabola $y^2 = 4x$ is

(a) $x = 0$ (b) $y = 0$
(c) $y = x + 1$ (d) $x + y + 1 = 0$

11. A function $y = f(x)$ satisfies

$$(x+1)\cdot f'(x) - 2(x^2+x)\,f(x) = \frac{e^{x^2}}{(x+1)},\ \forall\ x > -1.$$

If $f(0) = 5$, then $f(x)$ is

(a) $\left(\frac{3x+5}{x+1}\right)\cdot e^{x^2}$ (b) $\left(\frac{6x+5}{x+1}\right)\cdot e^{x^2}$
(c) $\left(\frac{6x+5}{(x+1)^2}\right)\cdot e^{x^2}$ (d) $\left(\frac{5-6x}{x+1}\right)\cdot e^{x^2}$

12. The curve, with the property that the projection of the ordinate on the normal is constant and has a length equal to 'a', is

(a) $x - a\ln\left(\sqrt{y^2 - a^2} + y\right) = C$

(b) $x + \sqrt{a^2 - y^2} = C$

(c) $(y - a)^2 = Cx$

(d) $ay = \tan^{-1}(x + C)$

13. The differential equation corresponding to the family of curves $y = e^x(ax + b)$ is

(a) $\frac{d^2y}{dx^2} + 2\frac{dy}{dx} - y = 0$ (b) $\frac{d^2y}{dx^2} - 2\frac{dy}{dx} + y = 0$

(c) $\frac{d^2y}{dx^2} + 2\frac{dy}{dx} + y = 0$ (d) $\frac{d^2y}{dx^2} - 2\frac{dy}{dx} - y = 0$

14. The equation to the orthogonal trajectories of the system of parabolas $y = ax^2$ is

(a) $\frac{x^2}{2} + y^2 = C$ (b) $x^2 + \frac{y^2}{2} = C$

(c) $\frac{x^2}{2} - y^2 = C$ (d) $x^2 - \frac{y^2}{2} = C$

15. A function $f(x)$ satisfying $\int_0^1 f(tx)\,dt = n\,f(x)$, where $x > 0$, is

(a) $f(x) = C \cdot x^{\frac{1-n}{n}}$ (b) $f(x) = C \cdot x^{\frac{n}{n-1}}$

(c) $f(x) = C \cdot x^{\frac{1}{n}}$ (d) $f(x) = C \cdot x^{(1-n)}$

16. The substitution $y = z^\alpha$ transforms the differential equation $(x^2y^2 - 1)\,dy + 2xy^3\,dx = 0$ into a homogeneous differential equation for

(a) $\alpha = -1$ (b) 0

(c) $\alpha = 1$ (d) No value of α

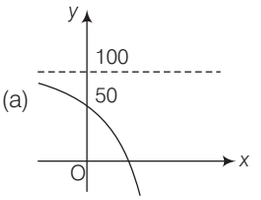
17. A curve passing through (2, 3) and satisfying the differential equation $\int_0^x ty(t)\,dt = x^2y(x), (x > 0)$ is

(a) $x^2 + y^2 = 13$ (b) $y^2 = \frac{9}{2}x$

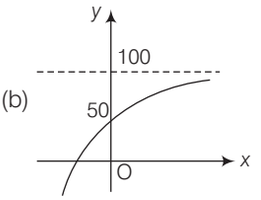
(c) $\frac{x^2}{8} + \frac{y^2}{18} = 1$ (d) $xy = 6$

18. Which one of the following curves represents the solution of the initial value problem $Dy = 100 - y$, where $y(0) = 50$?

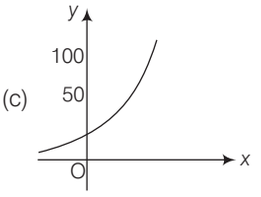
(a)



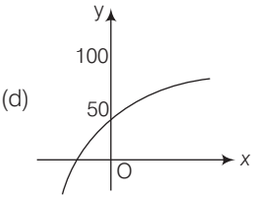
(b)



(c)



(d)



Differential Equations Exercise 2 : More than One Option Correct Type Questions

19. The differential equation $x\frac{dy}{dx} + \frac{3}{\frac{dy}{dx}} = y^2$

(a) is of order 1 (b) is of degree 2

(c) is linear (d) is non-linear

20. The function $f(x)$ satisfying the equation $f^2(x) + 4f'(x)\cdot f(x) + [f'(x)]^2 = 0$.

(a) $f(x) = C \cdot e^{(2-\sqrt{3})x}$

(b) $f(x) = C \cdot e^{(2+\sqrt{3})x}$

(c) $f(x) = C \cdot e^{(\sqrt{3}-2)x}$

(d) $f(x) = C \cdot e^{-(2+\sqrt{3})x}$

where C is an arbitrary constant.

21. Which of the following pair(s) is/are orthogonal?

(a) $16x^2 + y^2 = C$ and $y^{16} = kx$

(b) $y = x + Ce^{-x}$ and $x + 2 = y + ke^{-y}$

(c) $y = Cx^2$ and $x^2 + 2y^2 = k$

(d) $x^2 - y^2 = C$ and $xy = k$

22. Family of curves whose tangent at a point with its intersection with the curve $xy = c^2$ form an angle of $\frac{\pi}{4}$ is

(a) $y^2 - 2xy - x^2 = k$

(b) $y^2 + 2xy - x^2 = k$

(c) $y = x - 2c\tan^{-1}\left(\frac{x}{c}\right) + k$

(d) $y = c\ln\left|\frac{c + x}{c - x}\right| - x + k$

23. The general solution of the differential equation, $x\left(\frac{dy}{dx}\right) = y \cdot \log\left(\frac{y}{x}\right)$ is

(a) $y = xe^{1-Cx}$

(b) $y = xe^{1+Cx}$

(c) $y = ex \cdot e^{Cx}$

(d) $y = xe^{Cx}$

where C is an arbitrary constant.

24. Which of the following equation(s) is/are linear?

(a) $\frac{dy}{dx} + \frac{y}{x} = \ln x$

(b) $y\left(\frac{dy}{dx}\right) + 4x = 0$

(c) $dx + dy = 0$

(d) $\frac{d^2y}{dx^2} = \cos x$

25. The equation of the curve passing through (3, 4) and satisfying the differential equation,

$$y\left(\frac{dy}{dx}\right)^2 + (x - y)\frac{dy}{dx} - x = 0$$

can be

(a) $x - y + 1 = 0$

(b) $x^2 + y^2 = 25$

(c) $x^2 + y^2 - 5x - 10 = 0$

(d) $x + y - 7 = 0$

26. Identify the statement(s) which is/are true?

(a) $f(x, y) = e^{y/x} + \tan\frac{y}{x}$ is homogeneous of degree zero.

(b) $x \cdot \log\frac{y}{x}\,dx + \frac{y^2}{x}\sin^{-1}\frac{y}{x}\,dy = 0$ is homogeneous differential equation.

(c) $f(x, y) = x^2 + \sin x \cdot \cos y$ is not homogeneous.

(d) $(x^2 + y^2)\,dx - (xy^2 - y^3)\,dy = 0$ is a homogeneous differential equation.

27. The graph of the function $y = f(x)$ passing through the point $(0, -1)$ and satisfying the differential equation $\frac{dy}{dx} + y\cos x = \cos x$ is such that

(a) it is a constant function

(b) it is periodic

(c) it is neither an even nor an odd function

(d) it is continuous and differentiable for all x

28. A function $y = f(x)$ satisfying the differential equation

$$\frac{dy}{dx} \cdot \sin x - y\cos x + \frac{\sin^2 x}{x^2} = 0$$

is such that, $y \to 0$ as $x \to \infty$, then the statement which is correct?

(a) $\lim\limits_{x \to 0} f(x) = 1$ (b) $\int_0^{\pi/2} f(x)\,dx$ is less than $\frac{\pi}{2}$

(c) $\int_0^{\pi/2} f(x)\,dx$ is greater than unity

(d) $f(x)$ is an odd function

29. Identify the statement(s) which is/are true?

(a) The order of differential equation $\sqrt{1 + \frac{d^2y}{dx^2}} = x$ is 1.

(b) Solution of the differential equation $xdy - ydx = \sqrt{x^2 + y^2}\,dx$ is $y + \sqrt{x^2 + y^2} = Cx^2$.

(c) $\frac{d^2y}{dx^2} = 2\left(\frac{dy}{dx} - y\right)$ is differential equation of family of curves $y = e^x(A\cos x + B\sin x)$.

(d) The solution of differential equation $(1 + y^2) + (x - 2e^{\tan^{-1} y})\frac{dy}{dx} = 0$ is $xe^{\tan^{-1} y} = e^{2\tan^{-1} y} + k$.

30. Let $y = (A + Bx)e^{3x}$ is a solution of the differential equation $\frac{d^2y}{dx^2} + m\frac{dy}{dx} + ny = 0$, $m, n \in I$, then

(a) $m = -6$ (b) $n = -6$

(c) $m = 9$ (d) $n = 9$

Differential Equations Exercise 3 :
Statement I and II Type Questions

Directions
(Q. Nos. 31 to 40)

For the following questions, choose the correct answers from the codes (*a*), (*b*), (*c*) *and* (*d*) *defined as follows* :

(a) Statement I is true, Statement II is true and Statement II is the correct explanation for Statement I.
(b) Statement I is true, Statement II is true and Statement II is not the correct explanation for Statement I.
(c) Statement I is true, Statement II is false.
(d) Statement I is false, Statement II is true.

31. A curve C has the property that its initial ordinate of any tangent drawn is less than the abscissa of the point of tangency by unity.

Statement I Differential equation satisfying the curve is linear.

Statement II Degree of differential equation is one.

32. **Statement I** Differential equation corresponding to all lines, $ax + by + c = 0$ has the order 3.

Statement II General solution of a differential equation of nth order contains n independent arbitrary constants.

33. **Statement I** Integral curves denoted by the first order linear differential equation $\frac{dy}{dx} - \frac{1}{x}y = -x$ are family of parabolas passing through the origin.

Statement II Every differential equation geometrically represents a family of curve having some common property.

34. **Statement I** The solution of $(y\,dx - x\,dy)\cot\left(\frac{x}{y}\right) = ny^2\,dx$ is $\sin\left(\frac{x}{y}\right) = Ce^{nx}$

Statement II Such type of differential equations can only be solved by the substitution $x = vy$.

35. **Statement I** The order of the differential equation whose general solution is $y = c_1\cos 2x + c_2\sin^2 x + c_4e^{2x} + c_5e^{2x + c_6}$ is 3.

Statement II Total number of arbitrary parameters in the given general solution in the Statement I is 6.

36. Consider differential equation $(x^2 + 1)\cdot\frac{d^2y}{dx^2} = 2x\cdot\frac{dy}{dx}$

Statement I For any member of this family $y \to \infty$ as $x \to \infty$.

Statement II Any solution of this differential equation is a polynomial of odd degree with positive coefficient of maximum power.

37. **Statement I** Order of differential equation of family of parallel whose axis is parallel to Y-axis and latusrectum is fixed is 2.

Statement II Order of first equation is same as actual number of arbitrary constant present in differential equation.

38. **Statement I** The differential equation of all non-vertical lines in a plane is $\frac{d^2x}{dy^2} = 0$.

Statement II The general equation of all non-vertical lines in a plane is $ax + by = 1$, where $b \neq 0$.

39. **Statement I** The order of differential equation of all conics whose centre lies at origin is, 2.

Statement II The order of differential equation is same as number of arbitrary unknowns in the given curve.

40. **Statement I** $y = a\sin x + b\cos x$ is general solution of $y'' + y = 0$.

Statement II $y = a\sin x + b\cos x$ is a trigonometric function.

Differential Equations Exercise 4 : Passage Based Questions

Passage I

(Q. Nos. 41 to 43)

Let $y = f(x)$ *satisfies the equation*

$f(x) = (e^{-x} + e^{x})\cos x - 2x - \int_0^x (x - t)\, f'(t)\, dt.$

41. y satisfies the differential equation

(a) $\frac{dy}{dx} + y = e^{x}(\cos x - \sin x) - e^{-x}(\cos x + \sin x)$

(b) $\frac{dy}{dx} - y = e^{x}(\cos x - \sin x) + e^{-x}(\cos x + \sin x)$

(c) $\frac{dy}{dx} + y = e^{x}(\cos x + \sin x) - e^{-x}(\cos x - \sin x)$

(d) $\frac{dy}{dx} - y = e^{x}(\cos x - \sin x) + e^{-x}(\cos x - \sin x)$

42. The value of $f'(0) + f''(0)$ equals to

(a) -1 (b) 2
(c) 1 (d) 0

43. $f(x)$ as a function of x equals to

(a) $e^{-x}(\cos x - \sin x) + \frac{e^{x}}{5}(3\cos x + \sin x) + \frac{2}{5}e^{-x}$

(b) $e^{-x}(\cos x + \sin x) + \frac{e^{x}}{5}(3\cos x - \sin x) - \frac{2}{5}e^{-x}$

(c) $e^{-x}(\cos x - \sin x) + \frac{e^{x}}{5}(3\cos x - \sin x) + \frac{2}{5}e^{-x}$

(d) $e^{-x}(\cos x + \sin x) + \frac{e^{x}}{5}(3\cos x - \sin x) - \frac{2}{5}e^{-x}$

Passage II

(Q. Nos. 44 to 46)

For certain curves $y = f(x)$ *satisfying* $\frac{d^2y}{dx^2} = 6x - 4$, $f(x)$ *has local minimum value 5 when* $x = 1$.

44. Number of critical point for $y = f(x)$ for $x \in [0, 2]$

(a) 0 (b) 1
(c) 2 (d) 3

45. Global minimum value of $y = f(x)$ for $x \in [0, 2]$ is

(a) 5 (b) 7
(c) 8 (d) 9

46. Global maximum value of $y = f(x)$ for $x \in [0, 2]$ is

(a) 5 (b) 7
(c) 8 (d) 9

Passage III

(Q. Nos. 47 to 49)

If any differential equation in the form

$f(f_1(x, y))\, d(f_1(x, y)) + \phi(f_2(x, y))\, d(f_2(x, y)) + \ldots = 0$

then each term can be integrated separately.

For example,

$$\int \sin xy\, d(xy) + \int \left(\frac{x}{y}\right) d\left(\frac{x}{y}\right) = -\cos xy + \frac{1}{2}\left(\frac{x}{y}\right)^2 + C$$

47. The solution of the differential equation

$x dy - y\, dx = \sqrt{x^2 - y^2}\, dx$ is

(a) $Cx = e^{\sin^{-1}\frac{y}{x}}$ (b) $xe^{\sin^{-1}\frac{y}{x}} = C$

(c) $x + e^{\sin^{-1}\frac{y}{x}} = C$ (d) None of these

48. The solution of the differential equation

$(xy^4 + y)\, dx - x dy = 0$ is

(a) $\frac{x^3}{4} + \frac{1}{2}\left(\frac{x}{y}\right)^2 = C$ (b) $\frac{x^4}{4} + \frac{1}{3}\left(\frac{x}{y}\right)^3 = C$

(c) $\frac{x^4}{4} - \frac{1}{2}\left(\frac{x}{y}\right)^3 = C$ (d) $\frac{x^3}{4} - \frac{1}{2}\left(\frac{x}{y}\right)^2 = C$

49. Solution of differential equation

$(2x\cos y + y^2\cos x)\, dx + (2y\sin x - x^2\sin y)\, dy = 0$ is

(a) $x^2\cos y + y^2\sin x = C$

(b) $x\cos y - y\sin x = C$

(c) $x^2\cos^2 y + y^2\sin^2 x = C$

(d) None of the above

Passage IV

(Q. Nos. 50 to 52)

Differential equation $\frac{dy}{dx} = f(x)\, g(x)$ *can be solved by separating variable* $\frac{dy}{g(y)} = f(x)\, dx$.

50. The equation of the curve to the point (1, 0) which satisfies the differential equation $(1 + y^2)\, dx - xy\, dy = 0$ is

(a) $x^2 + y^2 = 1$ (b) $x^2 - y^2 = 1$
(c) $x^2 + y^2 = 2$ (d) $x^2 - y^2 = 2$

51. Solution of the differential equation $\frac{dy}{dx}+\frac{1+y^2}{\sqrt{1-x^2}}=0$ is

(a) $\tan^{-1} y+\sin^{-1} x=C$

(b) $\tan^{-1} x+\sin^{-1} y=C$

(c) $\tan^{-1} y\cdot\sin^{-1} x=C$

(d) $\tan^{-1} y-\sin^{-1} x=C$

52. If $\frac{dy}{dx}=1+x+y+xy$ and $y(-1)=0$, then y is equal to

(a) $e^{\frac{(1-x)^2}{2}}$ (b) $e^{\frac{(1+x)^2}{2}}-1$

(c) $\ln(1+x)-1$ (d) $1+x$

Passage V

(Q. Nos. 53 to 55)

Let C be the set of curves having the property that the point of intersection of tangent with y-axis is equidistant from the point of tangency and origin (0, 0)

53. If $C_1, C_2 \in C$

C_1: Curve is passing through (1, 0)

C_2: Curve is passing through $(-1,0)$

The number of common tangents for C_1 and C_2 is

(a) 1 (b) 2

(c) 3 (d) None of these

54. If $C_3 \in C$

C_3: is passing through (2, 4). If $\frac{x}{a}+\frac{y}{b}=1$. is tangent to C_3, then

(a) $25a+10b^2-ab^2=0$ (b) $25a+10b-13ab=0$

(c) $13a+25b-16ab=0$ (d) $29a+b+13ab=0$

55. If common tangents of C_1 and C_2 form an equilateral triangle, where $C_1, C_2 \in C$ and C_1: Curve passes through (2, 0), then C_2 may passes through

(a) $(-1/3, 1/3)$ (b) $(-1/3, 1)$

(c) $(-2/3, 4)$ (d) $(-2/3, 2)$

Differential Equations Exercise 5 : Matching Type Questions

56. Match the following :

	Column I		Column II
(A)	$\frac{xdx+ydy}{xdy-ydx}=\sqrt{\frac{a^2-x^2-y^2}{x^2+y^2}}$	(p)	$y=\frac{C}{x^3}e^{-1/x}$
(B)	Solution of $\cos^2 x\frac{dy}{dx}-\tan 2x\cdot y=\cos^4 x$, where $\lvert x\rvert<\frac{\pi}{4}$ and $y\left(\frac{\pi}{6}\right)=\frac{3\sqrt{3}}{8}$	(q)	$\sqrt{x^2+y^2}=a\sin\left\{C+\tan^{-1}\left(\frac{y}{x}\right)\right\}$
(C)	The equation of all possible curves that will cut each member of the family of circles $x^2+y^2-2cx=0$ at right angle	(r)	$x^2+y^2+Cy=0$
(D)	Solution of the equation $x\int_0^x y(t)\,dt=(x+1)\int_0^x ty(t)\,dt, x>0$ is	(s)	$y=\frac{\sin 2x}{2(1-\tan^2 x)}$

57. Match the following :

	Column I		Column II
(A)	Circular plate is expanded by heat from radius 5 cm to 5.06 cm. Approximate increase in area is	(p)	4
(B)	Side of cube increasing by 1%, then percentage increase in volume is	(q)	0.6π
(C)	If the rate of decrease of $\frac{x^2}{2}-2x+5$ is twice the rate of decrease of x, then x is equal to	(r)	3
(D)	Rate of increase in area of equilateral triangle of side 15 cm, when each side is increasing at the rate of 0.1 cm/s; is	(s)	$\frac{3\sqrt{3}}{4}$

58. Match the following :

	Column I		Column II
(A)	The differential equation of the family of curves $y = e^x (A\cos x + B\sin x)$, where A, B are arbitrary constants, has the degree n and order m. Then, the values of n and m are, respectively	(p)	2, 1
(B)	The degree and order of the differential equation of the family of all parabolas whose axis is the x-axis, are respectively	(q)	1, 1
(C)	The order and degree of the differential equations of the family of circles touching the x-axis at the origin, are respectively	(r)	2, 2
(D)	The degree and order of the differential equation of the family of ellipse having the same foci, are respectively.	(s)	1, 2

Differential Equations Exercise 6 :
Single Integer Answer Type Questions

59. Find the constant of integration by the general solution of the differential equation $(2x^2y - 2y^4)\,dx + (2x^3 + 3xy^3)\,dy = 0$ if curve passes through (1, 1).

60. A tank initially contains 50 gallons of fresh water. Brine contains 2 pounds per gallon of salt, flows into the tank at the rate of 2 gallons per minutes and the mixture kept uniform by stirring, runs out at the same rate. If it will take for the quantity of salt in the tank to increase from 40 to 80 pounds (in seconds) is 206λ, then find λ.

61. If $f : R - \{-1\} \to$ and f is differentiable function which satisfies :
$f\{x + f(y) + xf(y)) = y + f(x) + yf(x) \;\forall\; x, y \in R - \{-1\}$,
then find the value of $2010\,[1 + f(2009)]$.

62. If $\phi(x)$ is a differential real-valued function satisfying $\phi'(x) + 2\phi(x) \le 1$, then the value of $2\phi(x)$ is always less than or equal to ..... .

63. The degree of the differential equation satisfied by the curves $\sqrt{1+x} - a\sqrt{1+y} = 1$, is ..... .

64. Let $f(x)$ be a twice differentiable bounded function satisfayi $2f^5(x)\cdot f'(x) + 2(f'(x))^3 \cdot f^5(x) = f''(x)$. If $f(x)$ is bounded in between $y = k$, and $y = k_2$, Then the number of integers between k_1 and k_2 is/are (where $f(0) = f'(0) = 0$).

65. Let $y(x)$ be a function satisfying $d^2y/dx^2 - dy/dx + e^{2x} = 0, y(0) = 2$ and $y'(0) = 1$. If maximum value of $y(x)$ is $y(\alpha)$, Then Integral part of (2α) is ..... .

Differential Equations Exercise 7 :
Subjective Type Questions

66. Find the time required for a cylindrical tank of radius r and height H to empty through a round hole of area 'a' at the bottom. The flow through a hole is according to the law $U(t) = u\sqrt{2gh(t)}$ where $v(t)$ and $h(t)$ are respectively the velocity of flow through the hole and the height of the water level above the hole at time t and g is the acceleration due to gravity.

67. The hemispherical tank of radius 2 m is initially full of water and has an outlet of 12 cm^2 cross-sectional area at the bottom. The outlet is opened at some instant. The flow through the outlet is according to the law $v(t) = 0\cdot 6\sqrt{2gh(t)}$, where $v(t)$ and $h(t)$ are respectively velocity of the flow through the outlet and the height of water level above the outlet at time t and g is the acceleration due to gravity. Find the time it takes to empty the tank.

68. Let $f : R^+ \to R$ satisfies the functional equation $f(xy) = e^{xy-x-y}(e^y f(x) + e^x f(y)) \forall x, y \in R^+$. If $f'(1) = e$, determine $f(x)$.

69. Let $y = f(x)$ be curve passing through $(1, \sqrt{3})$ such that tangent at any point P on the curve lying in the first quadrant has positive slope and the tangent and the normal at the point P cut the x-axis at A and B respectively so that the mid-point of AB is origin. Find the differential equation of the curve and hence determine $f(x)$.

70. If y_1 and y_2 are the solution of differential equation $dy/dx + Py = Q$, where P and Q are function of x alone and $y_2 = y_1 z$, then prove that $z = 1 + c \cdot e^{-\int \frac{Q}{y_1} dx}$, where c is an arbitrary constant.

71. Let $y = f(x)$ be a differentiable function $\forall x \in R$ and satisfies :
$f(x) = x + \int_0^1 x^2 z f(z)\, dz + \int_0^1 x z^2 f(z)\, dz.$
Determine the function.

72. If $f : R - \{-1\} \to R$ and f is differentiable function satisfies :
$f((x) + f(y) + x f(y)) = y + f(x) + yf(x) \forall x$, $y \in R - \{-1\}$ Find $f(x)$.

Differential Equations Exercise 8 : Questions Asked in Previous 10 Years' Exams

(i) JEE Advanced & IIT-JEE

73. A solution curve of the differential equation $(x^2 + xy + 4x + 2y + 4)\frac{dy}{dx} - y^2 = 0, x > 0$, passes through the point $(1, 3)$. Then, the solution curve **[More than One Correct 2016]**

(a) intersects $y = x + 2$ exactly at one point
(b) intersects $y = x + 2$ exactly at two points
(c) intersects $y = (x + 2)^2$
(d) does not intersect $y = (x + 3)^2$

74. Let $f : (0, \infty) \to R$ be a differentiable function such that $f'(x) = 2 - \frac{f(x)}{x}$ for all $x \in (0, \infty)$ and $f(1) \neq 1$. Then **[More than One Correct 2016]**

(a) $\lim_{x \to 0+} f'\left(\frac{1}{x}\right) = 1$
(b) $\lim_{x \to 0+} x f\left(\frac{1}{x}\right) = 2$
(c) $\lim_{x \to 0+} x^2 f'(x) = 0$
(d) $|f(x)| \leq 2$ for all $x \in (0, 2)$

75. Let $y(x)$ be a solution of the differential equation $(1 + e^x)y' + ye^x = 1$. If $y(0) = 2$, then which of the following statement(s) is/are true? **[More than One Correct 2015]**

(a) $y(-4) = 0$
(b) $y(-2) = 0$
(c) $y(x)$ has a critical point in the interval $(-1, 0)$
(d) $y(x)$ has no critical point in the interval $(-1, 0)$

76. Consider the family of all circles whose centres lie on the straight line $y = x$. If this family of circles is represented by the differential equation $Py'' + Qy' + 1 = 0$, where P, Q are the functions of x, y and y' (here, $y' = \frac{dy}{dx}$, $y'' = \frac{d^2y}{dx^2}$), then which of the following statement(s) is/are true? **[More than One correct 2015]**

(a) $P = y + x$
(b) $P = y - x$
(c) $P + Q = 1 - x + y + y' + (y')^2$
(d) $P - Q = x + y - y' - (y')^2$

77. The function $y = f(x)$ is the solution of the differential equation $\frac{dy}{dx} + \frac{xy}{x^2 - 1} = \frac{x^4 + 2x}{\sqrt{1 - x^2}}$ in $(-1, 1)$ satisfying $f(0) = 0$. Then, $\int_{-\frac{\sqrt{3}}{2}}^{\sqrt{3}/2} f(x)\, dx$ is **[Only One correct 2014]**

(a) $\frac{\pi}{3} - \frac{\sqrt{3}}{2}$ (b) $\frac{\pi}{3} - \frac{\sqrt{3}}{4}$ (c) $\frac{\pi}{6} - \frac{\sqrt{3}}{4}$ (d) $\frac{\pi}{6} - \frac{\sqrt{3}}{2}$

78. Let $f : [1/2, 1] \to R$ (the set of all real numbers) be a positive, non-constant and differentiable function such that $f'(x) < 2f(x)$ and $f(1/2) = 1$. Then, the value of $\int_{1/2}^{1} f(x)\, dx$ lies in the interval **[Only One Correct 2013]**

(a) $(2e - 1, 2e)$ (b) $(e - 1, 2e - 1)$
(c) $\left(\frac{e-1}{2}, e - 1\right)$ (d) $\left(0, \frac{e-1}{2}\right)$

79. A curve passes through the point $\left(1, \frac{\pi}{6}\right)$. Let the slope of the curve at each point (x, y) be $\frac{y}{x} + \sec\left(\frac{y}{x}\right)$, $x > 0$. Then, the equation of the curve is **[Only One Correct 2013]**

(a) $\sin\left(\frac{y}{x}\right) = \log x + \frac{1}{2}$ (b) $\operatorname{cosec}\left(\frac{y}{x}\right) = \log x + 2$

(c) $\sec\left(\frac{2y}{x}\right) = \log x + 2$ (d) $\cos\left(\frac{2y}{x}\right) = \log x + \frac{1}{2}$

■ **Directions** (Q. Nos. 80 to 83) Let $f : [0, 1] \to R$ (the set of all real numbers) be a function. Suppose the function f is twice differentiable, $f(0) = f(1) = 0$ and satisfies

$$f''(x) - 2f'(x) + f(x) \geq e^x, \; x \in [0, 1]$$

[Passage Based Questions 2013]

80. If the function $e^{-x} f(x)$ assumes its minimum in interval $[0, 1]$ at $x = 1/4$, then which of the following is true?

(a) $f'(x) < f(x), \frac{1}{4} < x < \frac{3}{4}$ (b) $f'(x) > f(x), 0 < x < \frac{1}{4}$

(c) $f'(x) < f(x), 0 < x < \frac{1}{4}$ (d) $f'(x) < f(x), \frac{3}{4} < x < 1$

81. Which of the following is true?

(a) $0 < f(x) < \infty$ (b) $-\frac{1}{2} < f(x) < \frac{1}{2}$

(c) $-\frac{1}{4} < f(x) < 1$ (d) $-\infty < f(x) < 0$

82. Which of the following is true?

(a) g is increasing on $(1, \infty)$

(b) g is decreasing on $(1, \infty)$

(c) g is increasing on $(1, 2)$ and decreasing on $(2, \infty)$

(d) g is decreasing on $(1, 2)$ and increasing on $(2, \infty)$

83. Consider the statements.

I. There exists some $x \in R$ such that, $f(x) + 2x = 2(1 + x^2)$

II. There exists some $x \in R$ such that, $2f(x) + 1 = 2x(1 + x)$

(a) Both I and II are true (b) I is true and II is false

(c) I is false and II is true (d) Both I and II are false

84. If $y(x)$ satisfies the differential equation $y' - y \tan x = 2x \sec x$ and $y(0)$, then **[More than One Correct 2016]**

(a) $y\left(\frac{\pi}{4}\right) = \frac{\pi^2}{8\sqrt{2}}$ (b) $y'\left(\frac{\pi}{4}\right) = \frac{\pi^2}{18}$

(c) $y\left(\frac{\pi}{3}\right) = \frac{\pi^2}{9}$ (d) $y'\left(\frac{\pi}{3}\right) = \frac{4\pi}{3} + \frac{2\pi^2}{3\sqrt{3}}$

85. Let $y'(x) + y(x)g'(x) = g(x)g'(x)$, $y(0) = 0$, $x \in R$, where $f'(x)$ denotes $\frac{d f(x)}{dx}$ and $g(x)$ is a given non-constant differentiable function on R with $g(0) = g(2) = 0$. Then, the value of $y(2)$ is ..... **[Integer Type 2011]**

86. Let $f : R \to R$ be a continuous function, which satisfies $f(x) = \int_0^x f(t)\, dt$. Then, the value of $f(\ln 5)$ is ... . **[Integer Type 2009]**

■ **Direction** For the following question, choose the correct answer from the codes (a), (b), (c) and (d) defined as follows

(a) Statement I is true, Statement II is also true; Statement II is the correct explanation of Statement I.

(b) Statement I is true, Statement II is also true; Statement II is not the correct explanation of Statement I.

(c) Statement I is true; Statement II is false.

(d) Statement I is false; Statement II is true.

87. Let a solution $y = y(x)$ of the differential equation $x\sqrt{x^2 - 1}\, dy - y\sqrt{y^2 - 1}\, dx = 0$ satisfy $y(2) = \frac{2}{\sqrt{3}}$

Statement I $y(x) = \sec\left(\sec^{-1} x - \frac{\pi}{6}\right)$ and

Statement II $y(x)$ is given by $\frac{1}{y} = \frac{2\sqrt{3}}{x} - \sqrt{1 - \frac{1}{x^2}}$

[Statement Based Questions 2008]

(ii) JEE Main & AIEEE

88. If a curve $y = f(x)$ passes through the point $(1, -1)$ and satisfies the differential equation, $y(1 + xy)dx = x\, dy$, then $f\left(-\frac{1}{2}\right)$ is equal to **[2016 JEE Main]**

(a) $-\frac{2}{5}$ (b) $-\frac{4}{5}$ (c) $\frac{2}{5}$ (d) $\frac{4}{5}$

89. Let $y(x)$ be the solution of the differential equation $(x \log x)\frac{dy}{dx} + y = 2x \log x, (x \geq 1)$. Then, $y(e)$ is equal to **[2015 JEE Main]**

(a) e (b) 0 (c) 2 (d) $2e$

90. Let the population of rabbits surviving at a time t be governed by the differential equation $\frac{dp(t)}{dt} = \frac{1}{2}p(t) - 200$. If $p(0) = 100$, then $p(t)$ is equal to **[2014 JEE Main]**

(a) $400 - 300e^{\frac{t}{2}}$

(b) $300 - 200e^{-\frac{t}{2}}$

(c) $600 - 500e^{\frac{t}{2}}$

(d) $400 - 300e^{-\frac{t}{2}}$

91. At present, a firm is manufacturing 2000 items. It is estimated that the rate of change of production P with respect to additional number of workers x is given by $\frac{dP}{dx} = 100 - 12\sqrt{x}$. If the firm employees 25 more workers, then the new level of production of items is **[2013 JEE Main]**

(a) 2500 (b) 3000
(c) 3500 (d) 4500

92. The population $p(t)$ at time t of a certain mouse species satisfies the differential equation $\frac{dp(t)}{dt} = 0.5(t) - 450$. If $p(0) = 850$, then the time at which the population becomes zero is **[2012 AIEEE]**

(a) 2 log 18 (b) log 9
(c) $\frac{1}{2}$ log 18 (d) log 18

93. If $\frac{dy}{dx} = y + 3 > 0$ and $y(0) = 2$, then $y(\log 2)$ is equal to **[2011 JEE Main]**

(a) 5 (b) 13
(c) −2 (d) 7

94. Let I be the purchase value of an equipment and $V(t)$ be the value after it has been used for t years. The value $V(t)$ depreciates at a rate given by differential equation $\frac{dV(t)}{dt} = -k(T - t)$, where $k > 0$ is a constant and T is the total life in years of the equipment. Then, the scrap value $V(T)$ of the equipment is **[2010 AIEEE]**

(a) $I - \frac{kT^2}{2}$ (b) $I - \frac{k(T-t)^2}{2}$
(c) e^{-kT} (d) $T^2 - \frac{1}{k}$

95. Solution of the differential equation $\cos x\, dy = y(\sin x - y)\, dx,\ 0 < x < \frac{\pi}{2}$, is **[2010 AIEEE]**

(a) $\sec x = (\tan x + C)y$
(b) $y \sec x = \tan x + C$
(c) $y \tan x = \sec x + C$
(d) $\tan x = (\sec x + C)y$

96. The differential equation which represents the family of curves $y = c_1 e^{c_2 x}$, where c_1 and c_2 are arbitrary constants, is **[2009 AIEEE]**

(a) $y' = y^2$ (b) $y'' = y'y$
(c) $yy'' = y'$ (d) $yy'' = (y')^2$

97. The differential equation of the family of circles with fixed radius 5 units and centre on the line $y = 2$ is **[AIEEE 2008]**

(a) $(x-2)y'^2 = 25 - (y-2)^2$
(b) $(y-2)y'^2 = 25 - (y-2)^2$
(c) $(y-2)^2 y'^2 = 25 - (y-2)^2$
(d) $(x-2)^2 y'^2 = 25 - (y-2)^2$

Solutions

1. $y \cdot e^{-2x} = Ax\, e^{-2x} + B$

$e^{-2x} \cdot y_1 - 2ye^{-2x} = A(e^{-2x} - 2x\, e^{-2x})$

Cancelling e^{-2x} throughout

$$y_1 - 2y = A(1 - 2x) \qquad \ldots(i)$$

Differentiating again $y_2 - 2y_1 = -2A$

$$\Rightarrow \qquad A = \frac{2y_1 - y_2}{2}$$

On substituting A in Eq. (i)

$$2(y_2 - 2y) = (2y_1 - y_2)(1 - 2x)$$

$$2y_1 - 4y = 2y_1(1 - 2x) - (1 - 2x)y_2$$

$$(1 - 2x)\frac{d}{dx}\left(\frac{dy}{dx} - 2y\right) + 2\left(\frac{dy}{dx} - 2y\right) = 0$$

Hence, $k = 2$ and $l = -2$

$\Rightarrow$ Ordered pair $(k, l) \equiv (2, -2)$

2. $\frac{dy}{dx} = \frac{y}{x} - \cos^2\frac{y}{x}$ $y = vx$

$$v + x\frac{dv}{dx} = v - \cos^2 v$$

$$\int \frac{dv}{\cos^2 v} + \int \frac{dx}{x} = C \;\Rightarrow\; \tan v + \ln x = C$$

$$\tan\frac{y}{x} + \ln x = C$$

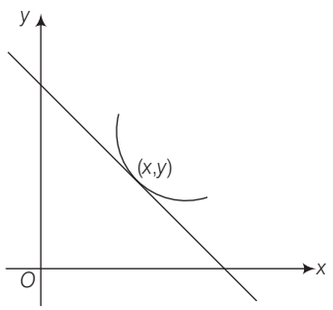
If $x = 1, y = \frac{\pi}{4} \Rightarrow C = 1 \Rightarrow \tan\frac{y}{x} = 1 - \ln x = \ln\frac{e}{x}$

$$y = x\tan^{-1}\left(\ln\frac{e}{x}\right)$$

3. $Y - y = m(X - x)$. For X-intercept $Y = 0$

$$X = x - \frac{y}{m}$$

Therefore, $x - \frac{y}{m} = y$



or $$\frac{dy}{dx} = \frac{y}{x - y}$$

Put $y = vx$ $\quad v + x\frac{dv}{dx} = \frac{v}{1 - v}$

$$x\frac{dv}{dx} = \frac{v}{1 - v} - v = \frac{v - v + v^2}{1 - v}$$

$$\int \frac{1 - v}{v^2}\, dv = \int \frac{dx}{x}$$

$$-\frac{1}{v} - \ln v = \ln x + C$$

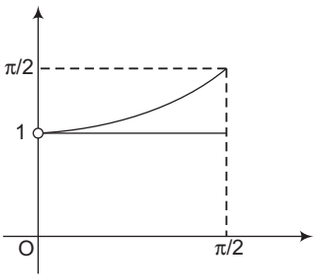
$$-\frac{x}{y} - \ln\frac{y}{x} = \ln x + C \;\Rightarrow\; -\frac{x}{y} = \ln y + C$$

$x = 1, y = 1 \Rightarrow C = -1$

$$1 - \frac{x}{y} = \ln y \;\Rightarrow\; y = e \cdot e^{-x/y}$$

$$e^{-x/y} = \frac{e}{y} \;\Rightarrow\; ye^{x/y} = e$$

4. $\sin x\frac{dy}{dx} + y\cos x = 1$



$$\frac{dy}{dx} + y\cot x = \text{cosec}\ x$$

$$\text{IF} = e^{\int \cot x\, dx} = e^{\ln(\sin x)} = \sin x$$

$$y\sin x = \int \text{cosec}\ x \cdot \sin x\, dx$$

$$y\sin x = x + C$$

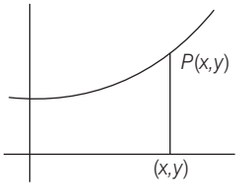
If $x = 0$, y is finite $\;\therefore\;\; C = 0$

$$y = x\,(\text{cosec}\ x) = \frac{x}{\sin x}$$

Now, $\qquad I < \frac{\pi^2}{4}$ and $I > \frac{\pi}{2}$

Hence, $\qquad \frac{\pi}{2} < I < \frac{\pi^2}{4}$

5. $\int_0^x f(x)\, dx = y^3$. Differentiating $f(x) = 3y^2 \cdot \frac{dy}{dx}$



$$y = 3y^2\frac{dy}{dx} \;\Rightarrow\; y = 0 \qquad \text{(rejected)}$$

or $\qquad 3y\, dy = dx$

$$\frac{3y^2}{2} = x + C \;\Rightarrow\; \text{Parabola}$$

6. $y = mx + c; \dfrac{dy}{dx} = m; \dfrac{d^2y}{dx^2} = 0$

Substituting in $\dfrac{d^2y}{dx^2} - 3\dfrac{dy}{dx} - 4y = -4x$

$$0 - 3m - 4(mx + c) = -4x$$

$$-3m - 4c - 4mx = -4x$$

$$-(3m + 4c) = 4x(m - 1) \qquad \ldots(i)$$

Eq. (i) is true for all real x, if $m = +1$ and $c = -3/4$.

7. $y = u^m \Rightarrow \dfrac{dy}{dx} = mu^{m-1}\dfrac{dy}{dx}$

Since, $2x^4 \cdot u^m \cdot mu^{m-1} \cdot \dfrac{du}{dx} + u^{4m} = 4x^6$

$$\frac{du}{dx} = \frac{4x^6 - u^{4m}}{2m\, x^4\, u^{2m-1}}$$

$$\Rightarrow \qquad 4m = 6 \;\Rightarrow\; m = \frac{3}{2}$$

and $\qquad 2m - 1 = 2 \;\Rightarrow\; m = \dfrac{3}{2}$

8. $\dfrac{dy}{dx} - \dfrac{y}{x^2}\tan\dfrac{1}{x} = -\sec\dfrac{1}{x}\cdot\dfrac{1}{x^2}$

$$\text{IF} = e^{-\int \frac{1}{x^2}\tan\frac{1}{x}dx} = \sec\frac{1}{x} \;\Rightarrow\; y\cdot\sec\frac{1}{x}$$

$$= -\int \sec^2\left(\frac{1}{x}\right)\frac{1}{x^2}\,dx = \tan\frac{1}{x} + C$$

If $y \to -1$, then $x \to \infty$

$$\Rightarrow \qquad C = -1 \;\Rightarrow\; y = \sin\frac{1}{x} - \cos\frac{1}{x}$$

9. $\dfrac{dM}{dt} = -KM \;\Rightarrow\; M = Ce^{-kt}$ when $t = 0$; $M = M_0$

$$\Rightarrow \qquad C = M_0$$

$$\Rightarrow \qquad M = M_0e^{-kt}$$

when $t = 1$, $M = \dfrac{M_0}{2}$

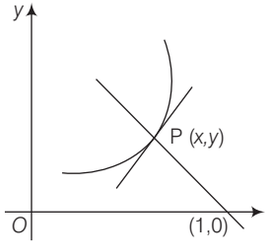
$$\Rightarrow \qquad k = \ln 2$$

Therefore, $M = M_0e^{-t\ln 2}$

when $\qquad M = \dfrac{M_0}{1000}$, then $t = \log_2 1000 = 9.98$

$= 10$ h approximately

10. Slope of the normal $= \dfrac{y}{x-1}$



$$\therefore \qquad \frac{dy}{dx} = \frac{1-x}{y}$$

$$\frac{y^2}{2} = x - \frac{x^2}{2} + C \qquad \ldots(ii)$$

Eq. (ii) passes through (0, 0).

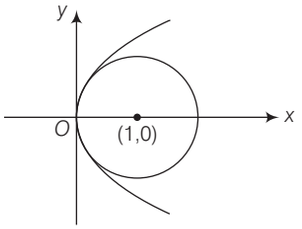
Thus, $C = 0$

$$x^2 + y^2 - 2x = 0$$

Now, tangent to $y^2 = 4x$

$$y = mx + \frac{1}{m} \qquad \ldots(iii)$$

If it touches the circle



$$x^2 + y^2 - 2x = 0$$

Then, $\left|\dfrac{m + (1/m)}{\sqrt{1+m^2}}\right| = 1$

$$\Rightarrow \qquad 1 + m^2 = m^2$$

$$\Rightarrow \qquad m \to \infty$$

Hence, tangent is y-axis *ie*, $x = 0$.

11. $f'(x) - \dfrac{2x(x+1)}{x+1}f(x) = \dfrac{e^{x^2}}{(x+1)^2}$

$$\text{IF} = e^{\int -2x\,dx} = e^{-x^2}$$

$$\therefore \qquad f(x)\cdot e^{-x^2} = \int \frac{dx}{(x+1)^2}$$

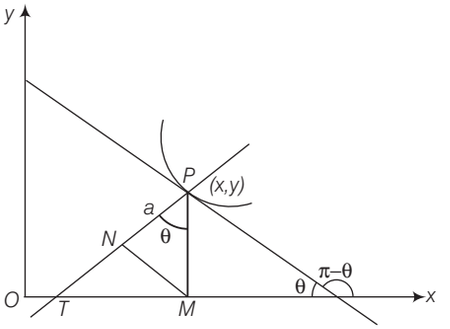
$$\Rightarrow \qquad f(x)\cdot e^{-x^2} = -\frac{1}{x+1} + C$$

At $x = 0$, $f(0) = 5 \;\Rightarrow\; C = 6$

$$\therefore \qquad f(x) = \left(\frac{6x+5}{x+1}\right)\cdot e^{x^2}$$

12. Ordinate = PM. Let $P \equiv (x, y)$

Projection of ordinate on normal = PN



$\therefore \quad PN = PN\cos\theta = a$ (given)

$\therefore \quad \dfrac{y}{\sqrt{1+\tan^2\theta}} = a$

$\Rightarrow \quad y = a\sqrt{1+(y_1)^2}$

$\Rightarrow \quad \dfrac{dy}{dx} = \dfrac{\sqrt{y^2-a^2}}{a}$

$\Rightarrow \quad \int \dfrac{a\,dy}{\sqrt{y^2-a^2}} = \int dx$

$\Rightarrow \quad a\ln|y+\sqrt{y^2-a^2}| = x + C$

13. $y = e^x(ax+b)$ ...(i)

Differentiating w.r.t. x, we get

$\dfrac{dy}{dx} = e^x(ax+b) + e^x\cdot a$ or $\dfrac{dy}{dx} = y + ae^x$ ...(ii)

Again, differentiating both the sides

$\dfrac{d^2y}{dx^2} = \dfrac{dy}{dx} + ae^x$ ...(iii)

From Eq. (iii) – Eq. (ii)

$\dfrac{d^2y}{dx^2} - \dfrac{2dy}{dx} + y = 0$

is required differential equation.

14. $\dfrac{dy}{dx} = 2ax = 2x\cdot\dfrac{y}{x^2};\ \dfrac{dy}{dx} = \dfrac{2y}{x};$

Now, $m\dfrac{dy}{dx} = -1 \ \Rightarrow\ m = -\dfrac{x}{2y} \ \Rightarrow\ \dfrac{dy}{dx} = -\dfrac{x}{2y}$

$y^2 = -\dfrac{x^2}{2} + C$

15. $\int_0^1 f(tx)\,dt = n\cdot f(x)$

Put, $x = y \ \Rightarrow\ dt = \dfrac{1}{x}\,dy$

$\therefore \quad \dfrac{1}{x}\int_0^x f(y)\,dy = nf(x)$

$\therefore \quad \int_0^x f(y)\,dy = x\cdot n\cdot f(x)$

Differentiating, $f(x) = n\,[f(x) + xf'(x)]$

$f(x)(1-n) = nx\,f'(x)$

$\therefore \quad \dfrac{f'(x)}{f(x)} = \dfrac{1-n}{nx}$

Integrating, $\ln f(x) = \left(\dfrac{1-n}{n}\right)\ln Cx = \ln(Cx)^{\frac{1-n}{n}};$

$\therefore \quad f(x) = Cx^{\frac{1-n}{n}}$

16. $(x^2z^{2\alpha}-1)\,\alpha z^{\alpha-1}\,dz + 2x\,z^{3\alpha}\,dx = 0$

or $\alpha(x^2\,z^{3\alpha-1} - z^{\alpha-1})\,dz + 2x\,z^{3\alpha}\,dx = 0$

for homogeneous every term must be of the same degree,

$3\alpha + 1 = \alpha - 1 \ \Rightarrow\ \alpha = -1$

17. Differentiate, $xy\,(x) = x^2y'(x) + 2\,xy(x)$

or $xy(x) + x^2\,y'(x) = 0$

$x\dfrac{dy}{dx} + y = 0$

$\ln y + \ln x = \ln C$

$xy = C$

At point (2, 3),

$2\times 3 = C \Rightarrow C = 6$

$\therefore \quad xy = 6$

18. $\int \dfrac{dy}{100-y} = \int dx$

$-\ln(100-y) = x + C$

$\ln(100-y) = -x + C$

Also $x = 0,\ y = 50$

$\therefore \quad C = \ln 50$

$x = \ln 50 - \ln(100-y)$

$\Rightarrow \quad \ln\dfrac{50}{100-y} = x$

$\Rightarrow \quad \dfrac{50}{100-y} = e^x$

$\Rightarrow \quad 100 - y = 50e^{-x}$

$\Rightarrow \quad y = 100 - 50e^{-x}$

19. Here, $x\left(\dfrac{dy}{dx}\right)^2 - 3y^2\left(\dfrac{dy}{dx}\right) + 3 = 0$

has order 1, degree 2 and non-linear.

20. Here, $(f'(x))^2 + 4f'(x)\cdot f(x) + (f(x))^2 = 0$

$\Rightarrow \quad \left(\dfrac{f'(x)}{f(x)}\right)^2 + 4\left(\dfrac{f'(x)}{f(x)}\right) + 1 = 0$

$\Rightarrow \quad \dfrac{f'(x)}{f(x)} = \dfrac{-4\pm\sqrt{16-4}}{2}$

$\Rightarrow \quad \dfrac{f'(x)}{f(x)} = -2\pm\sqrt{3}$

Integrating both the sides

$\log|f(x)| = (-2\pm\sqrt{3})\,x + C_1$

$\Rightarrow \quad f(x) = e^{(-2\pm\sqrt{3})x}\cdot C$

21. (a) $32x + 2y\dfrac{dy}{dx} = 0$

$\Rightarrow \quad \dfrac{dy}{dx} = m_1 = -\dfrac{16x}{y}$

and $16y^{15}\dfrac{dy}{dx} = k$

$\Rightarrow \quad \dfrac{dy}{dx} = m_2 = \dfrac{k}{16y^{15}}$

$m_1m_2 = -\dfrac{16x}{y}\cdot\dfrac{k}{16y^{15}} = -\dfrac{x}{y^{16}}\cdot k$

$= -\dfrac{x}{y^{16}}\cdot\dfrac{y^{16}}{x} = -1$

(b) $\dfrac{dy}{dx} = 1 - ce^{-x} = 1 - (y-x) = -(y-x-1)$ [using $ce^{-x} = y - x$]

and $\dfrac{dy}{dx} - k\cdot\dfrac{dy}{dx}e^{-y} = 1$

$\dfrac{dy}{dx}[1 - ke^{-y}] = 1$

or $[1-(x+2-y)]\dfrac{dy}{dx}=1 \qquad [\text{using } ke^{-y}=x-y+2]$

$$\frac{dy}{dx}=m_2=\frac{1}{y-x-1}$$

$\Rightarrow \quad m_1m_2=-1$

(c) $\dfrac{dy}{dx}=2cx=2x\cdot\dfrac{y}{x^2}=\dfrac{2y}{x}=m_1$

Also, $2x+4y\dfrac{dy}{dx}=0 \Rightarrow \dfrac{dy}{dx}=-\dfrac{x}{2y}=m_2$

Hence, $m_1m_2=-1$

(d) $x^2-y^2=c$

$$2x-2y\frac{dy}{dx}=0 \Rightarrow \frac{dy}{dx}=\frac{x}{y}=m_1$$

$$xy=k$$

$$x\frac{dy}{dx}+y=0 \Rightarrow \frac{dy}{dx}=-\frac{y}{x}=m_2$$

$\therefore \quad m_1m_2=-1$

Hence, (a), (b), (c) and (d) are all correct.

22. Let $m=\dfrac{dy}{dx}$ be the slope of tangent (x, y) to the required curve.

m_1 = slope of the tangent at $xy=c^2$

$$=-\frac{c^2}{x^2}=-\frac{y}{x}$$

Hence, $\dfrac{m+\dfrac{c^2}{x^2}}{1-\dfrac{c^2}{x^2}m}=\pm 1 \quad \text{or} \quad \dfrac{m+\dfrac{y}{x}}{1-\dfrac{y}{x}m}=\pm 1 \qquad \ldots(i)$

Consider $y^2-2xy-x^2=k$

$\Rightarrow \; 2y\dfrac{dy}{dx}-2\left(y+x\dfrac{dy}{dx}\right)-2x=0$

$$\Rightarrow \quad \frac{dy}{dx}(y-x)=x+y$$

$$\Rightarrow \quad \frac{dy}{dx}=\frac{x+y}{y-x}=m \qquad \text{(say)}$$

From Eq. (i)

$$\text{LHS}=\frac{\dfrac{x+y}{y-x}+\dfrac{y}{x}}{1-\dfrac{y}{x}\left(\dfrac{x+y}{y-x}\right)}$$

$$=\frac{x^2+y^2}{x^2+y^2}=1 \text{ RHS}$$

Similarly option, (b), (c) and (d) safisfy

23. $x\dfrac{dy}{dx}=y\log\left(\dfrac{y}{x}\right)\dfrac{dy}{dx}=\dfrac{y}{x}\log\left(\dfrac{y}{x}\right)$, put $y=vx$

$$\Rightarrow \quad \frac{dy}{dx}=v+x\frac{dv}{dx}$$

$$\therefore \quad v+x\frac{dv}{dx}=v\log v \Rightarrow x\frac{dv}{dx}=v(\log v-1)$$

$$\Rightarrow \quad \int\frac{dv}{v(\log v-1)}=\int\frac{dx}{x} \Rightarrow \int\frac{dt}{t-1}=\int\frac{dx}{x},$$

let $\log v=t$

$\Rightarrow \quad \log(t-1)=\log(x)+\log C$

$\Rightarrow \quad \log(t-1)=\log(xC)$

$\Rightarrow \quad t=1+xC$

$\Rightarrow \quad \log\dfrac{y}{x}=1+xC$

$\Rightarrow \quad y=x\cdot e^{1+Cx}$

or $\quad y=x\cdot e^{1-Cx}$

and $\quad \log\dfrac{y}{x}=\log e+Cx$

$\Rightarrow \quad y=ex\cdot e^{Cx}$

24. Clearly, (a) and (c) are of the form $\dfrac{dy}{dx}+Py=Q$, which is linear in y.

Also, (d) is $\dfrac{d^2y}{dx^2}=\cos x$, on integrating $\dfrac{dy}{dx}=\sin x+C$

which is also linear in y.

25. $\dfrac{dy}{dx}=\dfrac{(y-x)\pm\sqrt{(x-y)^2+4xy}}{2y}$

$$\Rightarrow \quad \frac{dy}{dx}=1 \quad \text{or} \quad \frac{dy}{dx}=-\frac{x}{y}$$

$\Rightarrow \quad x-y+1=0 \quad \text{and} \quad x^2+y^2=25$

26. (a) $f(x, tx)=e^t+\tan^{-1}(t)$, independent of x.

$\Rightarrow$ Homogeneous differential equation.

(b) $\log\left(\dfrac{y}{x}\right)dx+\dfrac{y^2}{x^2}\sin^{-1}\dfrac{y}{x}\cdot dy=0$

$$\Rightarrow \quad \frac{dy}{dx}=\frac{\log\left(\dfrac{y}{x}\right)}{\dfrac{y^2}{x^2}\sin^{-1}\left(\dfrac{y}{x}\right)}$$

$$f(x, y)=\frac{\log\left(\dfrac{y}{x}\right)}{\dfrac{y^2}{x^2}\sin^{-1}\left(\dfrac{y}{x}\right)}$$

$$\therefore \quad f(x, tx)=\frac{\log(t)}{t^2\sin^{-1}(t)}, \text{ independent of } x$$

$\Rightarrow$ Homogeneous differential equation.

(c) $f(x, y)=x^2+\sin x\cdot\cos y$

$f(x, tx)=x^2+\sin x\cdot\cos(tx)$, not independent of x.

$\Rightarrow$ Not homogeneous differential equation.

(d) $f(x, y)=\dfrac{x^2+y^2}{xy^2-y^3}$

$\Rightarrow f(x, tx)$ is not independent of x.

$\Rightarrow$ Not homogeneous differential equation.

27. Integrating Factor $= e^{\int \cos x\, dx} = e^{\sin x}$

or $\quad y \cdot e^{\sin x} = \int e^{+\sin x} \cos x = -e^{+\sin x} + C$

At point $(0, -1)$,

$$-1\, e^0 = -e^0 + C \Rightarrow 0$$

$\therefore \quad ye^{\sin x} = -e^{\sin x}$

$$y = -1$$

28. $\dfrac{dy}{dx} - y \cot x = -\dfrac{\sin x}{x^2}$

Integrating Factor $= e^{\int -\cot x\, dx} = e^{-\log \sin x} = \dfrac{1}{\sin x}$

$\therefore$ Required solution is $y \cdot \dfrac{1}{\sin x} = \int -\dfrac{\sin x}{x^2} \cdot \dfrac{1}{\sin x}\, dx + C$

$$y \cdot \frac{1}{\sin x} = \frac{1}{x} + C$$

As $x \to \infty, y \to 0 \Rightarrow C = 0$

$\therefore \quad y = \dfrac{\sin x}{x} \Rightarrow \lim\limits_{x \to 0} f(x) = 1 \qquad \ldots(i)$

$\therefore \quad I = \int_0^{\pi/2} \dfrac{\sin x}{x}\, dx$

Since, $\dfrac{\sin x}{x}$ is decreasing, when $x > 0$

$\Rightarrow \quad f(x) < f(0)$

$\Rightarrow \quad \int_0^{\pi/2} f(x) < \dfrac{\pi}{2}$ and $x < \dfrac{\pi}{2}$

$\Rightarrow \quad f(x) > \int\left(\dfrac{\pi}{2}\right) \Rightarrow \int_0^{\pi/2} f(x)\, dx > 1$

29. (a) Order of the differential equation is 2.

(b) $\dfrac{xdy - ydx}{\sqrt{x^2 + y^2}} = dx \Rightarrow \dfrac{\dfrac{xdy - ydx}{x^2}}{\sqrt{\left(1 + \dfrac{y^2}{x^2}\right)}} = \dfrac{dx}{x}$

$\therefore \quad \ln\left|\dfrac{y}{x} + \sqrt{1 + \dfrac{y^2}{x^2}}\right| = \ln|Cx|$

$\therefore \quad \dfrac{y}{x} + \dfrac{\sqrt{x^2 + y^2}}{x} = Cx$

i.e. $\quad y + \sqrt{x^2 + y^2} = Cx^2$

(c) $y = e^x (A \cos x + B \sin x)$

$$\frac{dy}{dx} = e^x (A \cos x + B \sin x) + e^x(-A \sin x + B \cos x)$$

$$= y + e^x (-A \sin x + B \cos x)$$

$\therefore \quad \dfrac{d^2y}{dx^2} = \dfrac{dy}{dx} + e^x (-A \sin x + B \cos x)$

$$+ e^x (-A \cos x - B \sin x)$$

$\therefore \quad \dfrac{d^2y}{dx^2} = \dfrac{dy}{dx} + e^x (-A \sin x + B \cos x) - y$

$$\frac{dy}{dx} + \frac{dy}{dx} - y - y = 2\left(\frac{dy}{dx} - y\right)$$

(d) $(1 + y^2)\dfrac{dy}{dx} + x = 2e^{\tan^{-1} y}$

$$\Rightarrow \frac{dx}{dy} + \frac{1}{1 + y^2} x = \frac{e^{\tan^{-1} y}}{1 + y^2}$$

$$\text{IF} = e^{\int \frac{1}{1 + y^2}} = e^{\tan^{-1} y}$$

$$\Rightarrow \quad xe^{\tan^{-1} y} = 2 \int e^{\tan^{-1} y} \cdot \frac{e^{\tan^1 y}}{1 + y^2}\, dy$$

$$\Rightarrow \quad xe^{\tan^{-1} y} = e^{2 \tan^{-1} y} + k$$

30. $\dfrac{dy}{dx} = 3(A + Bx)\, e^{3x} = Be^{3x}$

$$\Rightarrow \frac{dy}{dx} + my = (3 + m)(A + Bx)\, e^{3x} + Be^{3x}$$

$$\Rightarrow \frac{d^2y}{dx^2} + m\frac{dy}{dx} + ny = (9 + 3m + n)(A + Bx)\, e^{3x}$$

$$+ B(6 + m)\, e^{3x} = 0$$

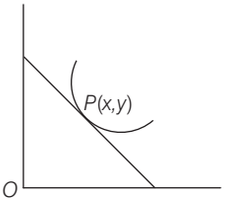
$\Rightarrow \quad 3m + n + 9 = 0 \quad$ and $\quad m + 6 = 0$

$\Rightarrow \quad m = -6 \quad$ and $\quad n = 9$

31. Equation of tangent

$$Y - y = m(X - x)$$

Put $X = 0, \qquad Y = y - mx$



Since, initial ordinate is

$$y - mx = x - 1$$

$\Rightarrow \quad mx - y = 1 - x$

$\dfrac{dy}{dx} - \dfrac{1}{x}y = \dfrac{1 - x}{x}$ which is a linear differential equation.

Hence, Statement I is correct and its degree is 1.

$\Rightarrow$ Statement II is also correct. Since, every 1st degree differential equation need not be linear, hence Statement II is not the correct explanation of Statement I.

32. **Statement I** The order of differential equation is 2.

$\therefore$ Statement I is false.

33. Integral curves are $y = cx - x^2$

The differential equation does not represent all the parabolas passing through origin but it represents all parabolas through origin with axis of symmetry parallel to y-axis and coefficient of x^2 as -1, hence Statement I is false.

Statement II is universally true.

34. $\dfrac{ydx - xdy}{y^2} \cdot \cot \dfrac{x}{y} = x\, dx$

or $\quad \int \cot \dfrac{x}{y} \cdot d\left(\dfrac{x}{y}\right) = \int x\, dx$

or $$\int \cot t\, dx = nx + C$$

$$\ln(\sin t) = nx + C; \sin\frac{x}{y} = Ce^{nx}$$

35. $y = c_1\cos 2x + c_2\sin^2 x + c_3\cos^2 x + c_4e^{2x} + c_5$

$$e^{2x+c_6} = c_1\cos 2x + c_2\left[\frac{1-\cos 2x}{2}\right] + c_3\left[\frac{\cos 2x+1}{2}\right] + c_4e^{2x} + c_5e^{2x}\cdot e^{c_6}$$

$$= \left(c_1 - \frac{c_2}{2} + \frac{c_3}{2}\right)\cos 2x + \left(\frac{c_2}{2} + \frac{c_3}{2}\right) + (c_4 + c'_5)\, e^{2x}$$

$$= \lambda_1\cos 2x + \lambda_2e^{2x} + \lambda_3$$

$\Rightarrow$ Total number of independent parameters in the given general solution is 3.

36. The given differential equation is

$$\frac{d\left(\frac{dy}{dx}\right)}{\frac{dy}{dx}} = \frac{2x}{x^2+1}\,dx$$

$$\Rightarrow \quad \ln\left(\frac{dy}{dx}\right) = \ln(x^2+1) + \ln C,\ C > 0$$

$$\Rightarrow \quad \frac{dy}{dx} = C(x^2+1)$$

$$\Rightarrow \quad y = C\left(\frac{x^3}{3} + x\right) + C',\ C' \in R$$

Obviously $y \to \infty$, as $x \to \infty$; as $C > 0$

37. $(x-h)^2 = 4b(y-k)$ here b is constant and h, k are parameters.

38. The general equation of all non-vertical lines in a plane is $ax + by = 1$, where $b \neq 0$.

Now, $$ax + by = 1$$

$$\Rightarrow \quad a + b\frac{dy}{dx} = 0 \qquad \text{(differentiating w.r.t. } x\text{)}$$

$$\Rightarrow \quad b\frac{d^2y}{dx^2} = 0 \qquad \text{(differentiating w.r.t. } x\text{)}$$

$$\Rightarrow \quad \frac{d^2y}{dx^2} = 0 \qquad (\text{as } b \neq 0)$$

Hence, the differential equation is $\frac{d^2y}{dx^2} = 0$.

39. The equation $ax^2 + 2hxy + by^2 = 1$ represents the family of all conics whose centre lies at the origin for different values of a, h, b.

$\therefore$ Order is 3.

Thus, Statement I is false and Statement II is true.

Hence, option (d) is the correct answer.

40. $y = a\sin x + b\cos x$

$$\frac{dy}{dx} = a\cos x - b\sin x$$

$$\Rightarrow \quad \frac{d^2y}{dx^2} = -a\cos x - b\sin x = -y$$

$$\Rightarrow \quad \frac{d^2y}{dx^2} + y = 0$$

But Statement II is not the correct explanation of the Statement I.

41. $f(0) = 2$

$$f(x) = (e^x + e^{-x})\cos x - 2x - \left[x\int_0^x f'(t)\,dt - \int_0^x \underbrace{t}_{\text{I}}\ \underbrace{f'(t)\,dt}_{\text{II}}\right]$$

$$f(x) = (e^x + e^{-x})\cos x - 2x - [x(f(x) - f(0)) - \{t\cdot f(t)|_0^x - \int_0^x f(t)dt\}]$$

$$f(x) = (e^x + e^{-x})\cos x - 2x - xf(x) + 2x + \left[x\ f(x) - \int_0^x f(t)\,dt\right]$$

$$f(x) = (e^x + e^{-x})\cos x - \int_0^x f(t)\,dt \qquad \ldots(\text{i})$$

On differentiating Eq. (i)

$$f'(x) + f(x) = \cos x\,(e^x - e^{-x}) - (e^x + e^{-x})\sin x \qquad \ldots(\text{ii})$$

Hence, $$\frac{dy}{dx} + y = e^x(\cos x - \sin x) - e^x(\cos x + \sin x)$$

42. $f'(0) + f(0) = 0 - 2\cdot 0 = 0$

43. IF of Eq. (i) is e^x

$$y\cdot e^x = \int e^{2x}(\cos x - \sin x)\,dx - \int(\cos x + \sin x)\,dx$$

$$y\cdot e^x = \int e^{2x}(\cos x - \sin x)\,dx - (\sin x - \cos x) + C$$

Let $$I = \int e^{2x}(\cos x - \sin x)\,dx = e^{2x}(A\cos x + B\sin x)$$

Solving, $A = 3/5$ and $B = -1/5$ and $C = 2/5$

$\therefore$ $$y = e^x\left(\frac{3}{5}\cos x - \frac{1}{5}\sin x\right) - (\sin x - \cos x)\,e^{-x} + \frac{2}{5}e^{-x}$$

Solutions (Q. Nos. 44 to 46)

Integrating, $\frac{d^2y}{dx^2} = 6x - 4$,

we get $\frac{dy}{dx} = 3x^2 - 4x + A$

When $x = 1$, $\frac{dy}{dx} = 0$ so that $A = 1$.

Hence, $$\frac{dy}{dx} = 3x^2 - 4x + 1 \qquad \ldots(\text{i})$$

Integrating, we get $y = x^3 - 2x^2 + x + B$.

When $x = 1$, $y = 5$, so that $B = 5$

Thus, we have $y = x^3 - 2x^2 + x + 5$

From Eq. (i), we get the critical points $x = \frac{1}{3}$, $x = 1$

At the critical point $x = \frac{1}{3}$, $\frac{d^2y}{dx^2}$ is negative.

Therefore, at $x = \frac{1}{3}$, y has a local maximum.

At $x = 1$, $\frac{d^2y}{dx^2}$ is positive. Therefore, at $x = 1$, y has a local minimum.

Also, $f(1) = 5$, $f\left(\frac{1}{3}\right) = \frac{157}{27}$, $f(0) = 5$, $f(2) = 7$

Hence, the global maximum value = 7.
and the global minimum value = 5.

47. $xdy - ydx = \sqrt{x^2 - y^2}\, dx$

$\Rightarrow \quad d\left(\frac{y}{x}\right) = \frac{\sqrt{1-(y/x)^2}}{x}\, dx \;\Rightarrow\; \int \frac{d(y/x)}{\sqrt{1-(y/x)^2}} = \int \frac{dx}{x}$

$\Rightarrow \sin^{-1}\frac{y}{x} = \ln x = \ln C$ or $Cx = e^{\sin^{-1} y/x}$

48. $(xy^4 + y)\, dx - x\, dy = 0$

$\Rightarrow \quad xy^4 dx + y\, dx - x\, dy = 0$

$\Rightarrow \quad \int x^3\, dx - \int \left(\frac{x}{y}\right)^2 d\left(\frac{x}{y}\right) = 0$

$\Rightarrow \quad \frac{x^4}{4} + \frac{1}{3}\left(\frac{x}{y}\right)^3 = C$

49. $2x\cos y\, dx - x^2 \sin y\, dy + y^2 \cos x\, dx + 2y \sin x\, dy = 0$

$\Rightarrow \quad \int d(x^2 \cos y) + \int d(y^2 \sin x) = 0$

$\Rightarrow \quad x^2 \cos y + y^2 \sin x = C$

50. $\frac{dx}{x} = \frac{ydy}{1+y^2}$

$\Rightarrow \quad \ln x = \frac{1}{2}\cdot \ln(1+y^2) + C$

From the given condition, $C = 0$

$\therefore \quad x^2 - y^2 = 1$

51. $\frac{dy}{dx} + \frac{1+y^2}{\sqrt{1-x^2}} = 0$

$\Rightarrow \quad \frac{dy}{1+y^2} + \frac{dx}{\sqrt{1-x^2}} = 0$

$\Rightarrow \quad \tan^{-1} y + \sin^{-1} x = C$

52. $\frac{dy}{dx} = (1+x)\cdot(1+y)$ gives $y = e^{\frac{(1+x)^2}{2}} - 1$

53. Tangent at point $P(x,y)$, is $y - y = f'(x)(x - x)$

$Q:(0, y - x f'(x))$

Then, $PQ = OQ$

$\Rightarrow \; x^2 + x^2(f'(x))^2 = y^2 + x^2(f'(x))^2 - 2xy(f'(x))$

$\Rightarrow \; x^2 = y^2 - 2xy \cdot f'(x)$
