(a) -1 (b) 1/2 (c) 1 (d) 2

Sol. (a, c)

$$\because f(x) = \frac{1}{2}\begin{vmatrix} p+\sin x & q+\sin x & p-r+\sin x \\ 2q+2\sin x & 2r+2\sin x & -2+2\sin x \\ r+\sin x & s+\sin x & s-q+\sin x \end{vmatrix}$$

Applying $R_2 \to R_2 - (R_1 + R_3)$, then

$$f(x) = \frac{1}{2}\begin{vmatrix} p+\sin x & q+\sin x & p-r+\sin x \\ & & \vdots \\ 0 \quad \dots & 0 \quad \dots & -2 \\ & & \vdots \\ r+\sin x & s+\sin x & s-q+\sin x \end{vmatrix}$$

$[\because 2q = p+r, 2r = q+s \text{ and } p+s = q+r]$

$$= -\frac{(-2)}{2}\begin{vmatrix} p+\sin x & q+\sin x \\ r+\sin x & s+\sin x \end{vmatrix}$$

Applying $C_2 \to C_2 - C_1$, then

$$f(x) = \begin{vmatrix} p + \sin x & D \\ p + 2D + \sin x & D \end{vmatrix}$$

[where D = common difference]

$$= D[p + \sin x - p - 2D - \sin x] = -2D^2$$

and $$\int_0^1 f(x)dx = -4$$

$$\Rightarrow \quad \int_0^1 (-2D^2)dx = -4 \Rightarrow -2D^2 = -2$$

$$\therefore \quad D^2 = 1 \Rightarrow D = \pm 1$$

● ***Ex. 15*** *If the system of equations $a^2x - by = a^2 - b$ and $bx - b^2y = 2 + 4b$ possess an infinite number of solutions, the possible values of a and b are*

(a) $a = 1, b = -1$ (b) $a = 1, b = -2$

(c) $a = -1, b = -1$ (d) $a = -1, b = -2$

Sol. (a, b, c, d)

Here, $\Delta = \begin{vmatrix} a^2 & -b \\ b & -b^2 \end{vmatrix} = -a^2b^2 + b^2 = -(a^2 - 1)b^2$

If $\Delta = 0$, then $a^2 = 1, b = 0$

Now, $$\Delta_1 = \begin{vmatrix} a^2 - b & -b \\ 2 + 4b & -b^2 \end{vmatrix}$$

For $a^2 = 1, \Delta_1 = \begin{vmatrix} 1 - b & -b \\ 2 + 4b & -b^2 \end{vmatrix} = b(b+1)(b+2)$

and $$\Delta_2 = \begin{vmatrix} a^2 & a^2 - b \\ b & 2 + 4b \end{vmatrix}$$

For $a^2 = 1, \Delta_2 = \begin{vmatrix} 1 & 1 - b \\ b & 2 + 4b \end{vmatrix} = (b+1)(b+2)$

For infinite number of solutions, $\Delta = \Delta_1 = \Delta_2 = 0$

$\therefore \; a^2 = 1, b = -1, -2 \Rightarrow a = \pm 1, b = -1, b = -2$

JEE Type Solved Examples : Passage Based Questions

■ This section contains **2 solved passages** based upon each of the passage **3 multiple choice** examples have to be answered. Each of these examples has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I

(Ex. Nos. 16 to 18)

Consider the system of equations

$$2x + ay + 6z = 8; \quad x + 2y + bz = 5$$

$$x + y + 3z = 4$$

16. The system has unique solution, if

(a) $a = 2, b = 3$ (b) $a = 2, b \neq 3$

(c) $a \neq 2, b = 3$ (d) $a \neq 2, b \neq 3$

17. The system has infinite solutions, if

(a) $a = 2, b \in R$ (b) $a = 3, b \in R$

(c) $a \in R, b = 2$ (d) $a \in R, b = 3$

18. The system has no solution, if

(a) $a = 2, b = 3$ (b) $a = 2, b \neq 3$

(c) $a \neq 2, b = 3$ (d) $a \neq 2, b \neq 3$

Sol. $\Delta = \begin{vmatrix} 2 & a & 6 \\ 1 & 2 & b \\ 1 & 1 & 3 \end{vmatrix} = 2(6 - b) - a(3 - b) + 6(1 - 2)$

$$= ab - 3a - 2b + 6 = (a - 2)(b - 3)$$

$$\Delta_1 = \begin{vmatrix} 8 & a & 6 \\ 5 & 2 & b \\ 4 & 1 & 3 \end{vmatrix} = 8(6 - b) - a(15 - 4b) + 6(5 - 8)$$

$$= 4ab - 15a - 8b + 30 = (a - 2)(4b - 15)$$

$$\Delta_2 = \begin{vmatrix} 2 & 8 & 6 \\ 1 & 5 & b \\ 1 & 4 & 3 \end{vmatrix} = 0 \qquad [\because R_1 = 2R_3]$$

$$\Delta_3 = \begin{vmatrix} 2 & a & 8 \\ 1 & 2 & 5 \\ 1 & 1 & 4 \end{vmatrix} = 2(8 - 5) - a(4 - 5) + 8(1 - 2)$$

$$= 6 + a - 8 = a - 2$$

16. (*d*) The system has unique solution, if

$$\Delta \neq 0$$

$$\Rightarrow \quad (a - 2)(b - 3) \neq 0$$

$$\Rightarrow \quad a \neq 2, b \neq 3$$

17. (*a*) The system has infinite solution, if

$$\Delta = \Delta_1 = \Delta_2 = \Delta_3 = 0$$

$$\Rightarrow \quad a - 2 = 0$$

or $$a = 2, b \in R$$

18. (*c*) The system has no solution, if

$\Delta = 0$ and atleast one of Δ_1, Δ_2 and Δ_3 is non-zero.

$$\Rightarrow \quad a \neq 2, b = 3$$

Passage II

(Ex. Nos. 19 to 20)

Let ${}^{x}C_i$, ${}^{x^2}C_i$ *and* ${}^{x^3}C_i\ (i=1,2,3)$ *be Binomial coefficients, where* $x \in N$

and $f(x)=12\begin{vmatrix} {}^{x}C_1 & {}^{x}C_2 & {}^{x}C_3 \\ {}^{x^2}C_1 & {}^{x^2}C_2 & {}^{x^2}C_3 \\ {}^{x^3}C_1 & {}^{x^3}C_2 & {}^{x^3}C_3 \end{vmatrix}$, *then*

19. $f(x)$ is a polynomial of degree

(a) 6 (b) 10

(c) 14 (d) 18

20. If $f(x)=(x-1)^m x^n (x+1)^p$, where $m, n, p \in N$, then the value of $\sum mn$ is

(a) 32 (b) 43

(c) 44 (d) 56

Sol.

$$\because f(x)=12\begin{vmatrix} {}^{x}C_1 & {}^{x}C_2 & {}^{x}C_3 \\ {}^{x^2}C_1 & {}^{x^2}C_2 & {}^{x^2}C_3 \\ {}^{x^3}C_1 & {}^{x^3}C_2 & {}^{x^3}C_3 \end{vmatrix}$$

$$=12\begin{vmatrix} x & \frac{x(x-1)}{2} & \frac{x(x-1)(x-2)}{6} \\ x^2 & \frac{x^2(x^2-1)}{2} & \frac{x^2(x^2-1)(x^2-2)}{6} \\ x^3 & \frac{x^3(x^3-1)}{2} & \frac{x^3(x^3-1)(x^3-2)}{6} \end{vmatrix}$$

Taking x, x^2 and x^3 common from R_1, R_2 and R_3, then

$$f(x)=x\cdot x^2\cdot x^3\begin{vmatrix} 1 & (x-1) & (x-1)(x-2) \\ 1 & (x^2-1) & (x^2-1)(x^2-2) \\ 1 & (x^3-1) & (x^3-1)(x^3-2) \end{vmatrix}$$

$$=x^6(x-1)^2\begin{vmatrix} 1 & 1 & x-2 \\ 1 & x+1 & (x+1)(x^2-2) \\ 1 & x^2+x+1 & (x^2+x+1)(x^3-2) \end{vmatrix}$$

Applying $R_1 \to R_1 - R_2$ and $R_3 \to R_3 - R_2$, then

$$f(x)=x^6(x-1)^2\begin{vmatrix} 0 & -x & x(3-x-x^2) \\ \vdots & & \\ 1 & \cdots\ x+1\ \cdots & (x+1)(x^2-2) \\ \vdots & & \\ 0 & x^2 & x^2(x^2+x^3-3) \end{vmatrix}$$

Expanding along C_1, then

$$=-x^6(x-1)^2\begin{vmatrix} -x & x(3-x-x^2) \\ x^2 & x^2(x^2+x^3-3) \end{vmatrix}$$

$$=-x^9(x-1)^2\begin{vmatrix} -1 & 3-x-x^2 \\ 1 & x^2+x^3-3 \end{vmatrix}$$

$$=-x^9(x-1)^2(-x^2-x^3+3-3+x+x^2)$$

$$=x^{10}(x-1)^2(x^2-1)=x^{10}(x-1)^3(x+1)$$

19. (*c*) $f(x)$ is a polynomial of degree 14.

20. (*b*) Here, $m=3, n=10$ and $p=1$

$\therefore \sum mn = mn + np + pm = 30 + 10 + 3 = 43$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **2 examples.** The answer to each example is a **single digit integer** ranging from **0** to **9** (both inclusive).

● ***Ex. 21*** *If* $\Delta_r = \begin{vmatrix} r & r-1 \\ r-1 & r \end{vmatrix}$, *where* r *is a natural number, the value of* $\sqrt[10]{\sum_{r=1}^{1024}\Delta_r}$ *is*

Sol. (4) $\because$ $\Delta_r = r^2-(r-1)^2$

$$\therefore \quad \sum_{r=1}^{1024}\Delta_r=(1024)^2-(1-1)^2=(1024)^2=2^{20}$$

$$\Rightarrow \quad \sqrt[10]{\sum_{r=1}^{1024}\Delta_r}=2^2=4$$

● ***Ex. 22*** *If* P, Q *and* R *are the angles of a triangle, the value of* $\begin{vmatrix} \tan P & 1 & 1 \\ 1 & \tan Q & 1 \\ 1 & 1 & \tan R \end{vmatrix}$ *is*

Sol. (2) $\begin{vmatrix} \tan P & 1 & 1 \\ 1 & \tan Q & 1 \\ 1 & 1 & \tan R \end{vmatrix} = \tan P(\tan Q \tan R - 1)$

$$-1(\tan R - 1) + 1(1 - \tan Q)$$

$$= \tan P \tan Q \tan R - (\tan P + \tan Q + \tan R) + 2$$

$$= 0 + 2$$

$[\because$ In ΔPQR, $\tan P + \tan Q + \tan R = \tan P \tan Q \tan R]$

$$= 2$$

JEE Type Solved Examples : Matching Type Questions

■ This section contains 2 eamples. Example 23 have four statements (A, B, C and D) given in **Column I** and four statement (p, q, r and s) in **Column II** and example 24 have three statements (A, B and C) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statements(s) given in **Column II.**

● ***Ex. 23*** *Let $f(x)$ denotes the determinant*

$$f(x)=\begin{vmatrix} x^2 & 2x & 1+x^2 \\ x^2+1 & x+1 & 1 \\ x & -1 & x-1 \end{vmatrix}.$$

On expansion $f(x)$ is seen to be a 4th *degree polynomial given by $f(x)=a_0x^4+a_1x^3+a_2x^2+a_3x+a_4$.*
Using differentiation of determinant or otherwise match the entries in Column I *with one or more entries of the elements of Column* II.

Column I		Column II	
(A)	$a_0^2+a_1$ is divisible by	(p)	2
(B)	$a_2^2+a_4$ is divisible by	(q)	3
(C)	$a_0^2+a_2$ is divisible by	(r)	4
(D)	$a_4^2+a_3^2+a_1^2$ is divisible by	(s)	5

Sol. (A) → (p, s); (B) → (p, r); (C) → (p, q); (D) → (q)

$\because$ $$f(x)=\begin{vmatrix} x^2 & 2x & 1+x^2 \\ x^2+1 & x+1 & 1 \\ x & -1 & x-1 \end{vmatrix}$$

Applying $C_1 \to C_1 - C_3$, then

$$f(x)=\begin{vmatrix} -1 & 2x & 1+x^2 \\ x^2 & x+1 & 1 \\ 1 & -1 & x-1 \end{vmatrix}$$

Expanding along R_1, then

$$f(x)=-(x^2-1+1)-2x(x^3-x^2-1)+(1+x^2)(-x^2-x-1)$$

$$=-3x^4+x^3-3x^2+x-1 \quad \ldots(i)$$

According to the question, we get

$$f(x)=a_0x^4+a_1x^3+a_2x^2+a_3x+a_4 \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$a_0=-3, a_1=1, a_2=-3, a_3=1, a_4=-1$$

(A) $a_0^2+a_1=(-3)^2+1=9+1=10=2\times5$

(B) $a_2^2+a_4=(-3)^2-1=9-1=8=2\times4$

(C) $a_0^2+a_2=(-3)^2-3=9-3=6=2\times3$

(D) $a_4^2+a_3^2+a_1^2=(-1)^2+(1)^2+(1)^2=1+1+1=3$

● ***Ex. 24*** *Suppose a, b and c are distinct and x, y and z are connected by the system of equations $x+ay+a^2z=a^3$, $x+by+b^2z=b^3$ and $x+cy+c^2z=c^3$.*

Column I		Column II	
(A)	For $x=1, y=2$ and $z=3$, $(a+b+c)^{-(ab+bc+ca)}$ is divisible by	(p)	3
(B)	For $x=4, y=3$ and $z=2$, $(ab+bc+ca)^{abc}$ is divisible by	(q)	6
(C)	For $x=6, y=4$ and $z=2$, $(abc)^{a+b+c}$ is divisible by	(r)	9
		(s)	12

Sol. (A) → (p, r) (B) → (p, r); (C) → (p, q, r, s)

$a\neq b\neq c$

$$\Delta=\begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix}=(a-b)(b-c)(c-a)$$

$$\Delta_1=\begin{vmatrix} a^3 & a & a^2 \\ b^3 & b & b^2 \\ c^3 & c & c^2 \end{vmatrix}=\begin{vmatrix} a & a^2 & a^3 \\ b & b^2 & b^3 \\ c & c^2 & c^3 \end{vmatrix}=abc\begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix}$$

$$=abc(a-b)(b-c)(c-a)$$

$$\Delta_2=\begin{vmatrix} 1 & a^3 & a^2 \\ 1 & b^3 & b^2 \\ 1 & c^3 & c^2 \end{vmatrix}=-\begin{vmatrix} 1 & a^2 & a^3 \\ 1 & b^2 & b^3 \\ 1 & c^2 & c^3 \end{vmatrix}$$

$$=-(a-b)(b-c)(c-a)(ab+bc+ca)$$

and $$\Delta_3=\begin{vmatrix} 1 & a & a^3 \\ 1 & b & b^3 \\ 1 & c & c^3 \end{vmatrix}=(a-b)(b-c)(c-a)(a+b+c)$$

By Cramer's rule, we get

$$x=\frac{\Delta_1}{\Delta}=abc$$

$$y=\frac{\Delta^2}{\Delta}=-(ab+bc+ca),\ z=\frac{\Delta_3}{\Delta}=a+b+c$$

(A) $(a+b+c)^{-(ab+bc+ca)}=z^y=3^2=9$, which is divisible by 3 and 9.

(B) $(ab+bc+ca)^{abc}=(-y)^x=(-3)^4=81$, which is divisible by 3 and 9.

(C) $(abc)^{a+b+c}=x^3=6^2=36$, which is divisible by 3, 6, 9 and 12.

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** Example numbers 25 and 26 are Assertion-Reason type examples. Each of these examples contains two statements:
Statement-1 (Assertion) and **Statement-2** (Reason)
Each of these examples also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below.
(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

● ***Ex. 25*** **Statement-1** *Let*

$$\Delta_r = \begin{vmatrix} (r-1) & n! & 6 \\ (r-1)^2 & (n!)^2 & 4n-2 \\ (r-1)^3 & (n!)^3 & 3n^2-2n \end{vmatrix}, \text{ then } \prod_{r=2}^{n+1} \Delta_r = 0.$$

Statement-2 $\prod_{r=2}^{n+1} \Delta_r = \Delta_2 \cdot \Delta_3 \cdot \Delta_4 \ldots \Delta_{n+1}$

Sol. (*d*) $\because \prod_{r=2}^{n+1} \Delta_r = \Delta_2 \cdot \Delta_3 \cdot \Delta_4 \ldots \Delta_{n+1}$

$$= \begin{vmatrix} 1 & n! & 6 \\ 1 & (n!)^2 & 4n-2 \\ 1 & (n!)^3 & 3n^3-2n \end{vmatrix} \times \begin{vmatrix} 2 & n! & 6 \\ 4 & (n!)^2 & 4n-2 \\ 8 & (n!)^3 & 3n^2-2n \end{vmatrix}$$

$$\times \ldots \times \begin{vmatrix} n & n! & 6 \\ n^2 & (n!)^2 & 4n-2 \\ n^3 & (n!)^3 & (3n^2-2n) \end{vmatrix} \neq 0$$

$\therefore$ Statement-1 is false and Statement-2 is true.

● ***Ex. 26*** *Consider the determinant*

$$f(x) = \begin{vmatrix} 0 & x^2-a & x^3-b \\ x^2+a & 0 & x^2+c \\ x^4+b & x-c & 0 \end{vmatrix}.$$

Statement-1 $f(x) = 0$ *has one root* $x = 0$.

Statement-2 *The value of skew-symmetric determinant of odd order is always zero.*

Sol. (a) For $x = 0$, the determinant reduces to the determinant of a skew-symmetric of odd order which is always zero. Hence, $x = 0$ is the solution of given equation $f(x) = 0$.

Subjective Type Examples

■ In this section, there are **20 subjective** solved examples.

● ***Ex. 27*** *A determinant of second order is made with the elements* 0 *and* 1. *Find the number of determinants with non-negative values.*

Sol. The number of determinants that can be made with 0 and 1

$$= 2 \times 2 \times 2 \times 2 = 16$$

and there are only three determinants of second order with negative values

i.e., $\begin{vmatrix} 1 & 1 \\ 1 & 0 \end{vmatrix}, \begin{vmatrix} 0 & 1 \\ 1 & 1 \end{vmatrix}, \begin{vmatrix} 0 & 1 \\ 1 & 0 \end{vmatrix}$

Therefore, number of determinants with non-negative values $= 16 - 3 = 13$

● ***Ex. 28*** *Prove that* $\begin{vmatrix} 1+a & 1 & 1 \\ 1 & 1+b & 1 \\ 1 & 1 & 1+c \end{vmatrix}$

$= abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)$, *hence find the value of the determinant, if* a, b *and* c *are the roots of the equation* $px^3 - qx^2 + rx - s = 0$.

Sol. Let $\Delta = \begin{vmatrix} 1+a & 1 & 1 \\ 1 & 1+b & 1 \\ 1 & 1 & 1+c \end{vmatrix}$

Since, the answer contain abc, then taking a, b and c common from R_1, R_2 and R_3 respectively, then

$$\Delta = abc \begin{vmatrix} \frac{1}{a}+1 & \frac{1}{a} & \frac{1}{a} \\ \frac{1}{b} & \frac{1}{b}+1 & \frac{1}{b} \\ \frac{1}{c} & \frac{1}{c} & \frac{1}{c}+1 \end{vmatrix}$$

But answer also contains $\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)$,

then applying $R_1 \to R_1 + R_2 + R_3$

$\therefore$ $\Delta = abc$

$$\begin{vmatrix} 1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c} & 1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c} & 1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c} \\ \frac{1}{b} & \frac{1}{b}+1 & \frac{1}{b} \\ \frac{1}{c} & \frac{1}{c} & \frac{1}{c}+1 \end{vmatrix}$$

Taking $\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)$ common from R_1, then

$$\Delta = abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)\begin{vmatrix} 1 & 1 & 1 \\ \frac{1}{b} & \frac{1}{b}+1 & \frac{1}{b} \\ \frac{1}{c} & \frac{1}{c} & \frac{1}{c}+1 \end{vmatrix}$$

Applying $C_2 \to C_2 - C_1$, then

$$\Delta = abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)\begin{vmatrix} 1 & 0 & 1 \\ \frac{1}{b} & 1 & \frac{1}{b} \\ \frac{1}{c} & 0 & \frac{1}{c}+1 \end{vmatrix}$$

Expanding along C_2, then

$$\Delta = abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)\begin{vmatrix} 1 & 1 \\ \frac{1}{c} & \frac{1}{c}+1 \end{vmatrix}$$

Hence, $\Delta = abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)$

2nd Part $\Delta = abc\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right) = abc + bc + ca + ab$

$$= \frac{s}{p} + \frac{r}{p} = \left(\frac{s+r}{p}\right)$$

● ***Ex. 29*** *If a, b and c are positive and are the pth, qth and rth terms, respectively of a GP. Show without expanding that*

$$\begin{vmatrix} \log a & p & 1 \\ \log b & q & 1 \\ \log c & r & 1 \end{vmatrix} = 0.$$

Sol. Let A be the first term and R be the common ratio of GP, then

$$a = p\text{th term} = AR^{p-1}$$
$$b = q\text{th term} = AR^{q-1}$$
$$c = r\text{th term} = AR^{r-1}$$

$\therefore$ $\log a = \log A + (p-1)\log R$,
$\log b = \log A + (q-1)\log R$ and
$\log c = \log A + (r-1)\log R$

$$\therefore \quad \text{LHS} = \begin{vmatrix} \log a & p & 1 \\ \log b & q & 1 \\ \log c & r & 1 \end{vmatrix}$$

$$= \begin{vmatrix} \log A + (p-1)\log R & p & 1 \\ \log A + (q-1)\log R & q & 1 \\ \log A + (r-1)\log R & r & 1 \end{vmatrix}$$

Applying $C_1 \to C_1 - (\log A)C_3$, then

$$= \begin{vmatrix} (p-1)\log R & p & 1 \\ (q-1)\log R & q & 1 \\ (r-1)\log R & r & 1 \end{vmatrix} = \log R \begin{vmatrix} (p-1) & p & 1 \\ (q-1) & q & 1 \\ (r-1) & r & 1 \end{vmatrix}$$

Applying $C_1 \to C_1 + C_3$, then

$$= \log R \begin{vmatrix} p & p & 1 \\ q & q & 1 \\ r & r & 1 \end{vmatrix} = 0 \text{ [since } C_1 \text{ and } C_2 \text{ are identical]}$$

$$= \text{RHS}$$

● ***Ex. 30*** *Prove that*

$$\begin{vmatrix} -2a & a+b & a+c \\ b+a & -2b & b+c \\ c+a & c+b & -2c \end{vmatrix} = 4(b+c)(c+a)(a+b).$$

Sol. Let $\Delta = \begin{vmatrix} -2a & a+b & a+c \\ b+a & -2b & b+c \\ c+a & c+b & -2c \end{vmatrix}$

On putting $a+b=0$, $b=-a$

Then, $\Delta = \begin{vmatrix} -2a & 0 & a+c \\ 0 & 2a & c-a \\ c+a & c-a & -2c \end{vmatrix}$

Expanding along R_1, then

$\Delta = -2a\{-4ac-(c-a)^2\} - 0 + (a+c)\{0-2a(c+a)\}$

$= 2a(c+a)^2 - 2a(c+a)^2 = 0$

Hence, $(a+b)$ is a factor of Δ, similarly $(b+c)$ and $(c+a)$ are the factors of Δ.

On expansion of determinant we can see that each term of the determinant is a homogeneous expression in a, b and c of degree 3 and also RHS is a homogeneous expression of degree 3.

Let $\Delta = k(a+b)(b+c)(c+a)$

or $\begin{vmatrix} -2a & a+b & a+c \\ b+a & -2b & b+c \\ c+a & c+b & -2c \end{vmatrix} = k(a+b)(b+c)(c+a)$

On putting $a=0$, $b=1$ and $c=2$, we get

$$\begin{vmatrix} 0 & 1 & 2 \\ 1 & -2 & 3 \\ 2 & 3 & -4 \end{vmatrix} = k(0+1)(1+2)(2+0)$$

$\Rightarrow \quad 0-1(-4-6)+2(3+4) = 6k$

$\Rightarrow \quad 24 = 6k$

$\therefore \quad k = 4$

Hence, $\begin{vmatrix} -2a & a+b & a+c \\ b+a & -2b & b+c \\ c+a & c+b & -2c \end{vmatrix} = 4(a+b)(b+c)(c+a)$

● ***Ex. 31*** *If $bc+qr = ca+rp = ab+pq = -1$, show that* $\begin{vmatrix} ap & bp & cr \\ a & b & c \\ p & q & r \end{vmatrix} = 0.$

Sol. Given equations can be rewritten as

$$bc + qr + 1 = 0 \quad \ldots(i)$$
$$ca + rp + 1 = 0 \quad \ldots(ii)$$
$$ab + pq + 1 = 0 \quad \ldots(iii)$$

On multiplying Eqs. (i), (ii) and (iii) by ap, bq and cr respectively, we get

$$(abc)p + (pqr)a + ap = 0$$
$$(abc)q + (pqr)b + bq = 0$$
$$(abc)r + (pqr)c + cr = 0$$

These equations are consistent, given equations three but abc and pqr are two.

Hence, $$\begin{vmatrix} p & a & ap \\ q & b & bq \\ r & c & cr \end{vmatrix} = 0$$

$$\Rightarrow \quad \begin{vmatrix} p & q & r \\ a & b & c \\ ap & bq & cr \end{vmatrix} = 0$$

[interchanging rows into columns]

$$\Rightarrow \quad (-1)\begin{vmatrix} ap & bq & cr \\ a & b & c \\ p & q & r \end{vmatrix} = 0 \qquad [R_1 \leftrightarrow R_3]$$

Hence, $$\begin{vmatrix} ap & bq & cr \\ a & b & c \\ p & q & r \end{vmatrix} = 0$$

● ***Ex. 32*** *If α and β are the roots of the equations $x^2 - 2x + 4 = 0$, find the value of* $\begin{vmatrix} \sum\alpha & \sum\alpha^2 & \sum\alpha^3 \\ \sum\alpha^2 & \sum\alpha^3 & \sum\alpha^4 \\ \sum\alpha^3 & \sum\alpha^4 & \sum\alpha^5 \end{vmatrix}$.

Sol. Given, $x^2 - 2x + 4 = 0$

$$\therefore \quad x = 1 \pm i\sqrt{3}$$
$$\therefore \quad \alpha = 1 + i\sqrt{3}$$
and $$\beta = 1 - i\sqrt{3}$$

$$\Rightarrow \quad \alpha = -2\left(\frac{-1 - i\sqrt{3}}{2}\right) \text{ and } \beta = -2\left(\frac{-1 + i\sqrt{3}}{2}\right)$$

$\alpha = -2\omega^2$ and $\beta = -2\omega$, where ω is the cube root of unity.

$$\sum\alpha = \alpha + \beta = -2(\omega + \omega)^2 = -2(-1) = 2$$
$$\sum\alpha^2 = \alpha^2 + \beta^2 = 4\omega^4 + 4\omega^2 = 4(\omega + \omega)^2 = 4(-1) = -4$$
$$\sum\alpha^3 = \alpha^3 + \beta^3 = -8\omega^6 - 8\omega^3 = -8 - 8 = -16$$
$$\sum\alpha^4 = \alpha^4 + \beta^4 = 16\omega^8 + 16\omega^4 = 16(\omega^2 + \omega)$$
$$= 16(-1) = -16$$

and $$\sum\alpha^5 = \alpha^5 + \beta^5 = -32\omega^{10} - 32\omega^5$$
$$= -32(\omega + \omega^2) = -32(-1) = 32$$

Let $$\Delta = \begin{vmatrix} \sum\alpha & \sum\alpha^2 & \sum\alpha^3 \\ \sum\alpha^2 & \sum\alpha^3 & \sum\alpha^4 \\ \sum\alpha^3 & \sum\alpha^4 & \sum\alpha^5 \end{vmatrix} = \begin{vmatrix} 2 & -4 & -16 \\ -4 & -16 & -16 \\ -16 & -16 & 32 \end{vmatrix}$$

$$= 2(-4)(-16)\begin{vmatrix} 1 & -2 & -8 \\ 1 & 4 & 4 \\ 1 & 1 & -2 \end{vmatrix} = 128\begin{vmatrix} 1 & -2 & -8 \\ 1 & 4 & 4 \\ 1 & 1 & -2 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\Delta = 128\begin{vmatrix} 1 & -2 & -8 \\ 0 & 6 & 12 \\ 0 & 3 & 6 \end{vmatrix}$$

Expanding along C_1, we get

$$\Delta = 128 \cdot 1 \cdot \begin{vmatrix} 6 & 12 \\ 3 & 6 \end{vmatrix} = 128(36 - 36) = 0$$

● ***Ex. 33*** *If $a^2 + b^2 + c^2 = 1$, prove that*

$$\begin{vmatrix} a^2 + (b^2 + c^2)\cos\phi & ab(1 - \cos\phi) & ac(1 - \cos\phi) \\ ba(1 - \cos\phi) & b^2 + (c^2 + a^2)\cos\phi & bc(1 - \cos\phi) \\ ca(1 - \cos\phi) & cb(1 - \cos\phi) & c^2 + (a^2 + b^2)\cos\phi \end{vmatrix}$$

is independent of a, b and c.

Sol. Let

$$\Delta = \begin{vmatrix} a^2 + (b^2 + c^2)\cos\phi & ab(1 - \cos\phi) & ac(1 - \cos\phi) \\ ba(1 - \cos\phi) & b^2 + (c^2 + a^2)\cos\phi & bc(1 - \cos\phi) \\ ca(1 - \cos\phi) & cb(1 - \cos\phi) & c^2 + (a^2 + b^2)\cos\phi \end{vmatrix}$$

On multiplying C_1, C_2 and C_3 by a, b and c respectively and taking a, b and c common from R_1, R_2 and R_3 respectively, we get

$$\Delta = \frac{abc}{abc}\begin{vmatrix} a^2 + (b^2 + c^2)\cos\phi & b^2(1 - \cos\phi) & c^2(1 - \cos\phi) \\ a^2(1 - \cos\phi) & b^2 + (c^2 + a^2)\cos\phi & c^2(1 - \cos\phi) \\ a^2(1 - \cos\phi) & b^2(1 - \cos\phi) & c^2 + (a^2 + b^2)\cos\phi \end{vmatrix}$$

Applying $C_1 \to C_1 + C_2 + C_3$, then

$$\Delta = \begin{vmatrix} a^2+b^2+c^2 & b^2 1-\cos\phi) & c^2(1-\cos\phi) \\ a^2+b^2+c^2 & b^2+(c^2+a^2)\cos\phi & c^2(1-\cos\phi) \\ a^2+b^2+c^2 & b^2(1-\cos\phi) & c^2+(a^2+b^2)\cos\phi \end{vmatrix}$$

Taking $a^2+b^2+c^2$ common from C_1, then

$$\Delta = (a^2+b^2+c^2)\begin{vmatrix} 1 & b^2(1-\cos\phi) & c^2(1-\cos\phi) \\ 1 & b^2+(c^2+a^2)\cos\phi & c^2(1-\cos\phi) \\ 1 & b^2(1-\cos\phi) & c^2+(a^2+b^2)\cos\phi \end{vmatrix}$$

Applying $R_1 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\Delta = 1\begin{vmatrix} 1 & b^2(1-\cos\phi) & c^2(1-\cos\phi) \\ 0 & (a^2+b^2+c^2)\cos\phi & 0 \\ 0 & 0 & (a^2+b^2+c^2)\cos\phi \end{vmatrix}$$

$$= (a^2+b^2+c^2)^2\cos^2\phi$$

[by property, since all elements zero below leading diagonal]

$$= 1^2 \cdot \cos\phi = \cos^2\phi \qquad [\because a^2+b^2+c^2 = 1]$$

which is independent of a, b and c.

● ***Ex. 34*** *If $a \neq 0$ and $a \neq 1$, show that*

$$\begin{vmatrix} x+1 & x & x \\ x & x+a & x \\ x & x & x+a^2 \end{vmatrix} = a^3\left[1+\frac{x(a^3-1)}{a^2(a-1)}\right].$$

Sol. Let

$$\text{LHS} = \Delta = \begin{vmatrix} x+1 & x & x \\ x & x+a & x \\ x & x & x+a^2 \end{vmatrix} = \begin{vmatrix} x+1 & x & x \\ x+0 & x+a & x \\ x+0 & x & x+a^2 \end{vmatrix}$$

$$= \begin{vmatrix} x & x & x \\ x & x+a & x \\ x & x & x+a^2 \end{vmatrix} + \begin{vmatrix} 1 & x & x \\ 0 & x+a & x \\ 0 & x & x+a^2 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$ in first determinant, then

$$\Delta = \begin{vmatrix} x & x & x \\ 0 & a & 0 \\ 0 & 0 & a^2 \end{vmatrix} + \begin{vmatrix} 1 & x & x \\ 0 & x+a & x \\ 0 & x & x+a^2 \end{vmatrix}$$

Expanding first determinant by property, since all elements below leading diagonal are zero and expanding second determinant along C_1, then

$$\Delta = x \cdot a \cdot a^2 + 1 \cdot \begin{vmatrix} x+a & x \\ x & x+a^2 \end{vmatrix}$$

$$= xa^3 + \{(x+a)(x+a^2) - x^2\}$$

$$= xa^3 + (x^2 + a^2x + ax + a^3 - x^2)$$

$$= xa^3 + a^2x + ax + a^3 = a^3 + x(a^3 + a^2 + a)$$

$$= a^3 + \frac{x \cdot a(a^3-1)}{(a-1)} = a^3\left[1 + \frac{x(a^3-1)}{a^2(a-1)}\right] = \text{RHS}$$

● ***Ex. 35*** (i) *Prove that* $\begin{vmatrix} bc-a^2 & ca-b^2 & ab-c^2 \\ ca-b^2 & ab-c^2 & bc-a^2 \\ ab-c^2 & bc-a^2 & ca-b^2 \end{vmatrix}$

$$= \frac{1}{2}(a+b+c)\left[(a-b)^2 + (b-c)^2 + (c-a)^2\right]$$

Now, $a - b = \sin x - \sin(x+h) = -2\cos\left(x + \frac{h}{2}\right)\sin\frac{h}{2}$

$b - c = \sin(x+h) - \sin(x+2h) = -2\cos\left(x + \frac{3h}{2}\right)\sin\frac{h}{2}$

and $c - a = \sin(x+2h) - \sin x = 2\cos(x+h)\sin h$

$$\therefore \quad \frac{\Delta}{h^2} = \frac{1}{2}(a+b+c) \left[\left(\frac{a-b}{h} \right)^2 + \left(\frac{b-c}{h} \right)^2 + \left(\frac{c-a}{h} \right)^2 \right]$$

$$= \frac{1}{2}\left[\sin x + \sin(x+h) + \sin(x+2h)\right] \times \left[\left(\frac{-2\cos\left(x + \frac{h}{2}\right)\sin\frac{h}{2}}{h} \right)^2 + \left(\frac{-2\cos\left(x + \frac{3h}{2}\right)\sin\frac{h}{2}}{h} \right)^2 + \left(\frac{2\cos(x+h)\sin h}{h} \right)^2 \right]$$

$$\therefore \quad \lim_{h \to 0} \frac{\Delta}{h^2} = \frac{1}{2}(3\sin x)(\cos^2 x + \cos^2 x + 4\cos^2 x)$$

$$\therefore \quad = 9 \sin x \cos^2 x$$

● ***Ex. 41*** *If* $f(x) = \begin{vmatrix} x+c_1 & x+a & x+a \\ x+b & x+c_2 & x+a \\ x+b & x+b & x+c_3 \end{vmatrix}$, *show that* $f(x)$ *is linear in x. Hence, deduce that* $f(0) = \frac{bg(a) - ag(b)}{(b-a)}$, *where* $g(x) = (c_1 - x)(c_2 - x)(c_3 - x)$.

Sol. Since, $f(x) = \begin{vmatrix} x+c_1 & x+a & x+a \\ x+b & x+c_2 & x+a \\ x+b & x+b & x+c_3 \end{vmatrix}$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_2$, then

$$f(x) = \begin{vmatrix} x+c_1 & a-c_1 & 0 \\ x+b & c_2-b & a-c_2 \\ x+b & 0 & c_3-b \end{vmatrix}$$

$$f(x) = x \begin{vmatrix} 1 & a-c_1 & 0 \\ 1 & c_2-b & a-c_2 \\ 1 & 0 & c_3-b \end{vmatrix} + \begin{vmatrix} c_1 & a-c_1 & 0 \\ b & c_2-b & a-c_2 \\ b & 0 & c_3-b \end{vmatrix}$$

So, $f(x)$ is linear.

Let $f(x) = Px + Q$

Then, $f(-a) = -aP + Q$, $f(-b) = -bP + Q$

$$f(0) = 0 \cdot P + Q = Q = \frac{bf(-a) - af(-b)}{(b-a)} \quad \text{...(ii)}$$

From Eq. (i), we get

$$f(-a) = \begin{vmatrix} c_1 - a & 0 & 0 \\ b-a & c_2-a & 0 \\ b-a & b-a & c_3-a \end{vmatrix}$$

$$= (c_1 - a)(c_2 - a)(c_3 - a)$$

Similarly, $f(-b) = (c_1 - b)(c_2 - b)(c_3 - b)$

and $g(x) = (c_1 - x)(c_2 - x)(c_3 - x)$

$$g(a) = f(-a)$$

$$\therefore \quad g(b) = f(-b)$$

Now, from Eq. (ii), we get

$$f(0) = \frac{bg(a) - ag(b)}{(b-a)}$$

● ***Ex. 42*** *If* $f(x)$ *is a polynomial of degree* < 3, *prove that*

$$\begin{vmatrix} 1 & a & f(a)/(x-a) \\ 1 & b & f(b)/(x-b) \\ 1 & c & f(c)/(x-c) \end{vmatrix} \div \begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix} = \frac{f(x)}{(x-a)(x-b)(x-c)}.$$

Sol. $\frac{f(x)}{(x-a)(x-b)(x-c)} = \frac{A}{(x-a)} + \frac{B}{(x-b)} + \frac{C}{(x-c)}$ [let] ...(i)

On comparing the various powers of x, we get

$$\Rightarrow \quad \begin{cases} A = \frac{f(a)}{(a-b)(a-c)} = -\frac{f(a)}{(a-b)(c-a)} \\ B = \frac{f(b)}{(b-a)(b-c)} = -\frac{f(b)}{(a-b)(b-c)} \\ C = \frac{f(c)}{(c-a)(c-b)} = -\frac{f(c)}{(b-c)(c-a)} \end{cases}$$

Now, from Eq. (i), we get

$$\frac{f(x)}{(x-a)(x-b)(x-c)}$$

$$= \frac{(c-b)\frac{f(a)}{(x-a)} - (c-a)\frac{f(b)}{(x-b)} + (b-a)\frac{f(c)}{(x-c)}}{(a-b)(b-c)(c-a)}$$

$$= \frac{\begin{vmatrix} 1 & a & f(a)/(x-a) \\ 1 & b & f(b)/(x-b) \\ 1 & c & f(c)/(x-c) \end{vmatrix}}{\begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix}}$$

● ***Ex. 43*** *If* $f(a,b) = \dfrac{f(b)-f(a)}{b-a}$ *and* $f(a,b,c) = \dfrac{f(b,c)-f(a,b)}{(c-a)}$, *prove that*

$$f(a,b,c) = \begin{vmatrix} f(a) & f(b) & f(c) \\ 1 & 1 & 1 \\ a & b & c \end{vmatrix} \div \begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix}.$$

Sol. LHS $= f(a,b,c) = \dfrac{f(b,c)-f(a,b)}{(c-a)}$

$$= \frac{\frac{f(c)-f(b)}{(c-b)} - \frac{f(b)-f(a)}{(b-a)}}{(c-a)}$$

$$= \frac{(b-a)\{f(c)-f(b)\} - (c-b)\{f(b)-f(a)\}}{(b-a)(c-b)(c-a)}$$

$$= \frac{(f(a)\cdot(c-b) - f(b)\cdot(c-a) + f(c)\cdot(b-a))}{(a-b)(b-c)(c-a)}$$

$$= \frac{f(a)\begin{vmatrix} 1 & 1 \\ b & c \end{vmatrix} - f(b)\begin{vmatrix} 1 & 1 \\ a & c \end{vmatrix} + f(c)\begin{vmatrix} 1 & 1 \\ a & b \end{vmatrix}}{\begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix}}$$

$$= \frac{\begin{vmatrix} f(a) & f(b) & f(c) \\ 1 & 1 & 1 \\ a & b & c \end{vmatrix}}{\begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix}}$$

$$= \begin{vmatrix} f(a) & f(b) & f(c) \\ 1 & 1 & 1 \\ a & b & c \end{vmatrix} \div \begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix} = \text{RHS}$$

● ***Ex. 44*** *Let S be the sum of all possible determinants of order 2 having 0, 1, 2 and 3 as their elements. Find the common root* α *of the equations*

$$x^2 + ax + [m+1] = 0,$$

$$x^2 + bx + [m+4] = 0$$

and $x^2 - cx + [m+15] = 0,$

such that $\alpha > S$, *where* $a+b+c=0$ *and*

$$m = \lim_{n\to\infty} \frac{1}{n} \sum_{r=1}^{2n} \frac{r}{\sqrt{(n^2+r^2)}}$$

and [.] denotes the greatest integer function.

Sol. Let α be a common root of the given equations, then

$$\alpha^2 + a\alpha + [m+1] = 0$$

$$\Rightarrow \quad \alpha^2 + a\alpha + [m] + 1 = 0 \qquad \ldots(i)$$

$$\alpha^2 + b\alpha + [m+4] = 0$$

$$\Rightarrow \quad \alpha^2 + b\alpha + [m] + 4 = 0 \qquad \ldots(ii)$$

and $\quad \alpha^2 - c\alpha + [m+15] = 0$

$$\Rightarrow \quad \alpha^2 - c\alpha + [m] + 15 = 0 \qquad \ldots(iii)$$

On adding Eqs. (i) and (ii) and subtracting Eq. (iii), we get

$$a^2 + (a+b+c)\alpha + [m] - 10 = 0$$

$$\alpha^2 + 0 + [m] - 10 = 0 \qquad [\because a+b+c=0]$$

$$\Rightarrow \quad \alpha^2 + [m] - 10 = 0 \qquad \ldots(iv)$$

Also, $\quad m = \lim_{n\to\infty} \frac{1}{n} \sum_{r=1}^{2n} \frac{r}{\sqrt{n^2+r^2}}$

$$= \lim_{n\to\infty} \sum_{r=1}^{2n} \frac{1}{n} \cdot \frac{r/n}{\sqrt{1+(r/n)^2}} = \int_0^2 \frac{x}{\sqrt{(1+x^2)}}\,dx$$

$$[\sqrt{(1+x^2)}]_0^2 = \sqrt{5} - 1$$

Now, $\quad [m] = [\sqrt{5} - 1] = 1$

From Eq. (iv), we get

$$\alpha^2 + 1 - 10 = 0 \Rightarrow \alpha^2 = 9$$

$$\therefore \quad \alpha = \pm 3$$

Now, number of determinants of order 2 having

$$0, 1, 2, 3 = 4! = 24$$

Let $\Delta_1 = \begin{vmatrix} a_1 & a_2 \\ a_3 & a_4 \end{vmatrix}$ be one such determinant and their exists another determinant.

Let $\quad \Delta_2 = \begin{vmatrix} a_3 & a_4 \\ a_1 & a_2 \end{vmatrix}$ [obtained on interchanging R_1 and R_2]

such that $\Delta_1 + \Delta_2 = 0$

$\because S$ = Sum of all the 24 determinants $= 0$

Since, $\quad \alpha > S \Rightarrow \alpha > 0$

$$\therefore \quad \alpha = 3$$

● ***Ex. 45*** *If a_1, a_2, a_3 and $b_1, b_2, b_3 \in R$ and are such that $a_i b_j \neq 1$ for $1 \le i, j \le 3$,*

$$\begin{vmatrix} \frac{1-a_1^3b_1^3}{1-a_1b_1} & \frac{1-a_1^3b_2^3}{1-a_1b_2} & \frac{1-a_1^3b_3^3}{1-a_1b_3} \\ \frac{1-a_2^3b_1^3}{1-a_2b_1} & \frac{1-a_2^3b_2^3}{1-a_2b_2} & \frac{1-a_2^3b_3^3}{1-a_2b_3} \\ \frac{1-a_3^3b_1^3}{1-a_3b_1} & \frac{1-a_3^3b_2^3}{1-a_3b_2} & \frac{1-a_3^3b_3^3}{1-a_3b_3} \end{vmatrix} > 0$$ *provided either*

$a_1 < a_2 < a_3$ and $b_1 < b_2 < b_3$ or $a_1 > a_2 > a_3$ and $b_1 > b_2 > b_3$.

Sol. Since, $\dfrac{x^3 - y^3}{x - y} = \dfrac{(x-y)(x^2 + xy + y^2)}{(x-y)} = x^2 + xy + y^2$

Hence, the given determinant becomes

$$\begin{vmatrix} 1 + a_1b_1 + a_1^2b_1^2 & 1 + a_1b_2 + a_1^2b_2^2 & 1 + a_1b_3 + a_1^2b_3^2 \\ 1 + a_2b_1 + a_2^2b_1^2 & 1 + a_2b_2 + a_2^2b_2^2 & 1 + a_2b_3 + a_2^2b_3^2 \\ 1 + a_3b_1 + a_3^2b_1^2 & 1 + a_3b_2 + a_3^2b_2^2 & 1 + a_3b_3 + a_3^2b_3^2 \end{vmatrix} > 0$$

$$\Rightarrow \quad \begin{vmatrix} 1 & a_1 & a_1^2 \\ 1 & a_2 & a_2^2 \\ 1 & a_3 & a_3^2 \end{vmatrix} \times \begin{vmatrix} 1 & b_1 & a_1^2 \\ 1 & b_2 & b_2^2 \\ 1 & b_3 & b_3^2 \end{vmatrix} > 0$$

$$\Rightarrow \quad (a_1 - a_2)(a_2 - a_3)(a_3 - a_1)(b_1 - b_2)(b_2 - b_3)(b_3 - b_1) > 0$$

$$\left\{ \because \begin{vmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{vmatrix} = (a-b)(b-c)(c-a) \right\}$$

***Case* I** If $a_1 < a_2 < a_3$ and $b_1 < b_2 < b_3$, then

$$(a_1 - a_2) < 0, (a_2 - a_3) < 0$$

and $(b_1 - b_2) < 0, (b_2 - b_3) < 0$

$(a_1 - a_3) < 0$

and $(b_1 - b_3) < 0$

$\therefore \quad (a_3 - a_1) > 0$

$\therefore \quad (b_3 - b_1) > 0$

Then, $(a_1 - a_2)(a_2 - a_3)(a_3 - a_1) > 0$

and $(b_1 - b_2)(b_2 - b_3)(b_3 - b_1) > 0$

$\therefore \quad (a_1 - a_2)(a_2 - a_3)(a_3 - a_1)(b_1 - b_2)(b_2 - b_3)(b_3 - b_1) > 0$

which is true.

***Case* II** If $a_1 > a_2 > a_3$ and $b_1 > b_2 > b_3$

$\therefore \quad a_1 - a_2 > 0, a_2 - a_3 > 0$

and $b_1 - b_2 > 0, b_2 - b_3 > 0$

$a_1 - a_3 > 0 \Rightarrow a_3 - a_1 < 0$

and $b_1 - b_3 > 0 \Rightarrow b_3 - b_1 < 0$

Hence, $(a_1 - a_2)(a_2 - a_3)(a_3 - a_1) < 0$

and $(b_1 - b_2)(b_2 - b_3)(b_3 - b_1) < 0$

$\therefore \quad (a_1 - a_2)(a_2 - a_3)(a_3 - a_1)(b_1 - b_2)(b_2 - b_3)(b_3 - b_1) > 0$

which is true.

● ***Ex. 46*** *Show that a six-digit number abcdef is divisible by 11, if and only if $ab + cd + ef$ is divisible by 11. Hence or otherwise, find one set of values of two-digit numbers x, y and z, so that the value of the determinant* $\begin{vmatrix} x & 23 & 42 \\ 13 & 37 & y \\ 19 & z & 34 \end{vmatrix}$ *is divisible by 99 (without expanding the determinant).*

Sol. Since, $abcdef = ab0000 + cd00 + ef$

$= (9999 + 1)\,ab + (99 + 1)\,cd + ef$

$= 9999\,ab + 99\,cd + ab + cd + ef$

Given, $abcdef$ is divisible by 11, if and only if $ab + cd + ef$ is divisible by 11. Now, let $x = ab$, $y = cd$ and $z = ef$.
[each being a two-digit number]

Again, let $\Delta = \begin{vmatrix} x & 23 & 42 \\ 13 & 37 & y \\ 19 & z & 34 \end{vmatrix} = \begin{vmatrix} ab & 23 & 42 \\ 13 & 37 & cd \\ 19 & ef & 34 \end{vmatrix}$

Applying $R_1 \to R_1 + 100\,R_2 + 10000\,R_3$, we get

$$\Delta = \begin{vmatrix} 1913ab & ef3723 & 34cd42 \\ 13 & 37 & cd \\ 19 & ef & 34 \end{vmatrix}$$

Now, $1913ab$ is divisible by 11, if and only if
$19 + 13 + ab = 32 + ab$ is divisible by $11 \Rightarrow ab = 01, 12, 23, \ldots$

Again, $1913ab$ is divisible by 9, if and only if

$1 + 9 + 1 + 3 + a + b = 14 + a + b$ is divisibe by 9.

The above two conditions are satisfied for $a = 6$, $b = 7$. Thus, $x = 67$. Similarly, $y = 23$ and $z = 39$.

Determinants Exercise 1 :
Single Option Correct Type Questions

■ This section contains **30 multiple choice questions.** Each question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct

1. If $f(n) = \alpha^n + \beta^n$ and $\begin{vmatrix} 3 & 1+f(1) & 1+f(2) \\ 1+f(1) & 1+f(2) & 1+f(3) \\ 1+f(2) & 1+f(3) & 1+f(4) \end{vmatrix}$ $= k(1-\alpha)^2 (1-\beta)^2 (\alpha-\beta)^2$, k^2 d is equal to

(a) 1 (b) -1
(c) $\alpha\beta$ (d) $\alpha\beta\gamma$

2. Let $\Delta(x) = \begin{vmatrix} x+a & x+b & x+a-c \\ x+b & x+c & x-1 \\ x+c & x+d & x-b+d \end{vmatrix}$ and

$\int_0^2 \Delta(x)\,dx = -16$, where a, b, c and d are in AP, then the common difference of the AP is equal to

(a) ± 1 (b) ± 2 (c) ± 3 (d) ± 4

3. If $\Delta(x) = \begin{vmatrix} x & 1+x^2 & x^3 \\ \log_e(1+x^2) & e^x & \sin x \\ \cos x & \tan x & \sin^2 x \end{vmatrix}$, then

(a) $\Delta(x)$ is divisible by x (b) $\Delta(x) = 0$
(c) $\Delta'(x) = 0$ (d) None of these

4. If a, b and c are sides of a triangle and

$\begin{vmatrix} a^2 & b^2 & c^2 \\ (a+1)^2 & (b+1)^2 & (c+1)^2 \\ (a-1)^2 & (b-1)^2 & (c-1)^2 \end{vmatrix} = 0$, then

(a) ΔABC is an equilateral triangle
(b) ΔABC is a right angled isosceles triangle
(c) ΔABC is an isosceles triangle
(d) None of the above

5. If $\begin{vmatrix} \alpha & x & x & x \\ x & \beta & x & x \\ x & x & \gamma & x \\ x & x & x & \delta \end{vmatrix} = f(x) - xf'(x)$, then $f(x)$ is equal to

(a) $(x-\alpha)(x-\beta)(x-\gamma)(x-\delta)$
(b) $(x+\alpha)(x+\beta)(x+\gamma)(x+\delta)$
(c) $2(x-\alpha)(x-\beta)(x-\gamma)(x-\delta)$
(d) None of the above

6. If $\begin{vmatrix} a & b-c & c+b \\ a+c & b & c-a \\ a-b & a+b & c \end{vmatrix} = 0$, the line $ax + by + c = 0$ passes through the fixed point which is

(a) (1, 2) (b) (1, 1) (c) (– 2, 1) (d) (1, 0)

7. If $f(x) = a + bx + cx^2$ and α, β and γ are the roots of the equation $x^3 = 1$, then $\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}$ is equal to

(a) $f(\alpha) + f(\beta) + f(\gamma)$
(b) $f(\alpha) f(\beta) + f(\beta) f(\gamma) + f(\gamma) f(\alpha)$
(c) $f(\alpha) f(\beta) f(\gamma)$
(d) $-f(\alpha) f(\beta) f(\gamma)$

8. When the determinant $\begin{vmatrix} \cos 2x & \sin^2 x & \cos 4x \\ \sin^2 x & \cos 2x & \cos^2 x \\ \cos 4x & \cos^2 x & \cos 2x \end{vmatrix}$ is expanded in powers of $\sin x$, the constant term in that expression is

(a) 1 (b) 0 (c) -1 (d) 2

9. If [ ] denotes the greatest integer less than or equal to the real number under consideration and $-1 \le x < 0, 0 \le y < 1, 1 \le z < 2$, the value of the determinant $\begin{vmatrix} [x]+1 & [y] & [z] \\ [x] & [y]+1 & [z] \\ [x] & [y] & [z]+1 \end{vmatrix}$ is

(a) $[x]$ (b) $[y]$
(c) $[z]$ (d) None of these

10. The determinant $\begin{vmatrix} y^2 & -xy & x^2 \\ a & b & c \\ a' & b' & c' \end{vmatrix}$ is equal to

(a) $\begin{vmatrix} bx+ay & cx+by \\ b'x+a'y & c'x+b'y \end{vmatrix}$ (b) $\begin{vmatrix} a'x+b'y & bx+cy \\ ax+by & b'x+c'y \end{vmatrix}$

(c) $\begin{vmatrix} bx+cy & ax+by \\ b'x+c'y & a'x+b'y \end{vmatrix}$ (d) $\begin{vmatrix} ax+by & bx+cy \\ a'x+b'y & b'x+c'y \end{vmatrix}$

11. If A, B and C are angles of a triangle, the value of $\begin{vmatrix} e^{2iA} & e^{-iC} & e^{-iB} \\ e^{-iC} & e^{2iB} & e^{-iA} \\ e^{-iB} & e^{-iBA} & e^{2iC} \end{vmatrix}$ is (where $i = \sqrt{-1}$)

(a) 1 (b) -1 (c) -2 (d) -4

12. If $\begin{vmatrix} x^n & x^{n+2} & x^{2n} \\ 1 & x^a & a \\ x^{n+5} & x^{a+6} & x^{2n+5} \end{vmatrix} = 0, \forall\ x \in R$, where $n \in N$, the value of a is

(a) n (b) $n-1$
(c) $n+1$ (d) None of these

13. If x, y and z are the integers in AP lying between 1 and 9 and $x\,51, y\,41$ and $z\,31$ are three digits number, the value of $\begin{vmatrix} 5 & 4 & 3 \\ x\,51 & y\,41 & z\,31 \\ x & y & z \end{vmatrix}$ is

(a) $x + y + z$
(b) $x - y + z$
(c) 0
(d) None of the above

14. If $a_1\,b_1\,c_1, a_2\,b_2\,c_2$ and $a_3 b_3 c_3$ are three digit even natural numbers and $\Delta = \begin{vmatrix} c_1 & a_1 & b_1 \\ c_2 & a_2 & b_2 \\ c_3 & a_3 & b_3 \end{vmatrix}$, then Δ is

(a) divisible by 2 but not necessarily by 4
(b) divisible by 4 but not necessarily by 8
(c) divisible by 8
(d) None of the above

15. If a, b and c are sides of ΔABC such that

$$\begin{vmatrix} c & b\cos B + c\beta & a\cos A + b\alpha + c\gamma \\ a & c\cos B + a\beta & b\cos A + c\alpha + a\gamma \\ b & a\cos B + b\beta & c\cos A + a\alpha + b\gamma \end{vmatrix} = 0$$

$\left(\text{where } \alpha, \beta, \gamma \in R^+ \text{ and } \angle A, \angle B, \angle C \neq \dfrac{\pi}{2}\right)$, ΔABC is

(a) an isosceles (b) an equilateral
(c) can't say (d) None of these

16. If x_1, x_2 and y_1, y_2 are the roots of the equations $3x^2 - 18x + 9 = 0$ and $y^2 - 4y + 2 = 0$, the value of the determinant $\begin{vmatrix} x_1x_2 & y_1y_2 & 1 \\ x_1 + x_2 & y_1 + y_2 & 2 \\ \sin(\pi x_1x_2) & \cos(\pi/2 y_1y_2) & 1 \end{vmatrix}$ is

(a) 0 (b) 1
(c) 2 (d) None of these

17. If the value of $\Delta = \begin{vmatrix} {}^{10}C_4 & {}^{10}C_5 & {}^{11}C_m \\ {}^{11}C_6 & {}^{11}C_7 & {}^{12}C_{m+2} \\ {}^{12}C_8 & {}^{12}C_9 & {}^{13}C_{m+4} \end{vmatrix}$ is equal to zero, then m is equal to

(a) 6 (b) 4
(c) 5 (d) None of these

18. The value of the determinant $\begin{vmatrix} 1 & \sin(\alpha - \beta)\theta & \cos(\alpha - \beta)\theta \\ a & \sin\alpha\theta & \cos\alpha\theta \\ a^2 & \sin(\alpha - \beta)\theta & \cos(\alpha - \beta)\theta \end{vmatrix}$ is independent of

(a) α (b) β
(c) θ (d) a

19. If $f(x)$, $g(x)$ and $h(x)$ are polynomials of degree 4 and $\begin{vmatrix} f(x) & g(x) & h(x) \\ a & b & c \\ p & q & r \end{vmatrix} = mx^4 + nx^3 + rx^2 + sx + t$ be an identity in x, then $\begin{vmatrix} f'''(0) - f''(0) & g'''(0) - g''(0) & h'''(0) - h''(0) \\ a & b & c \\ p & q & r \end{vmatrix}$ is equal to

(a) $2(3n + r)$ (b) $3(2n - r)$
(c) $3(2n + r)$ (d) $2(3n - r)$

20. If $f(x) = \begin{vmatrix} \cos(x + \alpha) & \cos(x + \beta) & \cos(x + \gamma) \\ \sin(x + \alpha) & \sin(x + \beta) & \sin(x + \gamma) \\ \sin(\beta - \gamma) & \sin(\gamma - \alpha) & \sin(\alpha - \beta) \end{vmatrix}$, then $f(\theta) - 2f(\phi) + f(\psi)$ is equal to

(a) 0 (b) $\alpha - \beta$
(c) $\alpha + \beta + \gamma$ (d) $\alpha + \beta - \gamma$

21. If $\begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^3 & b^3 & c^3 \end{vmatrix} = (a - b)(b - c)(c - a)(a + b + c)$, where a, b and c are all different, then the determinant $\begin{vmatrix} 1 & 1 & 1 \\ (x - a)^2 & (x - b)^2 & (x - c)^2 \\ (x - b)(x - c) & (x - c)(x - a) & (x - a)(x - b) \end{vmatrix}$ vanishes when

(a) $a + b + c = 0$ (b) $x = \dfrac{1}{3}(a + b + c)$
(c) $x = \dfrac{1}{2}(a + b + c)$ (d) $x = a + b + c$

22. Let $a, b, c \in R$ such that no two of them are equal and satisfy $\begin{vmatrix} 2a & b & c \\ b & c & 2a \\ c & 2a & b \end{vmatrix} = 0$, the equation $24ax^2 + 4bx + c = 0$ has

(a) atleast one root in $\left[0, \dfrac{1}{2}\right]$
(b) atleast one root in $\left[-\dfrac{1}{2}, \dfrac{1}{2}\right]$
(c) atleast one root in $[-1, 0]$
(d) atleast two roots in $[0, 2]$

23. The number of positive integral solution of the equation $\begin{vmatrix} x^3 + 1 & x^2y & x^2z \\ xy^2 & y^3 + 1 & y^2z \\ xz^2 & yz^2 & z^3 + 1 \end{vmatrix} = 11$ is

(a) 0 (b) 3 (c) 6 (d) 12

24. If $f(x) = ax^2 + bx + c, a, b, c \in R$ and equation $f(x) - x = 0$ has imaginary roots $\alpha, \beta\ \gamma$ and δ be the roots of $f(f(x)) - x = 0$, then $\begin{vmatrix} 2 & \alpha & \delta \\ \beta & 0 & \alpha \\ \gamma & \beta & 1 \end{vmatrix}$ is

(a) 0 (b) purely real
(c) purely imaginary (d) None of these

25. If the system of equations $2x - y + z = 0$, $x - 2y + z = 0$, $tx - y + 2z = 0$ has infinitely many solutions and $f(x)$ be a continuous function, such that $f(5 + x) + f(x) = 2$, then $\int_0^{-2t} f(x)\,dx$ is equal to

(a) 0 (b) $-2t$ (c) 5 (d) t

26. If $(1 + ax + bx^2)^4 = a_0 + a_1 x + a_2 x^2 + \ldots + a_8 x^8$, where $a, b, a_0, a_1, \ldots, a_8 \in R$ such that $a_0 + a_1 + a_2 \neq 0$ and $\begin{vmatrix} a_0 & a_1 & a_2 \\ a_1 & a_2 & a_0 \\ a_2 & a_0 & a_1 \end{vmatrix} = 0$, then

(a) $a = \frac{3}{4}, b = \frac{5}{8}$ (b) $a = \frac{1}{4}, b = \frac{5}{32}$
(c) $a = 1, b = \frac{2}{3}$ (d) None of these

27. Given, $f(x) = \log_{10} x$ and $g(x) = e^{\pi i x}$.
If $\phi(x) = \begin{vmatrix} f(x)\cdot g(x) & (f(x))^{g(x)} & 1 \\ f(x^2)\cdot g(x^2) & (f(x^2))^{g(x^2)} & 0 \\ f(x^3)\cdot g(x^3) & (f(x^3))^{g(x^3)} & 1 \end{vmatrix}$, the value of $\phi(10)$, is

(a) 1 (b) 2 (c) 0 (d) None of these

28. The value of the determinant $\begin{vmatrix} 1 & (\alpha^{2x} - \alpha^{-2x})^2 & (\alpha^{2x} + \alpha^{-2x})^2 \\ 1 & (\beta^{2x} - \beta^{-2x})^2 & (\beta^{2x} + \beta^{-2x})^2 \\ 1 & (\gamma^{2x} - \gamma^{-2x})^2 & (\gamma^{2x} + \gamma^{-2x})^2 \end{vmatrix}$, is

(a) 0 (b) $(\alpha\beta\gamma)^{2x}$ (c) $(\alpha\beta\gamma)^{-2x}$ (d) None of these

29. If a, b and c are non-zero real numbers and if the equations $(a-1)x = y + z, (b-1)y = z + x$, $(c-1)z = x + y$ has a non-trivial solution, then $ab + bc + ca$ equals to

(a) $a + b + c$ (b) abc (c) 1 (d) None of these

30. The set of equations $\lambda x - y + (\cos\theta) z = 0$, $3x + y + 2z = 0, (\cos\theta) x + y + 2z = 0, 0 \le \theta \le 2\pi$, has non-trivial solution(s)

(a) for no value of λ and θ
(b) for all value of λ and θ
(c) for all values of λ and only two values of θ
(d) for only one value of λ and all values of θ

Determinants Exercise 2 : More than One Correct Option Type Questions

■ This section contains **15 multiple choice questions**. Each question has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

31. The determinant $\Delta = \begin{vmatrix} a^2 + x^2 & ab & ac \\ ab & b^2 + x^2 & bc \\ ac & bc & c^2 + x^2 \end{vmatrix}$ is divisible by

(a) x (b) x^2 (c) x^3 (d) x^4

32. The value of the determinant $\begin{vmatrix} \sqrt{6} & 2i & 3 + \sqrt{6} \\ \sqrt{12} & \sqrt{3} + \sqrt{8}i & 3\sqrt{2} + \sqrt{6}\,i \\ \sqrt{18} & \sqrt{2} + \sqrt{12}\,i & \sqrt{27} + 2i \end{vmatrix}$, is (where $i = \sqrt{-1}$)

(a) complex (b) real (c) irrational (d) rational

33. If $D_k = \begin{vmatrix} 2^{k-1} & \frac{1}{k(k+1)} & \sin k\theta \\ x & y & z \\ 2^n - 1 & \frac{n}{n+1} & \frac{\sin\left(\frac{n+1}{2}\right)\theta \sin\frac{n}{2}\theta}{\sin\frac{\theta}{2}} \end{vmatrix}$, then $\sum_{k=1}^{n} D_k$ is equal to

(a) 0 (b) independent of n
(c) independent of θ (d) independent of x, y and z

34. The determinant $\begin{vmatrix} a & b & a\alpha + b \\ b & c & b\alpha + c \\ a\alpha + b & b\alpha + c & 0 \end{vmatrix}$ is equal to zero, if

(a) a, b and c are in AP
(b) a, b, c, are in GP
(c) a, b and c are in HP
(d) $(x - \alpha)$ is a factor of $ax^2 + 2bx + c$

35. Let $f(x) = \begin{vmatrix} 2\cos x & 1 & 0 \\ 1 & 2\cos x & 1 \\ 0 & 1 & 2\cos x \end{vmatrix}$, then

(a) $f\left(\frac{\pi}{3}\right) = -1$

(b) $f'\left(\frac{\pi}{3}\right) = \sqrt{3}$

(c) $\int_0^{\pi} f(x)dx = 0$

(d) $\int_{-\pi}^{\pi} f(x)\,dx = 0$

36. If $\Delta(x)=\begin{vmatrix} x^2-5x+3 & 2x-5 & 3 \\ 3x^2+x+4 & 6x+1 & 9 \\ 7x^2-6x+9 & 14x-6 & 21 \end{vmatrix}$
$= ax^3+bx^2+cx+d$, then
(a) $a=0$ (b) $b=0$ (c) $c=0$ (d) $d=47$

37. If a, b and c are the sides of a triangle and A, B and C are the angles opposite to a, b and c respectively, then
$\Delta=\begin{vmatrix} a^2 & b\sin A & C\sin A \\ b\sin A & 1 & \cos A \\ C\sin A & \cos A & 1 \end{vmatrix}$ is independent of
(a) a (b) b (c) c (d) A, B, C

38. Let $f(a,b)=\begin{vmatrix} a & a^2 & 0 \\ 1 & (2a+b) & (a+b)^2 \\ 0 & 1 & (2a+3b) \end{vmatrix}$, then
(a) $(a+b)$ is a factor of $f(a,b)$
(b) $(a+2b)$ is a factor of $f(a,b)$
(c) $(2a+b)$ is a factor of $f(a,b)$
(d) a is a factor of $f(a,b)$

39. If $f(x)=\begin{vmatrix} \sec^2 x & 1 & 1 \\ \cos^2 x & \cos^2 x & \operatorname{cosec}^2 x \\ 1 & \cos^2 x & \cot^2 x \end{vmatrix}$, then
(a) $\int_{-\pi/4}^{\pi/4} f(x)\,dx=\frac{1}{16}(3\pi+8)$
(b) $f'\left(\frac{\pi}{2}\right)=0$
(c) maximum value of $f(x)$ is 1
(d) minimum value of $f(x)$ is 0

40. If $\begin{vmatrix} a & a+x^2 & a+x^2+x^4 \\ 2a & 3a+2x^2 & 4a+3x^2+2x^4 \\ 3a & 6a+3x^2 & 10a+6x^2+3x^4 \end{vmatrix}$
$= a_0+a_1x+a_2x^2+a_3x^3+a_4x^4+a_5x^5+a_6x^6+a_7x^7$ and
$f(x)=+a_0x^2+a_3x+a_6$, then
(a) $f(x)\geq 0, \forall\ x\in R$ if $a>0$
(b) $f(x)=0$, only if $a=0$
(c) $f(x)=0$, has two equal roots
(d) $f(x)=0$, has more than two root if $a=0$

41. If $\Delta(x)=\begin{vmatrix} 4x-4 & (x-2)^2 & x^3 \\ 8x-4\sqrt{2} & (x-2\sqrt{2})^2 & (x+1)^3 \\ 12x-4\sqrt{3} & (x-2\sqrt{3})^2 & (x-1)^3 \end{vmatrix}$, then
(a) term independent of x in $\Delta(x)=16(5-\sqrt{2}-\sqrt{3})$
(b) coefficient of x in $\Delta(x)=48(1+\sqrt{2}-\sqrt{3})$
(c) coefficient of x in $\Delta(x)=16(5+\sqrt{2}-\sqrt{3})$
(d) coefficient of x in $\Delta(x)$ is divisible by 16

42. If
$f(x)=\begin{vmatrix} 3 & 3x & 3x^2+2a^2 \\ 3x & 3x^2+2a^2 & 3x^3+6a^2x \\ 3x^2+2a^3 & 3x^3+6a^2x & 3x^4+12a^2x^2+2a^4 \end{vmatrix}$,
then
(a) $f'(x)=0$
(b) $y=f(x)$ is a straight line parallel to X-axis
(c) $\int_0^2 f(x)\,dx=32a^4$
(d) None of the above

43. If $a>b>c$ and the system of equations $ax+by+cz=0$, $bx+cy+az=0$, $cx+ay+bz=0$ has a non-trivial solution, then both the roots of the quadratic equation at^2+bt+c, are
(a) real
(b) of opposite sign
(c) positive
(d) complex

44. The values of λ and b for which the equations $x+y+z=3$, $x+3y+2z=6$ and $x+\lambda y+3z=b$ have
(a) a unique solution, if $\lambda\neq 5$, $b\in R$
(b) no solution, if $\lambda\neq 5$, $b=9$
(c) infinite many solution, $\lambda=5$, $b=9$
(d) None of the above

45. Let λ and α be real. Let S denote the set of all values of λ for which the system of linear equations
$\lambda x+(\sin\alpha)y+(\cos\alpha)z=0$
$x+(\cos\alpha)y+(\sin\alpha)z=0$
$-x+(\sin\alpha)y-(\cos\alpha)z=0$
has a non-trivial solution, then S contains
(a) $(-1,1)$ (b) $[-\sqrt{2},-1]$
(c) $[1,\sqrt{2}]$ (d) $(-2,2)$

Determinants Exercise 3 : Passage Based Questions

- This section contains **7 passages**. Based upon each of the passage **3 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I

(Q. Nos. 46 to 48)

Consider the system of equations

$x + y + z = 5;\ x + 2y + 3z = 9;\ x + 3y + \lambda z = \mu$

The system is called smart, brilliant, good and lazy according as it has solution, unique solution, infinitely many solutions and no solution, respectively.

46. The system is smart, if

(a) $\lambda \neq 5$ or $\lambda = 5$ and $\mu = 13$ (b) $\lambda \neq 5$ and $\mu = 13$

(c) $\lambda \neq 5$ and $\mu \neq 13$ (d) $\lambda \neq 5$ or $\lambda = 5$ and $\mu \neq 13$

47. The system is good, if

(a) $\lambda \neq 5$ or $\lambda = 5$ and $\mu = 13$ (b) $\lambda = 5$ and $\mu = 13$

(c) $\lambda = 5$ and $\mu \neq 13$

(d) $\lambda \neq 5$, μ is any real number

48. The system is lazy, if

(a) $\lambda \neq 5$ or $\lambda = 5$ and $\mu = 13$ (b) $\lambda = 5$ and $\mu = 13$

(c) $\lambda = 5$ and $\mu \neq 13$ (d) $\lambda \neq 5$ or $\lambda = 5$ and $\mu \neq 13$

Passage II

(Q. Nos. 49 to 51)

If $\Delta = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$ *and* $C_{ij} = (-1)^{i+j} M_{ij}$, *where* M_{ij} *is a determinant obtained by deleting ith row and jth column, then* $\begin{vmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{vmatrix} = \Delta^2$.

49. If $\begin{vmatrix} 1 & x & x^2 \\ x & x^2 & 1 \\ x^2 & 1 & x \end{vmatrix} = 5$ and $\Delta = \begin{vmatrix} x^3 - 1 & 0 & x - x^4 \\ 0 & x - x^4 & x^3 - 1 \\ x - x^4 & x^3 - 1 & 0 \end{vmatrix}$, then sum of digits of Δ^2, is

(a) 7 (b) 8 (c) 13 (d) 11

50. Suppose $a, b, c \in R,\ a + b + c > 0,\ A = bc - a^2, B = ca - b^2$ and $C = ab - c^2$ and $\begin{vmatrix} A & B & C \\ B & C & A \\ C & A & B \end{vmatrix} = 49$, then the value of $a^3 + b^3 + c^3 - 3abc$, is

(a) –7 (b) 7 (c) –2401 (d) 2401

51. If $a^3 + b^3 + c^3 - 3abc = -3$ and $A = bc - a^2,\ B = ca - b^2$ and $C = ab - c^2$, then the value of $aA + bB + cC$, is

(a) –3 (b) 3 (c) –9 (d) 9

Passage III

(Q. Nos. 52 to 54)

If α, β, γ *are the roots of* $x^3 + 2x^2 - x - 3 = 0$

52. The value of $\begin{vmatrix} \alpha & \beta & \gamma \\ \gamma & \alpha & \beta \\ \beta & \gamma & \alpha \end{vmatrix}$ is equal to

(a) 14 (b) –2 (c) 10 (d) 14

53. If the absolute value of the expression $\frac{\alpha - 1}{\alpha + 2} + \frac{\beta - 1}{\beta + 2} + \frac{\gamma - 1}{\gamma + 2}$ can be expressed as $\frac{m}{n}$, where m and n are co-prime, the value of $\begin{vmatrix} m & n^2 \\ m - n & m + n \end{vmatrix}$, is

(a) 17 (b) 27 (c) 37 (d) 47

54. If $a = \alpha^2 + \beta^2 + \gamma^2,\ b = \alpha\beta + \beta\gamma + \gamma\alpha$, the value of $\begin{vmatrix} a & b & b \\ b & a & b \\ b & b & a \end{vmatrix}$, is

(a) 14 (b) 49 (c) 98 (d) 196

Passage IV

(Q. Nos. 55 to 57)

Suppose $f(x)$ *is a function satisfying the following conditions:*

(i) $f(0) = 2,\ f(1) = 1$

(ii) $f(x)$ *has a minimum value at* $x = \frac{5}{2}$

(iii) For all $x, f'(x) = \begin{vmatrix} 2ax & 2ax - 1 & 2ax + b + 1 \\ b & b + 1 & -1 \\ 2(ax + b) & 2ax + 2b + 1 & 2ax + b \end{vmatrix}$.

55. The value of $f(2) + f(3)$ is

(a) 1 (b) $\frac{3}{2}$ (c) 2 (d) $\frac{5}{2}$

56. The number of solutions of the equation $f(x) + 1 = 0$ is

(a) 0 (b) 1 (c) 2 (d) infinite

57. Range of $f(x)$ is

(a) $\left(-\infty, \frac{7}{16}\right]$ (b) $\left[\frac{3}{4}, \infty\right)$ (c) $\left[\frac{7}{16}, \infty\right)$ (d) $\left(-\infty, \frac{3}{4}\right]$

Passage V

(Q. Nos. 58 to 60)

$$If \begin{vmatrix} x & e^{x-1} & (x-1)^3 \\ x-\ln x & \cos(x-1) & (x-1)^2 \\ \tan x & \sin^2 x & \cos^2 x \end{vmatrix} = a_0 + a_1(x-1) + a_2(x-1)^2 + \ldots$$

58. The value of $\cos^{-1}(a_1)$, is

(a) 0 (b) $\frac{\pi}{4}$ (c) $\frac{\pi}{2}$ (d) π

59. The value of $\lim_{x \to a_0} (\sin x)^x$ is

(a) 1 (b) e (c) $e-1$ (d) None of these

60. The equation whose roots are a_0 and a_1, is

(a) $x^2 - x = 0$ (b) $x^2 - 2x = 0$
(c) $x^2 - 3x = 0$ (d) None of these

Passage VI

(Q. Nos. 61 to 63)

$$Let\ \Delta = \begin{vmatrix} -bc & b^2+bc & c^2+bc \\ a^2+ac & -ac & c^2+ac \\ a^2+ab & b^2+ab & -ab \end{vmatrix}\ and\ the\ equation$$

$x^3 - px^2 + qx - r = 0$ *has roots* $a,\ b,\ c$, *where* $a, b, c \notin R^+$.

61. The value of Δ is

(a) $\le 9r^3$ (b) $\ge 27r^2$ (c) $\le 27r^2$ (d) $\ge 81r^3$

62. If a, b, c are in GP, then

(a) $r^3 = p^3 q$ (b) $p^3 = r^3 q$ (c) $p^3 = q^3 r$ (d) $q^3 = p^3 r$

63. If $\Delta = 27$ and $a^2 + b^2 + c^2 = 2$, then the value of $\sum a^2 b$, is

(a) $3(2\sqrt{2} - p)$ (b) $3(2\sqrt{2} - r)$
(c) $3(2\sqrt{2} - q)$ (d) $3(2\sqrt{2} - p - q)$

Passage VII

(Q. Nos. 64 to 66)

$$If\ \Delta n = \begin{vmatrix} a^2+n & ab & ac \\ ab & b^2+n & bc \\ ac & bc & c^2+n \end{vmatrix},\ n \in N\ and\ the\ equation$$

$x^3 - \lambda x^2 + 11x - 6 = 0$ *has roots* $a,\ b,\ c$ *and* a, b, c *are in AP.*

64. The value of $\sum_{r=1}^{7} \Delta_n$ is

(a) $(12)^3$ (b) $(14)^3$ (c) $(26)^3$ (d) $(28)^3$

65. The value of $\frac{\Delta 2_n}{\Delta_n}$ is

(a) < 8 (b) = 8
(c) > 8 (d) None of these

66. The value of $\sum_{r=1}^{30} \left(\frac{27\Delta_r - \Delta 3_r}{27r^2} \right)$ is

(a) 130 (b) 190 (c) 280 (d) 340

Determinants Exercise 4 : Single Integer Answer Type Questions

- This section contains **10 questions**. The answer to each question is a **single digit integer**, ranging from 0 to 9 (both inclusive).

67. If $\begin{vmatrix} 3^2+k & 4^2 & 3^2+3+k \\ 4^2+k & 5^2 & 4^2+4+k \\ 5^2+k & 6^2 & 5^2+5+k \end{vmatrix} = 0$,

the value of $\sqrt{2^k \sqrt{2^k \sqrt{2^k \ldots \infty}}}$ is

68. Let α, β and γ are three distinct roots of

$\begin{vmatrix} x-1 & -6 & 2 \\ -6 & x-2 & -4 \\ 2 & -4 & x-6 \end{vmatrix} = 0$, the value of $\left(\frac{1}{\alpha} + \frac{1}{\beta} + \frac{1}{\gamma} \right)^{-1}$ is

69. If $\begin{vmatrix} x & e^{x-1} & (x-1)^3 \\ x-\ln x & \cos(x-1) & (x-1)^2 \\ \tan x & \sin^2 x & \cos^2 x \end{vmatrix} = \sum_{r=0}^{n} a_r (x-1)^r$,

the value of $(2^{a_0} + 3^{a_1})^{a_1 + 1}$ is

70. If $\begin{vmatrix} 1 & \cos\alpha & \cos\beta \\ \cos\alpha & 1 & \cos\gamma \\ \cos\beta & \cos\gamma & 1 \end{vmatrix} = \begin{vmatrix} 0 & \cos\alpha & \cos\beta \\ \cos\alpha & 0 & \cos\gamma \\ \cos\beta & \cos\gamma & 0 \end{vmatrix}$,

$\cos^2\alpha + \cos^2\beta + \cos^2\gamma$ is equal to

71. Let $f(a, b, c) = \begin{vmatrix} (b+c)^2 & a^2 & a^2 \\ b^2 & (c+a)^2 & b^2 \\ c^2 & c^2 & (a+b)^2 \end{vmatrix}$, the greatest integer $n \in N$ such that $(a+b+c)^{n'}$ divides $f(a, b, c)$ is

72. If $0 \le \theta \le \pi$ and the system of equations

$$x = (\sin\theta)\, y + (\cos\theta)\, z$$
$$y = z + (\cos\theta)\, x$$
$$z = (\sin\theta)\, x + y$$

has a non-trivial solution, then $\frac{8\theta}{\pi}$ is equal to

73. The value of the determinant $\begin{vmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{vmatrix}$ is

74. If a, b, c and d are the roots of the equation $x^4 + 2x^3 + 4x^2 + 8x + 16 = 0$, the value of the determinant $\begin{vmatrix} 1+a & 1 & 1 & 1 \\ 1 & 1+b & 1 & 1 \\ 1 & 1 & 1+c & 1 \\ 1 & 1 & 1 & 1+d \end{vmatrix}$ is

75. If $a \neq 0, b \neq 0, c \neq 0$ and $\begin{vmatrix} 1+a & 1 & 1 \\ 1+b & 1+2b & 1 \\ 1+c & 1+c & 1+3c \end{vmatrix} = 0$, the value of $|a^{-1} + b^{-1} + c^{-1}|$ is equal to

76. If the system of equations
$$ax + hy + g = 0; hx + by + f = 0$$
and $ax^2 + 2hxy + by^2 + 2gx + 2fy + c + \lambda = 0$ has a unique solution and
$\dfrac{abc + 2fgh - af^2 - bg^2 - ch^2}{h^2 - ab} = 8$, the value of λ is

Determinants Exercise 5 : Matching Type Questions

■ This section contains **5 questions**. Questions 77 to 81 have three statements (A, B and C) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

77.

	Column I		Column II
(A)	If a,b,c are three complex numbers such that $a^2+b^2+c^2=0$ and $\begin{vmatrix} b^2+c^2 & ab & ac \\ ab & c^2+a^2 & bc \\ ac & bc & a^2+b^2 \end{vmatrix} = \lambda a^2b^2c^2$, then λ is divisible by	(p)	2
(B)	If $a,b,c \in R$ and $\begin{vmatrix} a & a+b & a+b+c \\ 2a & 5a+2b & 7a+5b+2c \\ 3a & 7a+3b & 9a+7b+3c \end{vmatrix} = -1024$, then a is divisible by	(q)	3
(C)	Let $\Delta(x) = \begin{vmatrix} x-1 & 2x^2-5 & x^3-1 \\ 2x^2+5 & 2x+2 & x^3+3 \\ x^3-1 & x+1 & 3x^2-2 \end{vmatrix}$ and $ax+b$ be the remainder, when $\Delta(x)$ is divided by x^2-1, then $4a+2b$ is divisible by	(r)	4
		(s)	5
		(t)	6

78.

	Column I		Column II
(A)	Let $f_1(x) = x + a_1$, $f_2(x) = x^2 + b_1x + b_2$, $x_1 = 2$, $x_2 = 3$ and $x_3 = 5$ and $\Delta = \begin{vmatrix} 1 & 1 & 1 \\ f_1(x_1) & f_1(x_2) & f_1(x_3) \\ f_2(x_1) & f_2(x_2) & f_2(x_3) \end{vmatrix}$, then Δ is	(p)	Even number
(B)	If $\lvert a_1 - b_1 \rvert = 6$ and $f(x) = \begin{vmatrix} 1 & b_1 & a_1 \\ 1 & b_1 & 2a_1 - x \\ 1 & 2b_1 - x & a_1 \end{vmatrix}$, then the minimum value of $f(x)$ is	(q)	Prime number
(C)	If coefficient of x in $f(x) = \begin{vmatrix} x-2 & (x-1)^2 & x^3 \\ x-1 & x^2 & (x+1)^3 \\ x & (x+1)^2 & (x+2)^3 \end{vmatrix}$ is λ, then $\lvert\lambda\rvert$ is	(r)	Odd number
		(s)	Composite number
		(t)	Perfect number

79.

	Column I		Column II	
(A)	If $\begin{vmatrix} x^2+3x & x-1 & x+3 \\ x^2+1 & 2+3x & x-3 \\ x^2-3 & x+4 & 3x \end{vmatrix} = ax^4+bx^3+cx^2+dx+e$, then $e+a$ is divisible by	(p)	2
(B)	If $\begin{vmatrix} x-1 & 5x & 7 \\ x^2-1 & x-1 & 8 \\ 2x & 3x & 0 \end{vmatrix} = ax^3+bx^2+cx+d$, then $(e+a-3)$ is divisible by	(q)	3
(C)	If $\begin{vmatrix} x^3+4x & x+3 & x-2 \\ x-2 & 5x & x-1 \\ x-3 & x+2 & 4x \end{vmatrix} = ax^5+bx^4+cx^3+dx^2+ex+f$, then $(f+e)$ is divisible by	(r)	5
		(s)	6
		(t)	7

80.

	Column I		Column II
(A)	If $a^2+b^2+c^2=1$ and $\Delta = \begin{vmatrix} a^2+(b^2+c^2)d & ab(1-d) & ca(1-d) \\ ab(1-d) & b^2+(c^2+a^2)d & bc(1-d) \\ ca(1-d) & bc(1-d) & c^2+(a+b^2)d \end{vmatrix}$, then Δ is	(p)	independent of a
(B)	If $\Delta = \begin{vmatrix} \frac{1}{c} & \frac{1}{c} & \frac{-(a+b)}{c^2} \\ \frac{-(b+c)}{a^2} & \frac{1}{a} & \frac{1}{a} \\ \frac{-bd(b+c)}{a^2c} & \frac{(ad+2bd+cd)}{ac} & \frac{-(a+b)bd}{ac^2} \end{vmatrix}$, then Δ is	(q)	independent of b
(C)	If $\Delta = \begin{vmatrix} \sin a & \cos a & \sin(a+d) \\ \sin b & \cos b & \sin(b+d) \\ \sin c & \cos c & \sin(c+d) \end{vmatrix}$, then Δ is	(r)	independent of c
		(s)	independent of d
		(t)	zero

81.

	Column I		Column II
(A)	If n be the number of distinct values of 2×2 determinant whose entries are from the set $\{-1,0,1\}$, then $(n-1)^2$ is divisible by	(p)	2
(B)	If n be the number of 2×2 determinants with non-negative values whose entries from the set $\{0,1\}$, then $(n-1)$ is divisible by	(q)	3
(C)	If n be the number of 2×2 determinants with negative values whose entries from the set $\{-1, 1\}$, then $n(n+1)$ is divisible by	(r)	4
		(s)	5
		(t)	6

Determinants Exercise 6 : Statement I and II Type Questions

■ **Directions** (Q. Nos. 82 to 87) are Assertion-Reason type questions. Each of these questions contains two statements:

Statement-1 (Assertion) and **Statement-2** (Reason) Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(c) Statement1 is true, Statement-2 is false

(d) Statement-1 is false, Statement-2 is true

82. **Statement-1** If $\Delta(r)=\begin{vmatrix} r & r+1 \\ r+3 & r+4 \end{vmatrix}$ then $\sum_{r=1}^{n}\Delta(r)=-3n$

Statement-2 If $\Delta(r)=\begin{vmatrix} f_1(r) & f_2(r) \\ f_3(r) & f_4(r) \end{vmatrix}$

then $\sum_{r=1}^{n}\Delta(r)=\begin{vmatrix} \sum_{r=1}^{n} f_1(r) & \sum_{r=1}^{n} f_2(r) \\ \sum_{r=1}^{n} f_3(r) & \sum_{r=1}^{n} f_4(r) \end{vmatrix}$

83. Consider the determinant

$$\Delta=\begin{vmatrix} a_1+b_1x^2 & a_1x^2+b_1 & c_1 \\ a_2+b_2x^2 & a_2x^2+b_2 & c_2 \\ a_3+b_3x^2 & a_3x^2+b_3 & c_3 \end{vmatrix}=0,$$

where $a_i, b_i, c_i \in R (i=1,2,3)$ and $x \in R$.

Statement-1 The value of x satisfying $\Delta=0$ are $x=1,-1$

Statement-2 If $\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}=0$, then $\Delta=0$.

84. **Statement-1** The value of determinant

$$\begin{vmatrix} \sin\pi & \cos\left(x+\frac{\pi}{4}\right) & \tan\left(x-\frac{\pi}{4}\right) \\ \sin\left(x-\frac{\pi}{4}\right) & -\cos\left(\frac{\pi}{2}\right) & \ln\left(\frac{x}{y}\right) \\ \cot\left(\frac{\pi}{4}+x\right) & \ln\left(\frac{y}{x}\right) & \tan\pi \end{vmatrix}$$ is zero.

Statement-2 The value of skew-symmetric determinant of odd order equals zero.

85. **Statement-1** $f(x)=\begin{vmatrix} (1+x)^{11} & (1+x)^{12} & (1+x)^{13} \\ (1+x)^{21} & (1+x)^{22} & (1+x)^{23} \\ (1+x)^{31} & (1+x)^{32} & (1+x)^{33} \end{vmatrix}$,

the coefficient of x in $f(x)=0$

Statement-2 If $P(x)=a_0+a_1x+a_2x^2+a_3x^3+\ldots+a_nx^n$, then $a_1=P'(0)$, where dash denotes the differential coefficient.

86. **Statement-1** If system of equations $2x+3y=a$ and $bx+4y=5$ has infinite solution, then $a=\frac{15}{4}, b=\frac{8}{5}$

Statement-2 Straight lines $a_1x+b_1y+c_1=0$ and $a_2x+b_2y+c_2=0$ are parallel, if $\frac{a_1}{a_2}=\frac{b_1}{b_2}\neq\frac{c_1}{c_2}$

87. **Statement-1** The value of the determinant $\begin{vmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{vmatrix}\neq 0$

Statement-2 Neither of two rows or columns of $\begin{vmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{vmatrix}$ is identical.

88. **Statement-1** The digits A, B and C re such that the three digit numbers $A88$, $6B8$, $86C$ are divisible by 72, then the determinant $\begin{vmatrix} A & 6 & 8 \\ 8 & B & 6 \\ 8 & 8 & C \end{vmatrix}$ is divisible by 288.

Statement-2 $A=B=?$

Determinants Exercise 7 : Subjective Type Questions

■ In this section, there are **20 subjective** questions.

89. Prove that $\begin{vmatrix} b+c & c & b \\ c & c+a & a \\ b & a & a+b \end{vmatrix} = 4abc.$

90. Prove that $\begin{vmatrix} a-b-c & 2a & 2a \\ 2b & b-c-a & 2b \\ 2c & 2c & c-a-b \end{vmatrix} = (a+b+c)^3.$

91. Find the value of determinant $\begin{vmatrix} \sqrt{13}+\sqrt{3} & 2\sqrt{5} & \sqrt{5} \\ \sqrt{15}+\sqrt{26} & 5 & \sqrt{10} \\ 3+\sqrt{65} & \sqrt{15} & 5 \end{vmatrix}.$

92. Find the value of the determinant $\begin{vmatrix} bc & ca & ab \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix}$, where a, b and c respectively are the pth, qth and rth terms of a harmonic progression.

93. Without expanding the determinant at any stage, prove that $\begin{vmatrix} -5 & 3+5i & \frac{3}{2}-4i \\ 3-5i & 8 & 4+5i \\ \frac{3}{2}+4i & 4-5i & 9 \end{vmatrix}$ has a purely real value.

94. Prove without expanding that $\begin{vmatrix} ah+bg & g & ab+ch \\ bf+ba & f & hb+bc \\ af+bc & c & bg+fc \end{vmatrix} = a \begin{vmatrix} ah+bg & a & h \\ bf+ba & h & b \\ af+bc & g & f \end{vmatrix}.$

95. If A, B and C are the angles of a triangle and

$$\begin{vmatrix} 1 & 1 & 1 \\ 1+\sin A & 1+\sin B & 1+\sin C \\ \sin A+\sin^2 A & \sin B+\sin^2 B & \sin C+\sin^2 C \end{vmatrix} = 0,$$

then prove that ΔABC must be isosceles.

96. Prove that $\begin{vmatrix} \beta\gamma & \beta\gamma'+\beta'\gamma & \beta'\gamma' \\ \gamma\alpha & \gamma\alpha'+\gamma'\alpha & \gamma'\alpha' \\ \alpha\beta & \alpha\beta'+\alpha'\beta & \alpha'\beta' \end{vmatrix}$
$= (\alpha\beta'-\alpha'\beta)(\beta\gamma'-\beta'\gamma)(\gamma\alpha'-\gamma'\alpha).$

97. If $y = \frac{u}{v}$, where u and v are functions of x, show that

$$v^3 \frac{d^2y}{dx^2} = \begin{vmatrix} u & v & 0 \\ u' & v & v \\ u'' & v'' & 2v' \end{vmatrix}.$$

98. Show that the determinant $\Delta(x)$ is given by $\Delta(x) =$ $\begin{vmatrix} \sin(x+\alpha) & \cos(x+\alpha) & a+x\sin\alpha \\ \sin(x+\beta) & \cos(x+\beta) & b+x\sin\beta \\ \sin(x+\gamma) & \cos(x+\gamma) & c+x\sin\gamma \end{vmatrix}$. is independent of x.

99. Evaluate $\begin{vmatrix} {}^{x}C_1 & {}^{x}C_2 & {}^{x}C_3 \\ {}^{y}C_1 & {}^{y}C_2 & {}^{y}C_3 \\ {}^{z}C_1 & {}^{z}C_2 & {}^{z}C_3 \end{vmatrix}.$

100. (i) Find maximum value of

$$f(x) = \begin{vmatrix} 1+\sin^2 x & \cos^2 x & 4\sin 2x \\ \sin^2 x & 1+\cos^2 x & 4\sin 2x \\ \sin^2 x & \cos^2 x & 1+4\sin 2x \end{vmatrix}.$$

(ii) Let A, B and C be the angles of a triangle, such that $A \geq B \geq C$.

Find the minimum value of Δ, where

$$\Delta = \begin{vmatrix} \sin^2 A & \sin A\cos A & \cos^2 A \\ \sin^2 B & \sin B\cos B & \cos^2 B \\ \sin^2 C & \sin C\cos C & \cos^2 C \end{vmatrix}.$$

101. If $f(x) = \begin{vmatrix} x^2-4x+6 & 2x^2+4x+10 & 3x^2-2x+16 \\ x-2 & 2x+2 & 3x-1 \\ 1 & 2 & 3 \end{vmatrix}$, then find the value of $\int_{-3}^{3} \frac{x^2\sin x}{1+x^6} f(x)dx.$

102. If $Y = sX$ and $Z = tX$ all the variables beings functions of x, then prove that $\begin{vmatrix} X & Y & Z \\ X_1 & Y_1 & Z_1 \\ X_2 & Y_2 & Z_2 \end{vmatrix} = X^3 \begin{vmatrix} s_1 & t_1 \\ s_2 & t_2 \end{vmatrix}$, where suffixes denote the order of differentiation with respect to x.

103. If f, g and h are differentiable functions of x and $\Delta = \begin{vmatrix} f & g & h \\ (xf)' & (xg)' & (xh)' \\ (x^2f)'' & (x^2g)'' & (x^2h)'' \end{vmatrix}$, then prove that

$$\Delta' = \begin{vmatrix} f & g & h \\ f' & g' & h' \\ (x^3f'')' & (x^3g'')' & (x^3h'')' \end{vmatrix}.$$

104. If $|a_1| > |a_2| + |a_3|$, $|b_2| > |b_1| + |b_3|$ and $|c_3| > |c_1| + |c_2|$, then show that $\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} \neq 0.$

105. Show that $\begin{vmatrix} (a-a_1)^{-2} & (a-a_1)^{-1} & a_1^{-1} \\ (a-a_2)^{-2} & (a-a_2)^{-1} & a_2^{-1} \\ (a-a_3)^{-2} & (a-a_3)^{-1} & a_3^{-1} \end{vmatrix} = \pm \frac{a^2\,\Pi(a_i - a_j)}{\Pi a_i\,\Pi(a-a_i)^2}$. Write out the terms of the product in the numerator and give the resulting expression its correct sign.

106. Show that in general there are three values of t for which the following system of equations has a non-trivial solution $(a-t)x + by + cz = 0$, $bx + (c-t)y + az = 0$ and $cx + ay + (b-t)z = 0$.

Express the product of these values of t in the form of a determinant.

107. Eliminates

(i) a, b and c

(ii) x, y, z from the equations

$$-a + \frac{by}{z} + \frac{cz}{y} = 0,\quad -b + \frac{cz}{x} + \frac{ax}{z} = 0$$

and $$-c + \frac{ax}{y} + \frac{by}{x} = 0.$$

108. If x, z and y are not all zero and if

$ax + by + cz = 0$, $bx + cy + az = 0$ and $cx + ay + bz = 0$, then prove that $x : y : z = 1 : 1 : 1$ or $1 : \omega : \omega^2$ or $1 : \omega^2 : \omega$

Determinants Exercise 8 : Questions Asked in Previous 13 Year's Exam

- This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to year **2017**.

109. If $a^2 + b^2 + c^2 = -2$ and $f(x) = \begin{vmatrix} 1+a^2x & (1+b^2)x & (1+c^2)x \\ (1+a^2)x & 1+b^2x & (1+c^2)x \\ (1+a^2)x & (1+b^2)x & 1+c^2x \end{vmatrix}$, then $f(x)$ is a polynomial of degree **[AIEEE 2005, 3M]**

(a) 3 (b) 2 (c) 1 (d) 0

110. The system of equations

$$\alpha x + y + z = \alpha - 1,$$
$$x + \alpha y + z = \alpha - 1$$
and $$x + y + \alpha z = \alpha - 1$$

has no solution, if α is **[AIEEE 2005, 3M]**

(a) not -2 (b) 1

(c) -2 (d) Either -2 or 1

111. If $a_1, a_2, a_3, \ldots, a_n, \ldots$ are in GP, then the determinant $\Delta = \begin{vmatrix} \log a_n & \log a_{n+1} & \log a_{n+2} \\ \log a_{n+3} & \log a_{n+4} & \log a_{n+5} \\ \log a_{n+6} & \log a_{n+7} & \log a_{n+8} \end{vmatrix}$ is equal to **[AIEEE 2005, 3M]**

(a) 1 (b) 0 (c) 4 (d) 2

112. If $D = \begin{vmatrix} 1 & 1 & 1 \\ 1 & 1+x & 1 \\ 1 & 1 & 1+y \end{vmatrix}$ for $x \neq 0,\ y \neq 0$, then D is **[AIEEE 2007, 3M]**

(a) divisible by neither x nor y

(b) divisible by both x and y

(c) divisible by x but not y

(d) divisible by y but not x

113. Consider the system of equations

$$x - 2y + 3z = -1$$
$$-x + y - 2z = k$$
$$x - 3y + 4z = 1$$

Statement-1 The system of equations has no solutions for $k \neq 3$. **[IIT-JEE 2008, 3M]**

and

Statement-2 The determinant $\begin{vmatrix} 1 & 3 & -1 \\ -1 & -2 & k \\ 1 & 4 & 1 \end{vmatrix} \neq 0$, for $k \neq 3$.

(a) Statement-1 is true, Statement-2 is true and Statement-2 is a correct explanation for Statement-1.

(b) Statement-1 is true, Statement-2 is true and Statement-2 is not a correct explanation for Statement-1.

(c) Statement-1 is true, Statement-2 is false.

(d) Statement-1 is false, Statement-2 is true.

114. Let a, b, c be any real numbers. Suppose that there are real numbers x, y, z not all zero such that $x = cy + bz$, $y = az + cx$ and $z = bx + ay$. Then, $a^2 + b^2 + c^2 + 2abc$ is equal to **[AIEEE 2008, 3M]**

(a) -1 (b) 0 (c) 1 (d) 2

115. Let a, b, c be such that $b(a+c) \neq 0$. If $\begin{vmatrix} a & a+1 & a-1 \\ -b & b+1 & b-1 \\ c & c-1 & c+1 \end{vmatrix} + \begin{vmatrix} a+1 & b+1 & c-1 \\ a-1 & b-1 & c+1 \\ (-1)^{n+2}a & (-1)^{n+1}b & (-1)^n c \end{vmatrix} = 0$, then the value of n is **[AIEEE 2009, 4M]**

(a) any integer (b) zero

(c) an even integer (d) any odd integer

116. If $f(\theta)=\begin{vmatrix} 1 & \tan\theta & 1 \\ -\tan\theta & 1 & \tan\theta \\ -1 & -\tan\theta & 1 \end{vmatrix}$, then the set $\left\{f(\theta):0\le\theta<\frac{\pi}{2}\right\}$ is **[IIT-JEE 2011, 2M]**

(a) $(-\infty,-1)\cup(1,\infty)$ (b) $[2,\infty)$
(c) $(-\infty,0]\cup[2,\infty)$ (d) $(-\infty,-1]\cup[1,\infty)$

117. The number of values of k for which the linear equations

$$4x+ky+2z=0$$
$$kx+4y+z=0$$
$$2x+2y+z=0$$

Possess a non-zero solution is **[AIEEE 2011,4M]**

(a) zero (b) 3 (c) 2 (d) 1

118. If the trivial solution is the only solution of the system of equations

$$x-ky+z=0$$
$$kx+3y-kz=0$$
$$3x+y-z=0$$

Then, the set of values of k is

(a) $\{2,-3\}$ (b) $R-\{2,-3\}$
(c) $R-\{2\}$ (d) $R-\{-3\}$ **[AIEEE 2011, 4M]**

119. The number of values of k for which the system of equations $(k+1)x+8y=4k;\ kx+(k+3)y=3k-1$ has no solution, is

(a) 1 (b) 2
(c) 3 (d) infinite **[JEE Main 2013, 4M]**

120. If $\alpha,\ \beta\neq 0$ and $f(n)=\alpha^n+\beta^n$ and

$$\begin{vmatrix} 3 & 1+f(1) & 1+f(2) \\ 1+f(1) & 1+f(2) & 1+f(3) \\ 1+f(2) & 1+f(3) & 1+f(4) \end{vmatrix}=k(1-\alpha)^2(1-\beta)^2(\alpha-\beta)^2,$$

then k is equal to **[JEE Main 2014, 4M]**

(a) 1 (b) -1
(c) $\alpha\beta$ (d) $1/\alpha\beta$

121. The set of all values of λ for which the system of linear equations

$$2x_1-2x_2+x_3=\lambda x_1$$
$$2x_1-3x_2+2x_3=\lambda x_2$$
$$-x_1+2x_2=\lambda x_3$$

has a non-trivial solution **[JEE Main 2015, 4M]**

(a) contains two elements
(b) contains more than two elements
(c) is an empty set
(d) is a singleton

122. Which of the following values of α satisfy the equation

$$\begin{vmatrix} (1+\alpha)^2 & (1+2\alpha)^2 & (1+3\alpha)^2 \\ (2+\alpha)^2 & (2+2\alpha)^2 & (2+3\alpha)^2 \\ (3+\alpha)^2 & (3+2\alpha)^2 & (3+3\alpha)^2 \end{vmatrix}=-648\alpha\ ?$$

[JEE Advanced 2015, 4M]

(a) -4 (b) 9
(c) -9 (d) 4

123. The system of linear equations

$$x+\lambda y-z=0$$
$$\lambda x-y-z=0$$
$$x+y-\lambda z=0$$

has a non-trivial solution for **[JEE Main 2016, 4M]**

(a) exactly one-value of λ
(b) exactly two values of λ
(c) exactly three values of λ
(d) infinitely many values of λ.

124. The total number of distinct $x\in R$ for which

$$\begin{vmatrix} x & x^2 & 1+x^3 \\ 2x & 4x^2 & 1+8x^3 \\ 3x & 9x^2 & 1+27x^3 \end{vmatrix}=10 \text{ is}$$

[JEE Advanced 2016, 3M]

125. Let $a,\lambda,\mu\in R$. Consider the system of linear equations

$$ax+2y=\lambda$$
$$3x-2y=\mu$$

Which of the following statement(s) is (are) correct? **[JEE Advanced 2016, 4M]**

(a) If $a=-3$, then the system has infinitely many solutions for all values of λ and μ
(b) If $a\neq -3$, then the system has a unique solution for all values of λ and μ
(c) If $\lambda+\mu=0$, then the system has infinitely many solutions for $a=-3$
(d) If $\lambda+\mu\neq 0$, then the system has no solution for $a=-3$

126. If S is the set of distinct values of 'b' for which the following system of linear equations

$$x+y+z=1$$
$$x+ay+z=1$$
$$ax+by+z=0$$

has no solution, then S is **[JEE Main 2017, 4M]**

(a) an infinite set
(b) a finite set containing two or more elements
(c) a singleton
(d) an empty set

Solutions

1. $\because f(n)=\alpha^n+\beta^n$

Let $\Delta=\begin{vmatrix} 3 & 1+f(1) & 1+f(2) \\ 1+f(1) & 1+f(2) & 1+f(3) \\ 1+f(2) & 1+f(3) & 1+f(4) \end{vmatrix}$

$$=\begin{vmatrix} 3 & 1+\alpha+\beta & 1+\alpha^2+\beta^2 \\ 1+\alpha+\beta & 1+\alpha^2+\beta^2 & 1+\alpha^3+\beta^3 \\ 1+\alpha^2+\beta^2 & 1+\alpha^3+\beta^3 & 1+\alpha^4+\beta^4 \end{vmatrix}$$

$$=\begin{vmatrix} 1 & 1 & 1 \\ 1 & \alpha & \beta \\ 1 & \alpha^2 & \beta^2 \end{vmatrix}\times\begin{vmatrix} 1 & 1 & 1 \\ 1 & \alpha & \beta \\ 1 & \alpha^2 & \beta^2 \end{vmatrix}=\begin{vmatrix} 1 & 1 & 1 \\ 1 & \alpha & \beta \\ 1 & \alpha^2 & \beta^2 \end{vmatrix}^2$$

Applying $C_2\to C_2-C_1$ and $C_3\to C_3-C_1$, then

$$\Delta=\begin{vmatrix} 1 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ 1 & & \alpha-1 & & \beta-1 \\ \vdots & & & & \\ 1 & & \alpha^2-1 & & \beta^2-1 \end{vmatrix}^2$$

Expanding along R_1, we get

$$\Delta=\begin{vmatrix} \alpha-1 & \beta-1 \\ \alpha^2-1 & \beta^2-1 \end{vmatrix}^2=(\alpha-1)^2(\beta-1)^2\begin{vmatrix} 1 & 1 \\ \alpha+1 & \beta+1 \end{vmatrix}^2$$

$$=(\alpha-1)^2(\beta-1)^2(\beta-\alpha)^2=(1-\alpha)^2(1-\beta)^2(\alpha-\beta)^2$$

$$=k(1-\alpha)^2(1-\beta)^2(\alpha-\beta)^2 \qquad \text{[given]}$$

$\therefore\quad k=1$

2. $\because a, b, c$ and d are in AP. Let D be the common difference,then

$$b=a+D,\ c=a+2D,\ d=a+3D \qquad \text{...(i)}$$

and $\Delta(x)=\begin{vmatrix} x+a & x+b & x+a-c \\ x+b & x+c & x-1 \\ x+c & x+d & x-b+d \end{vmatrix}$

On putting the values of b, c and d from Eq.(i) in $\Delta(x)$, then

$$\Delta(x)=\begin{vmatrix} x+a & x+a+D & x-2D \\ x+a+D & x+a+2D & x-1 \\ x+a+2D & x+a+3D & x+2D \end{vmatrix}$$

Applying $R_2\to R_2-\frac{1}{2}(R_1+R_3)$, then

$$\Delta(x)=\begin{vmatrix} x+a & x+a+D & x-2D \\ & & \vdots \\ 0 & \cdots\quad 0 & \cdots\quad -1 \\ & & \vdots \\ x+a+2D & x+a+3D & x+2D \end{vmatrix}$$

Expanding along R_2, then

$$\Delta(x)=\begin{vmatrix} x+a & x+a+D \\ x+a+2D & x+a+3D \end{vmatrix}$$

Applying $R_2\to R_2-R_1$, then

$$\Delta(x)=\begin{vmatrix} x+a & x+a+D \\ 2D & 2D \end{vmatrix}$$

$$=2D(x+a-x-a-D)=-2D^2$$

Also, $\int_0^2\Delta(x)\,dx=-16$

$\Rightarrow\quad -2D^2(2)=-16$

$\therefore\quad D^2=4$ or $D=\pm 2$

3. Let $\Delta(x)=\begin{vmatrix} x & 1+x^2 & x^3 \\ \log_e(1+x^2) & e^x & \sin x \\ \cos x & \tan x & \sin^2 x \end{vmatrix}$

$$=a+bx+cx^2+\ldots$$

On putting $x=0$, we get

$$\begin{vmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{vmatrix}=a$$

$\therefore\quad 0=a$

or $a=0$, then

$$\Delta(x)=bx+cx^2+\ldots$$

Hence, $\Delta(x)$ is divisible by x.

4. Given, $\begin{vmatrix} a^2 & b^2 & c^2 \\ (a+1)^2 & (b+1)^2 & (c+1)^2 \\ (a-1)^2 & (b-1)^2 & (c-1)^2 \end{vmatrix}=0$

$$\Rightarrow\quad \begin{vmatrix} a^2 & b^2 & c^2 \\ a^2+2a+1 & b^2+2b+1 & c^2+2c+1 \\ a^2-2a+1 & b^2-2b+1 & c^2-2c+1 \end{vmatrix}=0$$

Applying $R_2\to R_2-R_3$, then

$$\begin{vmatrix} a^2 & b^2 & c^2 \\ 4a & 4b & 4c \\ a^2-2a+1 & b^2-2b+1 & c^2-2c+1 \end{vmatrix}=0$$

Applying $R_3\to R_3-R_1+\frac{1}{2}R_2$, then

$$4\begin{vmatrix} a^2 & b^2 & c^2 \\ a & b & c \\ 1 & 1 & 1 \end{vmatrix}=0$$

$$\Rightarrow\quad -\begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix}=0 \qquad [\because R_1\to R_3]$$

$$\Rightarrow\quad \begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^2 & b^2 & c^2 \end{vmatrix}=0$$

$\Rightarrow\quad (a-b)(b-c)(c-a)=0$

$\therefore\quad a-b=0$ or $b-c=0$ or $c-a=0$

$\Rightarrow\quad a=b$ or $b=c$ or $c=a$

Hence, ΔABC is an isosceles triangle.

5. Let $\Delta = \begin{vmatrix} \alpha & x & x & x \\ x & \beta & x & x \\ x & x & \gamma & x \\ x & x & x & \delta \end{vmatrix}$

Applying $C_2 \to C_2 - C_1$, $C_3 \to C_3 - C_1$ and $C_4 \to C_4 - C_1$, then

$$\Delta = \begin{vmatrix} \alpha & x-\alpha & x-\alpha & x-\alpha \\ x & \beta - x & 0 & 0 \\ x & 0 & \gamma - x & 0 \\ x & 0 & 0 & \delta - x \end{vmatrix}$$

Expanding along first column, then

$$\Delta = \alpha(\beta - x)(\gamma - x)(\delta - x) - x(x-\alpha)(\gamma - x)(\delta - x) + x(\delta - x)(x-\alpha)(x-\beta) - x(x-\alpha)(\beta - x)(\gamma - x)$$

$$= (x-\alpha)(x-\beta)(x-\gamma)(x-\delta) - x[(x-\alpha)(x-\gamma)(x-\delta) + (x-\beta)(x-\gamma)(x-\delta) + (x-\alpha)(x-\beta)(x-\delta) + (x-\alpha)(x-\beta)(x-\gamma)] \quad \text{[given]}$$

$$= f(x) - x f'(x)$$

$\therefore \quad f(x) = (x-\alpha)(x-\beta)(x-\gamma)(x-\delta)$

6. Given, $\begin{vmatrix} a & b-c & c+b \\ a+c & b & c-a \\ a-b & a+b & c \end{vmatrix} = 0$

$$\Rightarrow \quad \frac{1}{a}\begin{vmatrix} a^2 & b-c & c+b \\ a^2+ac & b & c-a \\ a^2-ab & a+b & c \end{vmatrix} = 0$$

Applying $C_1 \to C_1 + bC_2 + cC_3$, then

$$\Rightarrow \quad \frac{1}{a}\begin{vmatrix} a^2+b^2+c^2 & b-c & c+b \\ a^2+b^2+c^2 & b & c-a \\ a^2+b^2+c^2 & a+b & c \end{vmatrix} = 0$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\Rightarrow \quad \frac{1}{a}\begin{vmatrix} a^2+b^2+c^2 & \cdots & b-c & \cdots & c-b \\ \vdots & & & & \\ 0 & & c & & -b-a \\ \vdots & & & & \\ 0 & & a+c & & -b \end{vmatrix} = 0$$

Expanding along C_1, then

$$\Rightarrow \quad \frac{(a^2+b^2+c^2)}{a}\begin{vmatrix} c & -b-a \\ a+c & -b \end{vmatrix} = 0$$

$$\Rightarrow \quad \frac{(a^2+b^2+c^2)}{a}[(-bc + (b+a)(a+c)] = 0$$

$$\Rightarrow \quad \frac{(a^2+b^2+c^2)(-bc+ab+bc+a^2+ac)}{a} = 0$$

$$\Rightarrow \quad (a^2+b^2+c^2)(a+b+c) = 0$$

$\because \quad a^2+b^2+c^2 \neq 0$

$\therefore \quad a+b+c = 0$

Therefore, line $ax + by + c = 0$ passes through the fixed point (1, 1).

7. $\because \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = -(a^3+b^3+c^3-3abc)$

$$= -(a+b+c)(a+b\omega+c\omega^2)(a+b\omega^2+c\omega)$$

[where ω is cube roots of unity]

$$= -f(\alpha) f(\beta) f(\gamma) \qquad [\because \alpha = 1, \beta = \omega, \gamma = \omega^2]$$

8. Let $\Delta = \begin{vmatrix} \cos 2x & \sin^2 x & \cos 4x \\ \sin^2 x & \cos 2x & \cos^2 x \\ \cos 4x & \cos^2 x & \cos 2x \end{vmatrix}$

$$= \begin{vmatrix} 1-2\sin^2 x & \sin^2 x & 1-8\sin^2 x(1-\sin^2 x) \\ \sin^2 x & 1-2\sin^2 x & 1-\sin^2 x \\ 1-8\sin^2 x(1-\sin^2 x) & 1-\sin^2 x & 1-2\sin^2 x \end{vmatrix}$$

The required constant term is $\begin{vmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{vmatrix}$

Applying $C_3 \to C_3 - C_1$, then

$$\begin{vmatrix} 1 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ 0 & & 1 & & 1 \\ \vdots & & & & \\ 1 & & 1 & & 0 \end{vmatrix} = 1(0-1) = -1$$

9. $\because \quad -1 \le x < 0 \Rightarrow [x] = -1$

$0 \le y < 1 \Rightarrow [y] = 0$

$1 \le z < 2 \Rightarrow [z] = 1$

$$\text{Let } \Delta = \begin{vmatrix} [x]+1 & [y] & [z] \\ [x] & [y]+1 & [z] \\ [x] & [y] & [z]+1 \end{vmatrix} = \begin{vmatrix} 0 & & 0 & & 1 \\ & & \vdots & & \\ -1 & \cdots & 1 & \cdots & 1 \\ & & \vdots & & \\ -1 & & 0 & & 2 \end{vmatrix}$$

Expanding along C_2, then $\Delta = \begin{vmatrix} 0 & 1 \\ -1 & 2 \end{vmatrix} = 1 = [z]$

10. Let $\Delta = \begin{vmatrix} y^2 & -xy & x^2 \\ a & b & c \\ a' & b' & c' \end{vmatrix} = \frac{1}{xy}\begin{vmatrix} xy^2 & -xy & x^2y \\ ax & b & cy \\ a'x & b' & c'y \end{vmatrix}$

Applying $C_1 \to C_1 + yC_2$ and $C_3 \to C_3 + xC_2$, then

$$\Delta = \frac{1}{xy}\begin{vmatrix} 0 & \cdots & -xy & \cdots & 0 \\ & & \vdots & & \\ ax+by & & b & & bx+cy \\ & & \vdots & & \\ a'x+b'y & & b' & & b'x+c'y \end{vmatrix}$$

Expanding along R_1, then

$$= \frac{1}{xy} \cdot xy \cdot \begin{vmatrix} ax+by & bx+cy \\ a'x+b'y & b'x+c'y \end{vmatrix}$$

$$= \begin{vmatrix} ax+by & bx+cy \\ a'x+b'y & b'x+c'y \end{vmatrix}$$

11. $\because$ In a triangle $A + B + C = \pi$ and $e^{\pi} = \cos\pi + i\sin\pi = -1$

$$e^{i(B+C)} = e^{i(\pi - A)} = e^{i\pi}\cdot e^{iA} = -e^{-iA}$$

$\Rightarrow$ $e^{-i(B+C)} = -e^{iA}$

Similarly, $e^{-i(A+B)} = -e^{iC}$ and $e^{-i(C+A)} = -e^{iB}$

Taking e^{iA}, e^{iB}, e^{iC} common from R_1, R_2 and R_3 respectively, we get

$$\Delta = e^{iA}\cdot e^{iB}\cdot e^{iC}\begin{vmatrix} e^{iA} & e^{-i(A+C)} & e^{-i(A+B)} \\ e^{-i(B+C)} & e^{iB} & e^{-i(A+B)} \\ e^{-i(B+C)} & e^{-i(A+C)} & e^{iC} \end{vmatrix}$$

$$= e^{i\pi} = \begin{vmatrix} e^{iA} & -e^{iB} & -e^{iC} \\ -e^{iA} & e^{iB} & -e^{iC} \\ -e^{iA} & -e^{iB} & e^{iC} \end{vmatrix}$$

Taking e^{iA}, e^{iB}, e^{iC} common from C_1, C_2 and C_3 respectively, we get

$$\Delta = (-1)\,e^{iA}\cdot e^{iB}\cdot e^{iC}\begin{vmatrix} 1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \end{vmatrix}$$

$$= (-1)\,e^{i\pi}\begin{vmatrix} 1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \end{vmatrix}$$

$$= (-1)(-1)\begin{vmatrix} 1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \end{vmatrix} = \begin{vmatrix} 1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \end{vmatrix}$$

Applying $C_2 \to C_2 + C_1$ and $C_3 \to C_3 + C_1$, then

$$\Delta = \begin{vmatrix} 1 & 0 & 0 \\ -1 & 0 & -2 \\ -1 & -2 & 0 \end{vmatrix} = 1(0-4) = -4$$

12. Taking x^5 common from R_3, then

$$x^5\begin{vmatrix} x^n & x^{n+2} & x^{2n} \\ 1 & x^a & a \\ x^n & x^{a+1} & x^{2n} \end{vmatrix} = 0,\ \forall\ x \in R$$

$\Rightarrow$ $a + 1 = n + 2 \ \Rightarrow\ a = n + 1$

13. Since, x, y and z are in AP.

$\therefore$ $2y = x + z$ ...(i)

Let $\Delta = \begin{vmatrix} 5 & 4 & 3 \\ x51 & y41 & z31 \\ x & y & z \end{vmatrix}$

$$= \begin{vmatrix} 5 & 4 & 3 \\ 100x + 50 + 1 & 100y + 40 + 1 & 100z + 30 + 1 \\ x & y & z \end{vmatrix}$$

Applying $R_2 \to R_2 - \frac{1}{2}(R_1 + R_3)$, then

$$= \begin{vmatrix} 5 & 0 & 3 \\ 100x + 50 + 1 & 0 & 100z + 30 + 1 \\ x & 0 & z \end{vmatrix}$$ [from Eq. (i)]

$= 0$ [$\because$ all elements of C_2 are zeroes]

14. As $a_1b_1c_1$, $a_2b_2c_2$ and $a_3b_3c_3$ are even natural numbers each of c_1, c_2, c_3 is divisible by 2.

Let $C_i = 2\lambda_i$ for $i = 1, 2, 3$ and $\lambda_i \in N$, then

$$\Delta = \begin{vmatrix} 2\lambda_1 & a_1 & b_1 \\ 2\lambda_2 & a_2 & b_2 \\ 2\lambda_3 & a_3 & b_3 \end{vmatrix} = 2\begin{vmatrix} \lambda_1 & a_1 & b_1 \\ \lambda_2 & a_2 & b_2 \\ \lambda_3 & a_3 & b_3 \end{vmatrix} = 2m$$

where m is some natural number. Thus, Δ is divisible by 2. That Δ may not be divisible by 4 can be seen by taking the three numbers as 112, 122 and 134.

$$\Delta = \begin{vmatrix} 2 & 1 & 1 \\ 2 & 1 & 2 \\ 4 & 1 & 3 \end{vmatrix} = 2(3-2) - 1(6-8) + 1(2-4) = 2$$

which is divisible by 2 but not by 4.

15. Let $\Delta = \begin{vmatrix} c & b\cos B + c\beta & a\cos A + b\alpha + c\gamma \\ a & c\cos B + a\beta & b\cos A + c\alpha + a\gamma \\ b & a\cos B + b\beta & c\cos A + a\alpha + b\gamma \end{vmatrix}$

Applying $C_2 \to C_2 - \beta C_1$ and $C_3 \to C_3 - \gamma C_1$, then

$$\Delta = \begin{vmatrix} c & b\cos B & a\cos A + b\alpha \\ a & c\cos B & b\cos A + c\alpha \\ b & a\cos B & c\cos A + a\alpha \end{vmatrix}$$

Applying $C_3 \to C_3 - \alpha\sec B\, C_2$, then

$$\Delta = \begin{vmatrix} c & b\cos B & a\cos A \\ a & c\cos B & b\cos A \\ b & a\cos B & c\cos A \end{vmatrix} = \cos A\cos B\begin{vmatrix} c & b & a \\ a & c & b \\ b & a & c \end{vmatrix}$$

Applying $C_1 \leftrightarrow C_3$, then $\Delta = -\cos A\cos B\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}$

$$= -\cos A\cos B(a+b+c)\cdot\frac{1}{2}[(a-b)^2 + (b-c)^2 + (c-a)^2]$$

Given, $\cos A \neq 0$, $\cos B \neq 0$ and $a + b + c \neq 0$

$\because$ $\Delta = 0$

$\therefore$ $(a-b)^2 + (b-c)^2 + (c-a)^2 = 0$

which is independent, when $a - b = 0$, $b - c = 0$ and $c - a = 0$

i.e., $a = b = c$

Hence, ΔABC is an equilateral.

16. Here, $\left.\begin{matrix} x_1 + x_2 = 6, & x_1x_2 = 3 \\ \text{and}\quad y_1 + y_2 = 4, & y_1y_2 = 2 \end{matrix}\right\}$ ...(i)

Let $\Delta = \begin{vmatrix} x_1x_2 & y_1y_2 & 1 \\ x_1 + x_2 & y_1 + y_2 & 2 \\ \sin(\pi x_1x_2) & \cos\left(\frac{\pi}{2}y_1y_2\right) & 1 \end{vmatrix}$

$$= \begin{vmatrix} 3 & 2 & 1 \\ 6 & 4 & 2 \\ \sin 3\pi & \cos\left(\frac{\pi}{4}\right) & 1 \end{vmatrix}$$ [from Eq. (i)]

Applying $R_2 \to R_2 - 2R_1$, then $\Delta = \begin{vmatrix} 3 & 2 & 1 \\ 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & 1 \end{vmatrix} = 0$

17. $\because \Delta = \begin{vmatrix} {}^{10}C_4 & {}^{10}C_5 & {}^{11}C_m \\ {}^{11}C_6 & {}^{11}C_7 & {}^{12}C_{m+2} \\ {}^{12}C_8 & {}^{12}C_9 & {}^{13}C_{m+4} \end{vmatrix}$

Applying $C_2 \to C_2 + C_1$ and use Pascal's rule $({}^{n}C_r + {}^{n}C_{r-1} = {}^{n+1}C_r)$, then

$$\Delta = \begin{vmatrix} {}^{10}C_4 & {}^{11}C_5 & {}^{11}C_m \\ {}^{11}C_6 & {}^{12}C_7 & {}^{12}C_{m+2} \\ {}^{12}C_8 & {}^{13}C_9 & {}^{13}C_{m+4} \end{vmatrix} = 0 \qquad \text{[given]}$$

$\therefore \quad m = 5$

18. Let $\Delta = \begin{vmatrix} 1 & \sin(\alpha-\beta)\theta & \cos(\alpha-\beta)\theta \\ a & \sin\alpha\theta & \cos\alpha\theta \\ a^2 & \sin(\alpha-\beta)\theta & \cos(\alpha-\beta)\theta \end{vmatrix}$

Applying $R_1 \to R_1 - R_3$, then

$$\Delta = \begin{vmatrix} 1-a^2 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ a & & \sin\alpha\theta & & \cos\alpha\theta \\ \vdots & & & & \\ a^2 & & \sin(\alpha-\beta)\theta & & \cos(\alpha-\beta)\theta \end{vmatrix}$$

Expanding along R_1, then

$$\Delta = (1-a^2)\begin{vmatrix} \sin\alpha\theta & \cos\alpha\theta \\ \sin(\alpha-\beta)\theta & \cos(\alpha-\beta)\theta \end{vmatrix}$$

$$= (1-a^2)\,[\sin\alpha\theta \cdot \cos(\alpha-\beta)\theta - \cos\alpha\theta \cdot \sin(\alpha-\beta)\theta]$$

$$= (1-a^2)\sin(\alpha\theta - \alpha\theta + \beta\theta) = (1-a^2)\sin\beta\theta$$

19. Let $F(x) = \begin{vmatrix} f(x) & g(x) & h(x) \\ a & b & c \\ p & q & r \end{vmatrix} = mx^4 + nx^3 + rx^2 + sx + t$ ...(i)

On differentiating twice and thrice of Eq. (i) w.r.t.x, then

$$F''(x) = \begin{vmatrix} f''(x) & g''(x) & h''(x) \\ a & b & c \\ p & q & r \end{vmatrix}$$

$$= 12mx^2 + 6nx + 2r \qquad \text{...(ii)}$$

$$F'''(x) = \begin{vmatrix} f'''(x) & g'''(x) & h'''(x) \\ a & b & c \\ p & q & r \end{vmatrix} = 24mx + 6n \qquad \text{...(iii)}$$

On putting $x = 0$ in Eqs. (ii) and (iii), we get

$$\begin{vmatrix} f''(0) & g''(0) & h''(0) \\ a & b & c \\ p & q & r \end{vmatrix} = 2r \qquad \text{...(iv)}$$

and $$\begin{vmatrix} f''(0) & g''(0) & h''(0) \\ a & b & c \\ p & q & r \end{vmatrix} = 6n \qquad \text{...(v)}$$

Now, subtracting Eq. (iv) from Eq. (v), we get

$$\begin{vmatrix} f'''(0) & -f''(0) & g'''(0)-g''(0) & h'''(0) & -h''(0) \\ & a & & b & c \\ & p & & q & r \end{vmatrix}$$

$$= 6n - 2r = 2(3n - r)$$

20. $\because f(x) = \begin{vmatrix} \cos(x+\alpha) & \cos(x+\beta) & \cos(x+\gamma) \\ \sin(x+\alpha) & \sin(x+\beta) & \sin(x+\gamma) \\ \sin(\beta-\gamma) & \sin(\gamma-\alpha) & \sin(\alpha-\beta) \end{vmatrix}$

On differentiating both sides w.r.t. x, then

$$f'(x) = \begin{vmatrix} -\sin(x+\alpha) & -\sin(x+\beta) & -\sin(x+\gamma) \\ \sin(x+\alpha) & \sin(x+\beta) & \sin(x+\gamma) \\ \sin(\beta-\gamma) & \sin(\gamma-\alpha) & \sin(\alpha-\beta) \end{vmatrix}$$

$$+ \begin{vmatrix} \cos(x+\alpha) & \cos(x+\beta) & \cos(x+\gamma) \\ \cos(x+\alpha) & \cos(x+\beta) & \cos(x+\gamma) \\ \sin(\beta-\gamma) & \sin(\gamma-\alpha) & \sin(\alpha-\beta) \end{vmatrix}$$

$$= -\begin{vmatrix} \sin(x+\alpha) & \sin(x+\beta) & \sin(x+\gamma) \\ \sin(x+\alpha) & \sin(x+\beta) & \sin(x+\gamma) \\ \sin(\beta-\gamma) & \sin(\gamma-\alpha) & \sin(\alpha-\beta) \end{vmatrix}$$

$$+ \begin{vmatrix} \cos(x+\alpha) & \cos(x+\beta) & \cos(x+\gamma) \\ \cos(x+\alpha) & \cos(x+\beta) & \cos(x+\gamma) \\ \sin(\beta-\gamma) & \sin(\gamma-\alpha) & \sin(\alpha-\beta) \end{vmatrix}$$

$$= 0 + 0 \qquad [\because R_1 \text{ and } R_2 \text{ are identical}]$$

$$= 0$$

$\therefore f(x) = c$ [constant]

Now, $f(\theta) - 2f(\phi) + f(\psi) = c - 2c + c = 0$

21. Let $\Delta = \begin{vmatrix} 1 & 1 & 1 \\ a & b & c \\ a^3 & b^3 & c^3 \end{vmatrix}$

Taking a, b, c common from C_1, C_2, C_3, then $= abc \begin{vmatrix} \frac{1}{a} & \frac{1}{b} & \frac{1}{c} \\ 1 & 1 & 1 \\ a^2 & b^2 & c^2 \end{vmatrix}$

On multiplying in R_1 by abc, then

$$\Delta = \begin{vmatrix} bc & ca & ab \\ 1 & 1 & 1 \\ a^2 & b^2 & c^2 \end{vmatrix} = -\begin{vmatrix} 1 & 1 & 1 \\ bc & ca & ab \\ a^2 & b^2 & c^2 \end{vmatrix} \qquad [R_1 \leftrightarrow R_2]$$

$$= \begin{vmatrix} 1 & 1 & 1 \\ a^2 & b^2 & c^2 \\ bc & ca & ab \end{vmatrix} \qquad [R_2 \leftrightarrow R_3]$$

$$= (a-b)(b-c)(c-a)(a+b+c)$$

Now, $D = \begin{vmatrix} 1 & 1 & 1 \\ (x-a)^2 & (x-b)^2 & (x-c)^2 \\ (x-b)(x-c) & (x-c)(x-a) & (x-a)(x-b) \end{vmatrix}$

$$= (b-a)(c-b)(a-c)(3x-a-b-c)$$

Now, given that a, b and c are all different, then $D = 0$

$\therefore \quad 3x - a - b - c = 0$

$\Rightarrow \quad x = \frac{1}{3}(a+b+c)$

22. Given, determinant

$$2a(bc-4a^2)-b(b^2-2ac)+c(2ab-c^2)=0$$

$$\Rightarrow \quad -[(2a)^3+b^3+c^3-3\cdot 2a\cdot b\cdot c]=0$$

$$\Rightarrow \quad \frac{1}{2}(2a+b+c)[(2a-b)^2+(b-c)^2+(c-2a)^2]=0$$

$$\Rightarrow \quad 2a+b+c=0 \qquad \text{...(i) } [\because b\neq c]$$

Let $f(x)=8ax^3+2bx^2+cx+d$

$$\therefore\ f(0)=d \text{ and for } \left(\frac{1}{2}\right)=a+\frac{b}{2}+\frac{c}{2}+d=\frac{2a+b+c}{2}+d$$

$$=\frac{0}{2}+d=d \qquad [\text{from Eq. (i)}]$$

$$\Rightarrow \quad f(0)=f\left(\frac{1}{2}\right)$$

So, $f(x)$ satisfies Rolle's theorem and hence $f'(x)=0$ has atleast one root in $\left[0,\frac{1}{2}\right]$.

23. Given, $\begin{vmatrix} x^3+1 & x^2y & x^2z \\ xy^2 & y^3+1 & y^2z \\ xz^2 & yz^2 & z^3+1 \end{vmatrix}=11$

Taking x, y, z common from C_1, C_2, C_3 respectively, then

$$\Rightarrow \quad xyz\begin{vmatrix} \frac{x^3+1}{x} & x^2 & x^2 \\ y^2 & \frac{y^3+1}{y} & y^2 \\ z^2 & z^2 & \frac{z^3+1}{z} \end{vmatrix}=11$$

On multiplying R_1 by x, R_2 by y and R_3 by z, we get

$$\Rightarrow \quad \begin{vmatrix} x^3+1 & x^3 & x^3 \\ y^3 & y^3+1 & y^3 \\ z^3 & z^3 & z^3+1 \end{vmatrix}=11$$

Applying $R_1\to R_1+R_2+R_3$, then

$$\begin{vmatrix} x^3+y^3+z^3+1 & x^3+y^3+z^3+1 & x^3+y^3+z^3+1 \\ y^3 & y^3+1 & y^3 \\ z^3 & z^3 & z^3+1 \end{vmatrix}=11$$

Applying $C_2\to C_2-C_1$ and $C_3\to C_3-C_1$, then

$$\begin{vmatrix} x^3+y^3+z^3+1 & \ddots & 0 & 0 \\ y^3 & \ddots & 1 & 0 \\ z^3 & & 0 & \ddots\ 1 \end{vmatrix}=11$$

$$\Rightarrow \quad x^3+y^3+z^3+1=11$$

$$\Rightarrow \quad x^3+y^3+z^3=10$$

Therefore, the ordered triplets are (2, 1, 1), (1, 2, 1) and (1, 1, 2).

24. $\because f(x)-x=0$ has imaginary roots.

Then, $f(x)-x>0$ or $f(x)-x<0, \forall\ x\in R$

for $f(x)-x>0, \forall\ x\in R$,

then $f[f(x)]-f(x)>0, \forall\ x\in R$

On adding, we get

$$f[f(x)]-x>0, \forall\ x\in R$$

Similarly, $f[f(x)]-x<0, \forall\ x\in R$

Thus, roots of the equation $f[f(x)]-x=0$ are imaginary

Let $z=\begin{vmatrix} 2 & \alpha & \delta \\ \beta & 0 & \alpha \\ \gamma & \beta & 1 \end{vmatrix}$

Then, $\bar{z}=\begin{vmatrix} 2 & \bar{\alpha} & \bar{\delta} \\ \bar{\beta} & 0 & \bar{\alpha} \\ \bar{\gamma} & \bar{\beta} & 1 \end{vmatrix}=\begin{vmatrix} 2 & \beta & \gamma \\ \alpha & 0 & \beta \\ \delta & \alpha & 1 \end{vmatrix}=\begin{vmatrix} 2 & \alpha & \delta \\ \beta & 0 & \alpha \\ \gamma & \beta & 1 \end{vmatrix}=z$

Hence, z is purely real.

25. For infinitely many solutions

$$\Delta=\Delta_1=\Delta_2=\Delta_3=0$$

$$\Delta=0 \ \Rightarrow\ \begin{vmatrix} 2 & -1 & 1 \\ 1 & -2 & 1 \\ t & -1 & 2 \end{vmatrix}=0 \ \Rightarrow\ t=5$$

For $t=5, \Delta_1=\Delta_2=\Delta_3=0$

Now, $\int_0^{-2t} f(x)\,dx=\int_0^{-10} f(x)\,dx=\int_0^{-5} f(x)\,dx+\int_{-5}^{-10} f(x)\,dx$

$$=\int_{-5}^{-10} f(x+5)\,dx+\int_{-5}^{-10} f(x)\,dx$$

$$=\int_{-5}^{-10}[f(x+5)+f(x)]\,dx$$

$$=\int_{-5}^{-10} 2dx=2(-10+5)$$

$$=-10=-2t$$

26. On putting $x=0$, we get $a_0=1$

On differentiating both sides w.r.t. x and putting $x=0$, we get

$$a_1=4a$$

On differentiating again w.r.t. x and putting $x=0$, we get

$$2a_2=12a^2+8b$$

or $$a_2=6a^2+4b$$

Also, given $\begin{vmatrix} a_1 & a_1 & a_2 \\ a_0 & a_2 & a_0 \\ a_2 & a_0 & a_1 \end{vmatrix}=0$

$$\Rightarrow \quad -(a_0^3+a_1^3+a_2^3-3a_0a_1a_2)=0$$

$$\Rightarrow \quad \frac{1}{2}(a_0+a_1+a_2)[(a_0-a_1)^2+(a_1-a_2)^2+(a_2-a_0)^2]=0$$

$$\because \quad a_0+a_1+a_2\neq 0$$

$$\therefore \quad (a_0-a_1)^2+(a_1-a_2)^2+(a_2-a_0)^2=0$$

$$\Rightarrow \quad a_0-a_1=0, a_1-a_2=0, a_2-a_0=0$$

$$\therefore \quad a_0=a_1=a_2$$

$$\Rightarrow \quad 1=4a=6a^2+4b$$

$$\Rightarrow \quad a=\frac{1}{4} \text{ and } b=\frac{5}{32}$$

27. $\because f(x)=\log_{10}x$ and $g(x)=e^{\pi i x}$

$$\therefore \quad f(10)=\log_{10}10=1$$

and $$g(10)=e^{10\pi i}=(-1)^{10}=1$$

$$f(10^2) = \log_{10} 10^2 = 2$$

and $$g(10^2) = e^{100\pi i} = (-1)^{100} = 1$$

$$f(10^3) = \log_{10} 10^3 = 3$$

and $$g(10^3) = e^{1000\pi i} = (-1)^{1000} = 1$$

Given, $\phi(x) = \begin{vmatrix} f(x)\cdot g(x) & [f(x)]^{g(x)} & 1 \\ f(x^2)\cdot g(x^2) & [f(x^2)]^{g(x^2)} & 0 \\ f(x^3)\cdot g(x^3) & [f(x^3)]^{g(x^3)} & 1 \end{vmatrix}$

$\therefore \quad \phi(10) = \begin{vmatrix} f(10)\cdot g(10) & [f(10)]^{g(10)} & 1 \\ f(10^2)\cdot g(10^2) & [f(10^2)]^{g(10^2)} & 0 \\ f(10^3)\cdot g(10^3) & [f(10^3)]^{g(10^3)} & 1 \end{vmatrix}$

$$= \begin{vmatrix} 1 & 1 & 1 \\ 2 & 2 & 0 \\ 3 & 3 & 1 \end{vmatrix} = 0$$

28. Let $\Delta = \begin{vmatrix} 1 & (\alpha^{2x} - \alpha^{-2x})^2 & (\alpha^{2x} + \alpha^{-2x})^2 \\ 1 & (\beta^{2x} - \beta^{-2x})^2 & (\beta^{2x} + \beta^{-2x})^2 \\ 1 & (\gamma^{2x} - \gamma^{-2x})^2 & (\gamma^{2x} + \gamma^{-2x})^2 \end{vmatrix}$

Applying $C_3 \to C_3 - C_2$, then $\Delta = \begin{vmatrix} 1 & (\alpha^{2x} - \alpha^{-2x})^2 & 4 \\ 1 & (\beta^{2x} - \beta^{-2x})^2 & 4 \\ 1 & (\gamma^{2x} - \gamma^{-2x})^2 & 4 \end{vmatrix} = 0$

29. The given equations can be written as

$$(a-1)\,x - y - z = 0,$$

$$-x + (b-1)\,y - z = 0$$

and $$-x - y + (c-1)\,z = 0$$

For non-trivial solution

$$\begin{vmatrix} a-1 & -1 & -1 \\ -1 & b-1 & -1 \\ -1 & -1 & c-1 \end{vmatrix} = 0$$

Applying $C_1 \to C_1 - C_3$ and $C_2 \to C_2 - C_3$, then

$$\begin{vmatrix} a & 0 & -1 \\ 0 & b & -1 \\ -c & -c & c-1 \end{vmatrix} = 0$$

Expanding along R_1, then

$\Rightarrow \quad a(bc - b - c) - 0 - 1(0 + bc) = 0$

$\Rightarrow \quad ab + bc + ca = abc$

30. For non-trivial solution $\begin{vmatrix} \lambda & -1 & \cos\theta \\ 3 & 1 & 2 \\ \cos\theta & 1 & 2 \end{vmatrix} = 0$

Applying $R_3 \to R_3 - R_2$, then

$$\begin{vmatrix} \lambda & -1 & \cos\theta \\ \vdots & & \\ 3 & 1 & 2 \\ \vdots & & \\ \cos\theta - 3 & \cdots\ 0\ \cdots & 0 \end{vmatrix} = 0$$

Expanding along R_3, then

$\Rightarrow \quad (\cos\theta - 3)(-2 - \cos\theta) = 0$

$\Rightarrow \quad (\cos\theta - 3)(2 + \cos\theta) = 0$

$\cos\theta = 3, -2$, where -2 is neglected.

Hence, $\begin{vmatrix} \lambda & -1 & \cos\theta \\ 3 & 1 & 2 \\ \cos\theta & 1 & 2 \end{vmatrix} > 0$ only trivial solution is possible.

31. $\because \Delta = \begin{vmatrix} a^2 + x^2 & ab & ac \\ ab & b^2 + x^2 & bc \\ ac & bc & c^2 + x^2 \end{vmatrix}$

Taking a, b, c common from R_1, R_2, R_3 respectively, then

$$\Delta = abc \begin{vmatrix} \dfrac{a^2 + x^2}{a} & b & c \\ a & \dfrac{b^2 + x^2}{b} & c \\ a & b & \dfrac{c^2 + x^2}{c} \end{vmatrix}$$

On multiplying in C_1, C_2, C_3 by a, b, c respectively, then

$$\Delta = \begin{vmatrix} a^2 + x^2 & b^2 & c^2 \\ a^2 & b^2 + x^2 & c^2 \\ a^2 & b^2 & c^2 + x^2 \end{vmatrix}$$

Now, applying $C_1 \to C_1 + C_2 + C_3$, then

$$\Delta = \begin{vmatrix} x^2 + a^2 + b^2 + c^2 & b^2 & c^2 \\ x^2 + a^2 + b^2 + c^2 & b^2 + x^2 & c^2 \\ x^2 + a^2 + b^2 + c^2 & b^2 & c^2 + x^2 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\Delta = \begin{vmatrix} x^2 + a^2 + b^2 + c^2 & b^2 & c^2 \\ 0 & \ddots\ x^2 & 0 \\ 0 & 0\ \ddots & x^2 \end{vmatrix}$$

$$= x^4 (x^2 + a^2 + b^2 + c^2)$$

32. Let $\Delta = \begin{vmatrix} \sqrt{6} & 2i & 3 + \sqrt{6} \\ \sqrt{12} & \sqrt{3} + \sqrt{8}\,i & 3\sqrt{2} + \sqrt{6}\,i \\ \sqrt{18} & \sqrt{2} + \sqrt{12}\,i & \sqrt{27} + 2i \end{vmatrix}$

Applying $R_2 \to R_2 - \sqrt{2}\,R_1$ and $R_3 \to R_3 - \sqrt{3}\,R_1$, then

$$\Delta = \begin{vmatrix} \sqrt{6} & \cdots & 2i & \cdots & 3 + \sqrt{6} \\ \vdots & & & & \\ 0 & & \sqrt{3} & & -2\sqrt{3} + 6i \\ \vdots & & & & \\ 0 & & \sqrt{2} & & -3\sqrt{2} + 2i \end{vmatrix}$$

Expanding along C_1, we get

$$= \sqrt{6} \begin{vmatrix} \sqrt{3} & -2\sqrt{3} + \sqrt{6}i \\ \sqrt{2} & -3\sqrt{2} + 2i \end{vmatrix}$$

$$= \sqrt{6}\,[-3\sqrt{6} + 2i\sqrt{3} + 2\sqrt{6} - 2i\sqrt{3}]$$

$$= \sqrt{6}\,(-\sqrt{6}) = -6 \qquad \text{[real and rational]}$$

33. $\sum_{k=1}^{n} 2^{k-1} = 1 + 2 + 2^2 + \ldots + 2^n = 2^n - 1$

$$\sum_{k=1}^{n}\frac{1}{k(k+1)}=\sum_{k=1}^{n}\left(\frac{1}{k}-\frac{1}{k+1}\right)$$

$$=\frac{1}{1}-\frac{1}{n+1}=\frac{n}{n+1}$$

and $\sum_{k=1}^{n}\sin k\theta=\dfrac{\sin\left(\frac{n+1}{2}\right)\theta\sin\left(\frac{n\theta}{2}\right)}{\sin\left(\frac{\theta}{2}\right)}$

Given, $D_k=\begin{vmatrix} 2^{k-1} & \frac{1}{k(k+1)} & \sin k\theta \\ x & y & z \\ 2^n-1 & \frac{n}{n+1} & \frac{\sin\left(\frac{n+1}{2}\right)\theta\sin\left(\frac{n\theta}{2}\right)}{\sin\left(\frac{\theta}{2}\right)} \end{vmatrix}$

$$\therefore \sum_{k=1}^{n}D_k=\begin{vmatrix} \sum_{k=1}^{n}2^{k-1} & \sum_{k=1}^{n}\frac{1}{k(k+1)} & \sum_{k=1}^{n}\sin k\theta \\ x & y & z \\ 2^n-1 & \frac{n}{n+1} & \frac{\sin\left(\frac{n+1}{2}\right)\theta\sin\left(\frac{n\theta}{2}\right)}{\sin\left(\frac{\theta}{2}\right)} \end{vmatrix}$$

$$=\begin{vmatrix} 2^n-1 & \frac{n}{n+1} & \frac{\sin\left(\frac{n+1}{2}\right)\theta\sin\left(\frac{n\theta}{2}\right)}{\sin\left(\frac{\theta}{2}\right)} \\ x & y & z \\ 2^n-1 & \frac{n}{n+1} & \frac{\sin\left(\frac{n+1}{2}\right)\theta\sin\left(\frac{n\theta}{2}\right)}{\sin\left(\frac{\theta}{2}\right)} \end{vmatrix}=0$$

34. We have, $\begin{vmatrix} a & b & a\alpha+b \\ b & c & b\alpha+c \\ a\alpha+b & b\alpha+c & 0 \end{vmatrix}=0$

Applying $C_3\to C_3-\alpha C_1-C_2$, then

$$\begin{vmatrix} a & b & 0 \\ b & c & 0 \\ aa+b & ba+c & -(aa^2+2ba+c) \end{vmatrix}=0$$

Expanding along C_3, we get

$$-(a\alpha^2+2b\alpha+c)(ac-b^2)=0$$

$$\Rightarrow\quad (a\alpha^2+2b\alpha+c)(b^2-ac)=0$$

$$\Rightarrow\quad b^2-ac=0 \text{ and } a\alpha^2+2b\alpha+c=0$$

i.e. a, b and c are in GP and $(x-\alpha)$ is a factor of $ax^2+2bx+c=0$.

35. $\because\quad f(x)=\begin{vmatrix} 2\cos x & 1 & 0 \\ 1 & 2\cos x & 1 \\ 0 & 1 & 2\cos x \end{vmatrix}$

$$=2\cos x(4\cos^2 x-1)-1(2\cos x-0)+0$$

$$=2\cos x(4\cos^2 x-1-1)$$

$$=4\cos x(2\cos^2 x-1)$$

$$=4\cos x\cos 2x$$

$$=2(\cos 3x+\cos x)$$

Option (a)

$$f\left(\frac{\pi}{3}\right)=2\left(\cos\frac{3\pi}{3}+\cos\frac{\pi}{3}\right)=2\left(-1+\frac{1}{2}\right)=-1$$

Option (b)

$$f'(x)=2(-3\sin 3x-\sin x)$$

$$\therefore\quad f'\left(\frac{\pi}{3}\right)=2\left(-3\sin\pi-\sin\frac{\pi}{3}\right)=2\left(0-\frac{\sqrt{3}}{2}\right)=-\sqrt{3}$$

Option (c)

$$\int_0^{\pi}f(x)\,dx=2\int_0^{\pi}(\cos 3x+\cos x)\,dx=2\left[\frac{\sin 3x}{3}+\sin x\right]_0^{\pi}$$

$$=2[(0+0)-(0+0)]=0$$

Option (d)

$$\int_0^{\pi}f(x)\,dx=2\int_{-\pi}^{\pi}(\cos 3x+\cos x)\,dx=4\int_0^{\pi}(\cos 3x+\cos x)\,dx$$

$$=0 \qquad \text{[from option (c)]}$$

36. $\because\ \Delta(x)=\begin{vmatrix} x^2-5x+3 & 2x-5 & 3 \\ 3x^3+x+4 & 6x+1 & 9 \\ 7x^2-6x+9 & 14x-6 & 21 \end{vmatrix}$

Applying $R_2\to R_2-3R_1$ and $R_3\to R_3-7R_1$, then

$$=\begin{vmatrix} x^2-5x+3 & \cdots & 2x-5 & \cdots & 3 \\ & & & & \vdots \\ 16x-5 & & 16 & & 0 \\ & & & & \vdots \\ 29x-12 & & 29 & & 0 \end{vmatrix}$$

Expanding along C_3, we get $=3\begin{vmatrix} 16x-5 & 16 \\ 29x-12 & 29 \end{vmatrix}$

Applying $C_1\to C_1-xC_2$, then

$$\Delta(x)=3\begin{vmatrix} -5 & 16 \\ -12 & 29 \end{vmatrix}=3(-145+192)=3\times 47$$

$$=141=ax^3+bx^2+cx+d \text{ [given]}$$

$$\therefore\quad a=0, b=0, c=0, d=141$$

37. $\because\ \Delta=\begin{vmatrix} a^2 & b\sin A & c\sin A \\ b\sin A & 1 & \cos A \\ c\sin A & \cos A & 1 \end{vmatrix}$

Taking common a from each R_1 and C_1, then

$$\Delta = \begin{vmatrix} 1 & \frac{b\sin A}{a} & \frac{c\sin A}{a} \\ \frac{b\sin A}{a} & 1 & \cos A \\ \frac{c\sin A}{a} & \cos A & 1 \end{vmatrix} = \begin{vmatrix} 1 & \sin B & \sin C \\ \sin B & 1 & \cos A \\ \sin C & \cos A & 1 \end{vmatrix}$$

[by sine rule]

Applying $C_2 \to C_2 - \sin B C_1$ and $C_3 \to C_3 - \sin C C_1$, then

$$\Delta = \begin{vmatrix} 1 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ \sin B & & 1-\sin^2 B & & \cos A - \sin B \sin C \\ \vdots & & & & \\ \sin C & & \cos A - \sin B \sin C & & 1-\sin^2 C \end{vmatrix}$$

Expanding along R_1, then

$$\Delta = \begin{vmatrix} \cos^2 B & \cos[\pi - (B+C)] \\ \cos[\pi - (B+C)] - \sin B \sin C & -\sin B \sin C \\ & \cos^2 C \end{vmatrix}$$

$[\because A + B + C = \pi]$

Expanding along R_1, then

$$f(a,b) = a\begin{vmatrix} (a+b) & (a+b)^2 \\ 1 & (2a+3b) \end{vmatrix}$$

$$= a(a+b)\begin{vmatrix} 1 & (a+b) \\ 1 & (2a+3b) \end{vmatrix}$$

$$= a(a+b)(2a+3b-a-b)$$

$$= a(a+b)(a+2b)$$

39. $\because$ $f(x) = \begin{vmatrix} \sec^2 x & 1 & 1 \\ \cos^2 x & \cos^2 x & \operatorname{cosec}^2 x \\ 1 & \cos^2 x & \cot^2 x \end{vmatrix}$

Applying $C_2 \to C_2 - \cos^2 x\, C_1$, then

$$f(x) = \begin{vmatrix} \sec^2 x & 0 & 1 \\ & \vdots & \\ \cos^2 x & \cdots \quad \cos^2 x - \cos^4 x \quad \cdots & \operatorname{cosec}^2 x \\ & \vdots & \\ 1 & 0 & \cot^2 x \end{vmatrix}$$

Expanding along C_2, then

$$f(x) = \sin^2 x \cos^2 x \begin{vmatrix} \sec^2 x & 1 \\ 1 & \cot^2 x \end{vmatrix}$$

$$= \sin^2 x \cos^2 x (\operatorname{cosec}^2 x - 1)$$

$$= \sin^2 x \cos^2 x \cot^2 x = \cos^4 x$$

option (a)

$$\int_{-\pi/4}^{\pi/4} f(x)\,dx = \int_{-\pi/4}^{\pi/4} \cos^4 x\,dx = 2\int_0^{\pi/4} \cos^4 x\,dx$$

$$= 2\int_0^{\pi/4} \left(\frac{1+\cos 2x}{2}\right)^2 dx$$

$$= 2 \times \frac{1}{2}\int_0^{\pi/2} \left(\frac{1+\cos x}{2}\right)^2 dx$$

$$= \frac{1}{4}\int_0^{\pi/2} (1 + 2\cos x + \cos^2 x)\,dx$$

$$= \frac{1}{4}\int_0^{\pi/2} 1 \cdot dx + \frac{1}{2}\int_0^{\pi/2} \cos x\,dx + \frac{1}{4}\int_0^{\pi/2} \cos^2 x\,dx$$

$$= \frac{1}{4}\left(\frac{\pi}{2} - 0\right) + \frac{1}{2}(\sin x)_0^{\pi/2} + \frac{1}{4}\cdot\frac{1}{2}\cdot\frac{\pi}{2}$$

$$= \frac{\pi}{8} + \frac{1}{2}(1-0) + \frac{\pi}{16} = \frac{1}{16}(2\pi + 8 + \pi) = \frac{1}{16}(3\pi + 8)$$

option (b)

$\because$ $f'(x) = 4\cos^3 x \cdot (-\sin x)$

$\therefore$ $f'\left(\frac{\pi}{2}\right) = 0$

option (c) and (d)

$\because$ $0 \le \cos^4 x \le 1$

$\because$ Maximum value of $f(x)$ is 1.

and minimum value of $f(x)$ is 0.

40. Let $\Delta = \begin{vmatrix} a & a+x^2 & a+x^2+x^4 \\ 2a & 3a+2x^2 & 4a+3x^2+2x^4 \\ 3a & 6a+3x^2 & 10a+6x^2+3x^4 \end{vmatrix}$

Applying $R_2 \to R_2 - 2R_1$ and $R_3 \to R_3 - 3R_1$, then

$$\Delta = \begin{vmatrix} a & a+x^2 & a+x^2+x^4 \\ 0 & a & 2a+x^2 \\ 0 & 3a & 7a+3x^2 \end{vmatrix}$$

Applying $R_3 \to R_3 - 3R_2$, then

$$\Delta = \begin{vmatrix} a & \ddots & a+x^2 & a+x^2+x^4 \\ 0 & & a & 2a+x^2 \\ 0 & & 0 & \ddots \quad a \end{vmatrix}$$

$$= a^3 = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 \quad \text{[given]}$$

$\therefore \quad a_0 = a^3, a_1 = 0, a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0, a_6 = 0, a_7 = 0$

and $\quad f(x) = a_0 x^2 + a_3 x + a_6 = a^3 x^2$

option (a) $f(x) \geq 0 \Rightarrow a^3 x^2 \geq 0$

If $a^3 > 0$, then $x^2 \geq 0$

$\therefore \quad a > 0, x \in R$

option (b) If $a = 0$, then $f(x) = 0$

and $\quad$ If $x = 0$, then $f(x) = 0$

$\therefore$ Aliter (b) is fail

option (c) $f(x) = 0$

$\Rightarrow \quad a^3 x^2 = 0$ or $x^2 = 0$

$\therefore \quad x = 0, 0$

option (d) For $a = 0$, $f(x) = 0$ is an identity, then it has more than two roots.

41. Let $\Delta(x) = \begin{vmatrix} 4x-4 & (x-2)^2 & x^3 \\ 8x-4\sqrt{2} & (x-2\sqrt{2})^2 & (x+1)^3 \\ 12x-4\sqrt{3} & (x-2\sqrt{3})^2 & (x-1)^3 \end{vmatrix}$

$= a_0 + a_1 x + a_2 x^2 + \ldots \ldots$(i)

On putting $x = 0$ in Eq. (i), then

$$\begin{vmatrix} -4 & 4 & 0 \\ -4\sqrt{2} & 8 & 1 \\ -4\sqrt{3} & 12 & -1 \end{vmatrix} = a_0$$

or $\quad a_0 = -4(-8-12) - 4(4\sqrt{2} + 4\sqrt{3})$

$= 16(5 - \sqrt{2} - \sqrt{3}) =$ term independent of x in Δ.

Also, on differentiating Eq. (i) w.r.t. x and then put $x = 0$, we get

$$\begin{vmatrix} 4 & -4 & 0 \\ -4\sqrt{2} & 8 & 1 \\ -4\sqrt{3} & 12 & -1 \end{vmatrix} + \begin{vmatrix} -4 & 4 & 0 \\ 8 & -4\sqrt{2} & 3 \\ -4\sqrt{3} & 12 & -1 \end{vmatrix} + \begin{vmatrix} -4 & 4 & 0 \\ -4\sqrt{2} & 8 & 1 \\ 12 & -4\sqrt{3} & 3 \end{vmatrix} = a_1$$

$\therefore \quad a_1 = 4(-8-12) + 4(4\sqrt{2} + 4\sqrt{3})$

$- 4(4\sqrt{2} - 36) - 4(-8 + 12\sqrt{3})$

$- 4(24 + 4\sqrt{3}) - 4(-12\sqrt{2} - 12)$

$= 48 + 48\sqrt{2} - 48\sqrt{3} = 48(1 + \sqrt{2} - \sqrt{3})$

$=$ Coefficient of x in $\Delta(x)$

42. $\because \quad f(x) = \begin{vmatrix} 3 & 3x & 3x^2 + 2a^2 \\ 3x & 3x^2 + 2a^2 & 3x^3 + 6a^2 x \\ 3x^2 + 2a^2 & 3x^3 + 6a^2 x & 3x^4 + 12a^2 x^2 + 2a^4 \end{vmatrix}$

Applying $C_3 \to C_3 - xC_2$ and $C_2 \to C_2 - xC_1$, then

$$f(x) = \begin{vmatrix} 3 & 0 & 2a^2 \\ 3x & 2a^2 & 4a^2 x \\ 3x^2 + 2a^2 & 4a^2 x & 6a^2 x^2 + 2a^4 \end{vmatrix}$$

Applying $C_3 \to C_3 - x C_2$, then

$$= \begin{vmatrix} 3 & 0 & 2a^2 \\ 3x & 2a^2 & 2a^2 x \\ 3x^2 + 2a^2 & 4a^2 x & 2a^2 x^2 + 2a^4 \end{vmatrix}$$

$$= 4a^4 \begin{vmatrix} 3 & 0 & 1 \\ 3x & 1 & x \\ 3x^2 + 2a^2 & 2x & x^2 + a^2 \end{vmatrix}$$

Applying $C_1 \to C_1 - 3C_3$, then

$$f(x) = 4a^4 \begin{vmatrix} 0 & 0 & 1 \\ \vdots & & \\ 0 & 1 & x \\ \vdots & & \\ -a^2 \quad \cdots & 2x \quad \cdots & x^2 + a^2 \end{vmatrix}$$

Expanding along C_1, we get

$= 4a^4 [-a^2 (0 - 1)] = 4a^6$

$\therefore \quad f'(x) = 0$

i.e. $y = f(x)$ is a straight line parallel to X-axis.

43. $\because a > b > c$ and given equations are

$$ax + by + cz = 0,$$
$$bx + cy + az = 0$$

and $\quad cx + ay + bz = 0$

For non-trivial solution

$$\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = 0$$

$\Rightarrow \quad 3abc - (a^3 + b^3 + c^3) = 0$

$\therefore \quad a + b + c = 0$

If α and β be the roots of $at^2 + bt + c = 0$

$\therefore \quad \alpha + \beta = -\frac{b}{a}$ and $\alpha\beta = \frac{c}{a}$

and $\quad D = b^2 - 4ac = (-a - c)^2 - 4ac = (a - c)^2 > 0$

For opposite sign $|\alpha - \beta| > 0$

$\Rightarrow \quad (\alpha - \beta)^2 > 0 \Rightarrow (\alpha + \beta)^2 - 4\alpha\beta > 0$

$\Rightarrow \quad \frac{b^2}{a^2} - \frac{4c}{a} > 0 \Rightarrow (-a - c)^2 - 4ac > 0$

$\Rightarrow \quad (a - c)^2 > 0$, true

Hence, the roots are real and have opposite sign.

44. Here, $\Delta = \begin{vmatrix} 1 & 1 & 1 \\ 1 & 3 & 2 \\ 1 & \lambda & 3 \end{vmatrix} = 1(9 - 2\lambda) - 1(3 - 2) + 1(\lambda - 3)$

$= -(\lambda - 5)$

$$\Delta_1 = \begin{vmatrix} 3 & 1 & 1 \\ 6 & 3 & 2 \\ b & \lambda & 3 \end{vmatrix} = 3(9 - 2\lambda) - 1(18 - 2b) + 1(6\lambda - 3b)$$

$= -(b - 9)$

$$\Delta_2 = \begin{vmatrix} 1 & 3 & 1 \\ 1 & 6 & 2 \\ 1 & b & 3 \end{vmatrix} = 1$$

$$(18 - 2b) - 3(3 - 2) + 1(b - 6) = -(b - 9)$$

and $\Delta_3 = \begin{vmatrix} 1 & 1 & 3 \\ 1 & 3 & 6 \\ 1 & \lambda & b \end{vmatrix} = 1$

$$(3b - 6\lambda) - 1(b - 6) + 3(\lambda - 3) = (2b - 3\lambda - 3)$$

Aliter (a) for unique solution $\Delta \neq 0$

i.e. $\lambda \neq 5, b \in R$

Aliter (b) for no solution

$D = 0$ and atleast one of $\Delta_1, \Delta_2, \Delta_3$ is non-zero

$\therefore \quad \lambda = 5, b \neq 9$

Aliter (c) For infinite many solution

$\Delta = \Delta_1 = \Delta_2 = \Delta_3 = 0$

$\therefore \quad \lambda = 5, b = 9$

45. For non-trivial solutions

$$\begin{vmatrix} \lambda & \sin\alpha & \cos\alpha \\ 1 & \cos\alpha & \sin\alpha \\ -1 & \sin\alpha & -\cos\alpha \end{vmatrix} = 0$$

Expanding along C_1, we get

$\Rightarrow \quad \lambda(-\cos^2\alpha - \sin^2\alpha) - 1(-\sin\alpha\cos\alpha - \sin\alpha\cos\alpha)$

$$-1(\sin^2\alpha - \cos^2\alpha) = 0$$

$\Rightarrow \quad -\lambda + \sin2\alpha + \cos2\alpha = 0$

$\Rightarrow \quad \lambda = (\sin2\alpha + \cos2\alpha)$

$\because \quad -\sqrt{2} \le \sin2\alpha + \cos2\alpha \le \sqrt{2}$

$\therefore \quad -\sqrt{2} \le \lambda \le \sqrt{2}$

$\Rightarrow \quad S = [-\sqrt{2}, \sqrt{2}]$

Sol. (Q. Nos. 46 to 48)

$$\Delta = \begin{vmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & \lambda \end{vmatrix} = (\lambda - 5),$$

$$\Delta_1 = \begin{vmatrix} 5 & 1 & 1 \\ 9 & 2 & 3 \\ \mu & 3 & \lambda \end{vmatrix} = (\lambda + \mu - 18),$$

$$\Delta_2 = \begin{vmatrix} 1 & 5 & 1 \\ 1 & 9 & 3 \\ 1 & \mu & \lambda \end{vmatrix} = (4\lambda - 2\mu + 6)$$

and $\Delta_3 = \begin{vmatrix} 1 & 1 & 5 \\ 1 & 2 & 9 \\ 1 & 3 & \mu \end{vmatrix} = (\mu - 13)$

46. The system is smart, if

$\Delta \neq 0 \Rightarrow \lambda \neq 5$

or $\quad \Delta = \Delta_1 = \Delta_2 = \Delta_3 = 0$

$\Rightarrow \quad \lambda = 5$ and $\mu = 13$

47. The system is good, if

$\Delta = \Delta_1 = \Delta_2 = \Delta_3 = 0$

$\Rightarrow \quad \lambda = 5$ and $\mu = 13$

48. The system is lazy, if

$\Delta = 0$ and atleast one of $\Delta_1, \Delta_2, \Delta_3 \neq 0$

$\Rightarrow \quad \lambda = 5$ and $\mu \neq 13$

Sol. (Q. Nos. 49 to 51)

$$\because \quad \begin{vmatrix} bc - a^2 & ca - b^2 & ab - c^2 \\ ca - b^2 & ab - c^2 & bc - a^2 \\ ab - c^2 & bc - a^2 & ca - b^2 \end{vmatrix} = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}^2 \qquad \text{...(i)}$$

For $a = 1, b = x$ and $c = x^2$

$$\begin{vmatrix} x^3 - 1 & 0 & x - x^4 \\ 0 & x - x^4 & x^3 - 1 \\ x - x^4 & x^3 - 1 & 0 \end{vmatrix} = \begin{vmatrix} 1 & x & x^2 \\ x & x^2 & 1 \\ x^2 & 1 & x \end{vmatrix}^2$$

$\therefore \quad \Delta = 5^2 = 25$

49. $\because \quad \Delta^2 = (25)^2 = 625$

Sum of digits of $\Delta^2 = 6 + 2 + 5 = 13$

50. From Eq. (i), we get

$$\begin{vmatrix} A & B & C \\ B & C & A \\ C & A & B \end{vmatrix} = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}^2$$

$$\Rightarrow \quad 49 = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}^2$$

$$\Rightarrow \quad q \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = \pm 7$$

$\Rightarrow \quad -(a^3 + b^3 + c^3 - 3abc) = \pm 7$

$\Rightarrow \quad a^3 + b^3 + c^3 - 3abc = \mp 7$

$\therefore \quad a^3 + b^3 + c^3 - 3abc = 7 \qquad [\because a + b + c > 0]$

51. $\because \quad aA + bB + cC = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = -(a^3 + b^3 + c^3 - 3abc)$

$$= -(-3) = 3$$

Sol. (Q. Nos. 52 to 54)

$\because \quad \alpha + \beta + \gamma = -2, \alpha\beta + \beta\gamma + \gamma\alpha = -1$ and $\alpha\beta\gamma = 3$

52. $\begin{vmatrix} \alpha & \beta & \gamma \\ \gamma & \alpha & \beta \\ \beta & \gamma & \alpha \end{vmatrix} = -\begin{vmatrix} \alpha & \beta & \gamma \\ \beta & \gamma & \alpha \\ \gamma & \alpha & \beta \end{vmatrix} = \alpha^3 + \beta^3 + \gamma^3 - 3\alpha\beta\gamma$

$$= (\alpha + \beta + \gamma)(\alpha^2 + \beta^2 + \gamma^2 - \alpha\beta - \beta\gamma - \gamma\alpha)$$

$$= (\alpha + \beta + \gamma)[(\alpha + \beta + \gamma)^2 - 3(\alpha\beta + \beta\gamma + \gamma\alpha)]$$

$$= (-2)(4 - 9) = 10$$

53. Let $x = \dfrac{\alpha - 1}{\alpha + 2} \Rightarrow \alpha = \dfrac{2x + 1}{1 - x}$

$\because \quad \alpha$ is a root of $x^3 + 2x^2 - x - 3 = 0$

$\Rightarrow \quad \alpha^3 + 2\alpha^2 - \alpha - 3 = 0$

$$\Rightarrow \left(\frac{2x+1}{1-x}\right)^3+2\left(\frac{2x+1}{1-x}\right)^2-\left(\frac{2x+1}{1-x}\right)-3=0$$

$$\Rightarrow x^3+6x^2+21x-1=0 \quad ...(i)$$

Hence, $\frac{\alpha-1}{\alpha+2}, \frac{\beta-1}{\beta+2}$ and $\frac{\gamma-1}{\gamma+2}$ are the roots of Eq. (i), then

$$\frac{\alpha-1}{\alpha+2}+\frac{\beta-1}{\beta+2}+\frac{\gamma-1}{\gamma+2}=-6$$

$$\therefore \left|\frac{\alpha-1}{\alpha+2}+\frac{\beta-1}{\beta+1}+\frac{\gamma-1}{\gamma+2}\right|=\frac{6}{1}=\frac{m}{n}$$

$$\Rightarrow m=6 \text{ and } n=1,$$

then $$\begin{vmatrix} m & n^2 \\ m-n & m+n \end{vmatrix}=\begin{vmatrix} 6 & 1 \\ 5 & 7 \end{vmatrix}=42-5=37$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\Delta_n = \begin{vmatrix} n+a^2+b^2+c^2 & b^2 & c^2 \\ & \ddots & \\ 0 & n & 0 \\ & & \ddots \\ 0 & 0 & n \end{vmatrix}$$

$\Delta_n = n^3 + n^2(a^2+b^2+c^2) \qquad ...(i)$

Also, $a+b+c = \lambda$

$3b = \lambda \qquad [\because a, b, c \text{ are in AP}]$

$\therefore \quad b = \frac{\lambda}{3}$

Also, b is root of $x^3 - \lambda x^2 + 11x - 6 = 0$

$\Rightarrow \quad b^3 - \lambda b^2 + 11b - 6 = 0$

$\Rightarrow \quad \frac{\lambda^3}{27} - \frac{\lambda^3}{9} + \frac{11\lambda}{3} - 6 = 0$

$\Rightarrow \quad 2\lambda^3 - 99\lambda + 162 = 0$

$\because \quad \lambda = 6$

Then, equation becomes $x^3 - 6x^2 + 11x - 6 = 0$

$\therefore \quad x = 1, 2, 3$

Let $\quad a = 1, b = 2$ and $c = 3$

From Eq. (i), we get

$$\Delta_n = n^3 + 14n^2$$

$$\therefore \quad \sum_{n=1}^{n} \Delta_n = \frac{n(n+1)(3n^2+59n+28)}{12}$$

64. $\displaystyle\sum_{r=1}^{7} \Delta_r = \frac{7\cdot 8(147+59\cdot 7+28)}{12} = (14)^3$

65. $\dfrac{\Delta_{2n}}{\Delta_n} = \dfrac{8(n+7)}{(n+14)} < 8$

$\therefore \quad \dfrac{\Delta_{2n}}{\Delta_n} < 8$

66. $\because \quad \Delta_r = r^3 + 14r^2$

$$\therefore \quad \frac{27\Delta_r - \Delta_{3r}}{27r^2} = \frac{28}{3}$$

$$\Rightarrow \quad \sum_{r=1}^{30}\left(\frac{27\Delta_r - \Delta_{3r}}{27r^2}\right) = \frac{28}{3}\times 30 = 280$$

67. We have, $\begin{vmatrix} 3^2+k & 4^2 & 3^2+3+k \\ 4^2+k & 5^2 & 4^2+4+k \\ 5^2+k & 6^2 & 5^2+5+k \end{vmatrix} = 0$

Applying $C_3 \to C_3 - C_1$, then

$$\begin{vmatrix} 3^2+k & 4^2 & 3 \\ 4^2+k & 5^2 & 4 \\ 5^2+k & 6^2 & 5 \end{vmatrix} = 0$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\begin{vmatrix} 9+k & 16 & 3 \\ 7 & 9 & 1 \\ 16 & 20 & 2 \end{vmatrix} = 0$$

$$\Rightarrow (9+k)(18-20) - 16(14-16) + 3(140-144) = 0$$

$$\Rightarrow \quad -18 - 2k + 32 - 12 = 0 \quad \Rightarrow 2k = 2$$

$$\therefore \quad k = 1$$

Now, $\sqrt{2^k\sqrt{2^k\sqrt{2^k\ldots}}}\infty = (2^k)^{\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\ldots+\infty}$

$$= (2^k)^{\frac{\frac{1}{2}}{1-\frac{1}{2}}} = 2^k = 2^1 = 2$$

68. We have, $\begin{vmatrix} x-1 & -6 & 2 \\ -6 & x-2 & -4 \\ 2 & -4 & x-6 \end{vmatrix} = 0$

Applying $C_2 \to C_2 + 3C_3$, then

$$\begin{vmatrix} x-1 & 0 & 2 \\ -6 & x-14 & -4 \\ 2 & 3x-22 & x-6 \end{vmatrix} = 0$$

Expanding along R_1, then

$$(x-1)\{(x-14)(x-6) + 4(3x-22)\} - 0 + 2\{-18x + 132 - 2x + 2\} = 0$$

$$\Rightarrow (x-1)(x^2 - 8x - 4) + 2(-20x + 160) = 0$$

$$\Rightarrow \quad x^3 - 9x^2 - 36x + 324 = 0$$

$$\Rightarrow \quad (x-9)(x-6)(x+6) = 0$$

$$\therefore \quad x = 9 \text{ or } 6 \text{ or } -6$$

Now, let $\alpha = 9, \beta = 6, \gamma = -6$

$$\therefore \quad \frac{1}{\alpha} + \frac{1}{\beta} + \frac{1}{\gamma} = \frac{1}{9} + \frac{1}{6} - \frac{1}{6} = \frac{1}{9}$$

$$\therefore \quad \left(\frac{1}{\alpha} + \frac{1}{\beta} + \frac{1}{\gamma}\right)^{-1} = 9$$

69. We have, $\begin{vmatrix} x & e^{x-1} & (x-1)^3 \\ x - \ln x & \cos(x-1) & (x-1)^2 \\ \tan x & \sin^2 x & \cos^2 x \end{vmatrix}$

$$= a_0 + a_1(x-1) + a_2(x-1)^2 + \ldots + a_n(x-1)^n \quad \ldots(\text{i})$$

On putting $x = 1$ in Eq. (i), we get

$$\begin{vmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ \tan 1 & \sin^2 1 & \cos^2 1 \end{vmatrix} = a_0 + 0 + 0 + \ldots$$

$$\therefore \quad a_0 = 0 \qquad [\because R_1 \text{ and } R_2 \text{ an identical}]$$

On differentiating Eq. (i) both sides w.r.t.x, then

$$\begin{vmatrix} 1 & e^{x-1} & 3(x-1)^2 \\ x - \ln x & \cos(x-1) & (x-1)^2 \\ \tan x & \sin^2 x & \cos^2 x \end{vmatrix} + \begin{vmatrix} x & e^{x-1} & (x-1)^3 \\ \left(1-\frac{1}{x}\right) & -\sin(x-1) & 2(x-1) \\ \tan x & \sin^2 x & \cos^2 x \end{vmatrix} + \begin{vmatrix} x & e^{x-1} & (x-1)^3 \\ x - \ln x & \cos(x-1) & (x-1)^2 \\ \sec^2 x & \sin 2x & -\sin 2x \end{vmatrix}$$

$$= 0 + a_1 + 2a_2(x-1) + 3a_3(x-1)^2 + \ldots + na_n(x-1)^{n-1}$$

Now, on putting $x = 1$, we get

$$\begin{vmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ \tan 1 & \sin^2 1 & \cos^2 1 \end{vmatrix} + \begin{vmatrix} 1 & 1 & 0 \\ 0 & 0 & 0 \\ \tan 1 & \sin^2 1 & \cos^2 1 \end{vmatrix} + \begin{vmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ \sec^2 1 & \sin 2 & -\sin 2 \end{vmatrix}$$

$$= a_1 + 0 + 0 + \ldots + 0$$

$$\therefore a_1 = 0 + 0 + 0 = 0$$

Hence, $(2^{a_0} + 3^{a_1})^{a_1+1} = (2^0 + 3^0)^{0+1} = (1+1)^1 = 2^1 = 2$

70. Given, $\begin{vmatrix} 1 & \cos\alpha & \cos\beta \\ \cos\alpha & 1 & \cos\gamma \\ \cos\beta & \cos\gamma & 1 \end{vmatrix} = \begin{vmatrix} 0 & \cos\alpha & \cos\beta \\ \cos\alpha & 0 & \cos\gamma \\ \cos\beta & \cos\gamma & 0 \end{vmatrix}$

$$\Rightarrow \quad 1(1-\cos^2\gamma) - \cos\alpha(\cos\alpha - \cos\beta\cos\gamma) + \cos\beta(\cos\gamma\cos\alpha - \cos\beta)$$

$$= 0 - \cos\alpha(0 - \cos\beta\cos\gamma) + \cos\beta(\cos\gamma\cos\alpha - 0)$$

$$\Rightarrow 1 - \cos^2\alpha - \cos^2\beta - \cos^2\gamma + 2\cos\alpha\cos\beta\cos\gamma = 2\cos\alpha\cos\beta\cos\gamma$$

$$\Rightarrow 1 - \cos^2\alpha - \cos^2\beta - \cos^2\gamma = 0$$

Hence, $\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$

71. $\because f(a,b,c) = \begin{vmatrix} (b+c)^2 & a^2 & a^2 \\ b^2 & (c+a)^2 & b^2 \\ c^2 & c^2 & (a+b)^2 \end{vmatrix}$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$, then

$$f(a,b,c) = \begin{vmatrix} (b+c)^2 & a^2-(b+c)^2 & a^2-(b+c)^2 \\ b^2 & (c+a)^2-b^2 & 0 \\ c^2 & 0 & (a+b)^2-c^2 \end{vmatrix}$$

$$= \begin{vmatrix} (b+c)^2 & (a+b+c)(a-b-c) & (a+b+c)(a-b-c) \\ b^2 & (c+a+b)(c+a-b) & 0 \\ c^2 & 0 & (a+b+c)(a+b-c) \end{vmatrix}$$

$$= (a+b+c)^2 \begin{vmatrix} (b+c)^2 & a-b-c & a-b-c \\ b^2 & c+a-b & 0 \\ c^2 & 0 & a+b-c \end{vmatrix}$$

Applying $R_1 \to R_1 - (R_2 + R_3)$, then

$$f(a,b,c) = (a+b+c)^2 \begin{vmatrix} 2bc & -2c & -2b \\ b^2 & c+a-b & 0 \\ c^2 & 0 & a+b-c \end{vmatrix}$$

Applying $C_2 \to C_2 + \frac{1}{b} C_1$ and $C_3 \to C_3 + \frac{1}{c} C_1$, then

$$f(a,b,c) = (a+b+c)^2 \begin{vmatrix} 2bc & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ b^2 & & c+a & & \frac{b^2}{c} \\ \vdots & & & & \\ c^2 & & \frac{c^2}{b} & & a+b \end{vmatrix}$$

Expanding along R_1, then

$$f(a,b,c) = (a+b+c)^2 [2bc\{(c+a)(a+b)-bc\}]$$
$$= (a+b+c)^2 \{2bc(ac+bc+a^2+ab-bc)\}$$
$$= 2bc(a+b+c)^2 a(a+b+c)$$
$$= 2abc(a+b+c)^3$$

We get, greatest integer $n \in N$ such that $(a+b+c)^n$ divides $f(a,b,c)$ is 3.

72. The system of equations has a non-trivial solution, then

$$\begin{vmatrix} 1 & -\sin\theta & -\cos\theta \\ -\cos\theta & 1 & -1 \\ -\sin\theta & -1 & 1 \end{vmatrix} = 0$$

Applying $C_3 \to C_3 + C_2$, then

$$\begin{vmatrix} 1 & \cdots & -\sin\theta & \cdots & -\sin\theta - \cos\theta \\ & & & & \vdots \\ -\cos\theta & & 1 & & 0 \\ & & & & \vdots \\ -\sin\theta & & -1 & & 0 \end{vmatrix} = 0$$

Expanding along C_3, then

$$(-\sin\theta - \cos\theta)(\cos\theta + \sin\theta) = 0$$
$$\Rightarrow \quad (\sin\theta + \cos\theta)^2 = 0$$
$$\Rightarrow \quad \sin\theta + \cos\theta = 0$$
$$\Rightarrow \quad \sin\theta = -\cos\theta$$
$$\therefore \quad \tan\theta = -1$$
$$\Rightarrow \quad \theta = \frac{3\pi}{4} \qquad [\because \theta \in [0, \pi]]$$

Hence, $\frac{8\theta}{\pi} = 6$

73. Let $\Delta = \begin{vmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{vmatrix}$

Applying $R_2 \to R_2 - R_1$, $R_3 \to R_3 - R_1$ and $R_4 \to R_4 - R_1$, then

$$\Delta = \begin{vmatrix} 1 & \cdots & 1 & \cdots & 1 & \cdots & 1 \\ \vdots & & & & & & \\ 0 & & 1 & & 2 & & 3 \\ \vdots & & & & & & \\ 0 & & 2 & & 5 & & 9 \\ \vdots & & & & & & \\ 0 & & 3 & & 9 & & 19 \end{vmatrix}$$

Expanding along C_1, then $\Delta = \begin{vmatrix} 1 & 2 & 3 \\ 2 & 5 & 9 \\ 3 & 9 & 19 \end{vmatrix}$

Applying $R_2 \to R_2 - 2R_1$ and $R_3 \to R_3 - R_1$, then $= \begin{vmatrix} 1 & 2 & 3 \\ 0 & 1 & 3 \\ 0 & 3 & 10 \end{vmatrix}$

Expanding along C_1, we get $\Delta = 1 \begin{vmatrix} 1 & 3 \\ 3 & 10 \end{vmatrix} = 10 - 9 = 1$

74. Let $\Delta = \begin{vmatrix} 1+a & 1 & 1 & 1 \\ 1 & 1+b & 1 & 1 \\ 1 & 1 & 1+c & 1 \\ 1 & 1 & 1 & 1+d \end{vmatrix}$

Taking a, b, c, d common from R_1, R_2, R_3 and R_4 respectively, then

$$\Delta = abcd \begin{vmatrix} 1+\frac{1}{a} & \frac{1}{a} & \frac{1}{a} & \frac{1}{a} \\ \frac{1}{b} & 1+\frac{1}{b} & \frac{1}{b} & \frac{1}{b} \\ \frac{1}{c} & \frac{1}{c} & 1+\frac{1}{c} & \frac{1}{c} \\ \frac{1}{d} & \frac{1}{d} & \frac{1}{d} & 1+\frac{1}{d} \end{vmatrix}$$

Applying $R_1 \to R_1 + R_2 + R_3 + R_4$ and taking $\left(1 + \frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}\right)$ common, we get

$$\Delta = abcd \left(1 + \frac{1}{a} + \frac{1}{b} + \frac{1}{c} + \frac{1}{d}\right) \begin{vmatrix} 1 & 1 & 1 & 1 \\ \frac{1}{b} & 1+\frac{1}{b} & \frac{1}{b} & \frac{1}{b} \\ \frac{1}{c} & \frac{1}{c} & 1+\frac{1}{c} & \frac{1}{c} \\ \frac{1}{d} & \frac{1}{d} & \frac{1}{d} & 1+\frac{1}{d} \end{vmatrix}$$

Applying $C_2 \to C_2 - C_1$, $C_3 \to C_3 - C_1$ and $C_4 \to C_4 - C_1$, then

$$\Delta = abcd\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}+\frac{1}{d}\right)\begin{vmatrix} 1 & \ddots & 0 & 0 & 0 \\ \frac{1}{b} & & 1 & 0 & 0 \\ & \ddots & & & \\ \frac{1}{c} & & 0 & 1 & 0 \\ & & & \ddots & \\ \frac{1}{d} & & 0 & 0 & 1 \end{vmatrix}$$

$$= abcd\left(1+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}+\frac{1}{d}\right)1\cdot 1\cdot 1$$

$$= abcd + (bcd + acd + abd + abc) = \sigma_4 + \sigma_3$$

$$= \frac{16}{1} + \left(-\frac{8}{1}\right) = 8$$

75. Given, $\begin{vmatrix} 1+a & 1 & 1 \\ 1+b & 1+2b & 1 \\ 1+c & 1+c & 1+3c \end{vmatrix} = 0$

Taking a, b, c common from R_1, R_2 and R_3 respectively, then

$$abc\begin{vmatrix} 1+\frac{1}{a} & \frac{1}{a} & \frac{1}{a} \\ 1+\frac{1}{b} & 2+\frac{1}{b} & \frac{1}{b} \\ 1+\frac{1}{c} & 1+\frac{1}{c} & 3+\frac{1}{c} \end{vmatrix} = 0$$

Applying $R_1 \to R_1 + R_2 + R_3$ and taking $\left(3+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)$ common, we get

$$abc\left(3+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)\begin{vmatrix} 1 & 1 & 1 \\ 1+\frac{1}{b} & 2+\frac{1}{b} & \frac{1}{b} \\ 1+\frac{1}{c} & 1+\frac{1}{c} & 3+\frac{1}{c} \end{vmatrix} = 0$$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$, then

$$abc\left(3+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right)\begin{vmatrix} 1 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ 1+\frac{1}{2} & & 1 & & -1 \\ \vdots & & & & \\ 1+\frac{1}{c} & & 0 & & 2 \end{vmatrix} = 0$$

Expanding along R_1, we get

$$2\,abc\left(3+\frac{1}{a}+\frac{1}{b}+\frac{1}{c}\right) = 0$$

$\because \quad a \neq 0, b \neq 0, c \neq 0$

$\therefore \quad \frac{1}{a}+\frac{1}{b}+\frac{1}{c} = -3$ or $|a^{-1}+b^{-1}+c^{-1}| = 3$

76. Given equations

$$ax + hy + g = 0, \quad \ldots(i)$$

$$hx + by + f = 0 \quad \ldots(ii)$$

and $ax^2 + 2hxy + by^2 + 2gx + 2fy + c + \lambda = 0 \quad \ldots(iii)$

Eq. (iii), can be written as

$$x(ax + hy + g) + y(hx + by + f) + gx + fy + c + \lambda = 0$$

$\Rightarrow \quad x\cdot 0 + y\cdot 0 + gx + fy + c + \lambda = 0$ [from Eqs. (i) and (ii)]

$\Rightarrow \quad gx + fy + c + \lambda = 0 \quad \ldots(iv)$

According to the question Eqs. (i), (ii) and (iii) has unique solution. So, Eqs. (i), (ii) and (iv) has unique solution,

then $\begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c+\lambda \end{vmatrix} = 0$

$\Rightarrow \quad a(bc + b\lambda - f^2) - h(ch + h\lambda - fg) + g(hf - bg)$

$\Rightarrow \quad (abc + 2fgh - af^2 - bg^2 - ch^2) = \lambda(h^2 - ab)$

or $\quad \frac{abc + 2fgh - af^2 - bg^2 - ch^2}{h^2 - ab} = \lambda$

According to the question, $\lambda = 8$

77. (A) $\to$ (p, r); (B) $\to$ (p, r); (C) $\to$ (p, q, s, t)

(A) Using $a^2 + b^2 + c^2 = 0$, we get

$$\Delta = \begin{vmatrix} b^2+c^2 & ab & ac \\ ab & c^2+a^2 & bc \\ ac & bc & a^2+b^2 \end{vmatrix} = \begin{vmatrix} -a^2 & ab & ac \\ ab & -b^2 & bc \\ ac & bc & -c^2 \end{vmatrix}$$

$$= abc\begin{vmatrix} -a & a & a \\ b & -b & b \\ c & c & -c \end{vmatrix}$$

[taking a, b, c common from C_1, C_2, C_3 respectively]

Applying $C_2 \to C_2 + C_1$ and $C_3 \to C_3 + C_1$, then

$$\Delta = abc\begin{vmatrix} -a & \ldots & 0 & \ldots & 0 \\ \vdots & & & & \\ b & & 0 & & 2b \\ \vdots & & & & \\ c & & 2c & & 0 \end{vmatrix}$$

$$= (abc)(-a)(-4\,bc) = 4a^2\,b^2\,c^2$$

$\therefore \quad \lambda = 4$

(B) Let $\quad \Delta = \begin{vmatrix} a & a+b & a+b+c \\ 2a & 5a+2b & 7a+5b+2c \\ 3a & 7a+3b & 9a+7b+3c \end{vmatrix}$

Applying $R_2 \to R_2 - 2R_1$ and $R_3 \to R_3 - 3R_1$, then

$$\Delta = \begin{vmatrix} a & \cdots & a+b & \cdots & a+b+c \\ \vdots & & & & \\ 0 & & 3a & & 5a+3b \\ \vdots & & & & \\ 0 & & 4a & & 6a+4b \end{vmatrix}$$

$$= a\begin{vmatrix} 3a & 5a+3b \\ 4a & 6a+4b \end{vmatrix}$$

$$= a(18a^2 + 12ab - 20a^2 - 12ab)$$

$$= -2a^3 = -1024 \quad \text{[given]}$$

$\Rightarrow \quad a^3 = 512 = 8^3$

$\therefore \quad a = 8$

(C) Let $\Delta(x)=\begin{vmatrix} x-1 & 2x^2-5 & x^3-1 \\ 2x^2+5 & 2x+2 & x^3+3 \\ x^3-1 & x+1 & 3x^2-2 \end{vmatrix}$ ...(i)

According to the question,

$\Delta(x)=(x^2-1)\,P(x)+ax+b$

$\therefore\ \Delta(1)=a+b$ and $\Delta(-1)=-a+b$ ...(ii)

From Eq. (i), we get

$$\Delta(1)=\begin{vmatrix} 0 & \cdots & 3 & \cdots & 0 \\ & & \vdots & & \\ 7 & & 4 & & 4 \\ & & \vdots & & \\ 0 & & 2 & & 1 \end{vmatrix}=3(7-0)=21$$

$$\text{and } \Delta(-1)=\begin{vmatrix} -2 & \cdots & -3 & \cdots & 2 \\ & & \vdots & & \\ 7 & & 0 & & 2 \\ & & \vdots & & \\ -2 & & 0 & & 1 \end{vmatrix}=3(7+4)=33$$

From Eq. (ii), $a+b=21$ and $-a+b=33$,

we get $a=-6,\ b=27$

$\therefore\quad 4a+2b=-24+54=30$

78. (A) $\rightarrow$ (p, s, t); (B) $\rightarrow$ (r, t); (C) $\rightarrow$ (p, q)

(A) $\because\quad \Delta=\begin{vmatrix} 1 & 1 & 1 \\ f_1(x_1) & f_1(x_2) & f_1(x_3) \\ f_2(x_1) & f_2(x_2) & f_2(x_3) \end{vmatrix}=\begin{vmatrix} 1 & 1 & 1 \\ f_1(2) & f_1(3) & f_1(5) \\ f_2(2) & f_2(3) & f_2(5) \end{vmatrix}$

$$=\begin{vmatrix} 1 & 1 & 1 \\ 2+a_1 & 3+a_1 & 5+a_1 \\ 4+2b_1+b_2 & 9+3b_1+b_2 & 25+5b_1+b_2 \end{vmatrix}$$

Applying $C_2\rightarrow C_2-C_1$ and $C_3\rightarrow C_3-C_1$, then

$$\Delta=\begin{vmatrix} 1 & \cdots & 0 & \cdots & 0 \\ \vdots & & & & \\ 2+a_1 & & 1 & & 3 \\ \vdots & & & & \\ 4+2b_1+b_2 & & 5+b_1 & & 21+3b \end{vmatrix}$$

$$=\begin{vmatrix} 1 & 3 \\ 5+b_1 & 21+3b_1 \end{vmatrix}$$

$$=21+3b_1-15-3b_1=6$$

(B) $\because\ f(x)=\begin{vmatrix} 1 & b_1 & a_1 \\ 1 & b_1 & 2a_1-x \\ 1 & 2b_1-x & a_1 \end{vmatrix}$

Applying $R_2\rightarrow R_2-R_1$ and $R_3\rightarrow R_3-R_1$, then

$$f(x)=\begin{vmatrix} 1 & \cdots & b_1 & \cdots & a_1 \\ \vdots & & & & \\ 0 & & 0 & & a_1-x \\ \vdots & & & & \\ 0 & & b_1-x & & 0 \end{vmatrix}$$

$$=-(a_1-x)(b_1-x)=-x^2+(a_1+b_1)x-a_1\,b_1$$

Minimum value of $f(x)=-\dfrac{D}{4a}=-\dfrac{(a_1+b_1)^2-4a_1b_1}{4(-1)}$

$$=\frac{(a_1-b_1)^2}{4}=\frac{36}{4}=9$$

(C) $\because\ f(x)$ is a polynomial of degree atmost 6 in x.

If $f(x)=a_0+a_1x+a_2x^2+a_3x^3+a_4x^4+a_5x^5+a_6x^6$

$\Rightarrow \lambda=a_1=f'(0)$

$$=\begin{vmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 8 \end{vmatrix}+\begin{vmatrix} -2 & -2 & 0 \\ -1 & 0 & 1 \\ 0 & 2 & 8 \end{vmatrix}+\begin{vmatrix} -2 & 1 & 0 \\ -1 & 0 & 3 \\ 0 & 1 & 12 \end{vmatrix}$$

$$=-8-12+18=-2$$

$\therefore\qquad |\lambda|=2$

79. (A) $\rightarrow$ (r); (B) $\rightarrow$ (r, t); (C) $\rightarrow$ (p, q, s)

(A) Let $f(x)=\begin{vmatrix} x^2+3x & x-1 & x+3 \\ x^2+1 & 2+3x & x-3 \\ x^2-3 & x+4 & 3x \end{vmatrix}$

$$f(x)=ax^4+bx^3+cx^2+dx+e \qquad ...(i)$$

$$\therefore\quad e=f(0)=\begin{vmatrix} 0 & -1 & 3 \\ 1 & 2 & -3 \\ -3 & 4 & 0 \end{vmatrix}=0+1(0-9)+3(4+6)=21$$

Dividing both sides of Eq. (i) by x^4 i.e., C_1 by x^2, C_2 by x and C_3 by x and then taking $\lim\limits_{x\to\infty}$, we get

$$a=\begin{vmatrix} 1 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 3 \end{vmatrix}=1(8)-1(2)+1(-2)=4$$

Hence, $e+a=25$

(B) Let $f(x)=\begin{vmatrix} x-1 & 5x & 7 \\ x^2-1 & x-1 & 8 \\ 2x & 3x & 0 \end{vmatrix}=ax^3+bx^2+cx+d$ ...(i)

$$\therefore\quad c=f'(0)=\begin{vmatrix} 1 & 0 & 7 \\ 0 & -1 & 8 \\ 2 & 0 & 0 \end{vmatrix}+\begin{vmatrix} -1 & 5 & 7 \\ -1 & 1 & 8 \\ 0 & 3 & 0 \end{vmatrix}+\begin{vmatrix} -1 & 0 & 0 \\ -1 & -1 & 0 \\ 0 & 0 & 0 \end{vmatrix}$$

$$=2(0+7)-3(-8+7)+0=17$$

Dividing both sides of Eq. (i) by x^3 i.e., c_1 by x^2, c_2 by x and taking $\lim\limits_{x\to\infty}$, we get

$$a=\begin{vmatrix} 0 & & 5 & & 7 \\ \vdots & & & & \\ 1 & \cdots & 1 & \cdots & 8 \\ \vdots & & & & \\ 0 & & 3 & & 0 \end{vmatrix}=-1(0-21)=21$$

Hence, $c+a-3=35$

(C) Let $g(x)=\begin{vmatrix} x^3+4x & x+3 & x-2 \\ x-2 & 5x & x-1 \\ x-3 & x+2 & 4x \end{vmatrix}$

$$=ax^5+bx^4+cx^3+dx^2+ex+f$$

$$\therefore \quad f = g(0) = \begin{vmatrix} 0 & 3 & -2 \\ -2 & 0 & -1 \\ -3 & 2 & 0 \end{vmatrix} = 0 - 3(0-3) - 2(-4-0) = 17$$

$$\text{and } e = g'(0) = \begin{vmatrix} 4 & 3 & -2 \\ 1 & 0 & -1 \\ 1 & 2 & 0 \end{vmatrix} + \begin{vmatrix} 0 & 1 & -2 \\ -2 & 5 & -1 \\ -3 & 1 & 0 \end{vmatrix} + \begin{vmatrix} 0 & 3 & 1 \\ -2 & 0 & 1 \\ -3 & 2 & 4 \end{vmatrix}$$

$$= 1 - 23 + 11 = -11$$

Hence, $f + e = 17 - 11 = 6$

80. (A) $\rightarrow$ (p, q, r); (B) $\rightarrow$ (p, q, r, s, t); (C) $\rightarrow$ (p, q, r, s, t)

(A) Taking common a, b, c from R_1, R_2 and R_3 respectively and then multiplying in C_1, C_2 and C_3 by a, b, c respectively, then

$$\Delta = \begin{vmatrix} a + (b^2 + c^2)d & b^2(1-d) & c^2(1-d) \\ a^2(1-d) & b^2 + (c^2 + a^2)d & c^2(1-d) \\ a^2(1-d) & b^2(1-d) & c^2 + (a^2 + b^2)d \end{vmatrix}$$

Applying $C_1 \rightarrow C_1 + C_2 + C_3$, then

$$\Delta = \begin{vmatrix} 1 & b^2(1-d) & c^2(1-d) \\ 1 & b^2 + (c^2 + a^2)d & c^2(1-d) \\ 1 & b^2(1-d) & c^2 + (a^2 + b^2)d \end{vmatrix}$$

$$[\because a^2 + b^2 + c^2 = 1]$$

Applying $R_2 \rightarrow R_2 - R_1$ and $R_3 \rightarrow R_3 - R_1$, then

$$\Delta = \begin{vmatrix} 1 & b^2(1-d) & c^2(1-d) \\ 0 & d & 0 \\ 0 & 0 & d \end{vmatrix} = d^2$$

$$[\because a^2 + b^2 + c^2 = 1]$$

(B) Multiplying C_1 by a, C_2 by b and C_3 by c, then

$$\Delta = \frac{1}{abc} \begin{vmatrix} \frac{a}{c} & \frac{b}{c} & -\frac{(a+b)}{c} \\ -\frac{(b+c)}{a} & \frac{b}{a} & \frac{c}{a} \\ -\frac{bd(b+c)}{ac} & \frac{bd(a+2b+c)}{ac} & -\frac{(a+b)bd}{ac} \end{vmatrix}$$

Applying $C_1 \rightarrow C_1 + C_2 + C_3$, then

$$\Delta = \frac{1}{abc} \begin{vmatrix} 0 & \frac{b}{c} & -\frac{(a+b)}{c} \\ 0 & \frac{b}{a} & \frac{c}{a} \\ 0 & \frac{bd(a+2b+c)}{ac} & -\frac{(a+b)bd}{ac} \end{vmatrix} = 0$$

(C) Applying $C_3 \rightarrow C_3 - \cos d\, C_1 - \sin d\, C_2$, then

$$\Delta = \begin{vmatrix} \sin a & \cos a & 0 \\ \sin b & \cos b & 0 \\ \sin c & \cos c & 0 \end{vmatrix} = 0$$

81. (A) $\rightarrow$ (p, r); (B) $\rightarrow$ (p, q, r, t); (C) $\rightarrow$ (p, r, s)

(A) Possible values are -2 , -1, 0, 1, 2 and numbering determinant $= 3^4 = 81$

i.e., $\begin{vmatrix} 1 & 0 \\ -1 & 1 \end{vmatrix} = 1, \begin{vmatrix} 1 & -1 \\ 0 & 0 \end{vmatrix} = 0, \begin{vmatrix} 0 & 1 \\ 1 & -1 \end{vmatrix} = -1, \begin{vmatrix} 1 & -1 \\ 1 & 1 \end{vmatrix} = 2,$

$\begin{vmatrix} -1 & 1 \\ 1 & 1 \end{vmatrix} = -2 \quad \therefore n = 5 \Rightarrow (n-1)^2 = 16$

(B) There are only three determinants of second order with negative value

$$\begin{vmatrix} 0 & 1 \\ 1 & 0 \end{vmatrix}, \begin{vmatrix} 1 & 1 \\ 1 & 0 \end{vmatrix}, \begin{vmatrix} 0 & 1 \\ 1 & 1 \end{vmatrix}$$

Number of possible determinants with elements 0 and 1 are $2^4 = 16$. Therefore, number of determinants with non-negative values is 13.

$\therefore \qquad n = 13$

$\Rightarrow \qquad (n-1) = 12$

(C) There are only four determinants of second order with negative value

$$\begin{vmatrix} -1 & 1 \\ 1 & 1 \end{vmatrix}, \begin{vmatrix} 1 & 1 \\ 1 & -1 \end{vmatrix}, \begin{vmatrix} -1 & -1 \\ -1 & 1 \end{vmatrix}, \begin{vmatrix} 1 & -1 \\ -1 & -1 \end{vmatrix}$$

$\therefore \qquad n = 4 \Rightarrow n(n+1) = 20$

82. **Statement-1**

$$\Delta(r) = \begin{vmatrix} r & r+1 \\ r+3 & r+4 \end{vmatrix} = r(r+4) - (r+1)(r+3)$$

$$= (r^2 + 4r) - (r^2 + 4r + 3) = -3$$

$$\therefore \quad \sum_{r=1}^{n} \Delta(r) = \sum_{r=1}^{n} (-3)$$

$$= \underbrace{(-3) + (-3) + (-3) + \ldots + (-3)}_{n \text{ times}} = -3n$$

$\Rightarrow$ Statement-1 is true.

Statement-2

$$\Delta(r) = \begin{vmatrix} f_1(r) & f_2(r) \\ f_3(r) & f_4(r) \end{vmatrix} = f_1(r)\, f_4(r) - f_2(r)\, f_3(r)$$

$$\therefore \quad \sum_{r=1}^{n} \Delta(r) = \sum_{r=1}^{n} [f_1(r)\, f_4(r) - f_2(r)\, f_3(r)]$$

$$= \sum_{r=1}^{n} [f_1(r)\, f_4(r)] - \sum_{r=1}^{n} [f_2(r)\, f_3(r)] \qquad \ldots(i)$$

$$\text{and } \begin{vmatrix} \sum_{r=1}^{n} f_1(r) & \sum_{r=1}^{n} f_2(r) \\ \sum_{r=1}^{n} f_3(r) & \sum_{r=1}^{n} f_4(r) \end{vmatrix}$$

$$= \left(\sum_{r=1}^{n} f_1(r)\right)\left(\sum_{r=1}^{n} f_4(r)\right) - \left(\sum_{r=1}^{n} f_2(r)\right)\left(\sum_{r=1}^{n} f_3(r)\right) \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get $\sum_{r=1}^{n} \Delta(r) \neq \begin{vmatrix} \sum_{r=1}^{n} f_1(r) & \sum_{r=1}^{n} f_2(r) \\ \sum_{r=1}^{n} f_3(r) & \sum_{r=1}^{n} f_4(r) \end{vmatrix}$

$\therefore$ Statement-2 is false.

Hence, Statement-1 is true and Statement-2 is false.

83. $\because \quad \Delta = \begin{vmatrix} a_1 + b_1x^2 & a_1x^2 + b_1 & c_1 \\ a_2 + b_2x^2 & a_2x^2 + b_2 & c_2 \\ a_3 + b_3x^2 & a_3x^2 + b_3 & c_3 \end{vmatrix}$

$$= \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} \times \begin{vmatrix} 1 & x^2 & 0 \\ x^2 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} \qquad \ldots(i)$$

Statement-1 If $\Delta = 0$, then

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} \times \begin{vmatrix} 1 & x^2 & 0 \\ x^2 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} = 0$$

$$\Rightarrow \quad \begin{vmatrix} 1 & x^2 & 0 \\ \vdots & & \vdots \\ x^2 & 1 & 0 \\ \vdots & & \vdots \\ 0 \quad \cdots & 0 \quad \cdots & 1 \end{vmatrix} = 0 \Rightarrow 1 - x^4 = 0 \text{ or } x^4 = 1 \qquad [\because x^2 \neq -1]$$

Statement-1 is true

Now, if $\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0$, then

$\Delta = 0$ [from Eq. (i)]

Statement-2 is also true.

Hence, both the statements are true but Statement-2 is not a correct explanation of Statement-1.

84. Statement-2 is always true for Statement-1

$$\cos\left(x + \frac{\pi}{4}\right) = \cos\left(\frac{\pi}{2} - \left(\frac{\pi}{4} - x\right)\right) = \sin\left(\frac{\pi}{4} - x\right)$$

$$= -\sin\left(x - \frac{\pi}{4}\right)$$

$$\cot\left(\frac{\pi}{4} + x\right) = \cot\left(\frac{\pi}{2} - \left(\frac{\pi}{4} - x\right)\right) = \tan\left(\frac{\pi}{4} - x\right)$$

$$= -\tan\left(x - \frac{\pi}{4}\right)$$

Also, $\ln\left(\frac{y}{x}\right) = -\ln\left(\frac{x}{y}\right)$

Therefore, determinant given in Statement-1 is skew-symmetric and hence its value is zero. Hence, both statements are true and Statement-2 is a correct explanation of Statement-1.

85. $\begin{vmatrix} (1+x)^{11} & (1+x)^{12} & (1+x)^{13} \\ (1+x)^{21} & (1+x)^{22} & (1+x)^{23} \\ (1+x)^{31} & (1+x)^{32} & (1+x)^{33} \end{vmatrix} = A_0 + A_1x + A_2x^2 + \ldots \quad [\text{ let}]$

On differentiating both sides w.r.t.x and then put $x = 0$, we get

$$\begin{vmatrix} 11 & 12 & 13 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{vmatrix} + \begin{vmatrix} 1 & 1 & 1 \\ 21 & 22 & 23 \\ 1 & 1 & 1 \end{vmatrix} + \begin{vmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 31 & 32 & 33 \end{vmatrix} = 0 + A_1 + 0 + 0 + \ldots$$

$$\Rightarrow \qquad 0 + 0 + 0 = A_1 \quad \therefore \quad A_1 = 0$$

$\therefore$ Coefficient of x in $f(x) = 0$

Both statements are true, Statement-2 is a correct explanation of Statement-1.

86. Here, $\Delta = \begin{vmatrix} 2 & 3 \\ b & 4 \end{vmatrix} = 8 - 3b,$

$$\Delta_1 = \begin{vmatrix} a & 3 \\ 5 & 4 \end{vmatrix} = 4a - 15$$

and $\Delta_2 = \begin{vmatrix} 2 & a \\ b & 5 \end{vmatrix} = 10 - ab$

For infinite solutions, $\Delta = \Delta_1 = \Delta_2 = 0$

We get, $a = \frac{15}{4}$ and $b = \frac{8}{3}$

$\therefore$ Statement-1 is true and if lines $a_1x + b_1y + c_1 = 0$ and $a_2x + b_2y + c_2 = 0$ are parallel, then

$$\frac{a_1}{a_2} = \frac{b_1}{b_2} \neq \frac{c_1}{c_2}$$

$\therefore$ Statement-2 is true, but in Statement-1

$$\frac{2}{b} = \frac{3}{4} = \frac{a}{5}$$

$$\Rightarrow \qquad \frac{3}{4} = \frac{3}{4} = \frac{3}{4}$$

[both equation are identical]

$\therefore$ Statement-2 is not a correct explanation for Statement-1.

87. $\because \begin{vmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{vmatrix} = 1(0 - 48) - 2(0 - 42) + 3(32 - 35)$

$$= -48 + 84 - 9$$

$$= 84 - 57 = 27 \neq 0$$

$\therefore$ Statement-1 is true.

Also, in given determinant neither two rows or columns are identical, Statement-2 is true, Statement-2 is not a correct explanation for Statement-1.

88. $\because A88, 6B8, 86C$ are divisible by 72, then $A88 = 72\lambda$, $6B8 = 72\mu$ and $86C = 72\upsilon$, where $\lambda, \mu, \upsilon \in N$.

$$\because \qquad \begin{vmatrix} A & 6 & 8 \\ 8 & B & 6 \\ 8 & 8 & C \end{vmatrix}$$

Applying $R_3 \to R_3 + 10R_2 + 100R_1$, then

$$\begin{vmatrix} A & 6 & 8 \\ 8 & B & 6 \\ 100A + 80 + 8 & 600 + 10B + 8 & 800 + 60 + c \end{vmatrix}$$

$$= \begin{vmatrix} A & 6 & 8 \\ 8 & B & 6 \\ 72\lambda & 72\mu & 72\upsilon \end{vmatrix} = 72 \begin{vmatrix} A & 6 & 8 \\ 8 & B & 6 \\ \lambda & \mu & \upsilon \end{vmatrix} \qquad \ldots(i)$$

Now, $A88$ is also divisible by 9, then

$A + 8 + 8 = A + 16$ is divisible by 9

$\therefore \qquad A = 2$

and $6B8$ is also divisible by 9, then $6 + B + 8 = B + 14$ is divisible by 9

$\therefore \qquad B = 4$

From Eq. (i), we get

$$= 72\begin{vmatrix} 2 & 6 & 8 \\ 8 & 2 & 6 \\ \lambda & \mu & \upsilon \end{vmatrix} = 288\begin{vmatrix} 1 & 3 & 4 \\ 4 & 1 & 3 \\ \lambda & \mu & \upsilon \end{vmatrix} = 288 \qquad \text{[integer]}$$

Statement-1 is true and Statement-2 is false.

89. Let $\Delta = \begin{vmatrix} b+c & c & b \\ c & c+a & a \\ b & a & a+b \end{vmatrix}$

Applying $R_1 \to R_1 - (R_2 + R_3)$, then

$$\therefore \quad \Delta = \begin{vmatrix} 0 & -2a & -2a \\ c & c+a & a \\ b & a & a+b \end{vmatrix}$$

Taking $(-2a)$ common from R_1, then

$$\Delta = (-2a)\begin{vmatrix} 0 & 1 & 1 \\ c & c+a & a \\ b & a & a+b \end{vmatrix}$$

Applying $C_2 \to C_2 - C_3$, then

$$\therefore \quad \Delta = (-2a)\begin{vmatrix} 0 & 0 & 1 \\ c & c & a \\ b & -b & a+b \end{vmatrix}$$

Expanding along R_1, we get

$$\Delta = (-2a)\cdot 1 \cdot \begin{vmatrix} c & c \\ b & -b \end{vmatrix} = (-2a)(-2bc)$$

Hence, $\Delta = 4abc$

90. Let $\Delta = \begin{vmatrix} a-b-c & 2a & 2a \\ 2b & b-c-a & 2b \\ 2c & 2c & c-a-b \end{vmatrix}$

Since, the answer is $(a+b+c)^3$, we shall try to get $(a+b+c)$.

Applying $R_1 \to R_1 + R_2 + R_3$, then

$$\Delta = \begin{vmatrix} a+b+c & a+b+c & a+b+c \\ 2b & b-c-a & 2b \\ 2c & 2c & c-a-b \end{vmatrix}$$

Taking $(a+b+c)$ common from R_1, we get

$$\Delta = (a+b+c)\begin{vmatrix} 1 & 1 & 1 \\ 2b & b-c-a & 2b \\ 2c & 2c & c-a-b \end{vmatrix}$$

Applying $C_1 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$

$$\therefore \quad \Delta = (a+b+c)\begin{vmatrix} 1 & 0 & 0 \\ 2b & -a-b-c & 0 \\ 2c & 0 & -c-a-b \end{vmatrix}$$

[by property, since all elements above leading diagonal are zero]

$$= (a+b+c)\cdot 1 \cdot (-a-b-c)\cdot(-c-a-b)$$

Hence, $\Delta = (a+b+c)^3$

91. Let $\Delta = \begin{vmatrix} \sqrt{13}+\sqrt{3} & 2\sqrt{5} & \sqrt{5} \\ \sqrt{15}+\sqrt{26} & 5 & \sqrt{10} \\ 3+\sqrt{65} & \sqrt{15} & 5 \end{vmatrix}$

$$= \begin{vmatrix} \sqrt{3} & 2\sqrt{5} & \sqrt{5} \\ \sqrt{15} & 5 & \sqrt{10} \\ 3 & \sqrt{15} & 5 \end{vmatrix} + \begin{vmatrix} \sqrt{13} & 2\sqrt{5} & \sqrt{5} \\ \sqrt{26} & 5 & \sqrt{10} \\ \sqrt{65} & \sqrt{15} & 5 \end{vmatrix}$$

Taking common from 1st determinant $\sqrt{3}$, $\sqrt{5}$ and $\sqrt{5}$ from C_1, C_2 and C_3 respectively and taking common from 2nd determinant $\sqrt{13}$, $\sqrt{5}$ and $\sqrt{5}$ from C_1, C_3 and C_3 respectively, we get

$$= \sqrt{3}\times\sqrt{5}\times\sqrt{5}\begin{vmatrix} 1 & 2 & 1 \\ \sqrt{5} & \sqrt{5} & \sqrt{2} \\ \sqrt{3} & \sqrt{3} & \sqrt{5} \end{vmatrix} + \sqrt{13}\times\sqrt{5}\times\sqrt{5}\begin{vmatrix} 1 & 2 & 1 \\ \sqrt{2} & \sqrt{5} & \sqrt{2} \\ \sqrt{5} & \sqrt{3} & \sqrt{5} \end{vmatrix}$$

$$= \sqrt{3}\times 5\begin{vmatrix} 1 & 2 & 1 \\ \sqrt{5} & \sqrt{5} & \sqrt{2} \\ \sqrt{3} & \sqrt{3} & \sqrt{5} \end{vmatrix} + 0 \qquad [\because C_1 \text{ and } C_3 \text{ are identical}]$$

$$= 5\sqrt{3}\begin{vmatrix} 1 & 2 & 1 \\ \sqrt{5} & \sqrt{5} & \sqrt{2} \\ \sqrt{3} & \sqrt{3} & \sqrt{5} \end{vmatrix}$$

Applying $C_2 \to C_2 - C_1$,

$$\text{then } \Delta = 5\sqrt{3}\begin{vmatrix} 1 & 1 & 1 \\ \sqrt{5} & 0 & \sqrt{2} \\ \sqrt{3} & 0 & \sqrt{5} \end{vmatrix}$$

Expanding along C_2, then

$$\Delta = 5\sqrt{3}\cdot(-1)\begin{vmatrix} \sqrt{5} & \sqrt{2} \\ \sqrt{3} & \sqrt{5} \end{vmatrix} = -5\sqrt{3}(5-\sqrt{6})$$

$$= -25\sqrt{3} + 15\sqrt{2}$$

$$= 15\sqrt{2} - 25\sqrt{3}$$

92. Given that, a, b and c are p th, q th and r th terms of HP $\Rightarrow \frac{1}{a}, \frac{1}{b}$ and $\frac{1}{c}$ are p th, q th and r th terms of an AP. Let A and D are the first term and common difference of AP, then

$$\frac{1}{a} = A + (p-1)D \qquad \ldots(i)$$

$$\frac{1}{b} = A + (q-1)D \qquad \ldots(ii)$$

$$\frac{1}{c} = A + (r-1)D \qquad \ldots(iii)$$

Now, given determinant is

$$\Delta = \begin{vmatrix} bc & ca & ab \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix} = abc\begin{vmatrix} \frac{1}{a} & \frac{1}{b} & \frac{1}{c} \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix}$$

On substituting the values of $\frac{1}{a}, \frac{1}{b}$ and $\frac{1}{c}$ from Eqs. (i), (ii) and (iii) in Δ, then

$$\Delta = abc\begin{vmatrix} A+(p-1)D & A+(q-1)D & A+(r-1)D \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix}$$

Applying $R_1 \to R_1 - (A-D)R_3 - DR_2$, then

$$\Delta = abc\begin{vmatrix} 0 & 0 & 0 \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix} = 0$$

93. Let $z = \begin{vmatrix} -5 & 3+5i & \frac{3}{2}-4i \\ 3-5i & 8 & 4+5i \\ \frac{3}{2}+4i & 4-5i & 9 \end{vmatrix}$

Then, $\bar{z} = \begin{vmatrix} -5 & 3-5i & \frac{3}{2}+4i \\ 3+5i & 8 & 4-5i \\ \frac{3}{2}-4i & 4+5i & 9 \end{vmatrix}$ [i.e., conjugate of z]

$= \begin{vmatrix} -5 & 3+5i & \frac{3}{2}-4i \\ 3-5i & 8 & 4+5i \\ \frac{3}{2}+4i & 4-5i & 9 \end{vmatrix}$

[interchanging rows into columns]

$\Rightarrow \quad \bar{z} = z$

Hence, z is purely real.

94. LHS $= \begin{vmatrix} ah+bg & g & ab+ch \\ bf+ba & f & hb+bc \\ af+bc & c & bg+fc \end{vmatrix}$

$$= b\begin{vmatrix} ah+bg & g & a \\ bf+ba & f & h \\ af+bc & c & g \end{vmatrix} + c\begin{vmatrix} ah+bg & g & h \\ bf+ba & f & b \\ af+bc & c & f \end{vmatrix}$$

In second determinant, applying $C_1 \to C_1 - bC_2 - aC_3$, then

$$= \begin{vmatrix} ah+bg & bg & a \\ bf+ba & bf & h \\ af+bc & bc & g \end{vmatrix} + c\begin{vmatrix} 0 & g & h \\ 0 & f & b \\ 0 & c & f \end{vmatrix}$$

In first determinant, applying $C_2 \to C_2 - C_1$, then

$$= \begin{vmatrix} ah+bg & -ah & a \\ bf+ba & -ba & h \\ af+bc & -af & q \end{vmatrix} + 0 = a\begin{vmatrix} ah+bg & a & h \\ bf+ba & h & b \\ af+bc & g & f \end{vmatrix} = \text{RHS}$$

95. Let $\Delta = \begin{vmatrix} 1 & 1 & 1 \\ 1+\sin A & 1+\sin B & 1+\sin C \\ \sin A+\sin^2 A & \sin B+\sin^2 B & \sin C+\sin^2 C \end{vmatrix}$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$, then

$$\Delta = \begin{vmatrix} 1 & 0 & 0 \\ 1+\sin A & \sin B-\sin A & \sin C-\sin A \\ \sin A+\sin^2 A & (\sin B-\sin A)(\sin B+\sin A+1) & (\sin C-\sin A)(\sin C+\sin A+1) \end{vmatrix}$$

Expanding along R_1, then

$$\Delta = \begin{vmatrix} \sin B-\sin A & \sin C-\sin A \\ (\sin B-\sin A)(\sin B+\sin A+1) & (\sin C-\sin A)(\sin C+\sin A+1) \end{vmatrix}$$

$$= (\sin B-\sin A)(\sin C-\sin A)\begin{vmatrix} 1 & 1 \\ \sin B+\sin A+1 & \sin C+\sin A+1 \end{vmatrix}$$

$$= (\sin B-\sin A)(\sin C-\sin A)(\sin C-\sin B)$$

But, given $\Delta = 0$

$\therefore \quad (\sin B-\sin A)(\sin C-\sin A)(\sin C-\sin B) = 0$

$\therefore \quad \sin B-\sin A = 0$ or $\sin C-\sin A = 0$

or $\quad \sin C-\sin B = 0$

$\Rightarrow \quad \sin B = \sin A$ or $\sin C = \sin A$ or $\sin C = \sin B$

$B = A$ or $C = A$ or $C = B$

In all the three cases, we will have an isosceles triangle.

96. Let $\Delta = \begin{vmatrix} \beta\gamma & \beta\gamma'+\beta'\gamma & \beta'\gamma' \\ \gamma'\alpha & \gamma'\alpha'+\gamma'\alpha & \gamma'\alpha' \\ \alpha\beta & \alpha\beta'+\alpha'\beta & \alpha'\beta' \end{vmatrix}$

Taking $\beta'\gamma'$, $\gamma'\alpha'$ and $\alpha'\beta'$ common from R_1, R_2 and R_3 respectively, then

$$\Delta = (\beta'\gamma')(\gamma'\alpha')(\alpha'\beta')\begin{vmatrix} \frac{\beta}{\beta'}\frac{\gamma}{\gamma'} & \frac{\beta}{\beta'}+\frac{\gamma}{\gamma'} & 1 \\ \frac{\gamma}{\gamma'}\frac{\alpha}{\alpha'} & \frac{\gamma}{\gamma'}+\frac{\alpha}{\alpha'} & 1 \\ \frac{\alpha}{\alpha'}\frac{\beta}{\beta'} & \frac{\alpha}{\alpha'}+\frac{\beta}{\beta'} & 1 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$

Then, $\Delta = (\alpha'\beta'\gamma')^2\begin{vmatrix} \frac{\beta}{\beta'}\frac{\gamma}{\gamma'} & \frac{\beta}{\beta'}+\frac{\gamma}{\gamma'} & 1 \\ \frac{\gamma}{\gamma'}\left(\frac{\alpha}{\alpha'}-\frac{\beta}{\beta'}\right) & \left(\frac{\alpha}{\alpha'}-\frac{\beta}{\beta'}\right) & 0 \\ \frac{\beta}{\beta'}\left(\frac{\alpha}{\alpha'}-\frac{\gamma}{\gamma'}\right) & \left(\frac{\alpha}{\alpha'}-\frac{\gamma}{\gamma'}\right) & 0 \end{vmatrix}$

$$= (\alpha'\beta'\gamma')^2\left(\frac{\alpha}{\alpha'}-\frac{\beta}{\beta'}\right)\left(\frac{\alpha}{\alpha'}-\frac{\gamma}{\gamma'}\right)\begin{vmatrix} \frac{\beta}{\beta'}\frac{\gamma}{\gamma'} & \frac{\beta}{\beta'}+\frac{\gamma}{\gamma'} & 1 \\ \frac{\gamma}{\gamma'} & 1 & 0 \\ \frac{\beta}{\beta'} & 1 & 0 \end{vmatrix}$$

Expanding along C_3, then

$$\Delta = (\alpha'\beta'\gamma')^2\left(\frac{\alpha}{\alpha'}-\frac{\beta}{\beta'}\right)\left(\frac{\alpha}{\alpha'}-\frac{\gamma}{\gamma'}\right)\left(\frac{\gamma}{\gamma'}-\frac{\beta}{\beta'}\right)$$

$$= (\alpha'\beta'\gamma')^2\left(\frac{\alpha}{\alpha'}-\frac{\beta}{\beta'}\right)\left(\frac{\beta}{\beta'}-\frac{\gamma}{\gamma'}\right)\left(\frac{\gamma}{\gamma'}-\frac{\alpha}{\alpha'}\right)$$

$$= (\alpha'\beta'\gamma')^2\frac{(\alpha\beta'-\alpha'\beta)(\beta\gamma'-\beta'\gamma)(\gamma\alpha'-\gamma'\alpha)}{(\alpha'\beta'\gamma')^2}$$

Hence, $\Delta = (\alpha\beta'-\alpha'\beta)(\beta\gamma'-\beta'\gamma)(\gamma\alpha'-\gamma'\alpha)$

97. Since, $y = \frac{u}{v}$

$$\therefore \quad \frac{dy}{dx} = \frac{v\frac{du}{dx} - u\frac{dv}{dx}}{v^2} = \frac{vu' - uv'}{v^2}$$

$$\Rightarrow \quad v^2\frac{dy}{dx} = vu' - uv' \qquad \ldots(i)$$

On differentiating both sides w.r.t. x, we get

$$v^2\frac{d^2y}{dx^2} + \frac{dy}{dx}\cdot 2vv' = (vu'' + u'v') - (uv'' + v'u')$$

$$\Rightarrow \quad v^2\frac{d^2y}{dx^2} + 2vv'\frac{dy}{dx} = vu'' - uv''$$

On multiplying both sides by v, then

$$v^3\frac{d^2y}{dx^2} + 2v'\left(v^2\frac{dy}{dx}\right) = v^2u'' - uvv''$$

$$\Rightarrow \quad v^3\frac{d^2y}{dx^2} + 2v'(vu' - uv') = v^2u'' - uvv'' \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow \quad v^3\frac{d^2y}{dx^2} = 2uv^2 - uvv'' - 2vu'v' + v^2u'' \qquad \ldots(ii)$$

and $\begin{vmatrix} v & v & 0 \\ v' & v' & v \\ v'' & v'' & 2v'' \end{vmatrix} = u(2v'^2 - vu'') - v(2u'v' - u''v)$

$$= 2uv'^2 - 4vv'' - 2vu'v' + v^2u'' \qquad \ldots(iii)$$

From Eqs. (ii) and (iii), we get

$$v^3\frac{d^2y}{dx^2} = \begin{vmatrix} u & v & 0 \\ u' & v' & v \\ u' & v'' & 2v' \end{vmatrix}$$

98. Here, we have to prove that $\Delta(x)$ is independent of x. So, it is sufficient to prove that $\Delta'(x) = 0$

Now, $\Delta(x) = \begin{vmatrix} \sin(x+\alpha) & \cos(x+\alpha) & a + x\sin\alpha \\ \sin(x+\beta) & \cos(x+\beta) & b + x\sin\beta \\ \sin(x+\gamma) & \cos(x+\gamma) & c + x\sin\gamma \end{vmatrix}$

On differentiating w.r.t. x, we get

$$\Delta'(x) = \begin{vmatrix} \cos(x+\alpha) & \cos(x+\alpha) & a + x\sin\alpha \\ \cos(x+\beta) & \cos(x+\beta) & b + x\sin\beta \\ \cos(x+\gamma) & \cos(x+\gamma) & c + x\sin\gamma \end{vmatrix}$$

$$+ \begin{vmatrix} \sin(x+\alpha) & -\sin(x+\alpha) & a + x\sin\alpha \\ \sin(x+\beta) & -\sin(x+\beta) & b + x\sin\beta \\ \sin(x+\gamma) & -\sin(x+\gamma) & c + x\sin\gamma \end{vmatrix}$$

$$+ \begin{vmatrix} \sin(x+\alpha) & \cos(x+\alpha) & \sin\alpha \\ \sin(x+\beta) & \cos(x+\beta) & \sin\beta \\ \sin(x+\gamma) & \cos(x+\gamma) & \sin\gamma \end{vmatrix}$$

$$= 0 - 0 + \begin{vmatrix} \sin(x+\alpha) & \cos(x+\alpha) & \sin\alpha \\ \sin(x+\beta) & \cos(x+\beta) & \sin\beta \\ \sin(x+\gamma) & \cos(x+\gamma) & \sin\gamma \end{vmatrix}$$

$$= \begin{vmatrix} \sin(x+\alpha) & \cos(x+\alpha) & \sin\alpha \\ \sin(x+\beta) & \cos(x+\beta) & \sin\beta \\ \sin(x+\gamma) & \cos(x+\gamma) & \sin\gamma \end{vmatrix}$$

Applying $C_1 \to C_1 - (\cos x)\,C_3$ and $C_2 \to C_2 + (\sin x)C_3$, we get

$$\Delta'(x) = \begin{vmatrix} \sin x\cos\alpha & \cos x\cos\alpha & \sin\alpha \\ \sin x\cos\beta & \cos x\cos\beta & \sin\beta \\ \sin x\cos\gamma & \cos x\cos\gamma & \sin\gamma \end{vmatrix}$$

$$= \sin x\cdot\cos x \begin{vmatrix} \cos\alpha & \cos\alpha & \sin\alpha \\ \cos\beta & \cos\beta & \sin\beta \\ \cos\gamma & \cos\gamma & \sin\gamma \end{vmatrix}$$

$$= \sin x\cdot\cos x \times 0 \qquad [\because C_1 \text{ and } C_2 \text{ are identical}]$$

$$= 0$$

Thus, $\Delta(x)$ is independent of x.

99. Let $\Delta = \begin{vmatrix} {}^xC_1 & {}^xC_2 & {}^xC_3 \\ {}^yC_1 & {}^yC_2 & {}^yC_3 \\ {}^zC_1 & {}^zC_2 & {}^zC_3 \end{vmatrix} = \begin{vmatrix} x & \frac{x(x-1)}{1\cdot 2} & \frac{x(x-1)(x-2)}{1\cdot 2\cdot 3} \\ y & \frac{y(y-1)}{1\cdot 2} & \frac{y(y-1)(y-2)}{1\cdot 2\cdot 3} \\ z & \frac{z(z-1)}{1\cdot 2} & \frac{z(z-1)(z-2)}{1\cdot 2\cdot 3} \end{vmatrix}$

$$= \frac{xyz}{12}\begin{vmatrix} 1 & x-1 & x^2-3x+2 \\ 1 & y-1 & y^2-3y+2 \\ 1 & z-1 & z^2-3z+2 \end{vmatrix}$$

Applying $C_2 \to C_2 + C_1$, then

$$\Delta = \frac{xyz}{12}\begin{vmatrix} 1 & x & x^2-3x+2 \\ 1 & y & y^2-3y+2 \\ 1 & z & z^2-3z+2 \end{vmatrix}$$

Applying $C_3 \to C_3 + 3C_2 - 2C_1$, then

$$\Delta = \frac{xyz}{12}\begin{vmatrix} 1 & x & x^2 \\ 1 & y & y^2 \\ 1 & z & z^2 \end{vmatrix} = \frac{1}{12}xyz(x-y)(y-z)(z-x)$$

100. (i) $\because \quad f(x) = \begin{vmatrix} 1+\sin^2 x & \cos^2 x & 4\sin 2x \\ \sin^2 x & 1+\cos^2 x & 4\sin 2x \\ \sin^2 x & \cos^2 x & 1+4\sin 2x \end{vmatrix}$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$f(x) = \begin{vmatrix} 1+\sin^2 x & \cos^2 x & 4\sin 2x \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{vmatrix}$$

Applying $C_2 \to C_2 + C_1$, then

$$f(x) = \begin{vmatrix} 1+\sin^2 x & 2 & 4\sin 2x \\ \vdots & & \\ -1 & \ldots\ 0\ \ldots & 0 \\ \vdots & & \\ -1 & -1 & 1 \end{vmatrix}$$

Expanding along R_2, then

$$f(x) = \begin{vmatrix} 2 & 4\sin 2x \\ -1 & 1 \end{vmatrix} = 2 + 4\sin 2x$$

$\therefore$ Maximum value of

$$f(x) = 2 + 4(1) = 6$$

(ii) $\because \quad \Delta = \begin{vmatrix} \sin^2 A & \sin A \cos A & \cos^2 A \\ \sin^2 B & \sin B \cos B & \cos^2 B \\ \sin^2 C & \sin C \cos C & \cos^2 C \end{vmatrix}$

$$= \cos^2 A \cos^2 B \cos^2 C \begin{vmatrix} \tan^2 A & \tan A & 1 \\ \tan^2 B & \tan B & 1 \\ \tan^2 C & \tan C & 1 \end{vmatrix}$$

$$= -\cos^2 A \cos^2 B \cos^2 C \begin{vmatrix} 1 & \tan A & \tan^2 A \\ 1 & \tan B & \tan^2 B \\ 1 & \tan C & \tan^2 C \end{vmatrix}$$

$$= -\cos^2 A \cos^2 B \cos^2 C (\tan A - \tan B)$$
$$(\tan B - \tan C)(\tan C - \tan A)$$

$$= -\sin(A - B)\sin(B - C)\sin(C - A)$$

$$= \sin(A - B)\sin(B - C)\sin(A - C) \geq 0 \quad [\because A \geq B \geq C]$$

$\therefore \quad \Delta \geq 0$

Hence, minimum value of Δ is 0.

101. Let $f(x) = \begin{vmatrix} x^2 - 4x + 6 & 2x^2 + 4x + 10 & 3x^2 - 2x + 16 \\ x - 2 & 2x + 2 & 3x - 1 \\ 1 & 2 & 3 \end{vmatrix}$

On differentiating w.r.t. x, we get

$$f'(x) = \begin{vmatrix} 2x - 4 & 4x + 4 & 6x - 2 \\ x - 2 & 2x + 2 & 3x - 1 \\ 1 & 2 & 3 \end{vmatrix}$$

$$+ \begin{vmatrix} x^2 - 4x + 6 & 2x^2 + 4x + 10 & 3x^2 - 2x + 16 \\ 1 & 2 & 3 \\ 1 & 2 & 3 \end{vmatrix}$$

$$+ \begin{vmatrix} x^2 - 4x + 6 & 2x^2 + 4x + 10 & 3x^2 - 2x + 16 \\ x - 2 & 2x + 2 & 3x - 1 \\ 0 & 0 & 0 \end{vmatrix}$$

$f'(x) = 0, \forall\ x \in R$ and $f(x) =$ Constant

As, $\quad f(0) = \begin{vmatrix} 6 & 10 & 16 \\ -2 & 2 & -1 \\ 1 & 2 & 3 \end{vmatrix} = 2 \therefore \ f(x) = 2$

Now, $\quad I = \int_{-3}^{3} \frac{x^2 \sin x}{1 + x^6} f(x)\, dx = 2 \int_{-3}^{3} \frac{x^2 \sin x}{1 + x^6}\, dx$

Let $\quad g(x) = \frac{x^2 \sin x}{1 + x^6}$

$\therefore \quad g(-x) = \frac{-x^2 \sin x}{1 + x^6} = -g(x)$

Hence, g is an odd function.

$\therefore \quad I = 0$

102. Since, $\quad Y = X$ and $Z = tX$

$$Y_1 = sX_1 + Xs_1 \qquad \ldots(i)$$

$$Y_2 = sX_2 + Xs_2 + 2X_1 s_1 \qquad \ldots(ii)$$

$$Z_1 = tX_1 + Xt_1 \qquad \ldots(iii)$$

and $\quad Z_2 = tX_2 + Xt_2 + 2X_1 t_1 \qquad \ldots(iv)$

$$\text{LHS} = \begin{vmatrix} X & Y & Z \\ X_1 & Y_1 & Z_1 \\ X_2 & Y_2 & Z_2 \end{vmatrix}$$

$$= \begin{vmatrix} X & sX & tX \\ X_1 & sX_1 + Xs_1 & tX_1 + Xt_1 \\ X_2 & sX_2 + Xs_2 + 2X_1 s_1 & tX_2 + Xt_2 + 2X_1 t_1 \end{vmatrix}$$

[using Eqs. (i), (ii), (iii) and (iv)]

Applying $C_2 \to C_2 - sC_1$ and $C_3 \to C_3 - tC_1$, then

$$= \begin{vmatrix} X & 0 & 0 \\ X_1 & Xs_1 & Xt_1 \\ X_2 & Xs_2 + 2X_1 s_1 & Xt_2 + 2X_1 t_1 \end{vmatrix}$$

Expanding w.r.t. R_1, then

$$= X^2 \begin{vmatrix} s_1 & t_1 \\ Xs_2 + 2X_1 s_1 & Xt_2 + 2X_1 t_1 \end{vmatrix}$$

Applying $R_2 \to R_2 - 2X_1 R_1$, then

$$= X^2 \begin{vmatrix} s_1 & t_1 \\ Xs_2 & Xt_2 \end{vmatrix} = X^3 \begin{vmatrix} s_1 & t_1 \\ s_2 & t_2 \end{vmatrix} = \text{RHS}$$

103. Given determinant may be expressed as

$$\Delta = \begin{vmatrix} f & g & h \\ xf' + f & xg' + g & xh' + h \\ (x^2 f'' + 4xf' + 2f) & (x^2 g'' + 4xg' + 2g) & (x^2 h'' + 4xh' + 2h) \end{vmatrix}$$

Now, applying $R_3 \to R_3 - 4R_2 + 2R_1$, then

$$\Delta = \begin{vmatrix} f & g & h \\ xf' + f & xg' + g & xh' + h \\ x^2 f'' & x^2 g'' & x^2 h'' \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$, then $\Delta = \begin{vmatrix} f & g & h \\ xf' & xg' & xh' \\ x^2 f'' & x^2 g'' & x^2 h'' \end{vmatrix}$

$$\Rightarrow \quad \Delta = x \begin{vmatrix} f & g & h \\ f' & g' & h' \\ x^2 f'' & x^2 g'' & x^2 h'' \end{vmatrix}$$

$$\Rightarrow \quad \Delta = \begin{vmatrix} f & g & h \\ f' & g' & h' \\ x^3 f'' & x^3 g'' & x^3 h'' \end{vmatrix}$$

$$\therefore \quad \Delta' = \begin{vmatrix} f' & g & h' \\ f' & g' & h' \\ x^3 f'' & x^3 g'' & x^3 h'' \end{vmatrix} + \begin{vmatrix} f & g & h \\ f'' & g'' & h'' \\ x^3 f'' & x^3 g'' & x^3 h'' \end{vmatrix}$$

$$+ \begin{vmatrix} f & g & h \\ f' & g' & h' \\ (x^3 f'')' & (x^3 g'')' & (x^3 h'')' \end{vmatrix}$$

$$= 0 + 0 + \begin{vmatrix} f & g & h \\ f' & g' & h' \\ (x^3 f'')' & (x^3 g'')' & (x^3 h'')' \end{vmatrix}$$

Hence, $\Delta' = \begin{vmatrix} f & g & h \\ f' & g' & h' \\ (x^3 f'')' & (x^3 g'')' & (x^3 h'')' \end{vmatrix}$

104. Let the given determinant be equal to zero. Then, there exist x, y and z not all zero, such that

$$a_1 x + a_2 y + a_3 z = 0,\ b_1 x + b_2 y + b_3 z = 0$$

and $c_1 x + c_2 y + c_3 z = 0$

Assume that, $|x| \geq |y| \geq |z|$ and $x \neq 0$. Then, from $a_1 x = (-a_2 y) + (-a_3 z)$

$$\therefore \quad |a_1 x| = |-a_2 y - a_3 z| \leq |a_2 y| + |a_3 z|$$

$$\Rightarrow \quad |a_1|\ |x| \leq |a_2|\,|y| + |a_3|\,|z|$$

But $x \neq 0$ i.e. $|a_1| \leq |a_2| + |a_3|$

Similarly, $|b_2| \leq |b_1| + |b_3|$

$|c_3| \leq |c_1| + |c_2|$

which is contradiction. Hence, the assumption that the determinant is zero must be wrong.

105. $\text{LHS} = \begin{vmatrix} (a-a_1)^{-2} & (a-a_1)^{-1} & a_1^{-1} \\ (a-a_2)^{-2} & (a-a_2)^{-1} & a_2^{-1} \\ (a-a_3)^{-2} & (a-a_3)^{-1} & a_3^{-1} \end{vmatrix}$

$$= (a-a_1)^{-2}(a-a_2)^{-2}(a-a_3)^{-2} \begin{vmatrix} 1 & (a-a_1) & a_1^{-1}(a-a_1)^2 \\ 1 & (a-a_2) & a_2^{-1}(a-a_2)^2 \\ 1 & (a-a_3) & a_3^{-1}(a-a_3)^2 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to -R_3 - R_1$, then

$$\text{LHS} = \frac{1}{\prod (a-a_i)^2} \begin{vmatrix} 1 & (a-a_1) & a_1^{-1}(a-a_1)^2 \\ 0 & (a_1-a_2) & \dfrac{(a^2-a_1a_2)(a_1-a_2)}{a_1a_2} \\ 0 & (a_1-a_3) & \dfrac{(a^2-a_1a_3)(a_1-a_3)}{a_1a_3} \end{vmatrix}$$

Expanding w.r.t. 1st column, then

$$\text{LHS} = \frac{1}{\prod (a-a_i)^2} \begin{vmatrix} (a_1-a_2) & \dfrac{(a^2-a_1a_2)(a_1-a_2)}{a_1a_2} \\ (a_1-a_3) & \dfrac{(a^2-a_1a_3)(a_1-a_3)}{a_1a_3} \end{vmatrix}$$

$$= \frac{(a_1-a_2)(a_1-a_3)}{\prod (a-a_i)^2} \begin{vmatrix} 1 & \dfrac{a^2-a_1a_2}{a_1a_2} \\ 1 & \dfrac{a^2-a_1a_3}{a_1a_3} \end{vmatrix}$$

$$= \frac{(a_1-a_2)(a_1-a_3)\,a^2(a_2-a_3)}{a_1a_2a_3 \prod (a-a_i)^2} = \frac{-a^2 \prod (a_i - a_j)}{\prod a_i \prod (a-a_i)^2}$$

Numerator $= -a^2 (a_1-a_2)(a_2-a_3)(a_3-a_1)$

The resulting expression has negative sign.

106. The given system of equation will have a non-trivial solution in the determinant of coefficients.

$$\therefore \quad \Delta = \begin{vmatrix} a-t & b & c \\ b & c-t & a \\ c & a & b-t \end{vmatrix}$$

$\Delta = 0$ is a cubic equation in t.

So, it has in general three solutions t_1, t_2 and t_3.

Let $\Delta = a_0 t^3 + a_1 t^2 + a_2 t + a_3$

Clearly, $a_0 =$ Coefficient of $t^3 = -1$,

so $t_1 t_2 t_3 = -\dfrac{a_3}{a_0} = -\dfrac{a_3}{-1} = a_3 =$ Constant term in the expansion of Δ. i.e. Δ (at $t = 0$)

$$\therefore \quad t_1 t_2 t_3 = a_3 = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}$$

107. (i) Eliminating a, b and c from given equations, we obtain

$$\begin{vmatrix} -1 & \dfrac{y}{z} & \dfrac{z}{y} \\ -1 & \dfrac{z}{x} & \dfrac{x}{z} \\ -1 & \dfrac{x}{y} & \dfrac{y}{z} \end{vmatrix} = 0$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\begin{vmatrix} -1 & \dfrac{y}{z} & \dfrac{z}{y} \\ 0 & \dfrac{z}{x} - \dfrac{y}{z} & \dfrac{x}{z} - \dfrac{z}{y} \\ 0 & \dfrac{x}{y} - \dfrac{y}{z} & \dfrac{y}{x} - \dfrac{z}{y} \end{vmatrix} = 0$$

Expanding along C_1, then

$$-\left(\frac{z}{x} - \frac{y}{x}\right)\left(\frac{y}{x} - \frac{z}{y}\right) + \left(\frac{x}{y} - \frac{y}{z}\right)\left(\frac{x}{z} - \frac{z}{y}\right) = 0$$

$$\Rightarrow \quad \frac{yz}{x^2} + \frac{zx}{y^2} + \frac{xy}{z^2} + 1 = 0$$

(ii) To eliminate x, y and z.

Let $\alpha = \dfrac{y}{z}$, $\beta = \dfrac{z}{x}$ and $\gamma = \dfrac{x}{y}$ in the given equations,

$$b\alpha + \frac{c}{\alpha} = a, \qquad \ldots(\text{i})$$

$$c\beta + \frac{a}{\beta} = b \qquad \ldots(\text{ii})$$

and $$a\gamma + \frac{b}{\gamma} = c \qquad \ldots(\text{iii})$$

Also, $\alpha\beta\gamma = 1$

From Eqs. (i), (ii) and (iii), we get

$$\left(b\alpha + \frac{c}{\alpha}\right)\left(c\beta + \frac{a}{\beta}\right)\left(a\gamma + \frac{b}{\gamma}\right) = abc$$

$$\Rightarrow \quad 2abc + ac^2 \frac{\beta\gamma}{\alpha} + a^2 b \frac{\alpha\gamma}{\beta} + b^2 c \frac{\alpha\beta}{\gamma} + a^2 c \frac{\gamma}{\alpha\beta} + bc^2 \frac{\beta}{\gamma\alpha} + ab^2 \frac{\alpha}{\beta\gamma} = abc$$

$$\Rightarrow \quad ac^2 \frac{1}{\alpha^2} + a^2 b \frac{1}{\beta^2} + b^2 c \frac{1}{\gamma^2} + a^2 c\gamma^2 + bc^2\beta^2 + ab^2\alpha^2 = -abc \qquad [\because \alpha\beta\gamma = 1]$$

$$\Rightarrow a\left(\frac{c^2}{\alpha^2} + b^2\alpha^2\right) + b\left(\frac{a^2}{\beta^2} + \beta^2 c^2\right) + c\left(\frac{b^2}{\gamma^2} + a^2\gamma^2\right) = -abc \qquad \ldots(\text{iv})$$

On squaring Eqs. (i), (ii) and (iii), we get

$$b^2\alpha^2 + \frac{c^2}{\alpha^2} = a^2 - 2bc,\ c^2\beta^2 + \frac{a^2}{\beta^2} = b^2 - 2ca \text{ and}$$

$$a^2\gamma^2 + \frac{b^2}{\gamma^2} = c^2 - 2ab$$

On putting these values in Eq. (iv), we get

$$a(a^2 - 2bc) + b(b^2 - 2ca) + c(c^2 - 2ab) = -abc$$

$$a^3 + b^3 + c^3 = 5abc$$

108. Here, $\Delta = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix}$. According to the question, x, y and z not all zero. Hence, the given system of equations has non-trivial solution.

$$\Delta = 0$$

$$\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = 0$$

$$\Rightarrow \quad \frac{1}{2}(a+b+c)[(a-b)^2 + (b-c)^2 + (c-a)^2] = 0$$

$$\therefore \quad a + b + c = 0$$

or $$(a-b)^2 + (b-c)^2 + (c-a)^2 = 0$$

***Case* I** If $a + b + c = 0$

From first two equations,

$$ax + by - (a+b)z = 0$$

$$bx - (a+b)y + ax = 0$$

[by cross-multiplication law]

$$\therefore \quad \frac{x}{ab - (a+b)^2} = \frac{y}{-b(a+b) - a^2} = \frac{z}{-a(a+b) - b^2}$$

$$\Rightarrow \quad \frac{x}{-(a^2 + ab + b^2)} = \frac{y}{-(a^2 + ab + b^2)} = \frac{z}{-(a^2 + ab + b^2)}$$

$$\therefore \quad x : y : z = 1 : 1 : 1$$

***Case* II** If $(a-b)^2 + (b-c)^2 + (c-a)^2 = 0$

It is possible only, when

$$a - b = 0,\ b - c = 0 \text{ and } c - a = 0$$

Then, $$a = b = c$$

In this case all the three equations reduce in the forms

$$x + y + z = 0 \qquad \ldots(i)$$

Then, Eq. (i) will be satisfied, if

$$x = k,\ y = k\omega,\ z = k\omega^2$$

or $$x = k,\ y = k\omega^2,\ z = k\omega$$

where ω is the cube root of unity.

Then, $$x : y : z = 1 : \omega : \omega^2 \text{ or } 1 : \omega^2 : \omega$$

Hence, combined both cases, we get

$$x : y : z = 1 : 1 : 1$$

or $$1 : \omega : \omega^2$$

or $$1 : \omega^2 : \omega$$

109. Applying $C_1 \to C_1 + C_2 + C_3$, then

$$f(x) = \begin{vmatrix} 1 & (1+b^2)x & (1+c^2)x \\ 1 & 1+b^2x & (1+c^2)x \\ 1 & (1+b^2)x & 1+c^2x \end{vmatrix} \qquad [\because a^2 + b^2 + c^2 + 2 = 0]$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$= \begin{vmatrix} 1 & (1+b^2)x & (1+c^2)x \\ 0 & 1-x & 0 \\ 0 & 0 & 1-x \end{vmatrix} = (1-x^2)$$

Hence, degree of $f(x) = 2$

110. For no solution or infinitely many solutions

$$\begin{vmatrix} \alpha & 1 & 1 \\ 1 & \alpha & 1 \\ 1 & 1 & \alpha \end{vmatrix} = 0$$

Applying $C_1 \to C_1 + C_2 + C_3$, then

$$\begin{vmatrix} \alpha+2 & 1 & 1 \\ \alpha+2 & \alpha & 1 \\ \alpha+2 & 1 & \alpha \end{vmatrix} = 0$$

Applying $R_1 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\begin{vmatrix} \alpha+2 & 1 & 1 \\ 0 & \alpha-1 & 0 \\ 0 & 0 & \alpha-1 \end{vmatrix} = 0 \Rightarrow (\alpha-1)^2(\alpha+2) = 0$$

$$\therefore \quad \alpha = 1, -2$$

For $\alpha = 1$, clearly there an infinitely many solutions and when we put $\alpha = -2$ in given system of equations and adding them together LHS $\neq$ RHS. i.e., no solution.

111. $\because a_1, a_2, a_3, \ldots$ are in GP.

$\therefore$ Using $a_n = a_1 r^{n-1}$, we get the given determinant, as

$$\begin{vmatrix} \log(a_1r^{n-1}) & \log(a_1r^n) & \log(a_1r^{n+1}) \\ \log(a_1r^{n+2}) & \log(a_1r^{n+3}) & \log(a_1r^{n+4}) \\ \log(a_1r^{n+5}) & \log(a_1r^{n+6}) & \log(a_1r^{n+7}) \end{vmatrix}$$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$ and using $\log m - \log n = \log\left(\frac{m}{n}\right)$, we get

$$\begin{vmatrix} \log(a_1r^{n-1}) & \log r & 2\log r \\ \log(a_1r^{n+2}) & \log r & 2\log r \\ \log(a_1r^{n+5}) & \log r & 2\log r \end{vmatrix} = 0$$

[$\because C_2$ and C_3 are proportional]

112. Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$D = \begin{vmatrix} 1 & 1 & 1 \\ 0 & x & 0 \\ 0 & 0 & y \end{vmatrix} = xy$$

113. $\because$ $$D = \begin{vmatrix} 1 & -2 & 3 \\ -1 & 1 & -2 \\ 1 & -3 & 4 \end{vmatrix} = 0$$

and $$D_1 = \begin{vmatrix} -1 & -2 & 3 \\ k & 1 & -2 \\ 1 & -3 & 4 \end{vmatrix} = (3-k) = 0, \text{ if } k = 3$$

$$D_2 = \begin{vmatrix} 1 & -1 & 3 \\ -1 & k & -2 \\ 1 & -3 & 4 \end{vmatrix} = (k-3) = 0, \text{ if } k = 3$$

$$D_3=\begin{vmatrix}-1 & -2 & 3\\ k & 1 & -2\\ 1 & -3 & 4\end{vmatrix}=(k=3)=0, \text{ if } k=3$$

$\therefore$ System of equations has no solution for $k\neq 3$.

114. The system of equations

$x-cy-bz=0,\ -cx+y-az=0$ and $-bx-ay+z=0$

have non-trivial solution, if

$$\begin{vmatrix}1 & -c & -b\\ -c & 1 & -a\\ -b & -a & 1\end{vmatrix}=0$$

$$\Rightarrow \quad 1+2(-a)(-b)(-c)-a^2-b^2-c^2=0$$

or $$a^2+b^2+c^2+2abc=1$$

115. $$\begin{vmatrix}a & a+1 & a-1\\ -b & b+1 & b-1\\ c & c-1 & c+1\end{vmatrix}+(-1)^n\begin{vmatrix}a+1 & b+1 & c-1\\ a-1 & b-1 & c+1\\ a & -b & c\end{vmatrix}=0$$

$$\Rightarrow\begin{vmatrix}a & a+1 & a-1\\ -b & b+1 & b-1\\ c & c-1 & c+1\end{vmatrix}+(-1)^n\begin{vmatrix}a+1 & a-1 & a\\ b+1 & b-1 & -b\\ c-1 & c+1 & c\end{vmatrix}=0$$

[by property]

$$\Rightarrow\begin{vmatrix}a & a+1 & a-1\\ -b & b+1 & b-1\\ c & c-1 & c+1\end{vmatrix}+(-1)^{n+2}\begin{vmatrix}a & a+1 & a-1\\ -b & b+1 & b-1\\ c & c-1 & c+1\end{vmatrix}=0$$

116. Applying $R_1\to R_1+R_3$, then

$$f(\theta)=\begin{vmatrix}\theta & \cdots & 0 & \cdots & 2\\ & & & & \vdots\\ -\tan\theta & & 1 & & \tan\theta\\ & & & & \vdots\\ -1 & & -\tan\theta & & 1\end{vmatrix}$$

$$=2(1+\tan^2\theta)=2\sec^2\theta\geq 2$$

$\therefore f(\theta)\in[2,\infty)$

117. Non-zero solution means non-trivial solution.

For non-trivial solution of the given system of linear equations

$$\begin{vmatrix}4 & k & 2\\ k & 4 & 1\\ 2 & 2 & 1\end{vmatrix}=0$$

$$\Rightarrow\ 4(4-2)-k(k-2)+(2k-8)=0$$

$$\Rightarrow\quad -k^2+6k-8=0$$

$$\Rightarrow\quad k^2-6k+8=0$$

$$\Rightarrow\quad (k-2)(k-4)=0$$

$$\therefore\quad k=2,4$$

Clearly, there exist values of k.

118. For trivial solution $\begin{vmatrix}1 & -k & 1\\ k & 3 & -k\\ 3 & 1 & -1\end{vmatrix}\neq 0$

$$\Rightarrow 1(-3+k)+k(-k+3k)+1(k-9)\neq 0$$

$$\Rightarrow\quad 2k^2+2k-12\neq 0$$

$$\Rightarrow\quad k^2+k-6\neq 0$$

$$\Rightarrow\quad (k+3)(k-2)\neq 0$$

$$\Rightarrow\quad k\neq 2,-3$$

or $$k\in R-\{2,-3\}$$

119. $\Delta=\begin{vmatrix}k+1 & 8\\ k & k=3\end{vmatrix}=(k+1)(k+3)-8k=k^2-4k+3$

$\therefore\quad \Delta=(k-1)(k-3)$

$\Delta_1=\begin{vmatrix}4k & 8\\ 3k-1 & k+3\end{vmatrix}=4k^2+12k-24k+8=4k^2-12k+8$

$$\Delta_1=4(k-1)(k-2)$$

and $\Delta_2=\begin{vmatrix}k+1 & 4k\\ k & 3k-1\end{vmatrix}=(k+1)(3k-1)-4k^2=-k^2+2k+1$

$\therefore\quad \Delta_2=-(k-1)^2$

As given no solutions

$\Rightarrow\quad \Delta_1$ and $\Delta_2\neq 0$

but $\Delta=0$

$k=3$

120. $\because\begin{vmatrix}3 & 1+f(1) & 1+f(2)\\ 1+f(1) & 1+f(2) & 1+f(3)\\ 1+f(2) & 1+f(3) & 1+f(4)\end{vmatrix}$

$$=\begin{vmatrix}1+1+1 & 1+\alpha+\beta & 1+\alpha^2+\beta^2\\ 1+\alpha+\beta & 1+\alpha^2+\beta^2 & 1+\alpha^3+\beta^3\\ 1+\alpha^2+\beta^2 & 1+\alpha^3+\beta^3 & 1+\alpha^4+\beta^4\end{vmatrix}$$

$$=\begin{vmatrix}1 & 1 & 1\\ 1 & \alpha & \beta\\ 1 & \alpha^2 & \beta^2\end{vmatrix}\times\begin{vmatrix}1 & 1 & 1\\ 1 & \alpha & \beta\\ 1 & \alpha^2 & \beta^2\end{vmatrix}=\begin{vmatrix}1 & 1 & 1\\ 1 & \alpha & \beta\\ 1 & \alpha^2 & \beta^2\end{vmatrix}^2$$

$$=\{(1-\alpha)(1-\beta)(\alpha-\beta)\}^2$$

$$=(1-\alpha)^2(1-\beta)^2(\alpha-\beta)^2$$

So, $k=1$.

121. The given system can be written as

$$(2-\lambda)x_1-2x_2+x_3=0$$

$$2x_1-(3+\lambda)x_2+2x_3=0$$

$$-x_1+2x_2-\lambda x_3=0$$

For non-trivial solutions, $\Delta=0$

$$\begin{vmatrix}2-\lambda & -2 & 1\\ 2 & -(3+\lambda) & 2\\ -1 & 2 & -\lambda\end{vmatrix}=0$$

$$\Rightarrow (2-\lambda)(\lambda^2+3\lambda-4)+2(-2\lambda+2)+1(4-3-\lambda)=0$$

$$\Rightarrow\quad \lambda^3+\lambda^2-5\lambda+3=0$$

$$\Rightarrow\quad \lambda=1,1,-3$$

Hence, λ has two values.

122. Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$\begin{vmatrix} (1+\alpha)^2 & (1+2\alpha)^2 & (1+3\alpha)^2 \\ 2\alpha+3 & 4\alpha+3 & 6\alpha+3 \\ 4\alpha+8 & 8\alpha+8 & 12\alpha+8 \end{vmatrix} = -648\alpha$$

Applying $R_3 \to R_3 - 2R_2$, then

$$\begin{vmatrix} (1+\alpha)^2 & (1+2\alpha)^2 & (1+3\alpha)^2 \\ 2\alpha+3 & 4\alpha+3 & 6\alpha+3 \\ 2 & 2 & 2 \end{vmatrix} = -648\alpha$$

Applying $C_2 \to C_2 - \frac{1}{2}(C_1 + C_3)$, then

$$\begin{vmatrix} (1+\alpha)^2 & \cdots & -\alpha^2 & \cdots & (1+3\alpha)^2 \\ 2\alpha+3 & & 4\alpha+3 & & 6\alpha+3 \\ 2 & & 0 & & 2 \end{vmatrix} = -648\alpha$$

$\Rightarrow \quad \alpha^2(4\alpha + 6 - 12\alpha - 6) = -648\alpha$

$\Rightarrow \quad -8\alpha^3 = -648\alpha$

$\Rightarrow \quad \alpha^3 - 81\alpha = 0$

$\therefore \quad \alpha = 0, 9, -9$

123. For non-trivial solution

$$\begin{bmatrix} 1 & \lambda & -1 \\ \lambda & -1 & -1 \\ 1 & 1 & -\lambda \end{bmatrix} = 0$$

$\Rightarrow \quad 1(\lambda+1) - \lambda(-\lambda^2+1) - 1(\lambda+1) = 0$

$\Rightarrow \quad \lambda(\lambda^2 - 1) = 0$

$\Rightarrow \quad \lambda = 0, \ \pm 1$

124.

$$x^3 \begin{bmatrix} 1 & 1 & 1+x^3 \\ 2 & 4 & 1+8x^3 \\ 3 & 9 & 1+27x^3 \end{bmatrix} = 10$$

$\Rightarrow$

$$x^3 \begin{bmatrix} 1 & 1 & 1 \\ 2 & 4 & 1 \\ 3 & 9 & 1 \end{bmatrix} + x^6 \begin{bmatrix} 1 & 1 & 1 \\ 2 & 4 & 8 \\ 3 & 9 & 27 \end{bmatrix} = 10$$

Applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$, then

$$x^3 \begin{bmatrix} 1 & 0 & 0 \\ 2 & 2 & -1 \\ 3 & 6 & -2 \end{bmatrix} + x^6 \begin{bmatrix} 1 & 0 & 0 \\ 2 & 2 & 6 \\ 3 & 6 & 24 \end{bmatrix} = 10$$

$\Rightarrow \quad 2x^3 + 12x^6 = 10 \ \text{ or } 6x^6 + x^3 - 5 = 0$

or $\quad (6x^3 - 5)(x^3 + 1) = 0$

$\Rightarrow \quad x^3 = \frac{5}{6} \ \text{ or } \ x^3 = -1$

$\therefore \quad x = \left(\frac{5}{6}\right)^{1/3}, -1$

i.e. Two distinct values of x.

125.

$$\Delta = \begin{vmatrix} a & 2 \\ 3 & -2 \end{vmatrix} = -2a - 6,$$

$$\Delta_1 = \begin{vmatrix} \lambda & 2 \\ \mu & -2 \end{vmatrix} = -2(\lambda + \mu)$$

or $\quad \Delta_2 = \begin{vmatrix} a & \lambda \\ 3 & \mu \end{vmatrix} = \alpha\mu - 3\lambda$

System has unique solution for $\Delta \neq 0$

$\therefore \ a \neq -3$ for all values λ and μ

System has infinitely many solution for

$$\Delta = \Delta_1 = \Delta_2 = 0$$

$\therefore \ a = -3, \ \lambda + \mu = 0, \ a\mu - 3\lambda = 0$

and system has no solution

$$\Delta = 0 \Rightarrow a = -3$$

and $\quad \lambda + \mu \neq 0$

126. $\because \ \Delta = \begin{bmatrix} 1 & 1 & 1 \\ 1 & a & 1 \\ a & b & 1 \end{bmatrix} = 1(a-b) - 1(1-a) + 1(b-a^2) = -(a-1)^2$

$$\Delta_1 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & a & 1 \\ 0 & b & 1 \end{bmatrix} = 1(a-b) - 1(1) + 1(b) = (a-1)$$

$$\Delta_2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ a & 0 & 1 \end{bmatrix} = 1(1) - 1(1-a) + 1(0-a) = 0$$

and $\Delta_3 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & a & 1 \\ a & b & 0 \end{bmatrix} = 1(-b) - 1(-a) + 1(b-a^2) = -a(a-1)$

For $a = 1, \Delta = \Delta_1 = \Delta_2 = \Delta_3 = 0$

and for $b = 1$ only

$$x + y + z = 1$$
$$x + y + z = 1$$
$$x + y + z = 0$$

i.e. no solution ($\because$ RHS are not equal)

Hence, for no solution $b = 1$ only.

J. J. Sylvester was the first to use the word ''Matrix" in 1850 and later on in 1858 Arthur Cayley developed the theory of matrices in a systematic way. 'Matrices' is a powerful tool in mathematics and its study is becoming important day by day due to its wide applications in almost every branch of science. This mathematical tool is not only used in certain branches of sciences but also in genetics, economics, sociology, modern psychology and industrial management.

Session 1

Definition, Types of Matrices, Difference Between a Matrix and a Determinant, Equal Matrices, Operations of Matrices, Various Kinds of Matrices

Definition

A set of mn numbers (real or complex) arranged in the form of a rectangular array having m rows and n columns is called a matrix of order $m \times n$ or an $m \times n$ matrix (which is read as m by n matrix).

An $m \times n$ matrix is usually written as

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ a_{m_1} & a_{m_2} & a_{m_3} & \dots & a_{mn} \end{bmatrix}$$

In a compact form the above matrix is represented by $[a_{ij}]$, $i = 1, 2, 3, \dots, m$, $j = 1, 2, 3, \dots, n$ or simply by $[a_{ij}]_{m \times n}$, where the symbols a_{ij} represent any numbers (a_{ij} lies in the ith row (from top) and jth column (from left)).

Notations A matrix is denoted by capital letter such as A, B, C, ..., X, Y, Z.

Note

1. A matrix may be represented by the symbols $[a_{ij}], (a_{ij}), \| a_{ij} \|$ or by a single capital letter A (say)
   $$A = [a_{ij}]_{m \times n} \text{ or } (a_{ij})_{m \times n} \text{ or } \| a_{ij} \|$$
   Generally, the first system is adopted.
2. The numbers a_{11}, a_{12}, ..., etc., of rectangular array are called the elements or entries of the matrix.
3. A matrix is essentially an arrangement of elements and has no value.
4. The plural of 'matrix' is 'matrices'.

Example 1. If a matrix has 12 elements, what are the possible orders it can have? What will be the possible orders if it has 7 elements?

Sol. We know that, if a matrix is of order $m \times n$, it has mn elements. Thus, to find all possible orders of a matrix with 12 elements, we will find all ordered pairs of natural numbers, whose product is 12.

Thus, all possible ordered pairs are (1, 12), (12, 1), (2, 6), (6, 2), (3, 4), (4, 3).

Hence, possible orders are 1×12, 12×1, 2×6, 6×2, 3×4 and 4×3.

If the matrix has 7 elements, then the possible orders will be 1×7 and 7×1.

Example 2. Construct a 2×3 matrix $A = [a_{ij}]$, whose elements are given by

(i) $a_{ij} = \dfrac{(i+2j)^2}{2}$. (ii) $a_{ij} = \dfrac{1}{2} \left| 2i - 3j \right|$.

(iii) $a_{ij} = \begin{cases} i - j, & i \geq j \\ i + j, & i < j \end{cases}$.

(iv) $a_{ij} = \left[\dfrac{i}{j} \right]$,
where [.] denotes the greatest integer function.

(v) $a_{ij} = \left\{ \dfrac{2i}{3j} \right\}$,
where {.} denotes the fractional part function.

(vi) $a_{ij} = \left(\dfrac{3i + 4j}{2} \right)$,
where (.) denotes the least integer function.

Sol. We have, $A=\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \end{bmatrix}_{2\times 3}$

(i) Since, $a_{ij}=\dfrac{(i+2j)^2}{2}$, therefore

$$a_{11}=\frac{(1+2)^2}{2}=\frac{9}{2}, a_{12}=\frac{(1+4)^2}{2}=\frac{25}{2},$$

$$a_{13}=\frac{(1+6)^2}{2}=\frac{49}{2}, a_{21}=\frac{(2+2)^2}{2}=8,$$

$$a_{22}=\frac{(2+4)^2}{2}=18 \text{ and } a_{23}=\frac{(2+6)^2}{2}=32$$

Hence, the required matrix is $A=\begin{bmatrix} \frac{9}{2} & \frac{25}{2} & \frac{49}{2} \\ 8 & 18 & 32 \end{bmatrix}$.

(ii) Since, $a_{ij}=\dfrac{1}{2}\left|\,2i-3j\,\right|$, therefore

$$a_{11}=\frac{1}{2}\left|\,2-3\,\right|=\frac{1}{2}\left|\,-1\,\right|=\frac{1}{2},$$

$$a_{12}=\frac{1}{2}\left|\,2-6\,\right|=\frac{1}{2}\left|\,-4\,\right|=\frac{4}{2}=2,$$

$$a_{13}=\frac{1}{2}\left|\,2-9\,\right|=\frac{1}{2}\left|\,-7\,\right|=\frac{7}{2},$$

$$a_{21}=\frac{1}{2}\left|\,2-3\,\right|=\frac{1}{2}\left|\,-1\,\right|=\frac{1}{2},$$

$$a_{22}=\frac{1}{2}\left|\,2-6\,\right|=\frac{1}{2}\left|\,-4\,\right|=\frac{4}{2}=2$$

and $a_{23}=\dfrac{1}{2}\left|\,4-9\,\right|=\dfrac{1}{2}\left|\,-5\,\right|=\dfrac{5}{2}$

Hence, the required matrix is $A=\begin{bmatrix} \frac{1}{2} & 2 & \frac{7}{2} \\ \frac{1}{2} & 2 & \frac{5}{2} \end{bmatrix}$.

(iii) Since, $a_{ij}=\begin{cases} i-j, & i\geq j \\ i+j, & i<j \end{cases}$, therefore

$$a_{11}=1-1=0, a_{12}=1+2=3, a_{13}=1+3=4,$$
$$a_{21}=2-1=1, a_{22}=2-2=0 \text{ and } a_{23}=2+3=5$$

Hence, the required matrix is

$$A=\begin{bmatrix} 0 & 3 & 4 \\ 1 & 0 & 5 \end{bmatrix}$$

(iv) Since, $a_{ij}=\left[\dfrac{i}{j}\right]$, therefore $\quad[\because [x]\leq x\,]$

$$a_{11}=\left[\frac{1}{1}\right]=[1]=1, a_{12}=\left[\frac{1}{2}\right]=[0.5]=0,$$

$$a_{13}=\left[\frac{1}{3}\right]=[0.33]=0, a_{21}=\left[\frac{2}{1}\right]=[2]=2$$

and $a_{22}=\left[\dfrac{2}{2}\right]=[1]=1$ and $a_{23}=\left[\dfrac{2}{3}\right]=[0.67]=0$

Hence, the required matrix is $A=\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \end{bmatrix}$

(v) Since, $a_{ij}=\left\{\dfrac{2i}{3j}\right\}$, therefore $\quad[\because 0\leq\{x\}<1]$

$$a_{11}=\left\{\frac{2}{3}\right\}=\frac{2}{3}, a_{12}=\left\{\frac{2}{6}\right\}=\left\{\frac{1}{3}\right\}=\frac{1}{3},$$

$$a_{13}=\left\{\frac{2}{9}\right\}=\frac{2}{9}, a_{21}=\left\{\frac{4}{3}\right\}=\left\{1+\frac{1}{3}\right\}=\frac{1}{3},$$

$$a_{22}=\left\{\frac{4}{6}\right\}=\left\{\frac{2}{3}\right\}=\frac{2}{3} \text{ and } a_{23}=\left\{\frac{4}{9}\right\}=\frac{4}{9}$$

Hence, the required matrix is $A=\begin{bmatrix} \frac{2}{3} & \frac{1}{3} & \frac{2}{9} \\ \frac{1}{3} & \frac{2}{3} & \frac{4}{9} \end{bmatrix}$.

(vi) Since, $a_{ij}=\left(\dfrac{3i+4j}{2}\right)$, therefore $\quad[\because (x)\geq x\,]$

$$a_{11}=\left(\frac{3+4}{2}\right)=\left(\frac{7}{2}\right)=(3.5)=4,$$

$$a_{12}=\left(\frac{3+8}{2}\right)=\left(\frac{11}{2}\right)=(5.5)=6,$$

$$a_{13}=\left(\frac{3+12}{2}\right)=\left(\frac{15}{2}\right)=(7.5)=8,$$

$$a_{21}=\left(\frac{6+4}{2}\right)=\left(\frac{10}{2}\right)=(5)=5,$$

$$a_{22}=\left(\frac{6+8}{2}\right)=\left(\frac{14}{2}\right)=(7)=7$$

and $a_{23}=\left(\dfrac{6+12}{2}\right)=\left(\dfrac{18}{2}\right)=(9)=9$

Hence, the required matrix is

$$A=\begin{bmatrix} 4 & 6 & 8 \\ 5 & 7 & 9 \end{bmatrix}$$

Types of Matrices

1. Row Matrix or Row Vector

A matrix is said to be row matrix or row vector, if it contains only one row, i.e. a matrix $A=[a_{ij}]_{m\times n}$ is said to be row matrix, if $m=1$.

For example,

(i) $A=[a_{11}\quad a_{12}\quad a_{13}\quad \ldots\quad a_{1n}]_{1\times n}$

(ii) $B=[3\quad 5\quad -7\quad 9]_{1\times 4}$

are called row matrices.

2. Column Matrix or Column Vector

A matrix is said to be column matrix or column vector, if it contains only one column, i.e., a matrix $A=[a_{ij}]_{m\times n}$ is said to be column matrix, if $n=1$. *For example,*

(i) $A=\begin{bmatrix} a_{11} \\ a_{21} \\ a_{31} \\ \vdots \\ a_{mn} \end{bmatrix}_{m\times 1}$ (ii) $B=\begin{bmatrix} 7 \\ 0 \\ -8 \\ 2 \\ 1 \end{bmatrix}_{5\times 1}$

are called column matrices.

3. Rectangular Matrix

A matrix is said to be rectangular matrix, if the number of rows and the number of columns are not equal i.e., a matrix $A=[a_{ij}]_{m\times n}$ is called a rectangular matrix, iff $m \neq n$. *For example,*

(i) $A=\begin{bmatrix} 1 & 3 & 4 & 5 \\ 2 & 0 & -3 & 8 \\ 7 & 4 & 2 & 5 \end{bmatrix}_{3\times 4}$ (ii) $B=\begin{bmatrix} 2 & -3 \\ 3 & 0 \\ 4 & 8 \end{bmatrix}_{3\times 2}$

are called rectangular matrices.

4. Square Matrix

A matrix is said to be a square matrix, if the number of rows and the number of columns are equal i.e., a matrix $A=[a_{ij}]_{m\times n}$ is called a square matrix, iff $m=n$.

For example,

(i) $A=\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}_{3\times 3}$ (ii) $B=\begin{bmatrix} a & b \\ c & d \end{bmatrix}_{2\times 2}$

are called square matrices.

Remark

If $A=[a_{ij}]$ is a square matrix of order n, then elements (entries) $a_{11}, a_{22}, a_{33}, \ldots, a_{nn}$ are said to constitute the *diagonal* of the matrix A. The line along which the diagonal elements lie is called principal or leading diagonal. Thus, if $A=\begin{bmatrix} 1 & 4 & 0 \\ 8 & 3 & -2 \\ 9 & 2 & 5 \end{bmatrix}$, then the elements of the diagonal of A are 1, 3, 5.

5. Diagonal Matrix

A square matrix is said to be a diagonal matrix, if all its non-diagonal elements are zero. Thus, $A=[a_{ij}]_{n\times n}$ is called a diagonal matrix, if $a_{ij}=0$, when $i \neq j$.

For example,

(i) $A=[2]$ (ii) $B=\begin{bmatrix} -1 & 0 \\ 0 & 2 \end{bmatrix}$ (iii) $C=\begin{bmatrix} 3 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 7 \end{bmatrix}$

are diagonal matrices of order 1, 2 and 3, respectively. A diagonal matrix of order n having $d_1, d_2, d_3, \ldots, d_n$ as diagonal elements may be denoted by diag $(d_1, d_2, d_3, .., d_n)$.

Thus, $A=$ diag (2), $B=$ diag $(-1, 2)$ and $C=$ diag (3, 5, 7).

Remark

(i) No element of principal diagonal in a diagonal matrix is zero.

(ii) Minimum number of zero in a diagonal matrix is given by $n(n-1)$, where n is order of matrix.

6. Scalar Matrix

A diagonal matrix is said to be a scalar matrix, if its diagonal elements are equal. Thus, $A=[a_{ij}]_{n\times n}$ is called scalar matrix, if

$$a_{ij}=\begin{cases} 0, \text{ if } i \neq j \\ k, \text{ if } i=j \end{cases}, \text{ where } k \text{ is scalar.}$$

For example,

(i) $[7]$ (ii) $\begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$ (iii) $\begin{bmatrix} 5 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 5 \end{bmatrix}$

are scalar matrices of order 1, 2 and 3, respectively. They can be written as diag (7), diag (2, 2) and diag (5, 5, 5), respectively.

7. Unit or Identity Matrix

A diagonal matrix is said to be an identity matrix, if its diagonal elements are equal to 1.

Thus, $A=[a_{ij}]_{n\times n}$ is called unit or identity matrix, if

$$a_{ij}=\begin{cases} 0, \text{ if } i \neq j \\ 1, \text{ if } i=j \end{cases}$$

A unit matrix of order n is denoted by I_n or I. *For example,*

(i) $I_1=[1]$ (ii) $I_2=\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ (iii) $I_3=\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

are identity matrices of order 1, 2 and 3, respectively.

8. Singleton Matrix

A matrix is said to be singleton matrix, if it has only one element i.e. a matrix $A=[a_{ij}]_{m\times n}$ is said to be singleton matrix, if $m=n=1$.

For example, $[3], [k], [-2]$ are singleton matrices.

9. Triangular Matrix

A square matrix is called a triangular matrix, if its each element above or below the principal diagonal is zero. It is of two types:

(a) **Upper Triangular Matrix** A square matrix in which all elements below the principal diagonal are zero is called an upper triangular matrix i.e., a matrix $A=[a_{ij}]_{n\times n}$ is said to be an upper triangular matrix, if $a_{ij}=0$, when $i>j$.

For example,

(i) $\begin{bmatrix} 3 & -2 & 4 & 1 \\ 0 & 2 & -3 & 2 \\ 0 & 0 & 7 & 5 \\ 0 & 0 & 0 & 8 \end{bmatrix}_{4\times 4}$

(ii) $\begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} & a_{15} \\ 0 & a_{22} & a_{23} & a_{24} & a_{25} \\ 0 & 0 & a_{33} & a_{34} & a_{35} \\ 0 & 0 & 0 & a_{44} & a_{45} \\ 0 & 0 & 0 & 0 & a_{55} \end{bmatrix}_{5\times 5}$

are upper triangular matrices.

(b) **Lower Triangular Matrix** A square matrix in which all elements above the principal diagonal are zero is called a lower triangular matrix i.e., a matrix $A=[a_{ij}]_{n\times n}$ is said to be a lower triangular matrix, if $a_{ij}=0$, when $i<j$. *For example*,

(i) $\begin{bmatrix} 7 & 0 & 0 \\ 5 & 4 & 0 \\ 2 & 3 & 4 \end{bmatrix}_{3\times 3}$ (ii) $\begin{bmatrix} 10 & 0 & 0 & 0 \\ 8 & 9 & 0 & 0 \\ 5 & 6 & 7 & 0 \\ 1 & 2 & 3 & 4 \end{bmatrix}_{4\times 4}$

are lower triangular matrices.

Note

Minimum number of zeroes in a triangular matrix is given by $\frac{n(n-1)}{2}$, where n is order of matrix.

10. Horizontal Matrix

A matrix is said to be horizontal matrix, if the number of rows is less than the number of columns i.e., a matrix $A=[a_{ij}]_{m\times n}$ is said to horizontal matrix, iff $m<n$.

For example, $A=\begin{bmatrix} 2 & 3 & 4 & 5 \\ 8 & 9 & 7 & -2 \\ 2 & -2 & -3 & 4 \end{bmatrix}_{3\times 4}$ is a horizontal matrix. [$\because$ number of rows (3) < number of columns (4)]

11. Vertical Matrix

A matrix is said to be vertical matrix, if the number of rows is greater than the number of columns i.e., a matrix $A=[a_{ij}]_{m\times n}$ is said to vertical matrix, iff $m>n$.

For example, $A=\begin{bmatrix} 2 & 3 & 4 \\ 0 & -1 & 7 \\ 3 & 5 & 4 \\ 2 & 7 & 9 \\ -1 & 2 & -5 \end{bmatrix}_{5\times 3}$ is a vertical matrix.

[$\because$ number of rows (5) > number of columns (3)]

12. Null Matrix or Zero Matrix

A matrix is said to be null matrix or zero matrix, if all elements are zero i.e., a matrix $A=[a_{ij}]_{m\times n}$ is said to be a zero or null matrix, iff $a_{ij}=0,\ \forall\ i,\ j$. It is denoted by O.

For example,

(i) $O_{2\times 3}=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ (ii) $O_{3\times 3}=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$

are called the null matrices.

13. Sub-Matrix

A matrix which is obtained from a given matrix by deleting any number of rows and number of columns is called a sub-matrix of the given matrix.

For example, $\begin{bmatrix} 3 & 4 \\ -2 & 5 \end{bmatrix}$ is a sub-matrix of $\begin{bmatrix} 8 & 9 & 5 \\ 2 & 3 & 4 \\ 3 & -2 & 5 \end{bmatrix}$.

14. Trace of a Matrix

The sum of all diagonal elements of a square matrix $A=[a_{ij}]_{n\times n}$ (say) is called the **trace** of a matrix A and is denoted by $\text{Tr}\,(A)$.

Thus, $$\text{Tr}\,(A)=\sum_{i=1}^{n} a_{ii}$$

For example, If $A=\begin{bmatrix} 2 & -7 & 9 \\ 0 & 3 & 2 \\ 8 & 9 & 4 \end{bmatrix}$, then

$$\text{Tr}\,(A)=2+3+4=9$$

Properties of Trace of a Matrix

Let $A=[a_{ij}]_{n\times n}$, $B=[b_{ij}]_{n\times n}$ and k is a scalar, then

(i) $\text{Tr}\,(kA)=k\cdot\text{Tr}\,(A)$

(ii) $\text{Tr}\,(A\pm B)=\text{Tr}\,(A)\pm\text{Tr}\,(B)$

(iii) $\text{Tr}\,(AB)=\text{Tr}\,(BA)$

(iv) $\text{Tr}\,(A)=\text{Tr}\,(A')$

(v) $\text{Tr}\,(I_n)=n$

(vi) $\text{Tr}\,(AB)\neq\text{Tr}\,(A)\,\text{Tr}\,(B)$

(vii) $\text{Tr}\,(A)=\text{Tr}\,(C\,A\,C^{-1})$,
where C is a non-singular square matrix of order n.

15. Determinant of Square Matrix

Let $A=[a_{ij}]_{n\times n}$ be a matrix. The determinant formed by the elements of A is said to be the determinant of matrix A. This is denoted by $|A|$.

For example,

If $A=\begin{bmatrix}3 & 4 & 5\\ 6 & 7 & 8\\ 2 & -3 & 5\end{bmatrix}$, then $|A|=\begin{vmatrix}3 & 4 & 5\\ 6 & 7 & 8\\ 2 & -3 & 5\end{vmatrix}=-39.$

Remark

1. If $A_1, A_2, A_3, \ldots, A_n$ are square matrices of the same order, then $|A_1A_2A_3\ldots A_n|=|A_1||A_2||A_3|\ldots|A_n|$.
2. If k is a scalar and A is a square matrix of order n, then $|kA|=k^n|A|$

16. Comparable Matrices

Two matrices $A=[a_{ij}]_{m\times n}$ and $B=[b_{ij}]_{p\times q}$ are said to be comparable, if $m=p$ and $n=q$.

For example,

The matrices $\begin{bmatrix}a & b & c\\ d & e & f\end{bmatrix}$ and $\begin{bmatrix}p & q & r\\ s & t & u\end{bmatrix}$ are comparable

but the matrices $\begin{bmatrix}1 & 2\\ 4 & 8\end{bmatrix}$ and $\begin{bmatrix}2 & 4 & 6\\ 5 & 3 & 1\end{bmatrix}$ are not comparable.

Difference Between a Matrix and a Determinant

(i) A matrix cannot be reduced to a number but determinant can be reduced to a number.

(ii) The number of rows may or may not be equal to the number of columns in matrices but in determinant the number of rows is equal to the number of columns.

(iii) On interchanging the rows and columns, a different matrix is formed but in determinant it does not change the value.

(iv) A square matrix A such that $|A|\neq 0$, is called a non-singular matrix. If $|A|=0$, then the matrix A is called a singular matrix.

(v) Matrices represented by [ ], ( ), $\|\ \|$ but determinant is represented by $|\ |$.

Equal Matrices

Two matrices are said to be equal, if

(i) they are of the same order i.e., if they have same number of rows and columns.

(ii) the elements in the corresponding positions of the two matrices are equal.

Thus, if $A=[a_{ij}]_{m\times n}$, $B=[b_{ij}]_{p\times q}$, then $A=B$, iff

(i) $m=p, n=q$ (ii) $a_{ij}=b_{ij}, \forall\ i, j$

For example, If $A=\begin{bmatrix}-1 & 2 & 4\\ 3 & 0 & 5\end{bmatrix}_{2\times 3}$ and

$B=\begin{bmatrix}a & b & c\\ d & e & f\end{bmatrix}_{2\times 3}$ are equal matrices, then

$a=-1, b=2, c=4\ d=3, e=0, f=5$

Example 3. If $\begin{bmatrix}x+3 & 2y+x\\ z-1 & 4w-8\end{bmatrix}=\begin{bmatrix}-x-1 & 0\\ 3 & 2w\end{bmatrix}$, then find the value of $|x+y|+|z+w|$.

Sol. As the given matrices are equal so their corresponding elements are equal.

$$x+3=-x-1 \Rightarrow 2x=-4 \quad \ldots(i)$$

$$\therefore\quad x=-2$$

$$2y+x=0$$

$$\Rightarrow\quad 2y-2=0 \quad [\text{from Eq. (i)}]$$

$$\Rightarrow\quad y=1 \quad \ldots(ii)$$

$$z-1=3$$

$$\Rightarrow\quad z=4 \quad \ldots(iii)$$

$$4w-8=2w$$

$$\Rightarrow\quad 2w=8$$

$$\therefore\quad w=4 \quad \ldots(iv)$$

Hence, $|x+y|+|z+w|=|-2+1|+|4+4|=1+8=9$

Example 4. If $\begin{bmatrix}2\alpha+1 & 3\beta\\ 0 & \beta^2-5\beta\end{bmatrix}=\begin{bmatrix}\alpha+3 & \beta^2+2\\ 0 & -6\end{bmatrix}$, find the equation whose roots are α and β.

Sol. The given matrices will be equal, iff

$$2\alpha+1=\alpha+3\Rightarrow\alpha=2$$

$$3\beta=\beta^2+2\Rightarrow\beta^2-3\beta+2=0$$

$$\therefore\quad \beta=1,2 \text{ and } \beta^2-5\beta=-6 \quad \ldots(i)$$

$$\Rightarrow\quad \beta^2-5\beta+6=0$$

$$\therefore\quad \beta=2,3 \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get $\beta=2$

$$\Rightarrow\quad \alpha=2, \beta=2$$

$\therefore$ Required equation is $x^2-(2+2)x+2\cdot 2=0$

$$\Rightarrow\quad x^2-4x+4=0$$

Operations of Matrices

Addition of Matrices

Let A, B be two matrices, each of order $m\times n$. Then, their sum $A+B$ is a matrix of order $m\times n$ and is obtained by adding the corresponding elements of A and B.

Thus, if $A=[a_{ij}]_{m\times n}$ and $B=[b_{ij}]_{m\times n}$, then $A+B=[a_{ij}+b_{ij}]_{m\times n}, \forall\, i, j$

Example 5. Given, $A=\begin{bmatrix}1 & 3 & 5\\ -2 & 0 & 2\\ 0 & 4 & -3\end{bmatrix}, B=\begin{bmatrix}0 & 3\\ -2 & 0\\ 0 & -4\end{bmatrix}$ and $C=\begin{bmatrix}4 & 1 & -2\\ 3 & 2 & 1\\ 2 & -1 & 7\end{bmatrix}$. Find (whichever defined)

(i) $A+B$. (ii) $A+C$.

Sol. (i) Given, A is a matrix of the type 3×3 and B is a matrix of the type 3×2.
Since, A and B are not of the same type.
$\therefore$ Sum $A+B$ is not defined.

(ii) As A and C are two matrices of the same type, therefore the sum $A+C$ is defined.

$$\therefore\ A+C=\begin{bmatrix}1 & 3 & 5\\ -2 & 0 & 2\\ 0 & 4 & -3\end{bmatrix}+\begin{bmatrix}4 & 1 & -2\\ 3 & 2 & 1\\ 2 & -1 & 7\end{bmatrix}$$

$$=\begin{bmatrix}1+4 & 3+1 & 5-2\\ -2+3 & 0+2 & 2+1\\ 0+2 & 4-1 & -3+7\end{bmatrix}=\begin{bmatrix}5 & 4 & 3\\ 1 & 2 & 3\\ 2 & 3 & 4\end{bmatrix}$$

Example 6. If $a, b; b, c$ and c, a are the roots of $x^2-4x+3=0$, $x^2-8x+15=0$ and $x^2-6x+5=0$, respectively. Compute $\begin{bmatrix}a^2+c^2 & a^2+b^2\\ b^2+c^2 & a^2+c^2\end{bmatrix}+\begin{bmatrix}2ac & -2ab\\ -2bc & -2ac\end{bmatrix}$.

Sol. $\because$ $x^2-4x+3=0$

$\Rightarrow$ $(x-1)(x-3)=0$ $\quad\therefore\ x=1, 3$

$x^2-8x+15=0$

$\Rightarrow$ $(x-3)(x-5)=0$ $\quad\therefore\ x=3, 5$

and $x^2-6x+5=0$

$\Rightarrow$ $(x-5)(x-1)=0$ $\quad\therefore\ x=5, 1$

It is clear that $a=1$, $b=3$ and $c=5$

Now, $\begin{bmatrix}a^2+c^2 & a^2+b^2\\ b^2+c^2 & a^2+c^2\end{bmatrix}+\begin{bmatrix}2ac & -2ab\\ -2bc & -2ac\end{bmatrix}$

$$=\begin{bmatrix}a^2+c^2+2ac & a^2+b^2-2ab\\ b^2+c^2-2bc & a^2+c^2-2ac\end{bmatrix}=\begin{bmatrix}(a+c)^2 & (a-b)^2\\ (b-c)^2 & (a-c)^2\end{bmatrix}$$

$$=\begin{bmatrix}(1+5)^2 & (1-3)^2\\ (3-5)^2 & (1-5)^2\end{bmatrix}=\begin{bmatrix}36 & 4\\ 4 & 16\end{bmatrix}$$

Properties of Matrix Addition

Property 1 Addition of matrices is commutative,
i.e. $A+B=B+A$
where A and B are any two $m\times n$ matrices, i.e. matrices of the same order.

Property 2 Addition of matrices is associative
i.e. $(A+B)+C=A+(B+C)$
where A, B and C are any three matrices of the same order $m\times n$ (say).

Property 3 Existence of additive identity
i.e. $A+O=A=O+A$
where A be any $m\times n$ matrix and O be the $m\times n$ null matrix. The null matrix O is the identity element for matrix addition.

Property 4 Existence of additive inverse
If A be any $m\times n$ matrix, then there exists another $m\times n$ matrix B, such that $A+B=O=B+A$
where O is the $m\times n$ null matrix.
Here, the matrix B is called the additive inverse of the matrix A or the negative of A.

Property 5 Cancellation laws
If A, B and C are matrices of the same order $m\times n$ (say),
then $A+B=A+C\Rightarrow B=C$ [left cancellation law]
and $B+A=C+A\Rightarrow B=C$ [right cancellation law]

Scalar Multiplication

Let $A=[a_{ij}]_{m\times n}$ be a matrix and k be any number called a scalar. Then, the matrix obtained by multiplying every element of A by k is called the scalar multiple of A by k and is denoted by kA.
Thus, $kA=[ka_{ij}]_{m\times n}$

Properties of Scalar Multiplication

If $A=[a_{ij}]_{m\times n}$, $B=[b_{ij}]_{m\times n}$ are two matrices and k, l are scalars , then

(i) $k(A+B)=kA+kB$ (ii) $(k+l)A=kA+lA$

(iii) $(kl)A=k(lA)=l(kA)$

(iv) $(-k)A=-(kA)=k(-A)$

(v) $1A=A, (-1)A=-A$

Example 7. Determine the matrix A, when $A=4\begin{bmatrix}1 & 2 & 3\\ -1 & -2 & -3\\ 4 & 2 & 6\end{bmatrix}+2\begin{bmatrix}5 & 4 & 1\\ 3 & 2 & 4\\ 3 & 8 & 2\end{bmatrix}$.

Sol. $$A=\begin{bmatrix}4&8&12\\-4&-8&-12\\16&8&24\end{bmatrix}+\begin{bmatrix}10&8&2\\6&4&8\\6&16&4\end{bmatrix}$$

$$=\begin{bmatrix}4+10&8+8&12+2\\-4+6&-8+4&-12+8\\16+6&8+16&24+4\end{bmatrix}=\begin{bmatrix}14&16&14\\2&-4&-4\\22&24&28\end{bmatrix}$$

Example 8. If $A=\begin{bmatrix}0&2\\3&-4\end{bmatrix}$ and $kA=\begin{bmatrix}0&3a\\2b&24\end{bmatrix}$, then find the value of $b-a-k$.

Sol. We have, $$A=\begin{bmatrix}0&2\\3&-4\end{bmatrix}\Rightarrow kA=\begin{bmatrix}0&2k\\3k&-4k\end{bmatrix}$$

But $$kA=\begin{bmatrix}0&3a\\2b&24\end{bmatrix}$$

$$\therefore\quad\begin{bmatrix}0&2k\\3k&-4k\end{bmatrix}=\begin{bmatrix}0&3a\\2b&24\end{bmatrix}$$

$$\Rightarrow\quad 2k=3a,\ 3k=2b,\ -4k=24$$

$$\Rightarrow\quad k=-6,\ a=-4,\ b=-9$$

Hence, $$b-a-k=-9-(-4)-(-6)=-9+4+6=1$$

Subtraction of Matrices

Let A, B be two matrices, each of order $m\times n$. Then, their subtraction $A-B$ is a matrix of order $m\times n$ and is obtained by subtracting the corresponding elements of A and B. Thus, if $A=[a_{ij}]_{m\times n}$ and $B=[b_{ij}]_{m\times n}$,

then $$A-B=[a_{ij}-b_{ij}]_{m\times n},\ \forall\ i,j$$

For example, If $A=\begin{bmatrix}2&3\\4&5\\6&7\end{bmatrix}$ and $B=\begin{bmatrix}a&b\\c&d\\e&f\end{bmatrix}$,

then $$A-B=\begin{bmatrix}2&3\\4&5\\6&7\end{bmatrix}-\begin{bmatrix}a&b\\c&d\\e&f\end{bmatrix}=\begin{bmatrix}2-a&3-b\\4-c&5-d\\6-e&7-f\end{bmatrix}$$

Example 9. Given, $A=\begin{bmatrix}1&2&-3\\5&0&2\\1&-1&1\end{bmatrix}$ and $B=\begin{bmatrix}3&-1&2\\4&2&5\\2&0&3\end{bmatrix}$. Find the matrix C such that $A+2C=B$.

Sol. Given, $A+2C=B$

$$2C=B-A=\begin{bmatrix}3&-1&2\\4&2&5\\2&0&3\end{bmatrix}-\begin{bmatrix}1&2&-3\\5&0&2\\1&-1&1\end{bmatrix}$$

$$=\begin{bmatrix}3-1&-1-2&2+3\\4-5&2-0&5-2\\2-1&0+1&3-1\end{bmatrix}$$

$$\therefore\quad 2C=\begin{bmatrix}2&-3&5\\-1&2&3\\1&1&2\end{bmatrix}\Rightarrow C=\frac{1}{2}\begin{bmatrix}2&-3&5\\-1&2&3\\1&1&2\end{bmatrix}$$

$$=\begin{bmatrix}1&-3/2&5/2\\-1/2&1&3/2\\1/2&1/2&1\end{bmatrix}$$

Example 10. Solve the following equations for X and Y. $2X-Y=\begin{bmatrix}3&-3&0\\3&3&2\end{bmatrix}, 2Y+X=\begin{bmatrix}4&1&5\\-1&4&-4\end{bmatrix}$

Sol. Given, $$2X-Y=\begin{bmatrix}3&-3&0\\3&3&2\end{bmatrix}$$

On multiplying both sides by 2, we get

$$4X-2Y=2\begin{bmatrix}3&-3&0\\3&3&2\end{bmatrix};\ 4X-2Y=\begin{bmatrix}6&-6&0\\6&6&4\end{bmatrix}\quad\text{...(i)}$$

also given $$X+2Y=\begin{bmatrix}4&1&5\\-1&4&-4\end{bmatrix}\quad\text{...(ii)}$$

Adding Eqs. (i) and (ii), we get

$$5X=\begin{bmatrix}6&-6&0\\6&6&4\end{bmatrix}+\begin{bmatrix}4&1&5\\-1&4&-4\end{bmatrix}$$

$$=\begin{bmatrix}6+4&-6+1&0+5\\6-1&6+4&4-4\end{bmatrix}=\begin{bmatrix}10&-5&5\\5&10&0\end{bmatrix}$$

$$\therefore\quad X=\frac{1}{5}\begin{bmatrix}10&-5&5\\5&10&0\end{bmatrix}\Rightarrow\quad X=\begin{bmatrix}2&-1&1\\1&2&0\end{bmatrix}$$

Putting the value of X in Eq. (ii), we get

$$\begin{bmatrix}2&-1&1\\1&2&0\end{bmatrix}+2Y=\begin{bmatrix}4&1&5\\-1&4&-4\end{bmatrix}$$

$$\Rightarrow\quad 2Y=\begin{bmatrix}4&1&5\\-1&4&-4\end{bmatrix}-\begin{bmatrix}2&-1&1\\1&2&0\end{bmatrix}$$

$$=\begin{bmatrix}4-2&1+1&5-1\\-1-1&4-2&-4-0\end{bmatrix}=\begin{bmatrix}2&2&4\\-2&2&-4\end{bmatrix}$$

$$\therefore\quad Y=\begin{bmatrix}1&1&2\\-1&1&-2\end{bmatrix}$$

Hence, $$X=\begin{bmatrix}2&-1&1\\1&2&0\end{bmatrix}\text{ and }Y=\begin{bmatrix}1&1&2\\-1&1&-2\end{bmatrix}$$

Remark

If two matrices A and B are of the same order, then only their addition and subtraction is possible and these matrices are said to be conformable for addition or subtraction. On the other hand, if the matrices A and B are of different orders, then their addition and subtraction is not possible and these matrices are called non-conformable for addition and subtraction.

Multiplication

Conformable for Multiplication

If A and B be two matrices which are said to be conformable for the product AB. If the number of columns in A (called the pre-factor) is equal to the number of rows in B (called the post-factor) otherwise non-conformable for multiplication. Thus,

(i) AB is defined, if number of columns in A = number of rows in B.

(ii) BA is defined, if number of columns in B = number of rows in A.

Multiplication of Matrices

Let $A=[a_{ij}]_{m\times n}$ and $B=[b_{ij}]_{n\times p}$ be two matrices, then the product AB is defined as the matrix $C=[C_{ij}]_{m\times p}$,

where $C_{ij}=\sum_{j=1}^{n} a_{ij}\, b_{jk}, 1\le i\le m, 1\le k\le p$

$$=a_{i1}\, b_{1k}+a_{i2}\, b_{2k}+a_{i3}\, b_{3k}+\ldots+a_{in}\, b_{nk}$$

i.e., (i,k) th entry of the product AB is the sum of the product of the corresponding elements of the ith row of A (pre-factor) and kth column of B (post-factor).

Note

In the product AB, $\begin{cases} A = \text{Pre-factor} \\ B = \text{Post-factor} \end{cases}$

Example 11. If $A=\begin{bmatrix}0&1&2\\1&2&3\\2&3&4\end{bmatrix}$ and $B=\begin{bmatrix}1&-2\\-1&0\\2&-1\end{bmatrix}$, obtain the product AB and explain why BA is not defined?

Sol. Here, the number of columns in $A=3=$ the number of rows in B. Therefore, the product AB is defined.

$$AB=\begin{bmatrix}0&1&2\\1&2&3\\2&3&4\end{bmatrix}\begin{matrix}R_1\\R_2\\R_3\end{matrix}\times\begin{matrix}C_1&C_2\end{matrix}\begin{bmatrix}1&-2\\-1&0\\2&-1\end{bmatrix}$$

R_1, R_2, R_3 are rows of A and C_1, C_2 are columns of B.

$$\therefore\quad AB=\begin{bmatrix}R_1C_1&R_1C_2\\R_2C_1&R_2C_2\\R_3C_1&R_3C_2\end{bmatrix}_{3\times 2}$$

$$\begin{bmatrix}\boxed{0\ 1\ 2}\begin{bmatrix}1\\-1\\2\end{bmatrix} & \boxed{0\ 1\ 2}\begin{bmatrix}-2\\0\\-1\end{bmatrix}\\ \boxed{1\ 2\ 3}\begin{bmatrix}1\\-1\\2\end{bmatrix} & \boxed{1\ 2\ 3}\begin{bmatrix}-2\\0\\-1\end{bmatrix}\\ \boxed{2\ 3\ 4}\begin{bmatrix}1\\-1\\2\end{bmatrix} & \boxed{2\ 3\ 4}\begin{bmatrix}-2\\0\\-1\end{bmatrix}\end{bmatrix}_{3\times 2}$$

For convenience of multiplication we write columns in horizontal rectangles.

$$\begin{bmatrix}\{\boxed{0\ 1\ 2}\}\{\boxed{1\ -1\ 2}\} & \{\boxed{0\ 1\ 2}\}\{\boxed{-2\ 0\ -1}\}\\ \{\boxed{1\ 2\ 3}\}\{\boxed{1\ -1\ 2}\} & \{\boxed{1\ 2\ 3}\}\{\boxed{-2\ 0\ -1}\}\\ \{\boxed{2\ 3\ 4}\}\{\boxed{1\ -1\ 2}\} & \{\boxed{2\ 3\ 4}\}\{\boxed{-2\ 0\ -1}\}\end{bmatrix}$$

$$=\begin{bmatrix}0\times1+1\times(-1)+2\times2 & 0\times(-2)+1\times0+2\times(-1)\\ 1\times1+2\times(-1)+3\times2 & 1\times(-2)+2\times0+3\times(-1)\\ 2\times1+3\times(-1)+4\times2 & 2\times(-2)+3\times0+4\times(-1)\end{bmatrix}_{3\times2}$$

$$=\begin{bmatrix}0-1+4 & 0+0-2\\ 1-2+6 & -2+0-3\\ 2-3+8 & -4+0-4\end{bmatrix}_{3\times2}=\begin{bmatrix}3&-2\\5&-5\\7&-8\end{bmatrix}_{3\times2}$$

Since, the number of columns of B is 2 and the number of rows of A is 3, BA is not defined ($\because 2\neq 3$).

Remark

Verification for the product to be correct .

From above example

$$\begin{bmatrix}0&1&2\\1&2&3\\2&3&4\end{bmatrix}\times\begin{bmatrix}1&-2\\-1&0\\2&-1\end{bmatrix}=\begin{bmatrix}3&-2\\5&-5\\7&-8\end{bmatrix}$$

Sum $\underline{3\ \ 6\ \ 9}$ $\qquad$ $\underline{15\ -15}$

Now, $\boxed{3\,6\,9}\begin{bmatrix}1\\-1\\2\end{bmatrix}$ $\begin{matrix}=3\times1+6\times(-1)+9\times2\\=3-6+18\\=15\end{matrix}$

and $\boxed{3\,6\,9}\begin{bmatrix}-2\\0\\-1\end{bmatrix}$ $\begin{matrix}=3(-2)+6\times0+9\times(-1)\\=-6+0-9\\=-15\end{matrix}$

Example 12. If $A=\begin{bmatrix}0&-\tan(\alpha/2)\\\tan(\alpha/2)&0\end{bmatrix}$ and I is a 2×2 unit matrix, prove that

$$I+A=(I-A)\begin{bmatrix}\cos\alpha&-\sin\alpha\\\sin\alpha&\cos\alpha\end{bmatrix}.$$

Sol. Since, $I=\begin{bmatrix}1&0\\0&1\end{bmatrix}$ and given $A=\begin{bmatrix}0&-\tan(\alpha/2)\\\tan(\alpha/2)&0\end{bmatrix}$

$$\therefore\quad I+A=\begin{bmatrix}1&-\tan(\alpha/2)\\\tan(\alpha/2)&1\end{bmatrix}\qquad\ldots(i)$$

$$\text{RHS}=(I-A)\begin{bmatrix}\cos\alpha&-\sin\alpha\\\sin\alpha&\cos\alpha\end{bmatrix}$$

$$=\begin{bmatrix}1&\tan(\alpha/2)\\-\tan(\alpha/2)&1\end{bmatrix}\begin{bmatrix}\cos\alpha&-\sin\alpha\\\sin\alpha&\cos\alpha\end{bmatrix}$$

$$= \begin{bmatrix} 1 & \tan(\alpha/2) \\ -\tan(\alpha/2) & 1 \end{bmatrix} \begin{bmatrix} \frac{1-\tan^2(\alpha/2)}{1+\tan^2(\alpha/2)} & \frac{-2\tan(\alpha/2)}{1+\tan^2(\alpha/2)} \\ \frac{2\tan(\alpha/2)}{1+\tan^2(\alpha/2)} & \frac{1-\tan^2(\alpha/2)}{1+\tan^2(\alpha/2)} \end{bmatrix}$$

Let $\tan(\alpha/2) = \lambda$, then

$$\text{RHS} = \begin{bmatrix} 1 & \lambda \\ -\lambda & 1 \end{bmatrix} \begin{bmatrix} \frac{1-\lambda^2}{1+\lambda^2} & \frac{-2\lambda}{1+\lambda^2} \\ \frac{2\lambda}{1+\lambda^2} & \frac{1-\lambda^2}{1+\lambda^2} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{1-\lambda^2+2\lambda^2}{1+\lambda^2} & \frac{-2\lambda+\lambda(1-\lambda^2)}{1+\lambda^2} \\ \frac{-\lambda(1-\lambda^2)+2\lambda}{1+\lambda^2} & \frac{2\lambda^2+1-\lambda^2}{1+\lambda^2} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{1+\lambda^2}{1+\lambda^2} & \frac{-\lambda(1+\lambda^2)}{1+\lambda^2} \\ \frac{\lambda(1+\lambda^2)}{1+\lambda^2} & \frac{1+\lambda^2}{1+\lambda^2} \end{bmatrix} = \begin{bmatrix} 1 & -\lambda \\ \lambda & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & -\tan(\alpha/2) \\ \tan(\alpha/2) & 1 \end{bmatrix} [\because \lambda = \tan(\alpha/2)]$$

$= I + A$ [from Eq. (i)]

$=$ LHS

Pre-multiplication and Post-multiplication of Matrices

The matrix AB is the matrix B pre-multiplied by A and the matrix BA is the matrix B post-multiplied by A.

Properties of Multiplication of Matrices

Property 1 Multiplication of matrices is not commutative

i.e. $AB \neq BA$

Note

1. If $AB = -BA$, then A and B are said to anti-commute.
2. If $A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & 0 \\ 0 & 4 \end{bmatrix}$, then $AB = BA = \begin{bmatrix} 3 & 0 \\ 0 & 8 \end{bmatrix}$.

Observe that multiplication of diagonal matrices of same order will be commutative.

Property 2 Matrix multiplication associative if conformability assumed.

i.e. $A(BC) = (AB)\,C$

Property 3 Matrix multiplication is distributive with respect to addition. i.e. $A(B + C) = AB + AC$, whenever both sides of equality are defined.

Property 4 If A is an $m \times n$ matrix, then $I_m\ A = A = A\,I_n$.

Property 5 If product of two matrices is a zero matrix, it is not necessary that one of the matrices is a zero matrix.

For example,

$$\text{(i)} \begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} \times \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 1\cdot(-1)+1.1 & 1\cdot1+1\cdot(-1) \\ 2\cdot(-1)+2.1 & 2\cdot1+2\cdot(-1) \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} = O$$

$$\text{(ii)} \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \times \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 0\cdot0+0\cdot0 & 0\cdot0+0\cdot1 \\ 1\cdot0+0\cdot0 & 1\cdot0+0\cdot1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} = O$$

None of the matrices on the LHS is a null matrix whereas their product is a null matrix.

Note If A and B are two non-zero matrices such that $AB = 0$, then A and B are called the divisors of zero. Also, if

$AB = 0 \Rightarrow |AB| = 0 \Rightarrow |A||B| = 0$

$\Rightarrow$ $|A| = 0$ or $|B| = 0$ but not the converse.

Property 6 Multiplication of a matrix A by a null matrix conformable with A for multiplication.

For example, If $A = \begin{bmatrix} 3 & 4 \\ 5 & 6 \\ 7 & 8 \end{bmatrix}_{3\times2}$ and $O = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}_{2\times3}$,

then $AO = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}_{3\times3}$, which is a 3×3 null matrix.

Property 7 Multiplication of a matrix by itself

The product of $A\,A\,A$ ... m times $= A^m$ and $(A^m)^n = A^{mn}$

Note

1. If I be unit matrix, then $I^2 = I^3 = \ldots = I^m = I\ (m \in I_+)$
2. If A and B are two matrices of the same order, then
   (i) $(A+B)^2 = A^2 + AB + BA + B^2$
   (ii) $(A-B)^2 = A^2 - AB - BA + B^2$
   (iii) $(A-B)(A+B) = A^2 + AB - BA + B^2$
   (iv) $(A+B)(A-B) = A^2 - AB + BA - B^2$
   (v) $A(-B) = (-A)(B) = -AB$

Example 13. If $A = \begin{bmatrix} 1 & 2 \\ -2 & 3 \end{bmatrix}$, $B = \begin{bmatrix} 2 & 1 \\ 2 & 3 \end{bmatrix}$ and $C = \begin{bmatrix} -3 & 1 \\ 2 & 0 \end{bmatrix}$, verify that $(AB)\,C = A(BC)$ and $A(B + C) = AB + AC$.

Sol. We have, $AB = \begin{bmatrix} 1 & 2 \\ -2 & 3 \end{bmatrix} \times \begin{bmatrix} 2 & 1 \\ 2 & 3 \end{bmatrix}$

$$= \begin{bmatrix} 1\cdot2+2\cdot2 & 1\cdot1+2\cdot3 \\ (-2)\cdot2+3\cdot2 & (-2)\cdot1+3\cdot3 \end{bmatrix} = \begin{bmatrix} 6 & 7 \\ 2 & 7 \end{bmatrix}$$

$$BC=\begin{bmatrix}2&1\\2&3\end{bmatrix}\times\begin{bmatrix}-3&1\\2&0\end{bmatrix}=\begin{bmatrix}2\cdot(-3)+1\cdot2&2\cdot1+1\cdot0\\2\cdot(-3)+3\cdot2&2\cdot1+3\cdot0\end{bmatrix}$$

$$=\begin{bmatrix}-6+2&2+0\\-6+6&2+0\end{bmatrix}=\begin{bmatrix}-4&2\\0&2\end{bmatrix}$$

$$AC=\begin{bmatrix}1&2\\-2&3\end{bmatrix}\times\begin{bmatrix}-3&1\\2&0\end{bmatrix}=\begin{bmatrix}1\cdot(-3)+2\cdot2&1\cdot1+2\cdot0\\(-2)\cdot(-3)+3\cdot2&(-2)\cdot1+3\cdot0\end{bmatrix}$$

$$=\begin{bmatrix}-3+4&1+0\\6+6&-2+0\end{bmatrix}=\begin{bmatrix}1&1\\12&-2\end{bmatrix}$$

$$B+C=\begin{bmatrix}2&1\\2&3\end{bmatrix}+\begin{bmatrix}-3&1\\2&0\end{bmatrix}=\begin{bmatrix}2-3&1+1\\2+2&3+0\end{bmatrix}=\begin{bmatrix}-1&2\\4&3\end{bmatrix}$$

$$\text{Now, } (AB)C=\begin{bmatrix}6&7\\2&7\end{bmatrix}\times\begin{bmatrix}-3&1\\2&0\end{bmatrix}=\begin{bmatrix}-18+14&6+0\\-6+14&2+0\end{bmatrix}$$

$$=\begin{bmatrix}-4&6\\8&2\end{bmatrix} \quad \text{...(i)}$$

$$A(BC)=\begin{bmatrix}1&2\\-2&3\end{bmatrix}\times\begin{bmatrix}-4&2\\0&2\end{bmatrix}$$

$$=\begin{bmatrix}-4+0&2+4\\8+0&-4+6\end{bmatrix}=\begin{bmatrix}-4&6\\8&2\end{bmatrix} \quad \text{...(ii)}$$

Thus, from Eqs. (i) and (ii), we get, $(AB)C=A(BC)$

$$\text{Now, } A(B+C)=\begin{bmatrix}1&2\\-2&3\end{bmatrix}\times\begin{bmatrix}-1&2\\4&3\end{bmatrix}=\begin{bmatrix}-1+8&2+6\\2+12&-4+9\end{bmatrix}$$

$$=\begin{bmatrix}7&8\\14&5\end{bmatrix} \quad \text{...(iii)}$$

$$\text{and} \quad AB+AC=\begin{bmatrix}6&7\\2&7\end{bmatrix}+\begin{bmatrix}1&1\\12&-2\end{bmatrix}=\begin{bmatrix}6+1&7+1\\2+12&7-2\end{bmatrix}$$

$$=\begin{bmatrix}7&8\\14&5\end{bmatrix} \quad \text{...(iv)}$$

Thus, from Eqs. (iii) and (iv), we get

$$A(B+C)=AB+AC$$

Example 14. If $A=\begin{bmatrix}0&1&0\\0&0&1\\p&q&r\end{bmatrix}$, show that

$A^3=pI+qA+rA^2$.

Sol. We have, $A^2=A\cdot A$

$$=\begin{bmatrix}0&1&0\\0&0&1\\p&q&r\end{bmatrix}\times\begin{bmatrix}0&1&0\\0&0&1\\p&q&r\end{bmatrix}$$

$$=\begin{bmatrix}0&0&1\\p&q&r\\pr&p+qr&q+r^2\end{bmatrix}$$

$$\therefore \quad A^3=A^2\cdot A=\begin{bmatrix}0&0&1\\p&q&r\\pr&p+qr&q+r^2\end{bmatrix}\times\begin{bmatrix}0&1&0\\0&0&1\\p&q&r\end{bmatrix}$$

$$=\begin{bmatrix}p&q&r\\pr&p+qr&q+r^2\\pq+r^2p&pr+q^2+qr^2&p+2qr+r^3\end{bmatrix} \quad \text{...(i)}$$

$$\text{and } pI+qA+rA^2=p\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix}+q\begin{bmatrix}0&1&0\\0&0&1\\p&q&r\end{bmatrix}$$

$$+r\begin{bmatrix}0&0&1\\p&q&r\\pr&p+qr&q+r^2\end{bmatrix}$$

$$=\begin{bmatrix}p&0&0\\0&p&0\\0&0&p\end{bmatrix}+\begin{bmatrix}0&q&0\\0&0&q\\pq&q^2&qr\end{bmatrix}+\begin{bmatrix}0&0&r\\pr&qr&r^2\\pr^2&pr+qr^2&qr+r^3\end{bmatrix}$$

$$=\begin{bmatrix}p+0+0&0+q+0&0+0+r\\0+0+pr&p+0+qr&0+q+r^2\\0+pq+pr^2&0+q^2+pr+qr^2&p+qr+qr+r^3\end{bmatrix}$$

$$=\begin{bmatrix}p&q&r\\pr&p+qr&q+r^2\\pq+pr^2&q^2+pr+qr^2&p+2qr+r^3\end{bmatrix} \quad \text{...(ii)}$$

Thus, from Eqs. (i) and (ii), we get $A^3=pI+qA+rA^2$

Example 15. ***Find*** x***, so that***

$$[1\ x\ 1]\begin{bmatrix}1&3&2\\0&5&1\\0&3&2\end{bmatrix}\begin{bmatrix}1\\1\\x\end{bmatrix}=\boldsymbol{O}.$$

Sol. We have, $[1\quad x\quad 1]\begin{bmatrix}1&3&2\\0&5&1\\0&3&2\end{bmatrix}\begin{bmatrix}1\\1\\x\end{bmatrix}=O$

$$\Rightarrow \quad [1\quad 5x+6\quad x+4]\begin{bmatrix}1\\1\\x\end{bmatrix}=O$$

$$\Rightarrow \quad [1+5x+6+x^2+4x]=O$$

or $$x^2+9x+7=0$$

$$\therefore \quad x=\frac{-9\pm\sqrt{(81-28)}}{2} \Rightarrow x=\frac{-9\pm\sqrt{53}}{2}$$

Various Kinds of Matrices

Idempotent Matrix

A square matrix A is called idempotent provided it satisfies the relation $A^2 = A$.

Note

$A^n = A, \forall\, n \geq 2, n \in N$.

Example 16. Show that the matrix $A = \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix}$ is idempotent.

Sol. $A^2 = A \cdot A = \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix} \times \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix}$

$$= \begin{bmatrix} 2\cdot 2 + (-2)\cdot(-1) + (-4)\cdot 1 & 2\cdot(-2) + (-2)\cdot 3 + (-4)\cdot(-2) & 2\cdot(-4) + (-2)\cdot 4 + (-4)\cdot(-3) \\ (-1)\cdot 2 + 3\cdot(-1) + 4\cdot 1 & (-1)\cdot(-2) + 3\cdot 3 + 4\cdot(-2) & (-1)\cdot(-4) + 3\cdot 4 + 4\cdot(-3) \\ 1.2 + (-2)\cdot(-1) + (-3)\cdot 1 & 1\cdot(-2) + (-2)\cdot 3 + (-3)\cdot(-2) & 1\cdot(-4) + (-2)\cdot 4 + (-3)\cdot(-3) \end{bmatrix}$$

$$= \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix} = A$$

Hence, the matrix A is idempotent.

Periodic Matrix

A square matrix A is called periodic, if $A^{k+1} = A$, where k is a positive integer. If k is the least positive integer for which $A^{k+1} = A$, then k is said to be **period** of A.

For $k = 1$, we get $A^2 = A$ and we called it to be **idempotent matrix.**

Note

Period of an idempotent matrix is 1.

Nilpotent Matrix

A square matrix A is called nilpotent matrix of order m provided it satisfies the relation $A^k = O$ and $A^{k-1} \neq O$, where k is positive integer and O is null matrix and k is the order of the nilpotent matrix A.

Example 17. ***Show that*** $\begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$ ***is nilpotent matrix of order 3.***

Sol. Let $A = \begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$

$$\therefore\ A^2 = A \cdot A = \begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix} \times \begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$$

$$= \begin{bmatrix} 1+5-6 & 1+2-3 & 3+6-9 \\ 5+10-12 & 5+4-6 & 15+12-18 \\ -2-5+6 & -2-2+3 & -6-6+9 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 & 0 \\ 3 & 3 & 9 \\ -1 & -1 & -3 \end{bmatrix}$$

$$\therefore\ A^3 = A^2 \cdot A = \begin{bmatrix} 0 & 0 & 0 \\ 3 & 3 & 9 \\ -1 & -1 & -3 \end{bmatrix} \times \begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$$

$$= \begin{bmatrix} 0+0+0 & 0+0+0 & 0+0+0 \\ 3+15-18 & 3+6-9 & 9+18-27 \\ -1-5+6 & -1-2+3 & -3-6+9 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = O$$

$\therefore \quad A^3 = O$ i.e., $A^k = O$

Here, $k = 3$

Hence, the matrix A is nilpotent of order 3.

Involutory Matrix

A square matrix A is called involutory provided it satisfies the relation $A^2 = I$, where I is identity matrix.

Note $A = A^{-1}$ for an involutory matrix.

Example 18. ***Show that the matrix*** $A = \begin{bmatrix} -5 & -8 & 0 \\ 3 & 5 & 0 \\ 1 & 2 & -1 \end{bmatrix}$ is involutory.

Sol. $A^2 = A \cdot A = \begin{bmatrix} -5 & -8 & 0 \\ 3 & 5 & 0 \\ 1 & 2 & -1 \end{bmatrix} \times \begin{bmatrix} -5 & -8 & 0 \\ 3 & 5 & 0 \\ 1 & 2 & -1 \end{bmatrix}$

$$= \begin{bmatrix} 25-24+0 & 40-40+0 & 0+0+0 \\ -15+15+0 & -24+25+0 & 0+0+0 \\ -5+6-1 & -8+10-2 & 0+0+1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$$

Hence, the given matrix A is involutory.

Exercise for Session 1

1. If $A=\begin{bmatrix}\alpha & 2\\ 2 & \alpha\end{bmatrix}$ and $|A^3| = 125$, α is equal to

(a) ± 2 (b) ± 3
(c) ± 5 (d) 0

2. If $A=\begin{bmatrix}1 & -1\\ 2 & -1\end{bmatrix}$, $B=\begin{bmatrix}a & 1\\ b & -1\end{bmatrix}$ and $(A+B)^2 = A^2 + B^2$, the value of $a+b$ is

(a) 4 (b) 5
(c) 6 (d) 7

3. If $A=\begin{bmatrix}1 & 2\\ 2 & 3\end{bmatrix}$ and $A^2 - \lambda A - I_2 = O$, then λ is equal to

(a) -4 (b) -2
(c) 2 (d) 4

4. Let $A=\begin{bmatrix}0 & \alpha\\ 0 & 0\end{bmatrix}$ and $(A+I)^{50} - 50A = \begin{bmatrix}a & b\\ c & d\end{bmatrix}$, the value of $a+b+c+d$, is

(a) 1 (b) 2
(c) 4 (d) None of these

5. If $A=\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}$, then $A^2 = I$ is true for

(a) $\theta = 0$ (b) $\theta = \frac{\pi}{4}$
(c) $\theta = \frac{\pi}{2}$ (d) None of these

6. If $\begin{bmatrix}\alpha & \beta\\ \gamma & -\alpha\end{bmatrix}$ is to be the square root of two rowed unit matrix, then α, β and γ should satisfy the relation

(a) $1-\alpha^2+\beta\gamma = 0$ (b) $\alpha^2+\beta\gamma-1=0$
(c) $1+\alpha^2+\beta\gamma = 0$ (d) $1-\alpha^2-\beta\gamma = 0$

7. If $A=\begin{bmatrix}1 & 0\\ 1/2 & 1\end{bmatrix}$, then A^{100} is equal to

(a) $\begin{bmatrix}1 & 0\\ 25 & 0\end{bmatrix}$ (b) $\begin{bmatrix}1 & 0\\ 50 & 1\end{bmatrix}$
(c) $\begin{bmatrix}1 & 0\\ (1/2)^{100} & 1\end{bmatrix}$ (d) None of these

8. If the product of n matrices $\begin{bmatrix}1 & 1\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 2\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 3\\ 0 & 1\end{bmatrix}\cdots\begin{bmatrix}1 & n\\ 0 & 1\end{bmatrix}$ is equal to the matrix $\begin{bmatrix}1 & 378\\ 0 & 1\end{bmatrix}$, the value of n is equal to

(a) 26 (b) 27
(c) 377 (d) 378

9. If A and B are two matrices such that $AB = B$ and $BA = A$, then $A^2 + B^2$ is equal to

(a) $2AB$ (b) $2BA$
(c) $A+B$ (d) AB

Session 2

Transpose of a Matrix, Symmetric Matrix, Orthogonal Matrix, Complex Conjugate (or Conjugate) of a Matrix, Hermitian Matrix, Unitary Matrix, Determinant of a Matrix, Singular and Non-Singular Matrices,

Transpose of a Matrix

Let $A=[a_{ij}]_{m\times n}$ be any given matrix, then the matrix obtained by interchanging the rows and columns of A is called the transpose of A. Transpose of the matrix A is denoted by A' or A^T or A^t. In other words, if $A=[a_{ij}]_{m\times n}$, then $A'=[a_{ji}]_{n\times m}$.

For example,

If $$A=\begin{bmatrix} 2 & 3 & 4 & 5 \\ -2 & -1 & 4 & 8 \\ 7 & 5 & 3 & 1 \end{bmatrix}_{3\times 4},$$

then $$A'=\begin{bmatrix} 2 & -2 & 7 \\ 3 & -1 & 5 \\ 4 & 4 & 3 \\ 5 & 8 & 1 \end{bmatrix}_{4\times 3}$$

Properties of Transpose Matrices

If A' and B' denote the transpose of A and B respectively, then

(i) $(A')'=A$

(ii) $(A\pm B)'=A'\pm B'$; A and B are conformable for matrix addition.

(iii) $(kA)'=kA'$; k is a scalar.

(iv) $(AB)'=B'A'$; A and B are conformable for matrix product AB.

In general, $(A_1A_2A_3\ldots A_{n-1}A_n)'=A'_n\ A'_{n-1}\cdots A'_3\ A'_2\ A'_1$ (reversal law for transpose).

Remark

$I'=I$, where I is an identity matrix.

Example 19. ***If*** $A=\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$, ***find the values of*** θ ***satisfying the equation*** $A^T+A=I_2$.

Sol. We have, $A^T+A=I_2$

$$\Rightarrow \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}+\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\Rightarrow \quad \begin{bmatrix} 2\cos\theta & 0 \\ 0 & 2\cos\theta \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\Rightarrow \quad \cos\theta=\frac{1}{2}=\cos\left(\frac{\pi}{3}\right) \Rightarrow \theta=2n\pi\pm\frac{\pi}{3},\ n\in \mathrm{I}$$

Symmetric Matrix

A square matrix $A=[a_{ij}]_{n\times n}$ is said to be symmetric, if $A'=A$ i.e., $a_{ij}=a_{ji}$, $\forall\ i, j$.

For example,

If $A=\begin{bmatrix} a & h & g \\ h & b & f \\ g & f & c \end{bmatrix}$, then $A'=\begin{bmatrix} a & h & g \\ h & b & f \\ g & f & c \end{bmatrix}$

Here, A is symmetric matrix as $A'=A$.

Note

1. Maximum number of distinct entries in any symmetric matrix of order n is $\frac{n(n+1)}{2}$.
2. For any square matrix A with real number entries, then $A+A'$ is a symmetric matrix.

Proof $(A+A')'=A'+(A')'=A'+A=A+A'$

Skew-Symmetric Matrix

A square matrix $A=[a_{ij}]_{n\times n}$ is said to be skew-symmetric matrix, if $A'=-A$, i.e. $a_{ij}=-a_{ji}$, $\forall\ i, j$. (the pair of conjugate elements are additive inverse of each other)

Now, if we put $i=j$, we have $a_{ii}=-a_{ii}$.

Therefore, $2a_{ii}=0$ or $a_{ii}=0$, $\forall\ i$'s.

This means that all the diagonal elements of a skew-symmetric matrix are zero, but not the converse.

For example,

If $A=\begin{bmatrix}0 & h & g\\ -h & 0 & f\\ -g & -f & 0\end{bmatrix}$, then

$$A'=\begin{bmatrix}0 & -h & -g\\ h & 0 & -f\\ g & f & 0\end{bmatrix}=-\begin{bmatrix}0 & h & g\\ -h & 0 & f\\ -g & -f & 0\end{bmatrix}=-A$$

Here, A is skew-symmetric matrix as $A'=-A$.

Note

1. Trace of a skew-symmetric matrix is always 0.
2. For any square matrix A with real number entries, then $A-A'$ is a skew-symmetric matrix.

   Proof $(A-A')'=A'-(A')'=A'-A=-(A-A')$
3. Every square matrix can be uniquely expressed as the sum of a symmetric and a skew-symmetric matrix.

   i.e. If A is a square matrix, then we can write

   $$A=\frac{1}{2}(A+A')+\frac{1}{2}(A-A')$$

Example 20. ***The square matrix*** $A=[a_{ij}]_{m\times m}$ ***given by*** $a_{ij}=(i-j)^n$***, show that*** A ***is symmetric and skew-symmetric matrices according as*** n ***is even or odd, respectively.***

Sol. $\because a_{ij}=(i-j)^n=(-1)^n(j-i)^n$

$$=(-1)^n\ a_{ji}=\begin{cases}a_{ji}\ , n \text{ is even integer}\\ -a_{ji}, n \text{ is odd integer}\end{cases}$$

Hence, A is symmetric if n is even and skew-symmetric if n is odd integer.

Example 21. Express A as the sum of a symmetric and a skew-symmetric matrix, where $A=\begin{bmatrix}3 & 5\\ -1 & 2\end{bmatrix}$.

Sol. We have,

$$A=\begin{bmatrix}3 & 5\\ -1 & 2\end{bmatrix}, \text{ then } A'=\begin{bmatrix}3 & -1\\ 5 & 2\end{bmatrix}$$

Let $P=\frac{1}{2}(A+A')=\frac{1}{2}\begin{bmatrix}6 & 4\\ 4 & 4\end{bmatrix}=\begin{bmatrix}3 & 2\\ 2 & 2\end{bmatrix}=P'$

Thus, $P=\frac{1}{2}(A+A')$ is a symmetric matrix.

Also, let $Q=\frac{1}{2}(A-A')=\frac{1}{2}\begin{bmatrix}0 & 6\\ -6 & 0\end{bmatrix}=\begin{bmatrix}0 & 3\\ -3 & 0\end{bmatrix}$

Then, $Q'=\begin{bmatrix}0 & -3\\ 3 & 0\end{bmatrix}=-\begin{bmatrix}0 & 3\\ -3 & 0\end{bmatrix}=-Q$

Thus, $Q=\frac{1}{2}(A-A')$ is a skew-symmetric matrix.

Now, $P+Q=\begin{bmatrix}3 & 2\\ 2 & 2\end{bmatrix}+\begin{bmatrix}0 & 3\\ -3 & 0\end{bmatrix}=\begin{bmatrix}3 & 5\\ -1 & 2\end{bmatrix}=A$

Hence, A is represented as the sum of a symmetric and a skew-symmetric matrix.

Properties of Symmetric and Skew-Symmetric Matrices

(i) If A be a square matrix, then AA' and $A'A$ are symmetric matrices.

(ii) All positive integral powers of a symmetric matrix are symmetric, because

$$(A^n)'=(A')^n$$

(iii) All positive odd integral powers of a skew-symmetric matrix are skew-symmetric and positive even integral powers of a skew-symmetric matrix are symmetric, because $(A^n)'=(A')^n$

(iv) If A be a symmetric matrix and B be a square matrix of order that of A, then $-A, kA, A', A^{-1}, A^n$ and $B'AB$ are also symmetric matrices, where $n\in N$ and k is a scalar.

(v) If A be a skew-symmetric matrix, then
   (a) A^{2n} is a symmetric matrix for $n\in N$.
   (b) A^{2n+1} is a skew-symmetric matrix for $n\in N$.
   (c) kA is a skew-symmetric matrix, where k is scalar.
   (d) $B'AB$ is also skew-symmetric matrix, where B is a square matrix of order that of A.

(vi) If A and B are two symmetric matrices, then
   (a) $A\pm B, AB+BA$ are symmetric matrices.
   (b) $AB-BA$ is a skew-symmetric matrix
   (c) AB is a symmetric matrix, iff $AB=BA$
   (where A and B are square matrices of same order)

(vii) If A and B are two skew-symmetric matrices, then
   (a) $A\pm B, AB-BA$ are skew-symmetric matrices.
   (b) $AB+BA$ is a symmetric matrix.
   (where A and B are square matrices of same order)

(viii) If A be a skew-symmetric matrix and C is a column matrix, then $C'AC$ is a zero matrix, where $C'AC$ is conformable.

Orthogonal Matrix

A square matrix A is said to be orthogonal matrix, iff $AA'=I$, where I is an identity matrix.

Note

1. If $AA'=I$, then $A^{-1}=A'$.
2. If A and B are orthogonal, then AB is also orthogonal.
3. If A is orthogonal, then A^{-1} and A' are also orthogonal.

Example 22. If $\begin{bmatrix} 0 & 2\beta & \gamma \\ \alpha & \beta & -\gamma \\ \alpha & -\beta & \gamma \end{bmatrix}$ is orthogonal, then find the value of $2\alpha^2 + 6\beta^2 + 3\gamma^2$.

Sol. Let $A = \begin{bmatrix} 0 & 2\beta & \gamma \\ \alpha & \beta & -\gamma \\ \alpha & -\beta & \gamma \end{bmatrix}$, then $A' = \begin{bmatrix} 0 & \alpha & \alpha \\ 2\beta & \beta & -\beta \\ \gamma & -\gamma & \gamma \end{bmatrix}$

Since, A is orthogonal.

$\therefore \quad AA' = I$

$$\Rightarrow \begin{bmatrix} 0 & 2\beta & \gamma \\ \alpha & \beta & -\gamma \\ \alpha & -\beta & \gamma \end{bmatrix}\begin{bmatrix} 0 & \alpha & \alpha \\ 2\beta & \beta & -\beta \\ \gamma & -\gamma & \gamma \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 4\beta^2 + \gamma^2 & 2\beta^2 - \gamma^2 & -2\beta^2 + \gamma^2 \\ 2\beta^2 - \gamma^2 & \alpha^2 + \beta^2 + \gamma^2 & \alpha^2 - \beta^2 - \gamma^2 \\ -2\beta^2 + \gamma^2 & \alpha^2 - \beta^2 - \gamma^2 & \alpha^2 + \beta^2 + \gamma^2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Equating the corresponding elements, we get

$$4\beta^2 + \gamma^2 = 1 \quad \text{...(i)}$$

$$2\beta^2 - \gamma^2 = 0 \quad \text{...(ii)}$$

and $$\alpha^2 + \beta^2 + \gamma^2 = 1 \quad \text{...(iii)}$$

From Eqs. (i) and (ii), we get

$$\beta^2 = \frac{1}{6} \text{ and } \gamma^2 = \frac{1}{3}$$

From Eq. (iii),

$$\alpha^2 = 1 - \beta^2 - \gamma^2 = 1 - \frac{1}{6} - \frac{1}{3} = \frac{1}{2}$$

Hence, $2\alpha^2 + 6\beta^2 + 3\gamma^2 = 2 \times \frac{1}{2} + 6 \times \frac{1}{6} + 3 \times \frac{1}{3} = 3$

Aliter

The rows of matrix A are unit orthogonal vectors

$$\vec{R}_1 \cdot \vec{R}_2 = 0 \Rightarrow 2\beta^2 - \gamma^2 = 0 \Rightarrow 2\beta^2 = \gamma^2 \quad \text{...(i)}$$

$$\vec{R}_2 \cdot \vec{R}_3 = 0 \Rightarrow \alpha^2 - \beta^2 - \gamma^2 = 0 \Rightarrow \beta^2 + \gamma^2 = \alpha^2 \quad \text{...(ii)}$$

and $$\vec{R}_3 \cdot \vec{R}_3 = 1 \Rightarrow \alpha^2 + \beta^2 + \gamma^2 = 1 \quad \text{...(iii)}$$

From Eqs. (i), (ii) and (iii), we get

$$\alpha^2 = \frac{1}{2}, \beta^2 = \frac{1}{6} \text{ and } \gamma^2 = \frac{1}{3}$$

$\therefore \quad 2\alpha^2 + 6\beta^2 + 3\gamma^2 = 3$

Example 23. ***If*** $A = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ a & 2 & b \end{bmatrix}$ ***is a matrix satisfying*** $AA' = 9I_3$, ***find the value of*** $|a| + |b|$.

Sol. Since, $AA' = 9I_3$

$$\Rightarrow \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ a & 2 & b \end{bmatrix}\begin{bmatrix} 1 & 2 & a \\ 2 & 1 & 2 \\ 2 & -2 & b \end{bmatrix} = 9\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 9 & 0 & a + 2b + 4 \\ 0 & 9 & 2a - 2b + 2 \\ a + 2b + 4 & 2a - 2b + 2 & a^2 + b^2 + 4 \end{bmatrix} = \begin{bmatrix} 9 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & 9 \end{bmatrix}$$

Equating the corresponding elements, we get

$$a + 2b + 4 = 0 \quad \text{...(i)}$$

$$2a - 2b + 2 = 0 \quad \text{...(ii)}$$

and $$a^2 + b^2 + 4 = 9 \quad \text{...(iii)}$$

From Eqs. (i) and (ii), we get

$$a = -2 \text{ and } b = -1$$

Hence, $|a| + |b| = |-2| + |-1| = 2 + 1 = 3$

Complex Conjugate (or Conjugate) of a Matrix

If a matrix A is having complex numbers as its elements, the matrix obtained from A by replacing each element of A by its conjugate ($\overline{a \pm ib} = a \mp ib$, where $i = \sqrt{-1}$) is called the conjugate of matrix A and is denoted by $\overline{A}$.

For example, If $A = \begin{bmatrix} 2 + 5i & 3 - i & 7 \\ -2i & 6 + i & 7 - 5i \\ 1 - i & 3 & 6i \end{bmatrix}$, where $i = \sqrt{-1}$,

then $$\overline{A} = \begin{bmatrix} 2 - 5i & 3 + i & 7 \\ 2i & 6 - i & 7 + 5i \\ 1 + i & 3 & -6i \end{bmatrix}$$

Note

If all elements of A are real, then $\overline{A} = A$.

Properties of Complex Conjugate of a Matrix

If A and B are two matrices of same order, then

(i) $(\overline{\overline{A}}) = A$

(ii) $(\overline{A + B}) = \overline{A} + \overline{B}$, where A and B being conformable for addition.

(iii) $(\overline{kA}) = k\,\overline{A}$, where k is real.

(iv) $(\overline{AB}) = \overline{A}\,\overline{B}$, where A and B being conformable for multiplication.

Conjugate Transpose of a Matrix

The conjugate of the transpose of a matrix A is called the conjugate transpose of A and is denoted by A^{θ} i.e.
$A^{\theta} = \text{Conjugate of } A' = (\overline{A'})$

For example,

If $A = \begin{bmatrix} 2+4i & 3 & 5-9i \\ 4 & 5+2i & 3i \\ 2 & -5 & 4-i \end{bmatrix}$,

where $i = \sqrt{-1}$,

then $A^{\theta} = (\overline{A'}) = \begin{bmatrix} 2-4i & 4 & 2 \\ 3 & 5-2i & -5 \\ 5+9i & -3i & 4+i \end{bmatrix}$

Properties of Transpose Conjugate Matrix

If A and B are two matrices of same order, then

(i) $(\overline{A})' = (\overline{A'})$ (ii) $(A^{\theta})^{\theta} = A$

(iii) $(A+B)^{\theta} = A^{\theta} + B^{\theta}$, where A and B being conformable for addition.

(iv) $(kA)^{\theta} = k\,A^{\theta}$, where k is real.

(v) $(AB)^{\theta} = B^{\theta}A^{\theta}$, where A and B being conformable for multiplication

Hermitian Matrix

A square matrix $A = [a_{ij}]_{n\times n}$ is said to be hermitian, if $A^{\theta} = A$ i.e., $a_{ij} = \overline{a}_{ji}, \forall\, i, j$. If we put $j = i$, we have $a_{ii} = \overline{a}_{ii}$ $\Rightarrow a_{ii}$ is purely real for all i's.

This means that all the diagonal elements of a hermitian matrix must be purely real.

For example,

If $A = \begin{bmatrix} \alpha & \lambda + i\mu & \theta + i\phi \\ \lambda - i\mu & \beta & x + iy \\ \theta - i\phi & x - iy & \gamma \end{bmatrix}$

where $\alpha, \beta, \gamma, \lambda, \mu, \theta, \phi, x, y \in R$ and $i = \sqrt{-1}$, then

$$A' = \begin{bmatrix} \alpha & \lambda - i\mu & \theta - i\phi \\ \lambda + i\mu & \beta & x - iy \\ \theta + i\phi & x + iy & \gamma \end{bmatrix}$$

$$\therefore \quad A^{\theta} = (\overline{A'}) = \begin{bmatrix} \alpha & \lambda + i\mu & \theta + i\phi \\ \lambda - i\mu & \beta & x + iy \\ \theta - i\phi & x - iy & \gamma \end{bmatrix} = A$$

Here, A is hermitian matrix as $A^{\theta} = A$.

Note

For any square matrix A with complex number entries, then $A + A^{\theta}$ is a Hermitian matrix.

Proof $(A + A^{\theta})^{\theta} = A^{\theta} + (A^{\theta})^{\theta} = A^{\theta} + A = A + A^{\theta}$

Skew-Hermitian Matrix

A square matrix $A = [a_{ij}]_{n\times n}$ is said to be skew-hermitian matrix. If $A^{\theta} = -A$, i.e. $a_{ij} = -\overline{a}_{ij}, \forall\, i, j$. If we put $j = i$, we have $a_{ii} = -\overline{a}_{ii} \Rightarrow a_{ii} + \overline{a}_{ii} = 0 \Rightarrow a_{ii}$ is purely imaginary for all i's. This means that all the diagonal elements of a skew-hermitian matrix must be purely imaginary or zero.

For example,

If $A = \begin{bmatrix} 2i & -2-3i & -2+i \\ 2-3i & -i & 3i \\ 2+i & 3i & 0 \end{bmatrix}$, where $i = \sqrt{-1}$,

then $A' = \begin{bmatrix} 2i & 2-3i & 2+i \\ -2-3i & -i & 3i \\ -2+i & 3i & 0 \end{bmatrix}$

$$\therefore \quad A^{\theta} = (\overline{A'}) = \begin{bmatrix} -2i & 2+3i & 2-i \\ -2+3i & i & -3i \\ -2-i & -3i & 0 \end{bmatrix}$$

$$= -\begin{bmatrix} 2i & -2-3i & -2+i \\ 2-3i & -i & 3i \\ 2+i & 3i & 0 \end{bmatrix} = -A$$

Hence, A is skew-hermitian matrix.

Note

1. For any square matrix A with complex number entries, then $A - A^{\theta}$ is a skew-hermitian matrix.

   Proof $(A - A^{\theta})^{\theta} = (A^{\theta}) - (A^{\theta})^{\theta} = A^{\theta} - A = -(A - A^{\theta})$

2. Every square matrix (with complex elements) can be uniquely expressed as the sum of a hermitian and a skew-hermitian matrix i.e.
   If A is a square matrix, then we can write
   $$A = \frac{1}{2}(A + A^{\theta}) + \frac{1}{2}(A - A^{\theta})$$

Example 24. *Express A as the sum of a hermitian and a skew-hermitian matrix, where* $A = \begin{bmatrix} 2+3i & 7 \\ 1-i & 2i \end{bmatrix}, i = \sqrt{-1}$.

Sol. We have, $A = \begin{bmatrix} 2+3i & 7 \\ 1-i & 2i \end{bmatrix}$, then $A^{\theta} = (\overline{A'}) = \begin{bmatrix} 2-3i & 1+i \\ 7 & -2i \end{bmatrix}$

$$\text{Let } P = \frac{1}{2}(A + A^{\theta}) = \frac{1}{2}\begin{bmatrix} 4 & 8+i \\ 8-i & 0 \end{bmatrix} = \begin{bmatrix} 2 & 4+\frac{i}{2} \\ 4-\frac{i}{2} & 0 \end{bmatrix} = P^{\theta}$$

Thus, $P = \frac{1}{2}(A + A^{\theta})$ is a hermitian matrix.

Also, let $Q = \frac{1}{2}(A - A^{\theta}) = \frac{1}{2}\begin{bmatrix} 6i & 6-i \\ -6-i & 4i \end{bmatrix}$

$$= \begin{bmatrix} 3i & 3-\frac{i}{2} \\ -3-\frac{i}{2} & 2i \end{bmatrix} = -\begin{bmatrix} -3i & -3+\frac{i}{2} \\ 3+\frac{i}{2} & -2i \end{bmatrix} = -Q^{\theta}$$

Thus, $Q = \frac{1}{2}(A - A^{\theta})$ is a skew-hermitian matrix.

Now, $P + Q = \begin{bmatrix} 2 & 4+\frac{i}{2} \\ 4-\frac{i}{2} & 0 \end{bmatrix} + \begin{bmatrix} 3i & 3-\frac{i}{2} \\ -3-\frac{i}{2} & 2i \end{bmatrix}$

$$= \begin{bmatrix} 2+3i & 7 \\ 1-i & 2i \end{bmatrix} = A$$

Hence, A is represented as the sum of a hermitian and a skew-hermitian matrix.

Properties of Hermitian and Skew-Hermitian Matrices

(i) If A be a square matrix, then AA^{θ} and $A^{\theta}A$ are hermitian matrices.

(ii) If A is a hermitian matrix, then
- (a) iA is skew-hermitian matrix, where $i = \sqrt{-1}$.
- (b) iff $\overline{A}$ is hermitian matrix.
- (c) kA is hermitian matrix, where $k \in R$.

(iii) If A is a skew-hermitian matrix, then
- (a) iA is hermitian matrix, where $i = \sqrt{-1}$.
- (b) iff $\overline{A}$ is skew-hermitian matrix.
- (c) kA is skew-hermitian matrix, where $k \in R$.

(iv) If A and B are hermitian matrices of same order, then
- (a) $k_1A + k_2B$ is also hermitian, where $k_1, k_2 \in R$.
- (b) AB is also hermitian, if $AB = BA$.
- (c) $AB + BA$ is a hermitian matrix.
- (d) $AB - BA$ is a skew-hermitian matrix.

(v) If A and B are skew-hermitian matrices of same order, then $k_1A + k_2B$ is also skew-hermitian matrix.

Unitary Matrix

A square matrix A is said to be unitary matrix iff $AA^{\theta} = I$, where I is an identity matrix.

Note

1. If $AA^{\theta} = I$, then $A^{-1} = A^{\theta}$
2. If A and B are unitary, then AB is also unitary.
3. If A is unitary, then A^{-1} and A' are also unitary.

Example 25. Verify that the matrix $\frac{1}{\sqrt{3}}\begin{bmatrix} 1 & 1+i \\ 1-i & -1 \end{bmatrix}$ is unitary, where $i = \sqrt{-1}$.

Sol. Let $A = \frac{1}{\sqrt{3}}\begin{bmatrix} 1 & 1+i \\ 1-i & -1 \end{bmatrix}$, then

$$A^{\theta} = (\overline{A'}) = \frac{1}{\sqrt{3}}\begin{bmatrix} 1 & 1+i \\ 1-i & -1 \end{bmatrix}$$

$$\therefore \quad AA^{\theta} = \frac{1}{\sqrt{3}}\begin{bmatrix} 1 & 1+i \\ 1-i & -1 \end{bmatrix} \times \frac{1}{\sqrt{3}}\begin{bmatrix} 1 & 1+i \\ 1-i & -1 \end{bmatrix}$$

$$= \frac{1}{3}\begin{bmatrix} 3 & 0 \\ 0 & 3 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I$$

Hence, A is unitary matrix.

Determinant of a Matrix

Let A be a square matrix, then the determinant formed by the elements of A without changing their respective positions is called the determinant of A and is denoted by $\det A$ or $|A|$.

i.e., If $A = \begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix}$, then $|A| = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$.

Properties of the Determinant of a Matrix

If A and B are square matrices of same order, then

(i) $|A|$ exists $\Leftrightarrow$ A is a square matrix.

(ii) $|A'| = |A|$

(iii) $|AB| = |A||B|$ and $|AB| = |BA|$

(iv) If A is orthogonal matrix, then $|A| = \pm 1$

(v) If A is skew-symmetric matrix of odd order, then $|A| = 0$

(vi) If A is skew-symmetric matrix of even order, then $|A|$ is a perfect square.

(vii) $|kA| = k^n|A|$, where n is order of A and k is scalar.

(viii) $|A^n| = |A|^n$, where $n \in N$

(ix) If $A = \text{diag}(a_1, a_2, a_3, \ldots, a_n)$, then $|A| = a_1 \cdot a_2 \cdot a_3 \ldots a_n$

Example 26. If A, B and C are square matrices of order n and $\det(A) = 2$, $\det(B) = 3$ and $\det(C) = 5$, then find the value of $10\det(A^3B^2C^{-1})$.

Sol. Given, $|A| = 2$, $|B| = 3$ and $|C| = 5$.

Now, $10\det(A^3B^2C^{-1}) = 10 \times |A^3B^2C^{-1}|$

$$= 10 \times |A^3| \times |B^2| \times |C^{-1}| = 10 \times |A|^3 \times |B|^2 \times |C|^{-1}$$
$$= \frac{10 \times |A|^3 \times |B^2|}{|C|} = \frac{10 \times 2^3 \times 3^2}{5} = 144$$

Example 27. ***If*** $A = \begin{bmatrix} a & b & c \\ b & c & a \\ c & a & b \end{bmatrix}$, $abc = 1$, $A^T A = I$, ***then find the value of*** $a^3 + b^3 + c^3$.

Sol. $\because$ $A^T A = I$

$\Rightarrow$ $|A^T A| = |I| \Rightarrow |A^T||A| = 1$

$\Rightarrow$ $|A||A| = 1$ $[\because |A^T| = |A|]$

$\Rightarrow$ $|A| = \pm 1$

$\Rightarrow$ $\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = \pm 1$

$\Rightarrow$ $3abc - (a^3 + b^3 + c^3) = \pm 1$

or $3 - (a^3 + b^3 + c^3) = \pm 1$ $[\because abc = 1]$

or $a^3 + b^3 + c^3 = 3 \pm 1 = 2 \text{or } 4$

Singular and Non-Singular Matrices

A square matrix A is said to be a singular, if $|A| = 0$ and a square matrix A is said to be non-singular, if $|A| \neq 0$.

For example,

(i) $A = \begin{bmatrix} 1 & 2 & 3 \\ -1 & 0 & 2 \\ 2 & 4 & 6 \end{bmatrix}$ is a singular matrix.

Since, $|A| = 0$.

(ii) $A = \begin{bmatrix} 2 & 3 \\ 4 & 5 \end{bmatrix}$ is a non-singular matrix.

Since, $|A| = 10 - 12 = -2 \neq 0$

Example 28. If $\omega \neq 1$ is a complex cube root of unity, then prove that

$$\begin{bmatrix} 1 + 2\omega^{2017} + \omega^{2018} & \omega^{2018} & 1 \\ 1 & 1 + \omega^{2018} + 2\omega^{2017} & \omega^{2017} \\ \omega^{2017} & \omega^{2018} & 2 + \omega^{2017} + 2\omega^{2018} \end{bmatrix}$$ ***is singular.***

Sol. Let $A = \begin{bmatrix} 1 + 2\omega^{2017} + \omega^{2018} & \omega^{2018} & 1 \\ 1 & 1 + \omega^{2018} + 2\omega^{2017} & \omega^{2017} \\ \omega^{2017} & \omega^{2018} & 2 + \omega^{2017} + 2\omega^{2018} \end{bmatrix}$

$\because$ $\omega^3 = 1 \Rightarrow \omega^{2017} = \omega$

and $\omega^{2018} = \omega^2$, then

$$A = \begin{bmatrix} 1 + 2\omega + \omega^2 & \omega^2 & 1 \\ 1 & 1 + \omega^2 + 2\omega & \omega \\ \omega & \omega^2 & 2 + \omega + 2\omega^2 \end{bmatrix}$$
$$= \begin{bmatrix} \omega & \omega^2 & 1 \\ 1 & \omega & \omega \\ \omega & \omega^2 & -\omega \end{bmatrix} \quad [\because 1 + \omega + \omega^2 = 0]$$

Now, $|A| = \begin{vmatrix} \omega & \omega^2 & 1 \\ 1 & \omega & \omega \\ \omega & \omega^2 & -\omega \end{vmatrix} = \omega \begin{vmatrix} \omega & \omega & 1 \\ 1 & 1 & \omega \\ \omega & \omega & -\omega \end{vmatrix} = 0$ $[\because C_1 = C_2]$

Thus, $|A| = 0$.

Hence, A is singular matrix.

Example 29. Find the real values of x for which the matrix $\begin{bmatrix} x+1 & 3 & 5 \\ 1 & x+3 & 5 \\ 1 & 3 & x+5 \end{bmatrix}$ is non-singular.

Sol. Let $A = \begin{bmatrix} x+1 & 3 & 5 \\ 1 & x+3 & 5 \\ 1 & 3 & x+5 \end{bmatrix}$

$\therefore$ $|A| = \begin{vmatrix} x+1 & 3 & 5 \\ 1 & x+3 & 5 \\ 1 & 3 & x+5 \end{vmatrix}$

Applying $C_1 \to C_1 + C_2 + C_3$, then

$$|A| = \begin{vmatrix} x+9 & 3 & 5 \\ x+9 & x+3 & 5 \\ x+9 & 3 & x+5 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$|A| = \begin{vmatrix} x+9 & 3 & 5 \\ 0 & x & 0 \\ 0 & 0 & x \end{vmatrix} = x^2(x+9)$$

$\because$ A is non-singular.

$\therefore$ $|A| \neq 0 \Rightarrow x^2(x+9) \neq 0$

$\therefore$ $x \neq 0, -9$

Hence, $x \in R - \{0, -9\}$.

Exercise for Session 2

1 If $A=\begin{bmatrix} 4 & x+2 \\ 2x-3 & x+1 \end{bmatrix}$ is symmetric, then x is equal to

(a) 2 (b) 3
(c) 4 (d) 5

2 If A and B are symmetric matrices, then ABA is

(a) symmetric matrix (b) skew-symmetric matrix
(c) diagonal matrix (d) scalar matrix

3 If A and B are symmetric matrices of the same order and $P = AB + BA$ and $Q = AB - BA$, then $(PQ)'$ is equal to

(a) PQ (b) QP
(c) $-QP$ (d) None of these

4 If A is a skew-symmetric matrix and n is odd positive integer, then A^n is

(a) a skew-symmetric matrix (b) a symmetric matrix
(c) a diagonal matrix (d) None of these

5 If A is symmetric as well as skew-symmetric matrix, then A is

(a) diagonal matrix (b) null matrix
(c) triangular matrix (d) None of these

6 If A is square matrix order 3, then $|(A - A')^{2015}|$ is

(a) $|A|$ (b) $|A'|$
(c) 0 (d) None of these

7 The maximum number of different elements required to form a symmetric matrix of order 6 is

(a) 15 (b) 17
(c) 19 (d) 21

8 If A and B are square matrices of order 3×3 such that A is an orthogonal matrix and B is a skew-symmetric matrix, then which of the following statement is true?

(a) $|AB| = 1$ (b) $|AB| = 0$
(c) $|AB| = -1$ (d) None of these

9 The matrix $A=\begin{bmatrix} i & 1-2i \\ -1-2i & 0 \end{bmatrix}$, where $i=\sqrt{-1}$, is

(a) symmetric (b) skew-symmetric
(c) hermitian (d) skew-hermitian

10 If A and B are square matrices of same order such that $A^* = A$ and $B^* = B$, where A^* denotes the conjugate transpose of A, then $(AB - BA)^*$ is equal to

(a) null matrix (b) $AB - BA$
(c) $BA - AB$ (d) None of these

11 If matrix $A=\frac{1}{\sqrt{2}}\begin{bmatrix} 1 & i \\ -i & a \end{bmatrix}, i=\sqrt{-1}$ is unitary matrix, a is equal to

(a) 2 (b) -1
(c) 0 (d) 1

12 If A is a 3×3 matrix and $\det(3A) = k\{\det(A)\}$, k is equal to

(a) 9 (b) 6
(c) 1 (d) 27

13 If A and B are square matrices of order 3 such that $|A| = -1, |B| = 3$, then $|3AB|$ is equal to

(a) -9 (b) -81
(c) -27 (d) 81

14 If A is a square matrix such that $A^2 = A$, then $\det(A)$ is equal to

(a) 0 or 1 (b) -2 or 2

(c) -3 or 3 (d) None of these

15 If I is a unit matrix of order 10, the determinant of I is equal to

(a) 10 (b) 1

(c) $\frac{1}{10}$ (d) 9

16 If $A_i = \begin{bmatrix} 2^{-i} & 3^{-i} \\ 3^{-i} & 2^{-i} \end{bmatrix}$, then $\sum_{i=1}^{\infty} \det(A_i)$ is equal to

(a) $\frac{3}{4}$ (b) $\frac{5}{24}$

(c) $\frac{5}{4}$ (d) $\frac{7}{144}$

17 The number of values of x for which the matrix $A = \begin{bmatrix} 3-x & 2 & 2 \\ 2 & 4-x & 1 \\ -2 & -4 & -1-x \end{bmatrix}$ is singular, is

(a) 0 (b) 1

(c) 2 (d) 3

18 The number of values of x in the closed interval $[-4, -1]$, the matrix $\begin{bmatrix} 3 & -1+x & 2 \\ 3 & -1 & x+2 \\ x+3 & -1 & 2 \end{bmatrix}$ is singular, is

(a) 0 (b) 1

(c) 2 (d) 3

19 The values of x for which the given matrix $\begin{bmatrix} -x & x & 2 \\ 2 & x & -x \\ x & -2 & -x \end{bmatrix}$ will be non-singular are

(a) $-2 \le x \le 2$ (b) for all x other than 2 and -2

(c) $x \ge 2$ (d) $x \le -2$

Session 3

Adjoint of a Matrix, Inverse of a Matrix (Reciprocal Matrix), Elementary Row Operations (Transformations), Equivalent Matrices, Matrix Polynomial, Use of Mathematical Induction,

Adjoint of a Matrix

Let $A=[a_{ij}]$ be a square matrix of order n and let C_{ij} be cofactor of a_{ij} in A. Then, the transpose of the matrix of cofactors of elements of A is called the adjoint of A and is denoted by adj (A).

Thus, $\text{adj}\,(A)=[C_{ij}]'$

$\Rightarrow \quad (\text{adj}\,A)_{ij}=C_{ji}=\text{Cofactor of } a_{ji} \text{ in } A$

i.e. if $\quad A=\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$, then

$$\text{adj } A=\begin{bmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{bmatrix}'=\begin{bmatrix} C_{11} & C_{21} & C_{31} \\ C_{12} & C_{22} & C_{32} \\ C_{13} & C_{23} & C_{33} \end{bmatrix}$$

where C_{ij} denotes the cofactor of a_{ij} in A.

Here, $\quad C_{11}=\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix}=a_{22}a_{33}-a_{23}\,a_{32},$

$$C_{12}=-\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix}=a_{31}a_{23}-a_{33}a_{21},$$

$$C_{13}=\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix}=a_{21}a_{32}-a_{31}a_{22},$$

$$C_{21}=-\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix}=a_{13}a_{32}-a_{12}a_{33},$$

$$C_{22}=\begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix}=a_{11}a_{33}-a_{31}a_{13},$$

$$C_{23}=-\begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}=a_{12}a_{31}-a_{11}a_{32},$$

$$C_{31}=\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix}=a_{12}a_{23}-a_{22}a_{13},$$

$$C_{32}=-\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix}=a_{13}a_{21}-a_{11}a_{23}$$

and $\quad C_{33}=\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}=a_{11}a_{22}-a_{21}a_{12}$

Rule to Write Cofactors of an Element a_{ij}

Cross the row and column intersection at the element a_{ij} and the determinant which is left be denoted by D, then

$$\text{Cofactors of } a_{ij}=\begin{cases} D, & \text{if } i+j=\text{even integer} \\ -D, & \text{if } i+j=\text{odd integer} \end{cases}$$

Example 30. Find the cofactor of a_{23} in $\begin{bmatrix} 3 & 1 & 4 \\ 0 & 2 & -1 \\ 1 & -3 & 5 \end{bmatrix}$.

Sol. Let $\quad A=\begin{bmatrix} 3 & 1 & 4 \\ 0 & \cdots 2 & \cdots -1 \\ 1 & -3 & 5 \end{bmatrix}$

$\therefore \quad$ Cofactor of $a_{23}=-D \qquad [\because 2+3=\text{odd}]$

where $D=\begin{vmatrix} 3 & 1 \\ 1 & -3 \end{vmatrix}$

[after crossing the 2nd row and 3rd column]

$=-9-1=-10$

Hence, cofactor of $a_{23}=-(-10)=10$

Note

The adjoint of a square matrix of order 2 is obtained by interchanging the diagonal elements and changing signs of off-diagonal elements.

If $\quad A=\begin{bmatrix} a & b \\ c & d \end{bmatrix}$, then

$$(\text{adj } A)=\begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

Example 31. ***Find the adjoint of the matrix***

$$A=\begin{bmatrix} 1 & 2 & 3 \\ 0 & 5 & 0 \\ 2 & 4 & 3 \end{bmatrix}.$$

Sol. If C be the matrix of cofactors of the element in $|A|$, then

$$C=\begin{bmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{bmatrix}$$

$$= \begin{bmatrix} \begin{vmatrix} 5 & 0 \\ 4 & 3 \end{vmatrix} & -\begin{vmatrix} 0 & 0 \\ 2 & 3 \end{vmatrix} & \begin{vmatrix} 0 & 5 \\ 2 & 4 \end{vmatrix} \\ -\begin{vmatrix} 2 & 3 \\ 4 & 3 \end{vmatrix} & \begin{vmatrix} 1 & 3 \\ 2 & 3 \end{vmatrix} & -\begin{vmatrix} 1 & 2 \\ 2 & 4 \end{vmatrix} \\ \begin{vmatrix} 2 & 3 \\ 5 & 0 \end{vmatrix} & -\begin{vmatrix} 1 & 3 \\ 0 & 0 \end{vmatrix} & \begin{vmatrix} 1 & 2 \\ 0 & 5 \end{vmatrix} \end{bmatrix} = \begin{bmatrix} 12 & 0 & -10 \\ 6 & -3 & 0 \\ -15 & 0 & 5 \end{bmatrix}$$

$$\Rightarrow \text{adj}A = C' = \begin{bmatrix} 12 & 6 & -15 \\ 0 & -3 & 0 \\ -10 & 0 & 5 \end{bmatrix}$$

Maha Shortcut for Adjoint

(Goyal's Method)

This method applied only for third order square matrix.

Method : Let $A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 5 & 0 \\ 2 & 4 & 3 \end{bmatrix}$

Step I Write down the three rows of A and rewrite first two rows.
i.e.

1 2 3
0 5 0
2 4 3
1 2 3
0 5 0

Step II After Step I, rewrite first two columns.
i.e.

1 2 3 1 2
0 5 0 0 5
2 4 3 2 4
1 2 3 1 2
0 5 0 0 5

Step III After Step II, deleting first row and first column, then we get all elements of adj A i.e.,

1 ⋯ 2 ⋯ 3 ⋯ 1 ⋯ 2
⋮
0 5 0 0 5
⋮ ⤭ ⤭ ⤭ ⇒ 15 0 −10 first column of adj A
2 4 3 2 4
⋮ ⤭ ⤭ ⤭ ⇒ 6 −3 0 second column of adj A
1 2 3 1 2
⋮ ⤭ ⤭ ⤭ ⇒ −15 0 5 third column of adj A
0 5 0 0 5

$$\text{or} \quad \text{adj } A = \begin{bmatrix} 15 & 6 & -15 \\ 0 & -3 & 0 \\ -10 & 0 & 5 \end{bmatrix}$$

Properties of Adjoint Matrix

Property 1 If A be a square matrix order n, then

$$A(\text{adj } A) = (\text{adj } A)A = |A| I_n$$

i.e., the product of a matrix and its adjoint is commutative.

Deductions of Property 1

Deduction 1 If A be a square singular matrix of order n, then $A(\text{adj } A) = (\text{adj } A)\, A = O$ [null matrix]

Since, for singular matrix, $|A| = 0$.

Deduction 2 If A be a square non-singular matrix of order n, then $|\text{adj } A| = |A|^{n-1}$

Since, for non-singular matrix, $|A| \neq 0$.

Proof $\because$ $A(\text{adj } A) = |A| I_n$

Taking determinant on both sides, then

$$|A(\text{adj } A)| = ||A| I_n|$$

$$\Rightarrow \quad |A||\text{adj } A| = |A|^n |I_n| = |A|^n \qquad [\because |I_n| = 1]$$

$$\Rightarrow \quad |\text{adj } A| = |A|^{n-1} \qquad [\because |A| \neq 0]$$

Note

In general $\underbrace{|\text{adj (adj (adj} \ldots \text{(adj } A)))|}_{\text{adj repeat } m \text{ times}} = |A|^{(n-1)^m}$

Property 2 If A and B are square matrices of order n, then

$$\text{adj}(AB) = (\text{adj } B)(\text{adj } A)$$

Property 3 If A is a square matrix of order n, then

$$(\text{adj } A)' = \text{adj } A'$$

Property 4 If A be a square non-singular matrix of order n, then $\text{adj}(\text{adj} A) = |A|^{n-2} A$

Proof $\because$ $A(\text{adj } A) = |A| I_n$ ...(i)

Replace A by adj A, then

$$(\text{adj } A)(\text{adj (adj } A)) = |\text{adj } A| I_n$$
$$= |A|^{n-1} I_n \quad [\because |\text{adj } A| = |A|^{n-1}]$$
$$= I_n |A|^{n-1}$$

Pre-multiplying both sides by matrix A, then

$$A(\text{adj } A)(\text{adj (adj } A)) = AI_n |A|^{n-1} = A|A|^{n-1}$$

$$\Rightarrow \quad |A| I_n (\text{adj}(\text{adj} A)) = A|A|^{n-1}$$

$$\Rightarrow \quad (\text{adj (adj } A)) = A|A|^{n-2}$$

or $\text{adj}(\text{adj} A) = |A|^{n-2} A$

Property 5 If A be a square non-singular matrix of order n, then

$$|\text{adj (adj } A)| = |A|^{(n-1)^2}$$

Proof $\because$ $\text{adj (adj } A) = |A|^{n-2} A$

Taking determinant on both sides, then

$$|\text{adj (adj } A)| = ||A|^{n-2} A|$$

$$= |A|^{n(n-2)} |A| \qquad [\because |kA| = k^n |A|]$$
$$= |A|^{n^2-2n+1} = |A|^{(n-1)^2}$$

Note

In general, $\underbrace{|\text{adj (adj (adj ... (adj } A))) |}_{\text{adj } m \text{ times}} = |A|^{(n-1)^m}$

Property 6 If A be a square matrix of order n and k is a scalar, then

$$\text{adj}\,(kA) = k^{n-1} \cdot (\text{adj}\, A)$$

Proof $\because$ $A(\text{adj}\, A) = |A| I_n$ ...(i)

Replace A by kA, then

$$kA(\text{adj}\,(kA)) = |kA| I_n = k^n |A| I_n$$
$$\Rightarrow \quad A(\text{adj}\,(kA)) = k^{n-1} |A| I_n$$
$$= k^{n-1} A(\text{adj}\, A) \qquad [\text{from Eq. (i)}]$$

Hence, $\text{adj}\,(kA) = k^{n-1}(\text{adj}\, A)$

Property 7 If A be a square matrix of order n and $m \in N$, then $(\text{adj}\, A^m) = (\text{adj}\, A)^m$

Property 8 If A and B be two square matrices of order n such that B is the adjoint of A and k is a scalar, then

$$|AB + kI_n| = (|A| + k)^n$$

Proof $\because$ $B = \text{adj}\ A$

$\therefore$ $AB = A(\text{adj}\ A) = |A| I_n$

$$\text{LHS} = |AB + kI_n| = ||A| I_n + kI_n| = |(|A| + k) I_n|$$
$$= (|A| + k)^n |I_n| = (|A| + k)^n = \text{RHS}$$

Property 9 Adjoint of a diagonal matrix is a diagonal matrix.

i.e. If $A = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix}$, then $\text{adj}\, A = \begin{bmatrix} bc & 0 & 0 \\ 0 & ca & 0 \\ 0 & 0 & ab \end{bmatrix}$

Note

$\text{adj}\,(I_n) = I_n$.

Example 32. If $A = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix}$, find the values of

(i) $|A||\text{adj}\ A|$ (ii) $|\text{adj}(\text{adj}\ (\text{adj}\ A))|$
(iii) $|\text{adj}\ (3A)|$ (iv) $\text{adj}\ (\text{adj}\ A)$

Sol. $\because$ $A = \begin{bmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{bmatrix}$

$\therefore |A| = (-1)(1-1) - (1)(-1-1) + (1)(1+1) = 4 \neq 0$

$\Rightarrow$ A is non-singular.

(i) $|A||\text{adj}\ A| = |A||A|^2 \qquad [\because n = 3]$
$= |A|^3 = 4^3 = 64$

(ii) $|\text{adj}\,(\text{adj}\,(\text{adj}\ A))| = |A|^{(3-1)^3} = |A|^8 = 4^8 = 2^{16}$

(iii) $|\text{adj}\,(3A)| = |3^2\ \text{adj}\ A| = (3^2)^3 |\text{adj}\ A|$
$= 3^6 |A|^2 = 729 \times 4^2 = 11664$

(iv) $\text{adj}(\text{adj}\, A) = |A|^2 A = 16A$

Example 33. If $A = \begin{bmatrix} 3 & -3 & 4 \\ 2 & -3 & 4 \\ 0 & -1 & 1 \end{bmatrix}$ and B is the adjoint of A, find the value of $|AB + 2I|$, where I is the identity matrix of order 3.

Sol. $\because$ $A = \begin{bmatrix} 3 & -3 & 4 \\ 2 & -3 & 4 \\ 0 & -1 & 1 \end{bmatrix}$

$\therefore$ $|A| = \begin{vmatrix} 3 & -3 & 4 \\ 2 & -3 & 4 \\ 0 & -1 & 1 \end{vmatrix}$

$= 3(-3+4) + 3(2-0) + 4(-2-0) = 1 \neq 0$

$\therefore$ $|AB + 2I| = (|A| + 2)^3$ [by property 8]

$= (1+2)^3 = 3^3 = 27$

Inverse of a Matrix
(Reciprocal Matrix)

A square matrix A (non-singular) of order n is said to be invertible, if there exists a square matrix B of the same order such that $AB = I_n = BA$,

then B is called the inverse (reciprocal) of A and is denoted by A^{-1}. Thus, $A^{-1} = B \Leftrightarrow AB = I_n = BA$

We have, $A(\text{adj}\ A) = |A| I_n$

$\Rightarrow$ $A^{-1} A(\text{adj}\ A) = A^{-1} I_n |A|$

$\Rightarrow$ $I_n(\text{adj}\ A) = A^{-1} |A| I_n$

$\therefore$ $A^{-1} = \dfrac{\text{adj}\, A}{|A|}$; provided $|A| \neq 0$

Note The necessary and sufficient condition for a square matrix A to be invertible is that $|A| \neq 0$.

Properties of Inverse of a Matrix

Property 1 (Uniqueness of inverse) Every invertible matrix possesses a unique inverse.

Proof Let A be an invertible matrix of order $n \times n$. Let B and C be two inverses of A. Then,

$$AB = BA = I_n \qquad \text{...(i)}$$

and $AC = CA = I_n$ ...(ii)

Now, $AB = I_n$

$\Rightarrow$ $C(AB) = CI_n$ [pre-multiplying by C]

$\Rightarrow$ $(CA)B = CI_n$ [by associativity]

$\Rightarrow$ $I_n B = CI_n$ [$\because CA = I_n$ by Eq. (ii)]

$\Rightarrow$ $B = C$

Hence, an invertible matrix possesses a unique inverse.

Property 2 (Reversal law) If A and B are invertible matrices of order $n \times n$, then AB is invertible and $(AB)^{-1} = B^{-1}A^{-1}$.

Proof It is given that A and B are invertible matrices.

$$|A| \neq 0 \text{ and } |B| \neq 0 \Rightarrow |A||B| \neq 0$$

$\Rightarrow$ $|AB| \neq 0$

Hence, AB is an invertible matrix.

Now, $(AB)(B^{-1}A^{-1}) = A(BB^{-1})A^{-1}$ [by associativity]

$= (A I_n)A^{-1}$ [$\because BB^{-1} = I_n$]

$= A A^{-1}$ [$\because A I_n = A$]

$= I_n$ [$\because A A^{-1} = I_n$]

Also, $(B^{-1}A^{-1})(AB) = B^{-1}(A^{-1}A)B$ [by associativity]

$= B^{-1}(I_n B)$ [$\because A^{-1}A = I_n$]

$= B^{-1}B$ [$\because I_n B = B$]

$= I_n$ [$\because B^{-1}B = I_n$]

Thus, $(AB)(B^{-1}A^{-1}) = I_n = (B^{-1}A^{-1})(AB)$

Hence, $(AB)^{-1} = B^{-1}A^{-1}$

Note

If $A, B, C, \ldots, Y, Z$ are invertible matrices, then

$(ABC \ldots YZ)^{-1} = Z^{-1}Y^{-1} \ldots C^{-1}B^{-1}A^{-1}$ [reversal law]

Property 3 Let A be an invertible matrix of order n, then A' is also invertible and $(A')^{-1} = (A^{-1})'$.

Proof $\because A$ is invertible matrix

$\therefore$ $|A| \neq 0 \Rightarrow |A'| \neq 0$ [$\because |A| = |A'|$]

Hence, A^{-1} is also invertible.

Now, $AA^{-1} = I_n = A^{-1}A$

$\Rightarrow$ $(AA^{-1})' = (I_n)' = (A^{-1}A)'$

$\Rightarrow$ $(A^{-1})'A' = I_n = A'(A^{-1})'$

[by reversal law for transpose]

$\Rightarrow$ $(A')^{-1} = (A^{-1})'$ [by definition of inverse]

Property 4 Let A be an invertible matrix of order n and $k \in N$, then

$$(A^k)^{-1} = (A^{-1})^k = A^{-k}$$

Proof We have,

$$(A^k)^{-1} = \underbrace{(A \times A \times A \times \ldots \times A)^{-1}}_{\text{repeat } k \text{ times}}$$

$$= \underbrace{A^{-1} \times A^{-1} \times A^{-1} \times \ldots \times A^{-1}}_{\text{repeat } k \text{ times}}$$

[by reversal law for inverse]

$$= (A^{-1})^k = A^{-k}$$

Property 5 Let A be an invertible matrix of order n, then $(A^{-1})^{-1} = A$.

Proof We have, $A^{-1}A = I_n$

$\therefore$ Inverse of $A^{-1} = A \Rightarrow (A^{-1})^{-1} = A$

Note

$I_n^{-1} = I_n$ as $I_n^{-1} I_n = I_n$

Property 6 Let A be an invertible matrix of order n, then $|A^{-1}| = \dfrac{1}{|A|}$.

Proof $\because A$ is invertible, then $|A| \neq 0$.

Now, $A A^{-1} = I_n = A^{-1}A$

$\Rightarrow$ $|A A^{-1}| = |I_n|$

$\Rightarrow$ $|A||A^{-1}| = 1$

[$\because |AB| = |A||B|$ and $|I_n| = 1$]

$\Rightarrow$ $|A^{-1}| = \dfrac{1}{|A|}$ [$\because |A| \neq 0$]

Property 7 Inverse of a non-singular diagonal matrix is a diagonal matrix.

i.e. If $A = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix}$ and $|A| \neq 0$, then

$$A^{-1} = \begin{bmatrix} \frac{1}{a} & 0 & 0 \\ 0 & \frac{1}{b} & 0 \\ 0 & 0 & \frac{1}{c} \end{bmatrix}$$

Note

The inverse of a non-singular square matrix A of order 2 is obtained by interchanging the diagonal elements and changing signs of off-diagonal elements and dividing by $|A|$.

For example,

If $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ and $|A| = (ad - bc) \neq 0$, then

$$A^{-1} = \frac{1}{(ad - bc)} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

Example 34. Compute the inverse of the matrix $A=\begin{bmatrix}0&1&2\\1&2&3\\3&1&1\end{bmatrix}$.

Sol. We have, $A=\begin{bmatrix}0&1&2\\1&2&3\\3&1&1\end{bmatrix}$

Then, $|A|=\begin{vmatrix}0&1&2\\1&2&3\\3&1&1\end{vmatrix}=0\cdot(2-3)-1(1-9)+2(1-6)$

$=-2\neq 0$

$\therefore$ A^{-1} exists.

Now, cofactors along $R_1=-1, 8, -5$

cofactors along $R_2=1, -6, 3$

cofactors along $R_3=-1, 2, -1$

Let C is a matrix of cofactors of the elements in $|A|$

$\therefore \quad C=\begin{bmatrix}-1&8&-5\\1&-6&3\\-1&2&-1\end{bmatrix}$

$\therefore \quad \text{adj } A=C'=\begin{bmatrix}-1&1&-1\\8&-6&2\\-5&3&-1\end{bmatrix}$

Hence, $A^{-1}=\dfrac{\text{adj } A}{|A|}=-\dfrac{1}{2}\begin{bmatrix}-1&1&-1\\8&-6&2\\-5&3&-1\end{bmatrix}$

$=\begin{bmatrix}\frac{1}{2}&-\frac{1}{2}&\frac{1}{2}\\-4&3&-1\\\frac{5}{2}&-\frac{3}{2}&\frac{1}{2}\end{bmatrix}$

Example 35. If A and B are symmetric non-singular matrices of same order, $AB=BA$ and $A^{-1}B^{-1}$ exist, prove that $A^{-1}B^{-1}$ is symmetric.

Sol. $\because \quad A'=A,\ B'=B$ and $|A|\neq 0, |B|'\neq 0$

$\therefore \quad (A^{-1}B^{-1})'=(B^{-1})'(A^{-1})'$

[by reversal law of transpose]

$=(B')^{-1}(A')^{-1}$ [by property 3]

$=B^{-1}A^{-1}$ [$\because A'=A$ and $B'=B$]

$=(AB)^{-1}$ [by reversal law of inverse]

$=(BA)^{-1}$ [$\because AB=BA$]

$=A^{-1}B^{-1}$ [by reversal law of inverse]

Hence, $A^{-1}B^{-1}$ is symmetric.

Example 36. Matrices A and B satisfy $AB=B^{-1}$, where $B=\begin{bmatrix}2&-2\\-1&0\end{bmatrix}$, find the value of λ for which $\lambda A-2B^{-1}+I=O$, without finding B^{-1}.

Sol. $\because \quad AB=B^{-1}$ or $AB^2=I$

Now, $\lambda A-2B^{-1}+I=O$

$\Rightarrow \quad \lambda AB-2B^{-1}B+IB=O$ [post-multiplying by B]

$\Rightarrow \quad \lambda AB-2I+B=O$

$\Rightarrow \quad \lambda AB^2-2IB+B^2=O$

[again post-multiplying by B]

$\Rightarrow \quad \lambda AB^2-2B+B^2=O$

$\Rightarrow \quad \lambda I-2B+B^2=O$ [$\because AB^2=I$]

$\Rightarrow \lambda\begin{bmatrix}1&0\\0&1\end{bmatrix}-2\begin{bmatrix}2&-2\\-1&0\end{bmatrix}+\begin{bmatrix}2&-2\\-1&0\end{bmatrix}\begin{bmatrix}2&-2\\-1&0\end{bmatrix}=\begin{bmatrix}0&0\\0&0\end{bmatrix}$

$\Rightarrow \quad \begin{bmatrix}\lambda&0\\0&\lambda\end{bmatrix}-\begin{bmatrix}4&-4\\-2&0\end{bmatrix}+\begin{bmatrix}6&-4\\-2&2\end{bmatrix}=\begin{bmatrix}0&0\\0&0\end{bmatrix}$

$\Rightarrow \quad \begin{bmatrix}\lambda+2&0\\0&\lambda+2\end{bmatrix}=\begin{bmatrix}0&0\\0&0\end{bmatrix}$

$\Rightarrow \quad \lambda+2=0$

$\therefore \quad \lambda=-2$

Example 37. If A, B and C are three non-singular square matrices of order 3 satisfying the equation $A^2=A^{-1}$ and let $B=A^8$ and $C=A^2$, find the value of $\det(B-C)$.

Sol. $\because \quad B=A^8=(A^2)^4=(A^{-1})^4$ [$\because A^{-1}=A^2$]

$=(A^4)^{-1}=(A^{2\cdot 2})^{-1}$

$=((A^2)^2)^{-1}=((A^2)^{-1})^2$

$=((A^{-1})^{-1})^2=A^2=C$

So, $B=C\Rightarrow B-C=0$

$\therefore \quad \det(B-C)=0$

Elementary Row Operations
(Transformations)

The following three types of operations (transformations) on the rows of a given matrix are known as elementary row operation (transformations).

(i) The interchange of ith and jth rows is denoted by $R_i\leftrightarrow R_j$ or R_{ij}.

(ii) The multiplication of the ith row by a constant $k(k\neq 0)$ is denoted by $R_i\to kR_i$ or $R_i(k)$

(iii) The addition of the ith row to the elements of the jth row multiplied by constant $k(k \neq 0)$ is denoted by $R_i \to R_i + kR_j$ or $R_{ij}(k)$.

Note

Similarly, we can define the three column operations, $C_{ij}(C_i \leftrightarrow C_j)$, $C_i(k)(C_i \to kC_i)$ and $C_{ij}(k)(C_i \to C_i + kC_j)$.

Equivalent Matrices

Two matrices are said to be equivalent if one is obtained from the other by elementary operations (transformations). The symbol ~ is used for equivalence.

Properties of Equivalent Matrices

(i) If A and B are equivalent matrices, there exist non-singular matrices P and Q such that $B = PAQ$

(ii) If A and B are equivalent matrices such that $B = PAQ$, then $P^{-1}BQ^{-1} = A$

(iii) Every non-singular square matrix can be expressed as the product of elementary matrices.

Example 38. Transform $\begin{bmatrix} 1 & 3 & 3 \\ 2 & 4 & 10 \\ 3 & 8 & 4 \end{bmatrix}$ into a unit matrix.

Sol. Let $A = \begin{bmatrix} 1 & 3 & 3 \\ 2 & 4 & 10 \\ 3 & 8 & 4 \end{bmatrix}$

Applying $R_2 \to R_2 - 2R_1$ and $R_3 \to R_3 - 3R_1$, we get

$$A \sim \begin{bmatrix} 1 & 3 & 3 \\ 0 & -2 & 4 \\ 0 & -1 & -5 \end{bmatrix}$$

Applying $R_2 \to \left(-\frac{1}{2}\right)R_2$ and $R_2 \to (-1)R_2$, we get

$$A \sim \begin{bmatrix} 1 & 3 & 3 \\ 0 & 1 & -2 \\ 0 & 1 & 5 \end{bmatrix}$$

Applying $R_1 \to R_1 - 3R_2$ and $R_3 \to R_3 - R_2$, we get

$$A \sim \begin{bmatrix} 1 & 0 & 9 \\ 0 & 1 & -2 \\ 0 & 0 & 7 \end{bmatrix}$$

Applying $R_3 \to \left(\frac{1}{7}\right)R_3$, we get

$$A \sim \begin{bmatrix} 1 & 0 & 9 \\ 0 & 1 & -2 \\ 0 & 0 & 1 \end{bmatrix}$$

Applying $R_1 \to R_1 - 9R_3$ and $R_2 \to R_2 + 2R_3$, we get

$$A \sim \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Hence, $A \sim I$

Example 39. Given $A = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 4 & 1 \\ 2 & 3 & 1 \end{bmatrix}$, $B = \begin{bmatrix} 2 & 3 \\ 3 & 4 \end{bmatrix}$. Find P such that $BPA = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$.

Sol. Given, $BPA = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$

$$\therefore \quad P = B^{-1}\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}A^{-1} \qquad \text{...(i) [by property]}$$

$$\because \quad B = \begin{bmatrix} 2 & 3 \\ 3 & 4 \end{bmatrix} \Rightarrow B^{-1} = \frac{1}{(-1)}\begin{bmatrix} 4 & -3 \\ -3 & 2 \end{bmatrix} = \begin{bmatrix} -4 & 3 \\ 3 & -2 \end{bmatrix}$$

$$\therefore \quad B^{-1} = \begin{bmatrix} -4 & 3 \\ 3 & -2 \end{bmatrix} \qquad \text{...(ii)}$$

and $A = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 4 & 1 \\ 2 & 3 & 1 \end{bmatrix}$

$$\therefore \quad |A| = 1(4-3) - 1(2-2) + 1(6-8) = -1 \neq 0$$

$\Rightarrow A^{-1}$ exists.

Now, adj $A = \begin{bmatrix} 1 & 2 & -3 \\ 0 & -1 & 1 \\ -2 & -1 & 2 \end{bmatrix}$ [by shortcut method]

$$\therefore \quad A^{-1} = \frac{\text{adj } A}{|A|} = \begin{bmatrix} -1 & -2 & 3 \\ 0 & 1 & -1 \\ 2 & 1 & -2 \end{bmatrix} \qquad \text{...(iii)}$$

Substituting the values of A^{-1} and B^{-1} from Eqs. (ii) and (iii) in Eq. (i), then

$$P = \begin{bmatrix} -4 & 3 \\ 3 & -2 \end{bmatrix}\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}\begin{bmatrix} -1 & -2 & 3 \\ 0 & 1 & -1 \\ 2 & 1 & -2 \end{bmatrix}$$

$$= \begin{bmatrix} -4 & 3 \\ 3 & -2 \end{bmatrix}\begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & -1 \end{bmatrix} = \begin{bmatrix} -4 & 7 & -7 \\ 3 & -5 & 5 \end{bmatrix}$$

To Compute the Inverse of a Non-Singular Matrix by Elementary Operations
(Gauss-Jordan Method)

If A be a non-singular matrix of order n, then write $A = I_n A$.

If A is reduced to I_n by elementary operations (LHS), then suppose I_n is reduced to P(RHS) and not change A in RHS, then after elementary operations, we get

$$I_n = PA,$$

then P is the inverse of A

$$\therefore \quad P = A^{-1}$$

Example 40. ***Find the inverse of the matrix*** $\begin{bmatrix} 1 & 2 & 5 \\ 2 & 3 & 1 \\ -1 & 1 & 1 \end{bmatrix}$***, using elementary row operations.***

Sol. Let $A = \begin{bmatrix} 1 & 2 & 5 \\ 2 & 3 & 1 \\ -1 & 1 & 1 \end{bmatrix}$

$$\therefore \quad |A| = \begin{vmatrix} 1 & 2 & 5 \\ 2 & 3 & 1 \\ -1 & 1 & 1 \end{vmatrix} = 1(3-1) - 2(2+1) + 5(2+3) = 21 \neq 0$$

$\therefore \quad A^{-1}$ exists.

We write $A = IA$

$$\Rightarrow \quad \begin{bmatrix} 1 & 2 & 5 \\ 2 & 3 & 1 \\ -1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} A$$

Applying $R_2 \to R_2 - 2R_1$ and $R_3 \to R_3 + R_1$, we get

$$\begin{bmatrix} 1 & 2 & 5 \\ 0 & -1 & -9 \\ 0 & 3 & 6 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ -2 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} A$$

Applying $R_2 \to (-1)R_2$ and $R_3 \to \left(\frac{1}{3}\right)R_3$, we get

$$\begin{bmatrix} 1 & 2 & 5 \\ 0 & 1 & 9 \\ 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 2 & -1 & 0 \\ \frac{1}{3} & 0 & \frac{1}{3} \end{bmatrix} A$$

Applying $R_1 \to R_1 - 2R_2$ and $R_3 \to R_3 - R_2$, we get

$$\begin{bmatrix} 1 & 0 & -13 \\ 0 & 1 & 9 \\ 0 & 0 & -7 \end{bmatrix} = \begin{bmatrix} -3 & 2 & 0 \\ 2 & -1 & 0 \\ -\frac{5}{3} & 1 & \frac{1}{3} \end{bmatrix} A$$

Applying $R_3 \to \left(-\frac{1}{7}\right)R_3$, we get

$$\begin{bmatrix} 1 & 0 & -13 \\ 0 & 1 & 9 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} -3 & 2 & 0 \\ 2 & -1 & 0 \\ \frac{5}{21} & -\frac{1}{7} & -\frac{1}{21} \end{bmatrix} A$$

Applying $R_2 \to R_2 - 9R_3$ and $R_1 \to R_1 + 13R_3$, we get

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} \frac{2}{21} & \frac{1}{7} & -\frac{13}{21} \\ -\frac{1}{7} & \frac{2}{7} & \frac{3}{7} \\ \frac{5}{21} & -\frac{1}{7} & -\frac{1}{21} \end{bmatrix} A$$

Hence, $$A^{-1} = \begin{bmatrix} \frac{2}{21} & \frac{1}{7} & -\frac{13}{21} \\ -\frac{1}{7} & \frac{2}{7} & \frac{3}{7} \\ \frac{5}{21} & -\frac{1}{7} & -\frac{1}{21} \end{bmatrix}$$

Matrix Polynomial

Let $f(x) = a_0 x^m + a_1 x^{m-1} + a_2 x^{m-2} + \ldots + a_{m-1}x + a_m$ be a polynomial in x and let $A = [a_{ij}]_{n \times n}$, then expression of the form

$f(A) = a_0 A^m + a_1 A^{m-1} + a_2 A^{m-2} + \ldots + a_{m-1} A + a_m I_n$ is called a matrix polynomial.

Thus, to obtain $f(A)$ replace x by A in $f(x)$ and the constant term is multiplied by the identity matrix of order equal to that of A.

For example, If $f(x) = x^2 - 7x + 32$ is a polynomial in x and A is a square matrix of order 3, then $f(A) = A^2 - 7A + 32 I_3$ is a matrix polynomial.

Note

1. The polynomial equation $f(x) = 0$ is satisfied by the matrix $A = [a_{ij}]_{n \times n}$, then $f(A) = 0$.
2. Let $A = [a_{ij}]_{n \times n}$ satisfies the equation $a_0 + a_1 x + a_2 x^2 + \ldots + a_r x^r = 0$, then A is invertible of $a_0 \neq 0, |A| = 0$ and its inverse is given by $$A^{-1} = \frac{1}{a_0}(a_1 I_n + a_2 A + \ldots + a_r A^{r-1}).$$

Example 41. If $A = \begin{bmatrix} k & l \\ m & n \end{bmatrix}$ and $kn \neq lm$, show that $A^2 - (k+n)A + (kn - lm)I = O$. Hence, find A^{-1}.

Sol. We have, $A = \begin{bmatrix} k & l \\ m & n \end{bmatrix}$, then $|A| = \begin{vmatrix} k & l \\ m & n \end{vmatrix}$

$$= kn - ml \neq 0 \qquad \text{[given]}$$

$\therefore\ A^{-1}$ exists.

Now, $A^2 = A \cdot A = \begin{bmatrix} k & l \\ m & n \end{bmatrix}\begin{bmatrix} k & l \\ m & n \end{bmatrix} = \begin{bmatrix} k^2 + lm & kl + ln \\ mk + nm & ml + n^2 \end{bmatrix}$

$\therefore\ A^2 - (k+n)A + (kn - lm)I$

$$= \begin{bmatrix} k^2 + lm & kl + ln \\ mk + nm & ml + n^2 \end{bmatrix} - (k+n)\begin{bmatrix} k & l \\ m & n \end{bmatrix} + (kn - lm)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} k^2 + lm & kl + ln \\ mk + nm & ml + n^2 \end{bmatrix} - \begin{bmatrix} k^2 + nk & kl + nl \\ km + nm & kn + n^2 \end{bmatrix} + \begin{bmatrix} kn - lm & 0 \\ 0 & kn - lm \end{bmatrix}$$

$$= \begin{bmatrix} k^2 + lm - k^2 - nk + kn - lm & kl + ln - kl - ln \\ mk + nm - km - nm & ml + n^2 - kn - n^2 + kn - lm \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} = O$$

As $A^2 - (k+n)A + (kn - lm)I = O$

$\Rightarrow\quad (kn - lm)I = (k+n)A - A^2$

$\Rightarrow\quad (kn - lm)IA^{-1} = ((k+n)A - A^2)A^{-1}$

$\Rightarrow\quad (kn - lm)A^{-1} = (k+n)AA^{-1} - A(AA^{-1})$

$= (k+n)I - AI \qquad [\because AA^{-1} = I]$

$= (k+n)I - A$

$= (k+n)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - \begin{bmatrix} k & l \\ m & n \end{bmatrix}$

$= \begin{bmatrix} k+n & 0 \\ 0 & k+n \end{bmatrix} - \begin{bmatrix} k & l \\ m & n \end{bmatrix}$

$\Rightarrow\quad (kn - lm)A^{-1} = \begin{bmatrix} n & -l \\ -m & k \end{bmatrix}$

Hence, $A^{-1} = \dfrac{1}{(kn - lm)}\begin{bmatrix} n & -l \\ -m & k \end{bmatrix}$

Example 42. If $A = \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix}$, find the value of $|a| + |b|$ such that $A^2 + aA + bI = O$. Hence, find A^{-1}.

Sol. We have, $A = \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix}$, then $|A| = \begin{vmatrix} 3 & 1 \\ 2 & 1 \end{vmatrix} = 3 - 2 = 1 \neq 0$

$\therefore\quad A^{-1}$ exists.

Now, $A^2 = A \cdot A = \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix}\begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix} = \begin{bmatrix} 11 & 4 \\ 8 & 3 \end{bmatrix}$

Since, $A^2 + aA + bI = O$

$$\Rightarrow \begin{bmatrix} 11 & 4 \\ 8 & 3 \end{bmatrix} + a\begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix} + b\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 11 + 3a + b & 4 + a \\ 8 + 2a & 3 + a + b \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

Equating the corresponding elements, we get

$$11 + 3a + b = 0 \qquad \text{...(i)}$$

$$4 + a = 0 \qquad \text{...(ii)}$$

$$8 + 2a = 0 \qquad \text{...(iii)}$$

$$3 + a + b = 0 \qquad \text{...(iv)}$$

From Eqs. (ii) and (iv), we get $a = -4$ and $b = 1$

$\therefore\quad |a| + |b| = |-4| + |1| = 4 + 1 = 5$

As $A^2 + aA + bI = O$

$\Rightarrow\quad A^2 - 4A + I = O \Rightarrow I = 4A - A^2$

$\Rightarrow\quad IA^{-1} = (4A - A^2)A^{-1}$

$\Rightarrow\quad A^{-1} = 4(AA^{-1}) - A(AA^{-1})$

$= 4I - AI = 4I - A$

$$= 4\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix} = \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} - \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix}$$

$\therefore\ A^{-1} = \begin{bmatrix} 1 & -1 \\ -2 & 3 \end{bmatrix}$

Use of Mathematical Induction

Example 43. Let $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$, show that

$$(aI + bA)^n = a^n I + na^{n-1} bA,\ \forall\ n \in N.$$

Sol. Let $P(n) : (aI + bA)^n = a^n I + na^{n-1}bA$

Step I For $n = 1$,

LHS $= (aI + bA)^1 = aI + bA$

and RHS $= a^1\ I + 1 \cdot a^0\ bA = aI + bA$

LHS = RHS

Therefore, $P(1)$ is true.

Step II Assume that $P(k)$ is true, then

$$P(k) : (aI + bA)^k = a^k\ I + ka^{k-1}\ bA$$

Step III For $n = k + 1$, we have to prove that

$$P(k+1) : (aI + bA)^{k+1} = a^{k+1}\ I + (k+1)\ a^k bA$$

LHS $= (aI + bA)^{k+1} = (aI + bA)^k\ (aI + bA)$

$= (a^k I + ka^{k-1}bA)(aI + bA) \qquad$ [from step II]

$= a^{k+1}\ I^2 + a^k b\,(IA) + ka^k b\,(AI) + k\ a^{k-1}b^2\ A^2$

$= a^{k+1}\ I + (k+1)a^k b\ A + 0$

$[\because AI = A,\ A^2 = 0 \text{ and } I^2 = I]$

$= a^{k+1}I + (k+1)a^k bA = \text{RHS}$

Therefore, $P(k+1)$ is true.

Hence, by the principal of mathematical2 induction $P(n)$ is true for all $n \in N$.

Example 44. *If* $A=\begin{bmatrix}3 & -4\\ 1 & -1\end{bmatrix}$, *use mathematical induction to show that* $A^n=\begin{bmatrix}1+2n & -4n\\ n & 1-2n\end{bmatrix}$, $\forall$ $n\in N$.

Sol. Let $P(n):A^n=\begin{bmatrix}1+2n & -4n\\ n & 1-2n\end{bmatrix}$

Step I For $n=1$,

$\text{LHS}=A^1=A$

and $\text{RHS}=\begin{bmatrix}1+2 & -4\\ 1 & 1-2\end{bmatrix}=\begin{bmatrix}3 & -4\\ 1 & -1\end{bmatrix}=A$

$\Rightarrow$ LHS = RHS

Therefore, $P(1)$ is true.

Step II Assume that $P(k)$ is true, then

$P(k):A^k=\begin{bmatrix}1+2k & -4k\\ k & 1-2k\end{bmatrix}$

Step III For $n=k+1$, we have to prove that

$P(k+1):A^{k+1}=\begin{bmatrix}3+2k & -4(k+1)\\ k+1 & -1-2k\end{bmatrix}$

$\text{LHS}=A^{k+1}=A^k\cdot A$

$=\begin{bmatrix}1+2k & -4k\\ k & 1-2k\end{bmatrix}\begin{bmatrix}3 & -4\\ 1 & -1\end{bmatrix}$ [from step II]

$=\begin{bmatrix}3(1+2k)-4k & -4(1+2k)+4k\\ 3k+1(1-2k) & -4k-1(1-2k)\end{bmatrix}$

$=\begin{bmatrix}3+2k & -4(k+1)\\ k+1 & -1-2k\end{bmatrix}=\text{RHS}$

Therefore, $P(k+1)$ is true.

Hence, by the principal of mathematical induction $P(n)$ is true for all $n\in N$.

Exercise for Session 3

1 If $A=\begin{bmatrix}-1 & -2 & -2\\ 2 & 1 & -2\\ 2 & -2 & 1\end{bmatrix}$, then adj A equals to

(a) A (b) A^T (c) $3A$ (d) $3A^T$

2 If A is a 3×3 matrix and B is its adjoint such that $|B|=64$, then $|A|$ is equal to

(a) 64 (b) $\pm$ 64 (c) $\pm$ 8 (d) 18

3 For any 2×2 matrix A, if $A(\text{adj } A)=\begin{bmatrix}10 & 0\\ 0 & 10\end{bmatrix}$, then $|A|$ is equal to

(a) 0 (b) 10 (c) 20 (d) 100

4 If A is a singular matrix, then adj A is

(a) singular (b) non-singular (c) symmetric (d) not defined

5 If $A=\begin{bmatrix}1 & 2 & -1\\ -1 & 1 & 2\\ 2 & -1 & 1\end{bmatrix}$, then det (adj (adj A)) is

(a) 14^4 (b) 14^3 (c) 14^2 (d) 14

6 If $k\in R_0$, then det $(\text{adj}\,(k\,I_n))$ is equal to

(a) k^{n-1} (b) $k^{n(n-1)}$ (c) k^n (d) k

7 With $1,\omega,\omega^2$ as cube roots of unity, inverse of which of the following matrices exists?

(a) $\begin{bmatrix}1 & \omega\\ \omega & \omega^2\end{bmatrix}$ (b) $\begin{bmatrix}\omega^2 & 1\\ 1 & \omega\end{bmatrix}$

(c) $\begin{bmatrix} \omega & \omega^2 \\ \omega^2 & 1 \end{bmatrix}$ (d) None of these

8 If the matrix A is such that $A\begin{bmatrix} -1 & 2 \\ 3 & 1 \end{bmatrix} = \begin{bmatrix} -4 & 1 \\ 7 & 7 \end{bmatrix}$, then A is equal to

(a) $\begin{bmatrix} 1 & 1 \\ 2 & -3 \end{bmatrix}$ (b) $\begin{bmatrix} 1 & 1 \\ -2 & 3 \end{bmatrix}$ (c) $\begin{bmatrix} 1 & -1 \\ 2 & 3 \end{bmatrix}$ (d) $\begin{bmatrix} -1 & 1 \\ 2 & 3 \end{bmatrix}$

9 If $A = \begin{bmatrix} \cos x & \sin x & 0 \\ -\sin x & \cos x & 0 \\ 0 & 0 & 1 \end{bmatrix} = f(x)$, then A^{-1} is equal to

(a) $f(-x)$ (b) $f(x)$
(c) $-f(x)$ (d) $-f(-x)$

10 The element in the first row and third column of the inverse of the matrix $\begin{bmatrix} 1 & 2 & -3 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{bmatrix}$, is

(a) -2 (b) 0 (c) 1 (d) None of these

11 If $A = \begin{bmatrix} 0 & 1 & -1 \\ 2 & 1 & 3 \\ 3 & 2 & 1 \end{bmatrix}$, then $(A(\text{adj } A)\, A^{-1})\, A$ is equal to

(a) $\begin{bmatrix} -6 & 0 & 0 \\ 0 & -6 & 0 \\ 0 & 0 & -6 \end{bmatrix}$ (b) $\begin{bmatrix} 0 & \frac{1}{6} & -\frac{1}{6} \\ \frac{1}{3} & \frac{1}{6} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{6} \end{bmatrix}$ (c) $2\begin{bmatrix} 3 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{bmatrix}$ (d) $2\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

12 A is an involutory matrix given by $A = \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix}$, then the inverse of $\frac{A}{2}$ will be

(a) $2A$ (b) $\frac{A^{-1}}{2}$
(c) $\frac{A}{2}$ (d) A^2

13 If A satisfies the equation $x^3 - 5x^2 + 4x + \lambda = 0$, then A^{-1} exists, if

(a) $\lambda \neq 1$ (b) $\lambda \neq 2$
(c) $\lambda \neq -1$ (d) $\lambda \neq 0$

14 A square non-singular matrix A satisfies the equation $x^2 - x + 2 = 0$, then A^{-1} is equal to

(a) $I - A$ (b) $(I - A)/2$
(c) $I + A$ (d) $(I + A)/2$

15 Matrix A is such that $A^2 = 2A - I$, where I is the identity matrix, then for $n \geq 2$, A^n is equal to

(a) $nA - (n - 1)I$ (b) $nA - I$
(c) $2^{n-1}A - (n - 1)I$ (d) $2^{n-1}A - I$

16 If $X = \begin{bmatrix} 3 & -4 \\ 1 & -1 \end{bmatrix}$, the value of X^n is

(a) $\begin{bmatrix} 3n & -4n \\ n & -n \end{bmatrix}$ (b) $\begin{bmatrix} 2n + n & 5 - n \\ n & -n \end{bmatrix}$
(c) $\begin{bmatrix} 3^n & (-4)^n \\ 1^n & (-1)^n \end{bmatrix}$ (d) None of these

Session 4

Solutions of Linear Simultaneous Equations Using Matrix Method

Solutions of Linear Simultaneous Equations Using Matrix Method

Let us consider a system of n linear equations in n unknowns say $x_1, x_2, x_3, ..., x_n$ given as below

$$\left.\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \ldots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \ldots + a_{2n}x_n &= b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 + \ldots + a_{3n}x_n &= b_3 \\ \ldots \quad \ldots\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots &\\ \ldots \quad \ldots\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots\ \ldots &\\ a_{n1}x_1 + a_{n2}x_2 + a_{n3}x_3 + \ldots + a_{nn}x_n &= b_n \end{aligned}\right\} \quad \ldots(i)$$

If $b_1 = b_2 = b_3 = \ldots = b_n = 0$, then the system of Eq.(i) is called a system of homogeneous linear equations and if atleast one of $b_1, b_2, b_3, ..., b_n$ is non-zero, then it is called a system of non-homogeneous linear equation. We write the above system of Eq. (i) in the matrix form as

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \ldots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \ldots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \ldots & a_{3n} \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{n1} & a_{n2} & a_{n3} & \ldots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \ldots \\ \ldots \\ x_n \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ \ldots \\ \ldots \\ b_n \end{bmatrix}$$

$$\Rightarrow \qquad AX = B \qquad \ldots(ii)$$

where $$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \ldots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \ldots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \ldots & a_{3n} \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{n1} & a_{n2} & a_{n3} & \ldots & a_{nn} \end{bmatrix},$$

$$X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \ldots \\ \ldots \\ x_n \end{bmatrix} \text{ and } B = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ \ldots \\ \ldots \\ b_n \end{bmatrix}$$

Pre-multiplying Eq. (ii) by A^{-1}, we get

$$A^{-1}(AX) = A^{-1}B \Rightarrow (A^{-1}A)X = A^{-1}B$$

$$\Rightarrow \qquad IX = A^{-1}B$$

$$\Rightarrow \qquad X = A^{-1}B = \frac{(\text{adj } A)B}{|A|}$$

Types of Equations

(1) **When system of equations is non-homogeneous**

(i) If $|A| \neq 0$, then the system of equations is consistent and has a unique solution given by $X = A^{-1}B$.

(ii) If $|A| = 0$ and $(\text{adj}A) \cdot B \neq 0$, then the system of equations is inconsistent and has no solution.

(iii) If $|A| = 0$ and $(\text{adj}A) \cdot B = O$, then the system of equations is consistent and has an infinite number of solutions.

(2) **When system of equations is homogeneous**

(i) If $|A| \neq 0$, then the system of equations has only trivial solution and it has one solution.

(ii) If $|A| = 0$, then the system of equations has non-trivial solution and it has infinite solutions.

(iii) If number of equations < number of unknowns, then it has non-trivial solution.

Note

Non-homogeneous linear equations can also be solved by Cramer's rule, this method has been discussed in the chapter on determinants.

Example 45. Solve the system of equations $x + 2y + 3z = 1$, $2x + 3y + 2z = 2$ and $3x + 3y + 4z = 1$ with the help of matrix inversion.

Sol. We have,

$$x + 2y + 3z = 1,\ 2x + 3y + 2z = 2 \text{ and } 3x + 3y + 4z = 1$$

The given system of equations in the matrix form are written as below.

$$\begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 2 \\ 3 & 3 & 4 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

$$AX = B$$

$$\Rightarrow \quad X = A^{-1}B \qquad \ldots(i)$$

where $A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 2 \\ 3 & 3 & 4 \end{bmatrix}$, $X = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$ and $B = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$

$$|A| = 1(12-6) - 2(8-6) + 3(6-9)$$
$$= 6 - 4 - 9 = -7 \neq 0$$

$\therefore$ A^{-1} exists and has unique solution.

Let C be the matrix of cofactors of elements in $|A|$.

Now, cofactors along $R_1 = 6, -2, -3$

cofactors along $R_2 = 1, -5, 3$

and cofactors along $R_3 = -5, 4, -1$

$$\therefore \quad C = \begin{bmatrix} 6 & -2 & -3 \\ 1 & -5 & 3 \\ -5 & 4 & -1 \end{bmatrix}$$

$$\therefore \quad \text{adj } A = C^T$$

$$\Rightarrow \quad \text{adj } A = \begin{bmatrix} 6 & -2 & -3 \\ 1 & -5 & 3 \\ -5 & 4 & -1 \end{bmatrix}^T = \begin{bmatrix} 6 & 1 & -5 \\ -2 & -5 & 4 \\ -3 & 3 & -1 \end{bmatrix}$$

$$\Rightarrow \quad A^{-1} = \frac{\text{adj } A}{|A|} = -\frac{1}{7}\begin{bmatrix} 6 & 1 & -5 \\ -2 & -5 & 4 \\ -3 & 3 & -1 \end{bmatrix}$$

$$= \begin{bmatrix} -\frac{6}{7} & -\frac{1}{7} & \frac{5}{7} \\ \frac{2}{7} & \frac{5}{7} & -\frac{4}{7} \\ \frac{3}{7} & -\frac{3}{7} & \frac{1}{7} \end{bmatrix}$$

From Eq. (i), $X = A^{-1}B$

$$\Rightarrow \quad \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} -\frac{6}{7} & -\frac{1}{7} & \frac{5}{7} \\ \frac{2}{7} & \frac{5}{7} & -\frac{4}{7} \\ \frac{3}{7} & -\frac{3}{7} & \frac{1}{7} \end{bmatrix}\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} = \begin{bmatrix} -\frac{3}{7} \\ \frac{8}{7} \\ -\frac{2}{7} \end{bmatrix}$$

Hence, $x = -\frac{3}{7}, y = \frac{8}{7}$ and $z = -\frac{2}{7}$ is the required solution.

Example 46. Solve the system of equations $x + y + z = 6$, $x + 2y + 3z = 14$ and $x + 4y + 7z = 30$ with the help of matrix method.

Sol. We have, $x + y + z = 6$,

$$x + 2y + 3z = 14$$

and $$x + 4y + 7z = 30$$

The given system of equations in the matrix form are written as below :

$$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 4 & 7 \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 6 \\ 14 \\ 30 \end{bmatrix}$$

$$AX = B \qquad \ldots(i)$$

where, $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 4 & 7 \end{bmatrix}$, $X = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$ and $B = \begin{bmatrix} 6 \\ 14 \\ 30 \end{bmatrix}$

$$|A| = 1(14-12) - 1(7-3) + 1(4-2) = 2 - 4 + 2 = 0$$

$\therefore$ The equation either has no solution or an infinite number of solutions. To decide about this, we proceed to find

(adj A) B.

Let C be the matrix of cofactors of elements in $|A|$.

Now, cofactors along $R_1 = 2, -4, 2$

cofactors along $R_2 = -3, 6, -3$

and cofactors along $R_3 = 1, -2, 1$

$$\therefore \quad C = \begin{bmatrix} 2 & -4 & 2 \\ -3 & 6 & -3 \\ 1 & -2 & 1 \end{bmatrix}$$

$$\Rightarrow \quad \text{adj} = C^T = \begin{bmatrix} 2 & -3 & 1 \\ -4 & 6 & -2 \\ 2 & -3 & 1 \end{bmatrix},$$

then $$(\text{adj } A)\, B = \begin{bmatrix} 2 & -3 & 1 \\ -4 & 6 & -2 \\ 2 & -3 & 1 \end{bmatrix}\begin{bmatrix} 6 \\ 14 \\ 30 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = O$$

Hence, both conditions $|A| = 0$ and $(\text{adj } A)\, B = O$ are satisfied, then the system of equations is consistent and has an infinite number of solutions.

Proceed as follows :

$$[A : B] = \begin{bmatrix} 1 & 1 & 1 & \vdots & 6 \\ 1 & 2 & 3 & \vdots & 14 \\ 1 & 4 & 7 & \vdots & 30 \end{bmatrix}$$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, then

$$[A : B] = \begin{bmatrix} 1 & 1 & 1 & \vdots & 6 \\ 0 & 1 & 2 & \vdots & 8 \\ 0 & 2 & 4 & \vdots & 16 \end{bmatrix}$$

Applying $R_3 \to R_3 - 2R_2$, then

$$[A : B] = \begin{bmatrix} 1 & 1 & 1 & \vdots & 6 \\ 0 & 1 & 2 & \vdots & 8 \\ 0 & 0 & 0 & \vdots & 0 \end{bmatrix}$$

Then, Eq. (i) reduces to

$$\begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 2 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 6 \\ 8 \\ 0 \end{bmatrix} \Rightarrow \begin{bmatrix} x + y + z \\ y + 2z \\ 0 \end{bmatrix} = \begin{bmatrix} 6 \\ 8 \\ 0 \end{bmatrix}$$

On comparing $x + y + z = 6$ and $y + 2z = 8$

Taking $z = k \in R$, then $y = 8 - 2k$ and $x = k - 2$.

Since, k is arbitrary, hence the number of solutions is infinite.

Example 47. Solve the system of equations $x + 3y - 2z = 0$, $2x - y + 4z = 0$ and $x - 11y + 14z = 0$.

Sol. We have, $x + 3y - 2z = 0$

$$2x - y + 4z = 0$$

$$x - 11y + 14z = 0$$

The given system of equations in the matrix form are written as below.

$$\begin{bmatrix} 1 & 3 & -2 \\ 2 & -1 & 4 \\ 1 & -11 & 14 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$AX = O \quad \ldots(i)$$

where $A = \begin{bmatrix} 1 & 3 & -2 \\ 2 & -1 & 4 \\ 1 & -11 & 14 \end{bmatrix}$, $X = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$ and $O = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$

$\therefore \quad |A| = 1(-14 + 44) - 3(28 - 4) - 2(-22 + 1)$

$= 30 - 72 + 42 = 0$

and therefore the system has a non-trivial solution. Now, we may write first two of the given equations

$$x + 3y = 2z \text{ and } 2x - y = -4z$$

Solving these equations in terms of z, we get

$$x = -\frac{10}{7}z \text{ and } y = \frac{8}{7}z$$

Putting $x = -\frac{10}{7}z$ and $y = \frac{8}{7}z$ in third equation of the given system,

we get, LHS $= -\frac{10}{7}z - \frac{88}{7}z + 14z = 0 =$ RHS

Now, if $z = 7k$, then $x = -10k$ and $y = 8k$.

Hence, $x = -10k$, $y = 8k$ and $z = 7k$ (where k is arbitrary) are the required solutions.

Example 48. Solve the system of equations

$$2x + 3y - 3z = 0,$$

$$3x - 3y + z = 0$$

and $$3x - 2y - 3z = 0$$

Sol. We have, $2x + 3y - 3z = 0$

$$3x - 3y + z = 0$$

$$3x - 2y - 3z = 0$$

The given system of equations in the matrix form are written as below.

$$\begin{bmatrix} 2 & 3 & -3 \\ 3 & -3 & 1 \\ 3 & -2 & -3 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$AX = O \quad \ldots(i)$$

where $A = \begin{bmatrix} 2 & 3 & -3 \\ 3 & -3 & 1 \\ 3 & -2 & -3 \end{bmatrix}$, $X = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$ and $O = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$

$\therefore \quad |A| = 2(9 + 2) - 3(-9 - 3) - 3(-6 + 9)$

$= 22 + 36 - 9 = 49 \neq 0$

Hence, the equations have a unique trivial solution $x = 0$, $y = 0$ and $z = 0$ only.

Echelon Form of a Matrix

A matrix A is said to be in echelon form, if

(i) The first non-zero element in each row is 1.

(ii) Every non-zero row in A preceds every zero-row.

(iii) The number of zeroes before the first non-zero element in 1st, 2nd, 3rd, ... rows should be in increasing order.

For example,

(i) $\begin{bmatrix} 1 & 2 & 3 \\ 0 & 1 & 4 \\ 0 & 0 & 1 \end{bmatrix}$ (ii) $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 0 & 1 & 4 & 5 \\ 0 & 0 & 1 & 9 \\ 0 & 0 & 0 & 1 \end{bmatrix}$

(iii) $\begin{bmatrix} 1 & 2 & 3 & 4 & 5 \\ 0 & 1 & 2 & 4 & 3 \\ 0 & 0 & 1 & 2 & 5 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$

Rank of Matrix

The rank of a matrix is said to be r, if

(i) It has atleast minors of order r is different from zero.

(ii) All minors of A of order higher than r are zero.

The rank of A is denoted by $\rho(A)$.

Note

1. The rank of a zero matrix is zero and the rank of an identity matrix of order n is n.
2. The rank of a matrix in echelon form is equal to the number of non-zero rows of the matrix.
3. The rank of a non-singular matrix ($|A| \neq 0$) of order n is n.

Properties of Rank of Matrices

(i) If $A = [a_{ij}]_{m \times n}$ and $B = [b_{ij}]_{m \times n}$, then $\rho(A + B) \leq \rho(A) + \rho(B)$

(ii) If $A = [a_{ij}]_{m \times n}$ and $B = [b_{ij}]_{n \times p}$, then $\rho(AB) \leq \rho(A)$ and $\rho(AB) \leq \rho(B)$

(iii) If $A = [a_{ij}]_{n \times n}$, then $\rho(A) = \rho(A')$

Example 49. Find the rank of $\begin{bmatrix} 3 & -1 & 2 \\ -3 & 1 & 2 \\ -6 & 2 & 4 \end{bmatrix}$.

Sol. We have,

Let $A = \begin{bmatrix} 3 & -1 & 2 \\ -3 & 1 & 2 \\ -6 & 2 & 4 \end{bmatrix}$

Applying $R_2 \to R_2 + R_1$ and $R_3 \to R_3 + 2R_1$, we get

$$A = \begin{bmatrix} 3 & -1 & 2 \\ 0 & 0 & 4 \\ 0 & 0 & 8 \end{bmatrix}$$

Applying $R_3 \to R_3 - 2R_2$, we get

$$A = \begin{bmatrix} 3 & -1 & 2 \\ 0 & 0 & 4 \\ 0 & 0 & 0 \end{bmatrix}$$

Applying $R_1 \to \left(\frac{1}{3}\right) R_1$ and $R_2 \to \left(\frac{1}{4}\right) R_2$, then

$$A = \begin{bmatrix} 1 & -\frac{1}{3} & \frac{2}{3} \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

This is Echelon form of matrix A.

$\therefore$ Rank = Number of non-zero rows $\Rightarrow \rho(A) = 2$

Aliter $|A| = \begin{vmatrix} 3 & -1 & 2 \\ -3 & 1 & 2 \\ -6 & 2 & 4 \end{vmatrix}$

$$= 3(4-4) + 1(-12+12) + 2(-6+6) = 0$$

$\therefore$ Rank of $A \neq 3$ but less than 3.

There will be ${}^3C_2 \times {}^3C_2 = 9$ square minors of order 2. Now, we consider of there minors.

(i) $\begin{vmatrix} 1 & 2 \\ 2 & 4 \end{vmatrix} = 0$ (ii) $\begin{vmatrix} 3 & 2 \\ -6 & 4 \end{vmatrix} = 24 \neq 0$

Hence, all minors are not zero.

Hence, rank of A is 2. $\Rightarrow \rho(A) = 2$

Solutions of Linear Simultaneous Equations Using Rank Method

Let us consider a system of n linear equations in n unknowns say $x_1, x_2, x_3, ..., x_n$ given as below.

$$\left.\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \ldots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \ldots + a_{2n}x_n &= b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 + \ldots + a_{3n}x_n &= b_3 \\ \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \\ \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \\ a_{m1}x_1 + a_{m2}x_2 + a_{m3}x_3 + \ldots + a_{mn}x_n &= b_m \end{aligned}\right\} \quad \ldots(i)$$

We write the above system of Eq. (i) in the matrix form as

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \ldots & \ldots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \ldots & \ldots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \ldots & \ldots & a_{3n} \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{m1} & a_{m2} & a_{m3} & \ldots & \ldots & a_{mn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \ldots \\ \ldots \\ x_n \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ \ldots \\ \ldots \\ b_m \end{bmatrix}$$

$$\Rightarrow \quad AX = B \quad \ldots(ii)$$

where $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \ldots & \ldots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \ldots & \ldots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \ldots & \ldots & a_{3n} \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{m1} & a_{m2} & a_{m3} & \ldots & \ldots & a_{mn} \end{bmatrix}$,

$X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \ldots \\ \ldots \\ x_n \end{bmatrix}$ and $B = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \\ \ldots \\ \ldots \\ b_m \end{bmatrix}$

The matrix A is called the coefficient matrix and the matrix

$$C = [A : B] = \left[\begin{array}{cccccc:c} a_{11} & a_{12} & a_{13} & \ldots & \ldots & a_{1n} & b_1 \\ a_{21} & a_{22} & a_{23} & \ldots & \ldots & a_{2n} & b_2 \\ a_{31} & a_{32} & a_{33} & \ldots & \ldots & a_{3n} & b_3 \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ a_{m1} & a_{m2} & a_{m3} & \ldots & \ldots & a_{mn} & b_m \end{array}\right]$$

is called the augmented matrix of the given system of equations.

Types of Equations

1. **Consistent Equation** If $\rho(A) = \rho(C)$
   (i) **Unique Solution** If $\rho(A) = \rho(C) = n$, where $n =$ number of knowns.
   (ii) **Infinite Solution** If $\rho(A) = \rho(C) = r$, where $r < n$.
2. **Inconsistent Equation** If $\rho(A) \neq \rho(C)$, then no solution.

Example 50. Determine for what values of λ and μ the following system of equations

$$x + y + z = 6,$$
$$x + 2y + 3z = 10$$

and $x+2y+\lambda z=\mu$

have (i) no solution? (ii) a unique solution?
(iii) an infinite number of solutions?

Sol. We can write the above system of equations in the matrix form

$$\begin{bmatrix}1 & 1 & 1\\ 1 & 2 & 3\\ 1 & 2 & \lambda\end{bmatrix}\begin{bmatrix}x\\ y\\ z\end{bmatrix}=\begin{bmatrix}6\\ 10\\ \mu\end{bmatrix}$$

$\Rightarrow \quad AX=B$

where $A=\begin{bmatrix}1 & 1 & 1\\ 1 & 2 & 3\\ 1 & 2 & \lambda\end{bmatrix}$, $X=\begin{bmatrix}x\\ y\\ z\end{bmatrix}$ and $B=\begin{bmatrix}6\\ 10\\ \mu\end{bmatrix}$

$\therefore$ The augmented matrix

$$C=[A:B]=\begin{bmatrix}1 & 1 & 1 & \vdots & 6\\ 1 & 2 & 3 & \vdots & 10\\ 1 & 2 & \lambda & \vdots & \mu\end{bmatrix}$$

Applying $R_2\to R_2-R_1$ and $R_3\to R_3-R_1$, we get

$$C=\begin{bmatrix}1 & 1 & 1 & \vdots & 6\\ 0 & 1 & 2 & \vdots & 4\\ 0 & 1 & \lambda-1 & \vdots & \mu-6\end{bmatrix}$$

Applying $R_3\to R_3-R_2$, we get

$$C=\begin{bmatrix}1 & 1 & 1 & \vdots & 6\\ 0 & 1 & 2 & \vdots & 4\\ 0 & 0 & \lambda-3 & \vdots & \mu-10\end{bmatrix}$$

(i) No solution $\rho(A)\neq\rho(C)$
i.e. $\lambda-3=0$ and $\mu-10\neq 0$
$\therefore \quad \lambda=3$ and $\mu\neq 10$

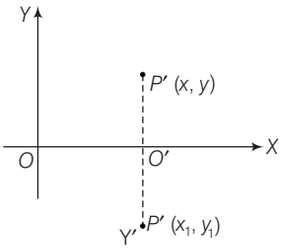
(ii) A unique solution $\rho(A)=\rho(C)=3$
i.e., $\lambda-3\neq 0$ and $\mu\in R$
$\therefore \quad \lambda\neq 3$ and $\mu\in R$

(iii) Infinite number of solutions
$\rho(A)=\rho(C)\ (\angle 3)$
i.e. $\lambda-3=0$ and $\mu-10=0$
$\therefore \quad \lambda=3$ and $\mu=10$

Reflection Matrix

(i) Reflection in the X-axis

Let $P(x,y)$ be any point and $P'(x_1,y_1)$ be its image after reflection in the X-axis, then



$$\begin{cases}x_1=x\\ y_1=-y\end{cases}\quad [O' \text{ is the mid-point of } P \text{ and } P']$$

These may be rewritten as

$$\begin{cases}x_1=1\cdot x+0\cdot y\\ y_1=0\cdot x+(-1)\cdot y\end{cases}$$

These system of equations in the matrix form are written as below.

$$\begin{bmatrix}x_1\\ y_1\end{bmatrix}=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}\begin{bmatrix}x\\ y\end{bmatrix}$$

Thus, **the matrix $\begin{bmatrix}\mathbf{1} & \mathbf{0}\\ \mathbf{0} & \mathbf{-1}\end{bmatrix}$ describes the reflection of a point $P(x,y)$ in the X-axis.**

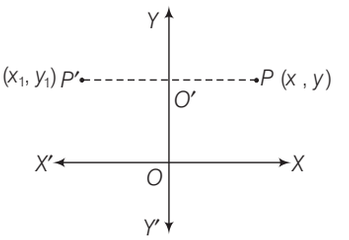
(ii) Reflection in the Y-axis

Let $P(x,y)$ be any point and $P'(x_1,y_1)$ be its image after reflection in the Y-axis, then

$$\begin{cases}x_1=-x\\ y_1=y\end{cases}\quad [O' \text{ is the mid-point of } P \text{ and } P']$$

These may be written as

$$\begin{cases}x_1=(-1)\cdot x+0\cdot y\\ y_1=\ 0\cdot x+1\cdot y\end{cases}$$



These system of equations in the matrix form are written as below.

$$\begin{bmatrix}x_1\\ y_1\end{bmatrix}=\begin{bmatrix}-1 & 0\\ 0 & 1\end{bmatrix}\begin{bmatrix}x\\ y\end{bmatrix}$$

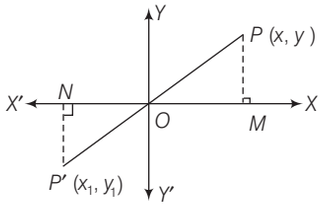
Thus, **the matrix $\begin{bmatrix}\mathbf{-1} & \mathbf{0}\\ \mathbf{0} & \mathbf{1}\end{bmatrix}$ describes the reflection of a point $P(x,y)$ in the Y-axis.**

(iii) Reflection through the origin

Let $P(x,y)$ be any point and $P'(x_1,y_1)$ be its image after reflection through the origin, then

$$\begin{cases}x_1=-x\\ y_1=-y\end{cases}\quad [O' \text{ is the mid-point of } P \text{ and } P']$$

These may be written as



$$\begin{cases} x_1 = (-1)\, x + 0 \cdot y \\ y_1 = 0 \cdot x + (-1) \cdot y \end{cases}$$

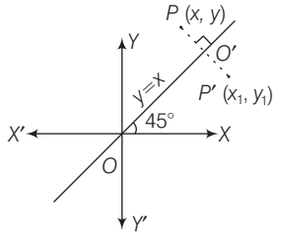
These system of equations in the matrix form are written as below.

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Thus, **the matrix** $\begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$ **describes the reflection of a point** $P(x, y)$ **through the origin.**

(iv) Reflection in the line $y = x$

Let $P(x, y)$ be any point and $P'(x_1, y_1)$ be its image after reflection in the line $y = x$, then



$$\begin{cases} x_1 = y \\ y_1 = x \end{cases} \quad [O' \text{ is the mid-point of } P \text{ and } P']$$

These may be written as

$$\begin{cases} x_1 = 0 \cdot x + 1 \cdot y \\ y_1 = 1 \cdot x + 0 \cdot y \end{cases}$$

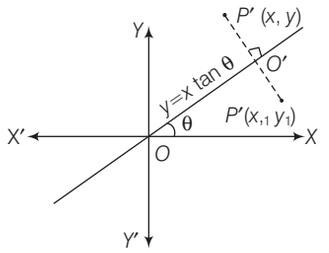
These system of equations in the matrix form are written as below.

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Thus, **the matrix** $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ **describes the reflection of a point** $P(x, y)$ **in the line** $y = x$**.**

(v) Reflection in the line $y = x \tan\theta$

Let $P(x, y)$ be any point and $P'(x_1, y_1)$ be its image after reflection in the line $y = x \tan\theta$, then



$$\begin{cases} x_1 = x\cos 2\theta + y \sin 2\theta \\ y_1 = x \sin 2\theta - y \cos 2\theta \end{cases}$$

$[O' \text{ is the mid-point of } P \text{ and } P']$

These may be written as

$$\begin{cases} x_1 = x \cdot \cos 2\theta + y \cdot \sin 2\theta \\ y_1 = x \cdot \sin 2\theta + y \cdot (-\cos 2\theta) \end{cases}$$

These system of equations in the matrix form are written as below.

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} \cos 2\theta & \sin 2\theta \\ \sin 2\theta & -\cos 2\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Thus, the matrix $\begin{bmatrix} \cos 2\theta & \sin 2\theta \\ \sin 2\theta & -\cos 2\theta \end{bmatrix}$ describes the reflection of a point $P(x, y)$ in the line $y = x \tan\theta$.

Note

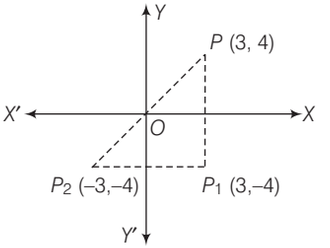
By putting $\theta = 0, \frac{\pi}{2}, \frac{\pi}{4}$, we can get the reflection matrices in the X-axis, Y-axis and the line $y = x$, respectively.

Example 51. The point $P(3, 4)$ undergoes a reflection in the X-axis followed by a reflection in the Y-axis. Show that their combined effect is the same as the single reflection of $P(3, 4)$ in the origin.

Sol. Let $P_1(x_1, y_1)$ be the image of $P(3, 4)$ after reflection in the X-axis. Then,

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 3 \\ 4 \end{bmatrix} = \begin{bmatrix} 3 \\ -4 \end{bmatrix}$$

Therefore, the image of $P(3, 4)$ after reflection in the X-axis is $P_1(3, -4)$.



Now, let $P_2(x_2, y_2)$ be the image of $P_1(3, -4)$ after reflection in the Y-axis, then

$$\begin{bmatrix} x_2 \\ y_2 \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ -4 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix}$$

Therefore, the image of $P_1(3, -4)$ after reflection in the Y-axis is $P_2(-3, -4)$.

Further, let $P_3(x_3, y_3)$ be the image of $P(3, 4)$ in the origin O. Then,

$$\begin{bmatrix} x_3 \\ y_3 \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 3 \\ 4 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix}$$

Therefore, the image of $P(3, 4)$ after reflection in the origin is $P_3(-3, -4)$. It is clear that $P_2 = P_3$

Hence, the image of P_2 of P often successive reflections in their X-axis and Y-axis is the same as P_3, which is single reflection of P in the origin.

Example 52. Find the image of the point $(-2, -7)$ under the transformations $(x, y) \to (x - 2y, -3x + y)$.

Sol. Let (x_1, y_1) be the image of the point (x, y) under the given transormations, then

$$\begin{cases} x_1 = x - 2y = 1 \cdot x + (-2) \cdot y \\ y_1 = -3x + y = (-3) \cdot x + 1 \cdot y \end{cases}$$

$$\Rightarrow \quad \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} 1 & -2 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

$$= \begin{bmatrix} 1 & -2 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} -2 \\ -7 \end{bmatrix} = \begin{bmatrix} -2+14 \\ 6-7 \end{bmatrix} = \begin{bmatrix} 12 \\ -1 \end{bmatrix}$$

Therefore, the required image is $(12, -1)$.

Example 53. The image of the point $A(2, 3)$ by the line mirror $y = x$ is the point B and the image of B by the line mirror $y = 0$ is the point (α, β). Find α and β.

Sol. Let $B(x_1, y_1)$ be the image of the point $A(2,3)$ about the line $y = x$, then

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 2 \\ 3 \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \end{bmatrix}$$

Therefore, the image of $A(2, 3)$ by the line mirror $y = x$ is $B(3, 2)$.

Given, image of B by the line mirror $y = 0$ (X-axis) is (α, β), then

$$\begin{bmatrix} \alpha \\ \beta \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \begin{bmatrix} 3 \\ -2 \end{bmatrix}$$

On comparing, we get $\alpha = 3$ and $\beta = -2$.

Example 54. Find the image of the point $(-\sqrt{2}, \sqrt{2})$ by the line mirror $y = x \tan\left(\frac{\pi}{8}\right)$.

Sol. Let (x_1, y_1) be the image of $(-\sqrt{2}, \sqrt{2})$ about the line $y = x \tan\left(\frac{\pi}{8}\right)$.

On comparing $y = x \tan\left(\frac{\pi}{8}\right)$ by $y = x \tan\theta$

$$\therefore \qquad \theta = \frac{\pi}{8}$$

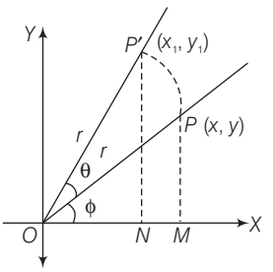
Now,
$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} \cos 2\theta & \sin 2\theta \\ \sin 2\theta & -\cos 2\theta \end{bmatrix} \begin{bmatrix} -\sqrt{2} \\ \sqrt{2} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} -\sqrt{2} \\ \sqrt{2} \end{bmatrix} = \begin{bmatrix} 0 \\ -2 \end{bmatrix}$$

On comparing $x_1 = 0$ and $y_1 = -2$.

Therefore, the required image is $(0, -2)$.

Rotation Through an Angle θ



Let $P(x, y)$ be any point such that $OP = r$ and $\angle POX = \phi$. Let OP rotate through an angle θ in the anti-clockwise direction such that $P'(x_1, y_1)$ is the new position.

$$\therefore \qquad OP' = r, \qquad [\because OP = OP']$$

then
$$\begin{cases} x_1 = x\cos\theta - y\sin\theta \\ x_1 = x\sin\theta + y\cos\theta \end{cases}$$

These system of equations in the matrix form are written as below.

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Thus, the matrix $\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$ describes a rotation of a line segment through an angle θ.

Remember Use of complex number

$$OP' = OP\, e^{i\theta},\ i = \sqrt{-1}$$

$$(x_1 + iy_1) = (x + iy)(\cos\theta + i\sin\theta)$$

$$= (x\cos\theta - y\sin\theta) + i(x\sin\theta + y\cos\theta)$$

$$\therefore \qquad x_1 = x\cos\theta - y\sin\theta$$

and
$$y_1 = x\sin\theta + y\cos\theta$$

Example 55. Find the matrices of transformation T_1T_2 and T_2T_1 when T_1 is rotation through an angle 60° and T_2 is the reflection in the Y-axis. Also, verify that $T_1T_2 \neq T_2T_1$.

Sol. $T_1 = \begin{bmatrix} \cos 60° & -\sin 60° \\ \sin 60° & \cos 60° \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix}$

and $T_2 = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$

$\therefore \quad T_1T_2 = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix} \times \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} = \frac{1}{2}\begin{bmatrix} -1+0 & 0-\sqrt{3} \\ -\sqrt{3}+0 & 0+1 \end{bmatrix}$

$$= \frac{1}{2}\begin{bmatrix} -1 & -\sqrt{3} \\ -\sqrt{3} & 1 \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} & \frac{1}{2} \end{bmatrix} \quad \text{...(i)}$$

and $T_2T_1 = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \times \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix} = \frac{1}{2}\begin{bmatrix} -1+0 & \sqrt{3}+0 \\ 0+\sqrt{3} & 0+1 \end{bmatrix}$

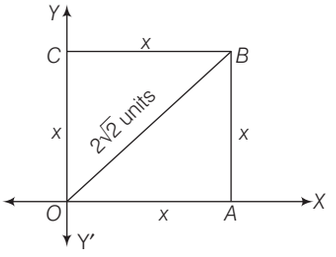
$$= \frac{1}{2}\begin{bmatrix} -1 & \sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{bmatrix} \quad \text{...(ii)}$$

It is clear from Eqs.(i) and (ii), then

$$T_1T_2 \neq T_2T_1$$

Example 56. Write down 2×2 matrix A which corresponds to a counterclockwise rotation of 60° about the origin. In the diagram the square $OABC$ has its diagonal OB of $2\sqrt{2}$ units in length. The square is rotated counterclockwise about O through 60°. Find the coordiates of the vertices of the square after rotating.

Sol. The matrix describes a rotation through an angle 60° in counterclockwise direction is



$$\begin{bmatrix} \cos 60° & -\sin 60° \\ \sin 60° & \cos 60° \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix}$$

Since, each side of the square be x,

then $\quad x^2 + x^2 = (2\sqrt{2})^2$

$\Rightarrow \quad 2x^2 = 8 \Rightarrow x^2 = 4$

$\therefore \quad x = 2$ units

Therefore, the coordinates of the vertices O, A, B and C are (0, 0), (2, 0), (2, 2) and (0, 2), respectively. Let after rotation A map into A', B map into B', C map into C' but the O map into itself.

If coordinates of A', B' and C' are (x', y'), (x'', y'') and (x''', y'''), respectively.

$\therefore \quad \begin{bmatrix} x' \\ y' \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix}\begin{bmatrix} 2 \\ 0 \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 2 \\ 2\sqrt{3} \end{bmatrix} = \begin{bmatrix} 1 \\ \sqrt{3} \end{bmatrix}$

$\therefore \quad x' = 1, y' = \sqrt{3} \Rightarrow A(2, 0) \to A'(1, \sqrt{3})$

and $\begin{bmatrix} x'' \\ y'' \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix}\begin{bmatrix} 2 \\ 2 \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 2-2\sqrt{3} \\ 2\sqrt{3}+2 \end{bmatrix} = \begin{bmatrix} 1-\sqrt{3} \\ \sqrt{3}+1 \end{bmatrix}$

$\therefore \quad x'' = 1 - \sqrt{3}, y'' = \sqrt{3} + 1$

$\Rightarrow \quad B(2, 2) \to B'(1 - \sqrt{3}, \sqrt{3} + 1)$

$\begin{bmatrix} x''' \\ y''' \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{bmatrix}\begin{bmatrix} 0 \\ 2 \end{bmatrix} = \frac{1}{2}\begin{bmatrix} -2\sqrt{3} \\ 2 \end{bmatrix} = \begin{bmatrix} -\sqrt{3} \\ 1 \end{bmatrix}$

$\therefore \quad x''' = -\sqrt{3}, y''' = 1$

$\Rightarrow \quad C(0, 2) \to C'(-\sqrt{3}, 1)$

Eigen Values or Characteristic roots and Characteristic Vectors of a square matrix

Let X be any non-zero vector satisfying

$$AX = \lambda X \quad \text{...(i)}$$

where λ is any scalar, then λ is said to be eigen value or characteristic root of square matrix A and the vector X is called eigen vector or characteristic vector of matrix A.

Now, from Eq. (i), we have

$$(A - \lambda I)\, X = O$$

Since, $X \neq O$, we deduce that the matrix $(A - \lambda I)$ is singular, so that its determinant is 0

i.e.

$$|A - \lambda I| = 0 \quad \text{...(ii)}$$

is called characteristic equation of matrix A.

If A be $n \times n$ matrix, then equation $|A - \lambda I| = 0$ reduces to polynomial equation of nth from degree in λ, which given n values of λ i.e., matrix A will have n characteristic roots or eigen values.

Important Properties of Eigen Values

(i) Any square matrix A and its transpose A^T have the same eigen values.

(ii) The sum of the eigen values of a matrix is equal to the trace of the matrix.

(iii) The product the eigen values of a matrix A is equal to the determinant of A.

(iv) If $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \ldots, \lambda_n$ are the eigen values of A, then the eigen values of

(a) kA are $k\lambda_1, k\lambda_2, k\lambda_3, k\lambda_4, \ldots, k\lambda_n$.

(b) A^m are $\lambda_1^m, \lambda_2^m, \lambda_3^m, \lambda_4^m, \ldots, \lambda_n^m$.

(c) A^{-1} are $\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \frac{1}{\lambda_3}, \frac{1}{\lambda_4}, \ldots, \frac{1}{\lambda_n}$.

Remark

1. All the eigen values of a real symmetric matrix are real and the eigen vectors corresponding to two distinct eigen values are orthogonal.
2. All the eigen values of a real skew-symmetric matrix are purely imaginary or zero. An odd order skew-symmetric matrix is singular and hence has zero as an eigen value.

Example 57. Let matrix $A = \begin{bmatrix} 4 & 6 & 6 \\ 1 & 3 & 2 \\ -1 & -4 & -3 \end{bmatrix}$, find the non-zero column vector X such that $AX = \lambda X$ for some scalar λ.

Sol. The characteristic equation is $|A - \lambda I| = 0$

$$\Rightarrow \quad \begin{bmatrix} 4-\lambda & 6 & 6 \\ 1 & 3-\lambda & 2 \\ -1 & -4 & -3-\lambda \end{bmatrix} = 0$$

$$\Rightarrow \quad \lambda^3 - 4\lambda^2 - \lambda + 4 = 0$$

or $\quad (\lambda + 1)(\lambda - 1)(\lambda - 4) = 0$

The eigen values are $\lambda = -1, 1, 4$

If $\lambda = -1$, we get $5x + 6y + 6z = 0$, $x + 4y + 2z = 0$

and $\quad -x - 4y - 2z = 0$

Giving $\quad \frac{x}{6} = \frac{y}{2} = \frac{z}{-7}$, $X = \begin{bmatrix} 6 \\ 2 \\ -7 \end{bmatrix}$

If $\lambda = 1$, we get $3x + 6y + 6z = 0$, $x + 2y + 2z = 0$

and $\quad -x - 4y - 4z = 0$

Giving, $\quad \frac{x}{0} = \frac{y}{1} = \frac{z}{-1}$, $X = \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix}$

If $\lambda = 4$, we get $0 \cdot x + 6y + 6z = 0$, $x - y + 2z = 0$

and $-x - 4y - 7z = 0$

Giving, $\quad \frac{x}{3} = \frac{y}{1} = \frac{3}{-1}$, $x = \begin{bmatrix} 3 \\ 1 \\ -1 \end{bmatrix}$

Hence, vector are $X = \begin{bmatrix} 6 \\ 2 \\ -7 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 3 \\ 1 \\ -1 \end{bmatrix}$.

Example 58. If A and P are the square matrices of the same order and if P be invertible, show that the matrices A and $P^{-1}AP$ have the same characteristic roots.

Sol. Let $\quad P^{-1}AP = B$

$$\therefore \quad |B - \lambda I| = |P^{-1}AP - \lambda I|$$

$$= |P^{-1}AP - P^{-1}\lambda P| \qquad [\because P^{-1}P = I]$$

$$= |P^{-1}(A - \lambda I)P|$$

$$= |P^{-1}||A - \lambda I||P|$$

$$= \frac{1}{|P|}|A - \lambda I||P| = |A - \lambda I|$$

Example 59. Show that the characteristic roots of an idempotent matrix are either zero or unity.

Sol. Let A be an idempotent matrix, then

$$A^2 = A \qquad \ldots(i)$$

If λ be an eigen value of the matrix A corresponding to eigen vector X, so that

$$AX = \lambda X \qquad \ldots(ii)$$

where $\quad X \neq 0$

From Eq. (ii), $\quad A(AX) = A(\lambda X)$

$\Rightarrow \quad (AA)X = \lambda(AX)$

$\Rightarrow \quad A^2X = \lambda(\lambda X)$ [from Eq. (ii)]

$\Rightarrow \quad AX = \lambda^2 X$ [from Eq. (i)]

$\Rightarrow \quad \lambda X = \lambda^2 X$ [from Eq. (ii)]

$\Rightarrow \quad (\lambda - \lambda^2)X = 0$

$\Rightarrow \quad \lambda - \lambda^2 = 0$ $[\because X \neq 0]$

$\therefore \quad \lambda = 0$

or $\quad \lambda = 1$

Example 60. If $3, -2$ are the eigen values of a non-singular matrix A and $|A| = 4$, find the eigen values of adj (A).

Sol. $\because A^{-1} = \frac{\text{adj } A}{|A|}$, if λ is eigen value of A, then λ^{-1} is eigen value of A^{-1}.

Thus, for adj $(A)X = (A^{-1}X)|A| = |A|\lambda^{-1}I$

Thus, eigen value corresponding to $\lambda = 3$ is $\frac{4}{3}$ and

corresponding to $\lambda = -2$ is $\frac{4}{-2} = -2$

Cayley-Hamilton Theorem

Every square matrix A satisfies its characteristic equation $|A - \lambda I| = 0$

i.e., $\quad a_0\lambda^n + a_1\lambda^{n-1} + a_2\lambda^{n-2} + \ldots + a_n = 0$

$\therefore$ By Cayley-Hamilton theorem

$$a_0A^n + a_1A^{n-1} + a_2A^{n-2} + \ldots + a_nI = O$$

$$\Rightarrow A^{-1} = -\left\{\frac{a_0}{a_n}A^{n-1} + \frac{a_1}{a_n}A^{n-2} + \frac{a_2}{a_n}A^{n-3} + \ldots + \frac{a_{n-1}}{a_n}I\right\}$$

Example 61. Find the characteristic equation of the matrix $A = \begin{bmatrix} 2 & 1 \\ 3 & 2 \end{bmatrix}$ and hence find its inverse using Cayley-hamilton theorem.

Sol. Characteristic equation is

$$|A - \lambda I| = 0 \Rightarrow \begin{bmatrix} 2-\lambda & 1 \\ 3 & 2-\lambda \end{bmatrix} = 0$$

$$\Rightarrow \quad (2-\lambda)^2 - 3 = 0$$

$$\Rightarrow \quad \lambda^2 - 4\lambda + 1 = 0$$

$\therefore$ By Cayley-hamilton theorem,

$$A^2 - 4A + I = O \text{ or } I = 4A - A^2$$

Multiplying by A^{-1}, we get

$$A^{-1} = 4A^{-1}A - A^{-1}AA$$

$$= 4I - IA = 4I - A$$

$$= 4\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - \begin{bmatrix} 2 & 1 \\ 3 & 2 \end{bmatrix}$$

$$= \begin{bmatrix} 2 & -1 \\ -3 & 2 \end{bmatrix}$$

Exercise for Session 4

1 If the system of equations $ax + y = 1, x + 2y = 3, 2x + 3y = 5$ are consistent, then a is given by

(a) 0 (b) 1 (c) 2 (d) None of these

2 The system of equations $x + y + z = 2, 2x + y - z = 3, 3x + 2y + \lambda z = 4$ has unique solution if

(a) $\lambda \neq 0$ (b) $-1 < \lambda < 1$ (c) $\lambda = 0$ (d) $-2 < \lambda < 2$

3 The value of a for which the following system of equations $a^3x + (a+1)^3y + (a+2)^3z = 0$, $ax + (a+1)y + (a+2)z = 0, x + y + z = 0$ has a non-trivial solution is equal to

(a) 2 (b) 1 (c) 0 (d) –1

4 The number of solutions of the set of equations

$\frac{2x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0, -\frac{x^2}{a^2} + \frac{2y^2}{b^2} - \frac{z^2}{c^2} = 0, -\frac{x^2}{a^2} - \frac{y^2}{b^2} + \frac{2z^2}{c^2} = 0$ is

(a) 6 (b) 7 (c) 8 (d) 9

5 The matrix $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ is the matrix reflection in the line

(a) $x = 1$ (b) $x + y = 1$ (c) $y = 1$ (d) $x = y$

6 The matrix S is rotation through an angle 45° and G is the reflection about the line $y = 2x$, then $(SG)^2$ is equal to

(a) $7I$ (b) $5I$ (c) $3I$ (d) I

7 If $A = \begin{bmatrix} -2 & 3 \\ -1 & 1 \end{bmatrix}$, then A^3 is equal to

(a) $2A$ (b) A (c) $2I$. (d) I

8 If $A = \begin{bmatrix} 2 & 2 & 1 \\ 1 & 3 & 1 \\ 1 & 2 & 2 \end{bmatrix}$ and the sum of eigen values of A is m and product of eigen values of A is n, then $m + n$ is equal to

(a) 10 (b) 12 (c) 14 (d) 16

9 If $A = \begin{bmatrix} 1 & 2 \\ -1 & 4 \end{bmatrix}$ and θ be the angle between the two non-zero column vectors X such that $AX = \lambda X$ for some scalar λ, then $9\sec^2\theta$ is equal to

(a) 13 (b) 12 (c) 11 (d) 10

Shortcuts And Important Results To Remember

1 $|A|$ exists $\Leftrightarrow$ A is square matrix.

2 No element of principal diagonal in a diagonal matrix is zero.

3 If A is a diagonal matrix of order n, then

(a) Number of zeroes in A is $n(n-1)$

(b) If $d_1, d_2, d_3, \ldots, d_n$ are diagonal elements, then

$$A = \text{diag}\{d_1, d_2, d_3, \ldots, d_n\}$$

and $$|A| = d_1 d_2 d_3 \ldots d_n$$

$$A^{-1} = \text{diag}(d_1^{-1}, d_2^{-1}, d_3^{-1}, \ldots, d_n^{-1})$$

(c) Diagonal matrix is both upper and lower triangular.

(d) $\text{diag}\{a_1, a_2, a_3, \ldots, a_n\} \times \text{diag}\{b_1, b_2, b_3, \ldots, b_n\}$

$$= \text{diag}\{a_1b_1, a_2b_2, a_3b_3, \ldots, a_nb_n\}$$

4 If $A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$, then $A^k = \begin{bmatrix} 1 & k \\ 0 & 1 \end{bmatrix}$ and $B^k = \begin{bmatrix} 1 & 0 \\ k & 1 \end{bmatrix}$, $\forall\, k \in N$.

5 If A and B are square matrices of order n, then

(a) $|kA| = k^n |A|$, k is scalar

(b) $|AB| = |A||B|$

(c) $|kAB| = k^n |A||B|$, k is scalar

(d) $|AB| = |BA|$

(e) $|A^T| = |A| = |A^\theta|$, where A^θ is conjugate transpose matrix of A

(f) $|A|^m = |A^m|$, $m \in N$

6 Minimum number of zeroes in a triangular matrix is given by $\frac{n(n-1)}{2}$, where n is order of matrix.

7 If A is a skew-symmetric matrix of odd order, then $|A| = 0$ and of even order is a non-zero perfect square.

8 If A is involutory matrix, then

(a) $|A| = \pm 1$

(b) $\frac{1}{2}(I + A)$ and $\frac{1}{2}(I - A)$ are idempotent and $\frac{1}{2}(I + A).\frac{1}{2}(I - A) = 0$

9 If A is orthogonal matrix, then $|A| = \pm 1$

10 To obtain an orthogonal matrix B from a skew-symmetric matrix A, then

$B = (I - A)^{-1}(I + A)$ or $B = (I - A)(I + A)^{-1}$

11 The sum of two orthogonal matrices is not orthogonal while the sum of two symmetric (skew-symmetric) matrices is symmetric (skew-symmetric)

12 The product of two orthogonal matrices is orthogonal while the product of two symmetric (skew-symmetric) matrices need not be symmetric (skew-symmetric)

13 The adjoint of a square matrix of order 2 can be easily obtained by interchanging the principal diagonal elements and changing the sign of the other diagonal.

i.e., If $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$, then $\text{adj}(A) = \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$

14 If $|A| \neq 0$, then $|A^{-1}| = \frac{1}{|A|}$.

15 If A and B are invertible matrices such that $AB = C$, then $|B| = \frac{|C|}{|A|}$.

16 Commutative law does not necessarily hold for matrices.

17 If $AB = -BA$, then matrices A and B are called anti-commutative matrices.

18 If $AB = O$, it is not necessary that atleast one of the matrix should be zero matrix.

For example, If $A = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & 0 \\ 0 & 0 \end{bmatrix}$, then $AB = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ while neither A nor B is the null matrix.

19 If A, B and C are invertible matrices, then

(a) $(AB)^{-1} = B^{-1}A^{-1}$

(b) $(ABC)^{-1} = C^{-1}B^{-1}A^{-1}$

20 If B is a non-singular matrix and A is any square matrix, then $\det(B^{-1}AB) = \det(A)$

21 If A is a non-singular square matrix of order n, then $\text{adj}(\text{adj } A) = |A|^{n-2} A$

22 If A is a non-singular square matrix of order n, then

$$\underbrace{|\text{adj}(\text{adj}(\text{adj} \ldots (\text{adj}(\text{adj } A))))|}_{m \text{ times}} = |A|^{(n-1)^m}$$

23 If $A = \begin{bmatrix} 0 & \alpha \\ 0 & 0 \end{bmatrix}$; $A^m = O$, $\forall\, m \geq 2$

$\therefore \quad (A + I)^n = I + nA$

24 If A and B are two symmetric matrices, then $A \pm B$, $AB + BA$ are symmetric matrices and $AB - BA$ is a skew-symmetric matrix.

25 If A and B are two square matrices of order n and λ be a scalar, then

(i) $\text{Tr}(\lambda A) = \lambda \text{Tr}(A)$

(ii) $\text{Tr}(A \pm B) = \text{Tr}(A) \pm \text{Tr}(B)$

(iii) $\text{Tr}(AB) = \text{Tr}(BA)$

(iv) $\text{Tr}(A) = \text{Tr}(A')$

(v) $\text{Tr}(I_n) = n$

(vi) $\text{Tr}(O) = 0$

(vii) $\text{Tr}(AB) \neq \text{Tr}(A) \cdot \text{tr}(B)$

contd...

26 If rank of a matrix A is denoted by $\rho(A)$, then

(i) $\rho(A) = 0$, if A is zero matrix.

(ii) $\rho(A) = 1$, if every element of A is same.

(iii) If A and B are square matrices of order n each and $\rho(A) = \rho(B) = n$, then $\rho(AB) = n$

(iv) If A is a square matrix of order n and $\rho(A) = n - 1$, then $\rho(\text{adj } A) = 1$ and if $\rho(A) < n - 1$, then $\rho(\text{adj } A) = 0$

27 System of planes

$$a_{11}x + a_{12}y + a_{13}z = b_1,$$

$$a_{21}x + a_{22}y + a_{23}z = b_2$$

and $$a_{31}x + a_{32}y + a_{33}z = b_3$$

Augmented matrix $C = [A : B]$ and if Rank of $A = r$ and Rank of $C = s$, then

(i) If $r = s = 1$, then planes are coincident

(ii) If $r = 1$, $s = 2$, then planes are parallel

(iii) If $r = s = 2$, then planes intersect along a single straight line

(iv) If $r = 2$, $s = 3$, then planes form a triangular prism

(v) If $r = s = 3$, then planes meet at a single point

28 If P is an orthogonal matrix, then $\det(P) = \pm 1$

(i) P represents a reflection about a line, then $\det(P) = -1$.

(ii) P represents a rotation about a point, then $\det(P) = 1$.

29 **Cayley-Hamilton Theorem** : Every matrix satisfies its characteristic equation.

For Example, Let A be a square matrix, then $|A - \lambda I| = 0$ is the characteristic equation for A.

If $\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$ is the characteristic equation for A, then $A^3 - 6A^2 + 11A - 6I = O$. Roots of characteristic equation for A are called eigen values of A or characteristic roots of A or latent roots of A. If λ is a characteristic root of A, then λ^{-1} is characteristic root of A^{-1}.

JEE Type Solved Examples :
Single Option Correct Type Questions

▪ This section contains **10 multiple choice examples.** Each example has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

● ***Ex. 1*** *If A is a square matrix of order 2 such that $A\begin{bmatrix}1\\-1\end{bmatrix}=\begin{bmatrix}-1\\2\end{bmatrix}$ and $A^2\begin{bmatrix}1\\-1\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}$. The sum of elements and product of elements of A are S and P, then $S+P$ is*

(a) -1 (b) 2 (c) 4 (d) 5

Sol. (*d*) Let $A=\begin{bmatrix}a & b\\ c & d\end{bmatrix}$

From first part, $A\begin{bmatrix}1\\-1\end{bmatrix}=\begin{bmatrix}-1\\2\end{bmatrix}$ ...(i)

$\Rightarrow$ $\begin{bmatrix}a & b\\ c & d\end{bmatrix}\begin{bmatrix}1\\-1\end{bmatrix}=\begin{bmatrix}-1\\2\end{bmatrix}$

or $a-b=-1$ ...(ii)

and $c-d=2$ ...(iii)

From second part,

$$A^2\begin{bmatrix}1\\-1\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}\Rightarrow A\left(A\begin{bmatrix}1\\-1\end{bmatrix}\right)=\begin{bmatrix}1\\0\end{bmatrix}$$

From Eq. (i), we get

$$A\begin{bmatrix}-1\\2\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}\Rightarrow\begin{bmatrix}a & b\\ c & d\end{bmatrix}\begin{bmatrix}-1\\2\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}$$

or $-a+2b=1$ ...(iv)

and $-c+2d=0$ ...(v)

From Eqs. (ii) and (iv), we get

$$a=-1,\ b=0$$

and from Eqs. (iii) and (v), we get

$$c=4,\ d=2$$

$\therefore$ $S=a+b+c+d=5$

and $P=abcd=0$

Hence, $S+P=5$

● ***Ex. 2*** *If P is an orthogonal matrix and $Q=PAP^T$ and $B=P^TQ^{1000}P$, then B^{-1} is, where A is involutory matrix*

(a) A (b) A^{1000} (c) I (d) None of these

Sol. (*c*) Given, P is orthogonal

$\therefore$ $P^TP=I$ ...(i)

and $Q=PAP^T$ ...(ii)

Now, $B=P^TQ^{1000}P=P^T(PAP^T)^{1000}P$ [from Eq. (ii)]

$$=P^TPAP^T(PAP^T)^{999}P$$
$$=IAP^T\cdot PAP^T(PAP^T)^{998}P$$
$$=AIAP^T(PAP^T)^{998}P$$
$$=A^2P^TPAP^T(PAP^T)^{997}P$$
$$=A^2IAP^T(PAP^T)^{997}P$$
$$=A^3P^T(PAP^T)^{997}P$$
$$\ldots\quad\ldots\quad\ldots$$
$$=A^{1000}P^TP=A^{1000}=I\quad[\because A\text{ is involutory}]$$

Hence, $B^{-1}=I^{-1}=I$

● ***Ex. 3*** *If A is a diagonal matrix of order 3×3 is commutative with every square matrix of order 3×3 under multiplication and trace $(A)=12$, then*

(a) $|A|=64$ (b) $|A|=16$

(c) $|A|=12$ (d) $|A|=4$

Sol. (*a*) A diagonal matrix is commutative with every square matrix, if it is scalar matrix so every diagonal element is 4.

$\therefore$ $A=\begin{bmatrix}4 & 0 & 0\\ 0 & 4 & 0\\ 0 & 0 & 4\end{bmatrix}$

$\Rightarrow$ $|A|=4\cdot4\cdot4=64$

● ***Ex. 4*** *If $A=[a_{ij}]_{4\times4}$, such that $a_{ij}=\begin{cases}2, & \text{when } i=j\\ 0, & \text{when } i\neq j\end{cases}$, then $\left\{\dfrac{\det(\text{adj}(\text{adj}\,A))}{7}\right\}$ is [when $\{\cdot\}$ represents fractional part function]*

(a) $\frac{1}{7}$ (b) $\frac{2}{7}$ (c) $\frac{3}{7}$ (d) $\frac{4}{7}$

Sol. (*a*) $\because$ $A=\begin{bmatrix}2 & 0 & 0 & 0\\ 0 & 2 & 0 & 0\\ 0 & 0 & 2 & 0\\ 0 & 0 & 0 & 2\end{bmatrix}$

$\therefore$ $|A|=\begin{vmatrix}2 & 0 & 0 & 0\\ 0 & 2 & 0 & 0\\ 0 & 0 & 2 & 0\\ 0 & 0 & 0 & 2\end{vmatrix}=2^4=16$

$\because$ $\det(\text{adj}(\text{adj}\,A))=|\text{adj}(\text{adj}\,A)|=|A|^{3^2}=|A|^9$

$$=(2^4)^9=2^{36}=(2^3)^{12}=(1+7)^{12}$$
$$=1+{}^{12}C_1(7)+{}^{12}C_2(7)^2+\ldots$$

$$\frac{\det(\text{adj}(\text{adj}\,A))}{7}=\frac{1}{7}+\text{Positive integer}$$

$\therefore$ $\left\{\dfrac{\det(\text{adj}(\text{adj}\,A))}{7}\right\}=\dfrac{1}{7}$

● ***Ex. 5*** *If* $A=\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix}$ *and* $\det(A^n - I) = 1-\lambda^n$, $n \in N$, *then the value of* λ, *is*

(a) 1 (b) 2 (c) 3 (d) 4

Sol. (*b*) $\because$ $A=\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix}$

$\therefore$ $A^2=\begin{bmatrix}2 & 2\\ 2 & 2\end{bmatrix}=2\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix}=2A$

$\Rightarrow$ $A^3 = A^2 \cdot A = 2A^2 = 2^2 A$

Similarly, $A^n = 2^{n-1}A$

$\therefore$ $A^n - I = \begin{bmatrix}2^{n-1} & 2^{n-1}\\ 2^{n-1} & 2^{n-1}\end{bmatrix} - \begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}$

$$= \begin{bmatrix}2^{n-1}-1 & 2^{n-1}\\ 2^{n-1} & 2^{n-1}-1\end{bmatrix}$$

$\Rightarrow$ $\det(A^n - I) = (2^{n-1}-1)^2 - (2^{n-1})^2$

$= 1 - 2^n = 1 - \lambda^n$ [given]

$\therefore$ $\lambda = 2$

● ***Ex. 6*** *If* $A=\begin{bmatrix}1 & 2\\ 2 & 1\end{bmatrix}$ *and* $f(x)=\dfrac{1+x}{1-x}$, *then* $f(A)$ *is*

(a) $\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix}$ (b) $\begin{bmatrix}2 & 2\\ 2 & 2\end{bmatrix}$

(c) $\begin{bmatrix}-1 & -1\\ -1 & -1\end{bmatrix}$ (d) None of these

Sol. (*c*) $\because$ $f(x)=\dfrac{1+x}{1-x}$

$\Rightarrow$ $(1-x)f(x) = 1+x$

$\Rightarrow$ $(I-A)f(A) = (I+A)$

$\Rightarrow$ $f(A) = (I-A)^{-1}(I+A)$

$$= \left(\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} - \begin{bmatrix}1 & 2\\ 2 & 1\end{bmatrix}\right)^{-1}\left(\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix} + \begin{bmatrix}1 & 2\\ 2 & 1\end{bmatrix}\right)$$

$$= \begin{bmatrix}0 & -2\\ -2 & 0\end{bmatrix}^{-1}\begin{bmatrix}2 & 2\\ 2 & 2\end{bmatrix} = -\frac{1}{4}\begin{bmatrix}0 & 2\\ 2 & 0\end{bmatrix}\begin{bmatrix}2 & 2\\ 2 & 2\end{bmatrix}$$

$$= -\frac{1}{4}\begin{bmatrix}4 & 4\\ 4 & 4\end{bmatrix} = \begin{bmatrix}-1 & -1\\ -1 & -1\end{bmatrix}$$

● ***Ex. 7*** *The number of solutions of the matrix equation* $X^2=\begin{bmatrix}1 & 1\\ 2 & 3\end{bmatrix}$ *is*

(a) more than 2 (b) 2

(c) 0 (d) 1

Sol. (*a*) Let $X=\begin{bmatrix}a & b\\ c & d\end{bmatrix}$

$\therefore$ $X^2=\begin{bmatrix}a^2+bc & b(a+d)\\ c(a+d) & bc+d^2\end{bmatrix}=\begin{bmatrix}1 & 1\\ 2 & 3\end{bmatrix}$ [given]

$\Rightarrow$ $a^2 + bc = 1, b(a+d) = 1,$

$c(a+d) = 2$ and $bc + d^2 = 3$

$\Rightarrow$ $d^2 - a^2 = 2$

$\Rightarrow$ $d - a = \dfrac{2}{d+a} = 2b$ and $d + a = \dfrac{1}{b}$

$\therefore$ $2d = 2b + \dfrac{1}{b}$ and $2a = \dfrac{1}{b} - 2b$

Also, $c = 2b$

Now, from $bc + d^2 = 3$

$\Rightarrow$ $2b^2 + \left(b + \dfrac{1}{2b}\right)^2 = 3 \Rightarrow 3b^2 + \dfrac{1}{4b^2} - 2 = 0$

$\Rightarrow$ $12b^4 - 8b^2 + 1 = 0$

or $(6b^2 - 1)(2b^2 - 1) = 0$

$\Rightarrow$ $b = \pm\dfrac{1}{\sqrt{6}}$ or $b = \pm\dfrac{1}{\sqrt{2}}$

Therefore, matrices are

$$\begin{bmatrix}0 & \frac{1}{\sqrt{2}}\\ \sqrt{2} & \sqrt{2}\end{bmatrix}, \begin{bmatrix}0 & -\frac{1}{\sqrt{2}}\\ -\sqrt{2} & -\sqrt{2}\end{bmatrix}, \begin{bmatrix}\frac{2}{\sqrt{6}} & \frac{1}{\sqrt{6}}\\ \frac{2}{\sqrt{6}} & \frac{4}{\sqrt{6}}\end{bmatrix} \text{ and } \begin{bmatrix}-\frac{2}{\sqrt{6}} & -\frac{1}{\sqrt{6}}\\ -\frac{2}{\sqrt{6}} & -\frac{4}{\sqrt{6}}\end{bmatrix}.$$

● ***Ex. 8*** *For a matrix* $A=\begin{bmatrix}1 & 2r-1\\ 0 & 1\end{bmatrix}$, *the value of* $\prod_{r=1}^{50}\begin{bmatrix}1 & 2r-1\\ 0 & 1\end{bmatrix}$ *is equal to*

(a) $\begin{bmatrix}1 & 100\\ 0 & 1\end{bmatrix}$ (b) $\begin{bmatrix}1 & 4950\\ 0 & 1\end{bmatrix}$ (c) $\begin{bmatrix}1 & 5050\\ 0 & 1\end{bmatrix}$ (d) $\begin{bmatrix}1 & 2500\\ 0 & 1\end{bmatrix}$

Sol. (*d*) $\prod_{r=1}^{50}\begin{bmatrix}1 & 2r-1\\ 0 & 1\end{bmatrix}=\begin{bmatrix}1 & 1+3+5+\ldots+99\\ 0 & 1\end{bmatrix}$

$$=\begin{bmatrix}1 & (50)^2\\ 0 & 1\end{bmatrix}=\begin{bmatrix}1 & 2500\\ 0 & 1\end{bmatrix}$$

● ***Ex. 9*** *If* $A_1, A_2, A_3, \ldots, A_{2n-1}$ *are n skew-symmetric matrices of same order, then* $B=\sum_{r=1}^{n}(2r-1)(A_{2r-1})^{2r-1}$ *will be*

(a) symmetric
(b) skew-symmetric
(c) neither symmetric nor skew-symmetric
(d) data not adequate

Sol. $(b)\ \because\ B = A_1 + 3A_3^3 + 5A_5^5 + \ldots + (2n-1)(A_{2n-1})^{2n-1}$

$$\therefore\ B^T = (A_1 + 3A_3^3 + 5A_5^5 + \ldots + (2n-1)(A_{2n-1})^{2n-1})^T$$

$$= A_1^T + 3(A_3^T)^3 + 5(A_5^T)^5 + \ldots + (2n-1)(A_{2n-1}^T)^{2n-1}$$

$$= -A_1 + 3(-A_3)^3 + 5(-A_5)^5 + \ldots + (2n-1)(-A_{2n-1})^{2n-1}$$

$$= -(A_1 + 3A_3^3 + 5A_5^5 + \ldots + (2n-1)A_{2n-1}^{2n-1})$$

$$= -B$$

Hence, B is skew-symmetric.

● ***Ex. 10*** *Elements of a matrix A of order* 10×10 *are defined as* $a_{ij} = \omega^{i+j}$ *(where* ω *is cube root of unity), then trace* (A) *of the matrix is*

(a) 0 (b) 1 (c) 3 (d) None of these

Sol. $(d)\ \text{tr}(A) = \sum_{i=j=1}^{10} a_{ij} = \sum_{i=j=1}^{10} \omega^{i+j} = \sum_{i=1}^{10} \omega^{2i}$

$$= \omega^2 + \omega^4 + \omega^6 + \omega^8 + \ldots + \omega^{20}$$

$$= (\omega^2 + \omega + 1) + (\omega^2 + \omega + 1) + (\omega^2 + \omega + 1) + \omega^{20}$$

$$= 0 + 0 + 0 + \omega^2 = \omega^2$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **5 multiple choice examples.** Each example has four choices (a), (b), (c) and (d) out of **which more than one** may be correct.

● ***Ex. 11*** *If* $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ *(where* $bc \neq 0$*) satisfies the equations* $x^2 + k = 0$*, then*

(a) $a + d = 0$ (b) $k = -|A|$

(c) $k = |A|$ (d) None of these

Sol. (a, c) We have, $A^2 = \begin{bmatrix} a & b \\ c & d \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} a^2 + bc & ab + bd \\ ac + cd & bc + d^2 \end{bmatrix}$

As A satisfies $x^2 + k = 0$, therefore

$$A^2 + kI = 0$$

$$\Rightarrow \quad \begin{bmatrix} a^2 + bc + k & (a+d)b \\ (a+d)c & bc + d^2 + k \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

$$\Rightarrow \quad a^2 + bc + k = 0, (a+d)b = 0,$$

$$(a+d)c = 0 \text{ and } bc + d^2 + k = 0$$

As $bc \neq 0 \Rightarrow b \neq 0, c \neq 0$

So, $a + d = 0 \ \Rightarrow\ a = -d$

Also, $k = -(a^2 + bc) = -(-ad + bc) = (ad - bc) = |A|$

● ***Ex. 12*** *If* $A = [a_{ij}]_{n \times n}$ *and f is a function, we define* $f(A) = [f(a_{ij})]_{n \times n}$*. Let* $A = \begin{bmatrix} \frac{\pi}{2} - \theta & \theta \\ -\theta & \frac{\pi}{2} - \theta \end{bmatrix}$*, then*

(a) $\sin A$ is invertible (b) $\sin A = \cos A$

(c) $\sin A$ is orthogonal (d) $\sin 2A = 2 \sin A \cos A$

Sol. $(a, c)\ \ \sin A = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$ and $\cos\theta = \begin{bmatrix} \sin\theta & \cos\theta \\ \cos\theta & \sin\theta \end{bmatrix}$

$$\therefore \quad |\sin A| = \cos^2\theta + \sin^2\theta = 1 \neq 0$$

Hence, $\sin A$ is invertible.

$$\text{Also, } (\sin A)(\sin A)^T = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I$$

Hence, $\sin A$ is orthogonal.

$$\text{Also, } 2\sin A \cos A = 2\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} \sin\theta & \cos\theta \\ \cos\theta & \sin\theta \end{bmatrix}$$

$$= 2\begin{bmatrix} \sin 2\theta & 1 \\ \cos 2\theta & 0 \end{bmatrix} \neq \sin 2A$$

● ***Ex. 13*** *Let A and B are two square idempotent matrices such that* $AB \pm BA$ *is a null matrix, the value of* $\det(A - B)$ *can be equal*

(a) -1 (b) 0

(c) 1 (d) 2

Sol. (a, b, c)

$$\because (A - B)^2 = A^2 - AB - BA + B^2$$

$$= A + B \qquad [\because AB + BA = 0 \text{ and } A^2 = A, B^2 = B]$$

$$\therefore \quad |A - B|^2 = |A + B| \qquad \ldots(i)$$

$$\text{and } (A + B)^2 = A^2 + AB + BA + B^2$$

$$= A + B \quad [\because AB + BA = 0 \text{ and } A^2 = A, B^2 = B]$$

$$\Rightarrow \quad |A + B|^2 = |A + B|$$

$$\Rightarrow \quad |A + B|(|A + B| - 1) = 0$$

$$\therefore \quad |A + B| = 0, 1$$

From Eq. (i),

$$|A-B|^2 = 0, 1 \Rightarrow |A-B| = 0, \pm 1$$

or $$\det(A-B) = 0, -1, 1$$

● ***Ex. 14*** *If $AB = A$ and $BA = B$, then*

(a) $A^2B = A^2$ (b) $B^2A = B^2$

(c) $ABA = A$ (d) $BAB = B$

Sol. (*a, b, c, d*)

We have, $A^2B = A(AB) = A \cdot A = A^2$,

$B^2A = B(BA) = BB = B^2$,

$ABA = A(BA) = AB = A$, $BAB = B(AB) = BA = B$

● ***Ex. 15*** *If A is a square matrix of order 3 and I is an Identity matrix of order 3 such that $A^3 - 2A^2 - A + 2I = 0$, then A is equal to*

(a) I (b) $2I$ (c) $\begin{bmatrix} 2 & -1 & 2 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$ (d) $\begin{bmatrix} 2 & 1 & -2 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$

Sol. (*a, b, d*) It is clear that $A = I$ and $A = 2I$ satisfy the given equaion $A^3 - 2A^2 - A + 2I = 0$ and the characteristic equation of the matrix in (c) is

$$\begin{vmatrix} 2-\lambda & -1 & 2 \\ 1 & -\lambda & 0 \\ 0 & 1 & -\lambda \end{vmatrix} = 0$$

$$\Rightarrow \quad \lambda^3 - 2\lambda^2 + \lambda - 2 = 0,$$

giving $$A^3 - 2A^2 + A - 2I = 0$$

$$\neq A^3 - 2A^2 - A + 2I = 0$$

and the characteristic equation of the matrix in (d) is

$$\begin{vmatrix} 2-\lambda & 1 & -2 \\ 1 & -\lambda & 0 \\ 0 & 1 & -\lambda \end{vmatrix} = 0$$

$$\Rightarrow \quad \lambda^3 - 2\lambda^2 - \lambda + 2 = 0,$$

giving $$A^3 - 2A^2 - A + 2I = 0$$

JEE Type Solved Examples : Passage Based Questions

■ This section contains **2 solved passages**. Base upon each of the passage **3 multiple choice question** have to be answered. Each of these question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I

(Ex. Nos. 16 to 18)

If $A_0 = \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix}$ and $B_0 = \begin{bmatrix} -4 & -3 & -3 \\ 1 & 0 & 1 \\ 4 & 4 & 3 \end{bmatrix}$ and

$B_n = \text{adj}(B_{n-1}), n \in N$ and I is an identity matrix of order 3.

16. $\det(A_0 + A_0^2 B_0^2 + A_0^3 + A_0^4 B_0^4 + \ldots$ upto 12 terms) is equal to

(a) 1200 (b) −960

(c) 0 (d) −9600

17. $B_2 + B_3 + B_4 + \ldots + B_{50}$ is equal to

(a) B_0 (b) $7B_0$

(c) $49B_0$ (d) $49I$

18. For a variable matrix X, the equation $A_0 X = B_0$ will have

(a) unique solution

(b) infinite solution

(c) finitely many solution

(d) no solution

Sol. (Ex. Nos 16 to 18)

$$\because \quad A_0 = \begin{bmatrix} 2 & -2 & -4 \\ -1 & 3 & 4 \\ 1 & -2 & -3 \end{bmatrix} \Rightarrow |A_0| = 0$$

and $$\text{adj}\, B_0 = \begin{bmatrix} -4 & 1 & 4 \\ -3 & 0 & 4 \\ -3 & 1 & 3 \end{bmatrix}^T = \begin{bmatrix} -4 & -3 & -3 \\ 1 & 0 & 1 \\ 4 & 4 & 3 \end{bmatrix} = B_0$$

$$\because \quad B_n = \text{adj}(B_{n-1}), n \in N$$

$$\therefore \quad B_1 = \text{adj}(B_0) = B_0$$

$$\Rightarrow \quad B_2 = \text{adj}(B_1) = \text{adj}(B_0) = B_0,$$

Similarly $B_3 = B_0, B_4 = B_0, \ldots$

$$\therefore \quad B_n = B_0 \ \forall\ n \in N$$

16. (*c*) $\det(A_0 + A_0^2 B_0^2 + A_0^3 + A_0^4 B_0^4 + \ldots$ upto 12 terms) $= \det$

$\{A_0 (I + A_0 B_0^2 + A_0^2 + A_0^3 B_0^4 + \ldots \text{upto} 12 \text{ terms})\}$

$= |A_0|(I + A_0 B_0^2 + A_0^2 + A_0^3 B_0^4 + \ldots$ upto 12 terms)

$= 0 \qquad [\because |A_0| = 0]$

17. (*c*) $B_2 + B_3 + B_4 + \ldots + B_{50} = B_0 + B_0 + B_0 + \ldots + B_0 = 49B_0$

18. (*d*) $\because |A_0| = 0$

$\Rightarrow$ A_0^{-1} is not possible.

Hence, system of equation $A_0 X = B_0$ has no Sol.

Passage II
(Ex. Nos. 19 to 21)

Let $A=\begin{bmatrix}1&0&0\\1&0&1\\0&1&0\end{bmatrix}$ satisfies $A^n=A^{n-2}+A^2-I$ for $n\geq 3$ and consider a matrix $\underset{3\times 3}{U}$ with its columns as U_1, U_2, U_3, such that

$$A^{50}U_1=\begin{bmatrix}1\\25\\25\end{bmatrix},\ A^{50}U_2=\begin{bmatrix}0\\1\\0\end{bmatrix} \text{ and } A^{50}U_3=\begin{bmatrix}0\\0\\1\end{bmatrix}$$

19. The value of $|A^{50}|$ equals

(a) -1 (b) 0 (c) 1 (d) 25

20. Trace of A^{50} equals

(a) 0 (b) 1 (c) 2 (d) 3

21. The value of $|U|$ equals

(a) -1 (b) 0 (c) 1 (d) 2

Sol. (Ex. Nos. 19 to 21)

$\because \quad A^n=A^{n-2}+A^2-I \Rightarrow A^{50}=A^{48}+A^2-I$

Further, $A^{48}=A^{46}+A^2-I$

$A^{46}=A^{44}+A^2-I$

$\vdots \quad \vdots \quad \vdots \quad \vdots$

$A^4=A^2+A^2-I^4$

On adding all, we get

$$A^{50}=25A^2-24I \qquad ...(i)$$

19. (*c*) $|A^{50}|=|A|^{50}=\begin{vmatrix}1&0&0\\1&0&1\\0&1&0\end{vmatrix}^{50}=(-1)^{50}=1$

20. (*d*) $\because A^2=\begin{bmatrix}1&0&0\\1&0&1\\0&1&0\end{bmatrix}\begin{bmatrix}1&0&0\\1&0&1\\0&1&0\end{bmatrix}=\begin{bmatrix}1&0&0\\1&1&0\\1&0&1\end{bmatrix}$

$$\therefore\ A^{50}=25A^2-24I=\begin{bmatrix}25&0&0\\25&25&0\\25&0&25\end{bmatrix}-\begin{bmatrix}24&0&0\\0&24&0\\0&0&24\end{bmatrix}$$ [from Eq. (i)]

$$=\begin{bmatrix}1&0&0\\25&1&0\\25&0&1\end{bmatrix} \qquad ...(ii)$$

Hence, trace of $A^{50}=1+1+1=3$

21. (*c*) Let $U_1=\begin{bmatrix}x\\y\\z\end{bmatrix}$

Given, $A^{50}U_1=\begin{bmatrix}1\\25\\25\end{bmatrix}\Rightarrow\begin{bmatrix}1&0&0\\25&1&0\\25&0&1\end{bmatrix}\begin{bmatrix}x\\y\\z\end{bmatrix}=\begin{bmatrix}1\\25\\25\end{bmatrix}$ [from Eq. (ii)]

$\Rightarrow \begin{bmatrix}x\\25x+y\\25x+z\end{bmatrix}=\begin{bmatrix}1\\25\\25\end{bmatrix}$, we get $x=1, y=20$ and $z=0$

$\therefore \quad U_1=\begin{bmatrix}1\\0\\0\end{bmatrix}$, similarly $U_2=\begin{bmatrix}0\\1\\0\end{bmatrix}$

and $U_3=\begin{bmatrix}0\\0\\1\end{bmatrix} \Rightarrow U=\begin{bmatrix}1&0&0\\0&1&0\\0&0&1\end{bmatrix}=I$

$\therefore \quad |U|=1$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **2 examples.** The answer to each example is a **single digit integer** ranging from **0** to **9** (both inclusive).

● ***Ex. 22*** *Let A be a* 3×3 *diagonal matrix which commutes with every* 3×3 *matrix. If* $\det(A)=8$*, then tr A is*

Sol. (6) Let $A=\begin{bmatrix}\alpha&0&0\\0&\beta&0\\0&0&\gamma\end{bmatrix}$

$$\therefore\ \begin{bmatrix}\alpha&0&0\\0&\beta&0\\0&0&\gamma\end{bmatrix}\begin{bmatrix}a&h&g\\h&b&f\\g&f&c\end{bmatrix}=\begin{bmatrix}a&h&g\\h&b&f\\g&f&c\end{bmatrix}\begin{bmatrix}\alpha&0&0\\0&\beta&0\\0&0&\gamma\end{bmatrix}$$

$\Rightarrow \quad \alpha=\beta=\gamma$

$\therefore \quad A=\begin{bmatrix}\alpha&0&0\\0&\alpha&0\\0&0&\alpha\end{bmatrix}$

$\Rightarrow \quad \det(A)=\alpha^3=8$ [given]

$\therefore \quad \alpha=2$

$\therefore \quad A=\begin{bmatrix}2&0&0\\0&2&0\\0&0&2\end{bmatrix}$

$\Rightarrow \quad \text{tr } A=2+2+2=6$

● ***Ex. 23*** *Let A and B be two non-singular matrices such that $A \neq I$, $B^3 = I$ and $AB = BA^2$, where I is the identity matrix, the least value of k such that $A^k = I$ is*

Sol. (7) Given, $AB = BA^2 \Rightarrow B = A^{-1}BA^2 \Rightarrow B^3 = I$

$\Rightarrow (A^{-1}BAA)(A^{-1}BAA)(A^{-1}BAA) = I$

$\Rightarrow (A^{-1}BA)(BA)(BAA) = I \quad [\because A^{-1}A = I]$

$\Rightarrow A^{-1}B(AB)(AB)AA = I$

$\Rightarrow A^{-1}B(BA^2)(BA^2)AA = I \quad [\because AB = BA^2]$

$\Rightarrow A^{-1}BBA(AB)A^4 = I$

$\Rightarrow A^{-1}BBA(BA^2)A^4 = I \quad [\because AB = BA^2]$

$\Rightarrow A^{-1}BB(AB)A^6 = I$

$\Rightarrow A^{-1}BB(BA^2)A^6 = I \quad [\because AB = BA^2]$

$\Rightarrow A^{-1}B^3A^8 = I$

$\Rightarrow (A^{-1}I)A^8 = I \quad . \quad [\because B^3 = I]$

$\Rightarrow A^{-1}A^8 = I$

$\Rightarrow A^7 = I = A^k \quad [\because A^k = I]$

$\Rightarrow A^k = A^7$

$\therefore$ Least value of k is 7.

JEE Type Solved Examples : Matching Type Questions

■ This section contains **2 examples.** Example 24 have three statements (A, B and C) given in **Column I** and four statements (p, q, r and s) in **Column II** and example 25 have three statements (A, B and C) given in **Column I** and five statements (p, q, r, s and t). In **Column II** any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II.**

● ***Ex. 24***

	Column I		Column II
(A)	If A is a square matrix of order 3 and $\det(A) = 3$, then $\det(6A^{-1})$ is divisible by	(p)	3
(B)	If A is a square matrix of order 3 and $\det(A) = \frac{1}{4}$, then det [adj (adj (2A))] is divisible by	(q)	4
(C)	If A and B are square matrices of odd order and $(A+B)^2 = A^2 + B^2$, if det $(A) = 2$, then det(B) is divisible by	(r)	5
		(s)	6

Sol. (A) → (p, q, s); (B) →(q); (C) →(p, q, r, s)

(A) $\det(6A^{-1}) = 6^3 \det(A^{-1}) = \dfrac{216}{\det(A)} = \dfrac{216}{3} = 72$

(B) $\det[\text{adj (adj } (2A))] = [\det(2A)]^4 = [2^3 \det(A)]^4$

$= 2^{12}[\det(A)]^4$

$= 2^{12}\left(\dfrac{1}{4}\right)^4 = 2^4 = 16$

(C) $\because \quad (A+B)^2 = A^2 + AB + BA + B^2$

$\Rightarrow A^2 + B^2 = A^2 + AB + BA + B^2 \quad [\because (A+B)^2 = A^2 + B^2]$

$\Rightarrow AB + BA = O \Rightarrow AB = -BA$

$\therefore \det(AB) = \det(-BA) = -\det(BA)$

$\Rightarrow \det(A)\cdot\det(B) = -\det(B)\cdot\det(A)$

$\Rightarrow 2\det(A)\cdot\det(B) = 0 \Rightarrow 4\det(B) = 0 \quad [\because \det(A) = 2]$

$\therefore \det(B) = 0$

● ***Ex. 25***

	Column I		Column II
(A)	If $\begin{bmatrix}1 & 2 & a\\ 0 & 1 & 4\\ 0 & 0 & 1\end{bmatrix}^n = \begin{bmatrix}1 & 18 & 2007\\ 0 & 1 & 36\\ 0 & 0 & 1\end{bmatrix}$, then $(n+a)$ is divisible by	(p)	4
(B)	If A is a square matrix of order 3 such that $\lvert A\rvert = a$, $B = \text{adj}(A)$ and $\lvert B\rvert = b$, then $(ab^2 + a^2b + 1)\lambda$ is divisible by, where $\frac{1}{2}\lambda = \frac{a}{b} + \frac{a^2}{b^3} + \frac{a^3}{b^5} + \ldots$ upto ∞ and $a = 3$	(q)	6
(C)	Let $A = \begin{bmatrix}a & b & c\\ p & q & r\\ 1 & 1 & 1\end{bmatrix}$ and $B = A^2$. If $(a-b)^2 + (p-q)^2 = 25$, $(b-c)^2 + (q-r)^2 = 36$ and $(c-a)^2 + (r-p)^2 = 49$, then det $\left(\frac{B}{2}\right)$ is divisible by	(r)	10
		(s)	12
		(t)	15

Sol. (A) → (p, r); (B) →(t); (C) → (q, s)

(A) $\because \quad A = \begin{bmatrix}1 & 2 & a\\ 0 & 1 & 4\\ 0 & 0 & 1\end{bmatrix}$

$\therefore \quad A^2 = \begin{bmatrix}1 & 2 & a\\ 0 & 1 & 4\\ 0 & 0 & 1\end{bmatrix}\begin{bmatrix}1 & 2 & a\\ 0 & 1 & 4\\ 0 & 0 & 1\end{bmatrix} = \begin{bmatrix}1 & 4 & 2a+8\\ 0 & 1 & 8\\ 0 & 0 & 1\end{bmatrix}$

$$\Rightarrow \quad A^3 = \begin{bmatrix} 1 & 4 & 2a+8 \\ 0 & 1 & 8 \\ 0 & 0 & 1 \end{bmatrix}\begin{bmatrix} 1 & 2 & a \\ 0 & 1 & 4 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 6 & 3a+24 \\ 0 & 1 & 12 \\ 0 & 0 & 1 \end{bmatrix}$$

Similarly, we get

$$A^n = \begin{bmatrix} 1 & 2n & na + 8\sum_{r=0}^{n-1} r \\ 0 & 1 & 4n \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 18 & 2007 \\ 0 & 1 & 36 \\ 0 & 0 & 1 \end{bmatrix} \text{ [given]}$$

$\Rightarrow \quad 2n = 18 \Rightarrow n = 9$

$\therefore \quad na + 8\sum_{r=0}^{n-1} r = 2007 \Rightarrow 9a + 8\sum_{r=0}^{8} r = 2007$

$\Rightarrow \quad 9a + 8\cdot\left(\frac{8\times 9}{2}\right) = 2007 \Rightarrow 9a = 2007 - 288 = 1719$

$\therefore \quad a = 191$

Hence, $n + a = 9 + 191 = 200$

(B) $B = \text{adj } A$

$\Rightarrow \quad b = |B| = |\text{adj}\, A| = |A|^2 = a^2 = 9 \Rightarrow a = 3, b = 9$

and $\quad \frac{1}{2}\lambda = \frac{3}{9} + \frac{3^2}{9^3} + \frac{3^3}{9^5} + \ldots + \infty$

$$= \frac{1}{3} + \frac{1}{81} + \frac{1}{27\times 81} + \ldots + \infty = \frac{\frac{1}{3}}{1 - \frac{1}{27}} = \frac{9}{26}$$

$$\Rightarrow \qquad \lambda = \frac{9}{13}$$

Now, $(ab^2 + a^2b + 1)\lambda = (3\times 81 + 9\times 9 + 1)\times \frac{9}{13} = 225$

(C) $\det(A) = \begin{vmatrix} a & b & c \\ p & q & r \\ 1 & 1 & 1 \end{vmatrix} = \begin{vmatrix} a & p & 1 \\ b & q & 1 \\ c & r & 1 \end{vmatrix} = 2\times\frac{1}{2}\begin{vmatrix} a & p & 1 \\ b & q & 1 \\ c & r & 1 \end{vmatrix}$

$= 2 \times$ Area of the triangle with vertices $(a, p), (b, q)$ and (c, r) with sides 5, 6, 7

$= 2\times\sqrt{s(s-a)(s-b)(s-c)} = 2\times 6\sqrt{6} = 12\sqrt{6}$

Hence, $\det\left(\frac{B}{2}\right) = \left(\frac{1}{2}\right)^3 \det(B) = \frac{1}{8}\det(A^2)$

$$= \frac{1}{8}(\det A)^2 = \frac{1}{8}(12\sqrt{6})^2 = 108$$

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Direction** example numbers 26 and 27 are Assertion-Reason type examples. Each of these examples contains two statements:

Statement-1 (Assertion) and **Statement-2** (Reason)

Each of these examples also has four alternative choices, **ONLY ONE** of which is the correct answer. You have to select the correct choice as given below.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

● ***Ex. 26*** **Statement-1** *A is singular matrix of order $n \times n$, then adj A is singular.*

Statement-2 $|\text{adj}\, A| = |A|^{n-1}$

Sol. (*d*) If A is non-singular matrix of order $n \times n$, then

$$|\text{adj}\, A| = |A|^{n-1}$$

Hence, Statement-1 is false and Statement-2 is true.

● ***Ex. 27*** **Statement-1** *If A and B are two matrices such that $AB = B$, $BA = A$, then $A^2 + B^2 = A + B$.*

Statement-2 *A and B are idempotent matrices, then $A^2 = A$, $B^2 = B$.*

Sol. (*b*) $\because AB = B$

$\Rightarrow \quad B(AB) = B\cdot B$

$\Rightarrow \quad (BA)\,B = B^2$ [by associative law]

$\Rightarrow \quad AB = B^2$ [$\because BA = A$]

$\Rightarrow \quad B = B^2$ [$\because AB = B$]

and $\quad BA = A$

$\Rightarrow \quad A(BA) = A\cdot A$

$\Rightarrow \quad (AB)\,A = A^2$ [by associative law]

$\Rightarrow \quad BA = A^2$ [$\because AB = B$]

$\Rightarrow \quad A = A^2$ [$\because BA = A$]

Hence, $\therefore \quad A^2 + B^2 = A + B$

Here, both statements are true and Statement-2 is not a correct explanation for Statement-1.

Subjective Type Examples

■ In this section, there are **12 subjective** solved examples.

● ***Ex. 28*** *If $A^n = 0$, then evaluate*

(i) $I + A + A^2 + A^3 + \ldots + A^{n-1}$

(ii) $I - A + A^2 - A^3 + \ldots + (-1)^{n-1} A^{n-1}$ for odd 'n', where I is the identity matrix having the same order of A.

Sol. (i) $A^n = 0 \Rightarrow A^n - I = -I$

$$\Rightarrow \quad A^n - I^n = -I \Rightarrow I^n - A^n = I$$

$$\Rightarrow (I - A)(I + A + A^2 + A^3 + \ldots + A^{n-1}) = I$$

$$\Rightarrow (I + A + A^2 + A^3 + \ldots + A^{n-1}) = (I - A)^{-1} I = (I - A)^{-1}$$

(ii) $A^n = 0 \Rightarrow A^n + I = I$

$$\Rightarrow A^n + I^n = I$$

$$\Rightarrow I^n + A^n = I$$

$$\Rightarrow (I + A)(I - A + A^2 - A^3 + \ldots + A^{n-1}) = I \quad [\because n \text{ is odd}]$$

$$\Rightarrow I - A + A^2 - A^3 + \ldots + A^{n-1} = (I + A)^{-1} I = (I + A)^{-1}$$

● ***Ex. 29*** *If A is idempotent matrix, then show that $(A + I)^n = I + (2^n - 1)A, \forall\, n \in N$, where I is the identity matrix having the same order of A.*

Sol. $\because$ A is idempotent matrix

$$\therefore \quad A^2 = A,$$

similarly $A = A^2 = A^3 = A^4 = \ldots = A^n$ ...(i)

Now, $(A + I)^n = (I + A)^n$

$$= I + {}^nC_1 A + {}^nC_2 A^2 + {}^nC_3 A^3 + \ldots + {}^nC_n A^n$$

$$= I + ({}^nC_1 + {}^nC_2 + {}^nC_3 + \ldots + {}^nC_n)A \quad \text{[from Eq. (i)]}$$

$$= I + (2^n - 1)A$$

Hence, $(A + I)^n = I + (2^n - 1)A, \forall\, n \in N$.

● ***Ex. 30*** *If the matrices $A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ and $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ (a, b, c, d not all simultaneously zero) commute, find the value of $\dfrac{d-b}{a+c-b}$. Also, show that the matrix which commutes with A is of the form $\begin{bmatrix} \alpha - \beta & \frac{2\beta}{3} \\ \beta & \alpha \end{bmatrix}$.*

Sol. Given, $AB = BA$

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} a + 2c & b + 2d \\ 3a + 4c & 3b + 4d \end{bmatrix} = \begin{bmatrix} a + 3b & 2a + 4b \\ c + 3d & 2c + 4d \end{bmatrix}$$

On comparing, we get

$$a + 2c = a + 3b$$

$$\Rightarrow \quad b = \frac{2c}{3} \qquad \ldots(i)$$

$$b + 2d = 2a + 4b$$

$$\Rightarrow \quad d = a + \frac{3b}{2} \qquad \ldots(ii)$$

$$\Rightarrow \quad 3a + 4c = c + 3d$$

$$d = a + c \qquad \ldots(iii)$$

and $\quad 3b + 4d = 2c + 4d$

$$\Rightarrow \quad b = \frac{2c}{3} \qquad \ldots(iv)$$

$$\Rightarrow \quad \frac{d-b}{a+c-b} = \frac{d-b}{d-b} = 1 \qquad \text{[from Eq. (iii)]}$$

Now, $\quad B = \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} d - c & \frac{2c}{3} \\ c & d \end{bmatrix}$

If $c = \beta$ and $d = \alpha$, then $B = \begin{bmatrix} \alpha - \beta & \frac{2\beta}{3} \\ \beta & \alpha \end{bmatrix}$

● ***Ex. 31*** *Given the matrix $A = \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix}$ and X be the solution set of the equation $A^x = A$, where $x \in N - \{1\}$. Evaluate $\prod\left(\dfrac{x^3 + 1}{x^3 - 1}\right)$, where the continued extends for all $x \in X$.*

Sol. $\because$ $A^2 = \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix}\begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix} = \begin{bmatrix} -1 & 3 & 5 \\ 1 & -3 & -5 \\ -1 & 3 & 5 \end{bmatrix}$

$= A$

$$\therefore \quad A^2 = A^3 = A^4 = A^5 = \ldots = A$$

but given $\quad A^x = A$

$$\Rightarrow \quad x = 2, 3, 4, 5, \ldots \qquad [\because x \neq 1, \text{ given}]$$

$$\therefore \quad \prod\left(\frac{x^3 + 1}{x^3 - 1}\right) = \prod\left(\frac{x + 1}{x - 1}\right)\prod\left(\frac{x^2 - x + 1}{x^2 + x + 1}\right)$$

On putting $\quad x = 2, 3, 4, 5, \ldots$

$$\prod\left(\frac{x^3+1}{x^3-1}\right)=\lim_{n\to\infty}\prod_{x=2}^{n}\left(\frac{x+1}{x-1}\right)\prod_{x=2}^{n}\left(\frac{x^2-x+1}{x^2+x+1}\right)$$

$$=\lim_{n\to\infty}\left(\frac{3\cdot4\cdot5\ldots(n-1)n(n+1)}{1\cdot2\cdot3\ldots(n-3)(n-2)(n-1)}\right)\times\lim_{n\to\infty}\left(\frac{3\cdot7\cdot\ldots(n^2-n+1)}{7\cdot13\ldots(n^2-n+1)(n^2+n+1)}\right)$$

$$=\lim_{n\to\infty}\frac{n(n+1)}{2}\times\frac{3}{(n^2+n+1)}$$

$$=\frac{3}{2}\lim_{n\to\infty}\frac{\left(1+\frac{1}{n}\right)}{\left(1+\frac{1}{n}+\frac{1}{n^2}\right)}=\frac{3}{2}\cdot\frac{(1+0)}{(1+0+0)}=\frac{3}{2}$$

● ***Ex. 32*** *If P is a non-singular matrix, with $\text{adj}(P^{-1})$ in terms of 'P ', then show that $\text{adj}(Q^{-1}BP^{-1})=PAQ$. Given that, $\text{adj}(B)=A$ and $|P|=|Q|=1$.*

Sol. $\because\ \text{adj}(P^{-1})=|P|(P^{-1})^{-1}=|P|P=P \qquad [\because |P|=1]$

and $\text{adj}(Q^{-1}BP^{-1})=\text{adj}(P^{-1})\cdot\text{adj}B\cdot\text{adj}(Q^{-1})$

$$=\frac{P}{|P|}A\cdot\frac{Q}{|Q|}=PAQ \qquad [\because |P|=|Q|=1]$$

● ***Ex. 33*** *Let A and B be matrices of order n. Prove that if $(I-AB)$ is invertible, $(I-BA)$ is also invertible and $(I-BA)^{-1}=I+B(I-AB)^{-1}A$, where I be the identity matrix of order n.*

Sol. Here, $I-BA=BIB^{-1}-BABB^{-1}=B(I-AB)B^{-1}$ ...(i)

Hence, $|I-BA|=|B||I-AB||B^{-1}|=|B||I-AB|\frac{1}{|B|}$

$=|I-AB|$

If $|I-AB|\neq0$, then $|I-BA|\neq0$

i.e. if $(I-AB)$ is invertible, then $(I-BA)$ is also invertible.

Now, $(I-BA)[I+B(I-AB)^{-1}A]$

$=(I-BA)+(I-BA)B(I-AB)^{-1}A$ [using Eq. (i)]

$=(I-BA)+B(I-AB)B^{-1}B(I-AB)^{-1}A$

$=(I-BA)+B(I-AB)(I-AB^{-1})A$

$=(I-BA)+BA=I$

Hence, $(I-BA)^{-1}=I+B(I-AB)^{-1}A$.

● ***Ex. 34*** *Prove that the inverse of* $\begin{bmatrix}A & O\\ B & C\end{bmatrix}$ *is* $\begin{bmatrix}A^{-1} & O\\ -C^{-1}BA^{-1} & C^{-1}\end{bmatrix}$, *where A, C are non-singular matrices and O is null matrix and find the inverse.* $\begin{bmatrix}1&0&0&0\\1&1&0&0\\1&1&1&0\\1&1&1&1\end{bmatrix}$

Sol. We have, First part $\begin{bmatrix}A & O\\ B & C\end{bmatrix}\begin{bmatrix}A^{-1} & O\\ -C^{-1}BA^{-1} & C^{-1}\end{bmatrix}$

$$=\begin{bmatrix}AA^{-1} & O\\ BA^{-1}-CC^{-1}BA^{-1} & CC^{-1}\end{bmatrix}$$

$$=\begin{bmatrix}I & O\\ BA^{-1}-BA^{-1} & I\end{bmatrix}=\begin{bmatrix}I & O\\ 0 & I\end{bmatrix}$$

Hence, $\begin{bmatrix}A^{-1} & O\\ -C^{-1}BA^{-1} & C^{-1}\end{bmatrix}$ is the inverse of $\begin{bmatrix}A & O\\ B & C\end{bmatrix}$.

Second part $\begin{bmatrix}1&0&0&0\\1&1&0&0\\1&1&1&0\\1&1&1&1\end{bmatrix}=\begin{bmatrix}A & O\\ B & C\end{bmatrix}$

where $A=\begin{bmatrix}1&0\\1&1\end{bmatrix}$, $B=\begin{bmatrix}1&1\\1&1\end{bmatrix}$, $C=\begin{bmatrix}1&0\\1&1\end{bmatrix}$ and $O=\begin{bmatrix}0&0\\0&0\end{bmatrix}$

and $A^{-1}=\begin{bmatrix}1&0\\-1&1\end{bmatrix}$, $C^{-1}=\begin{bmatrix}1&0\\-1&1\end{bmatrix}$

Now, $C^{-1}BA^{-1}=\begin{bmatrix}1&0\\-1&1\end{bmatrix}\begin{bmatrix}1&1\\1&1\end{bmatrix}\begin{bmatrix}1&0\\-1&1\end{bmatrix}=\begin{bmatrix}0&1\\0&0\end{bmatrix}$

$\therefore$ Inverse of $\begin{bmatrix}1&0&0&0\\1&1&0&0\\1&1&1&0\\1&1&1&1\end{bmatrix}$ is $\begin{bmatrix}1&0&0&0\\-1&1&0&0\\0&-1&1&0\\0&0&-1&1\end{bmatrix}$

● ***Ex. 35*** *Let* $A=\begin{bmatrix}3&a&-1\\2&5&c\\b&8&2\end{bmatrix}$ *is symmetric and* $B=\begin{bmatrix}d&3&a\\b-a&e&-2b-c\\-2&6&-f\end{bmatrix}$ *is skew-symmetric, find AB. If AB is symmetric or skew-symmetric or neither of them. Justify your answer.*

Sol. $\because\ A$ is symmetric

$\therefore\quad c=8, b=-1$ and $a=2$ ...(i)

and B is skew-symmetric

$\therefore\quad d=e=f=0$ and $2b+c=6, a=2, b-a=-3$ ...(ii)

From Eqs. (i) and (ii), we get

$a=2, b=-1, c=8, d=0, e=0, f=0$

$\therefore\quad A=\begin{bmatrix}3&2&-1\\2&5&8\\-1&8&2\end{bmatrix}$ and $B=\begin{bmatrix}0&3&2\\-3&0&-6\\-2&6&0\end{bmatrix}$

$\Rightarrow\quad AB=\begin{bmatrix}-4&3&-6\\-31&54&-26\\-28&9&-50\end{bmatrix}$

which neither symmetric nor skew-symmetric.

● ***Ex. 36*** *If B, C are square matrices of order n and if $A = B + C$, $BC = CB$, $C^2 = 0$, show that for any positive integer p, $A^{p+1} = B^p[B + (p+1)C]$.*

Sol. $\because\ A = B + C \Rightarrow A^{p+1} = (B + C)^{p+1}$

$$= {}^{p+1}C_0 B^{p+1} + {}^{p+1}C_1 B^p C + {}^{p+1}C_2 B^{p-1} C^2 + \ldots + {}^{p+1}C_{p+1} C^{p+1}$$

$$= B^{p+1} + {}^{p+1}C_1 B^p C + 0 + 0 + \ldots \quad [\because C^2 = 0 \Rightarrow C^2 = C^3 = \ldots = 0]$$

$$= B^p[B + (p+1)C]$$

Hence, $A^{p+1} = B^p[B + (p+1)C]$

● ***Ex. 37*** *If there an three square matrices A, B, C of same order satisfying the equation $A^2 = A^{-1}$ and let $B = A^{2^n}$ and $C = A^{2^{(n-2)}}$, prove that $\det(B - C) = 0$.*

Sol. $\because\ B = A^{2^n} = A^{2\cdot 2^{n-1}} = (A^2)^{2^{n-1}} = (A^{-1})^{2^{n-1}}\ [\because A^2 = A^{-1}]$

$$= (A^{2^{n-1}})^{-1} = (A^{2\cdot 2^{n-2}})^{-1} = [(A^2)^{2^{n-2}}]^{-1}$$

$$= [(A^{-1})^{2^{n-2}}]^{-1} = ((A^{-1})^{-1})^{2^{n-2}} = A^{2^{n-2}} = C$$

$\Rightarrow\quad B - C = 0 \Rightarrow \det(B - C) = 0$

● ***Ex. 38*** *Construct an orthogonal matrix using the skew-symmetric matrix $A = \begin{bmatrix} 0 & 2 \\ -2 & 0 \end{bmatrix}$.*

Sol. $\because\ A = \begin{bmatrix} 0 & 2 \\ -2 & 0 \end{bmatrix} \Rightarrow I - A = \begin{bmatrix} 1 & -2 \\ 2 & 1 \end{bmatrix}$

$$\Rightarrow\quad (I - A)^{-1} = \frac{1}{5}\begin{bmatrix} 1 & 2 \\ -2 & 1 \end{bmatrix} \text{ and } (I + A) = \begin{bmatrix} 1 & 2 \\ -2 & 1 \end{bmatrix}$$

Let B be the orthogonal matrix from a skew-symmetric matrix A, then $B = (I - A)^{-1}(I + A)$

$$= \frac{1}{5}\begin{bmatrix} 1 & 2 \\ -2 & 1 \end{bmatrix}\begin{bmatrix} 1 & 2 \\ -2 & 1 \end{bmatrix} = \frac{1}{5}\begin{bmatrix} -3 & 4 \\ -4 & -3 \end{bmatrix} = \begin{bmatrix} -\frac{3}{5} & \frac{4}{5} \\ -\frac{4}{5} & -\frac{3}{5} \end{bmatrix}$$

● ***Ex. 39*** *If $A = \begin{bmatrix} 3 & 2 & 2 \\ 2 & 4 & 1 \\ -2 & -4 & -1 \end{bmatrix}$ and X, Y are two non-zero column vectors such that $AX = \lambda X$, $AY = \mu Y$, $\lambda \neq \mu$, find angle between X and Y.*

Sol. $\because AX = \lambda X \Rightarrow (A - \lambda I)X = 0$

$\because\quad X \neq 0$

$\therefore\quad \det(A - \lambda I) = 0$

$$\Rightarrow\quad \begin{vmatrix} 3-\lambda & 2 & 2 \\ 2 & 4-\lambda & 1 \\ -2 & -4 & -1-\lambda \end{vmatrix} = 0$$

Applying $R_3 \to R_3 + R_2$, then

$$\begin{vmatrix} 3-\lambda & 2 & 2 \\ 2 & 4-\lambda & 1 \\ 0 & -\lambda & -\lambda \end{vmatrix} = 0$$

Applying $C_2 \to C_2 - C_3$, then

$$\Rightarrow\quad \begin{vmatrix} 3-\lambda & 0 & 2 \\ 2 & 3-\lambda & 1 \\ 0 & 0 & -\lambda \end{vmatrix} = 0$$

$$\Rightarrow\quad -\lambda(3-\lambda)^2 = 0$$

$$\Rightarrow\quad \lambda = 0, 3$$

It is clear that $\lambda = 0, \mu = 3$

For $\lambda = 0$, $AX = 0 \Rightarrow \begin{bmatrix} 3 & 2 & 2 \\ 2 & 4 & 1 \\ -2 & -4 & -1 \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$

$\Rightarrow\quad 3x + 2y + 2z = 0$ and $2x + 4y + z = 0$

$\therefore\quad \frac{x}{-6} = \frac{y}{1} = \frac{z}{8}$

So, $X = \begin{bmatrix} -6 \\ 1 \\ 8 \end{bmatrix}$

For $\mu = 3$, $(A - 3I)Y = 0$

$$\Rightarrow\quad \begin{bmatrix} 0 & 2 & 2 \\ 2 & 1 & 1 \\ -2 & -4 & -4 \end{bmatrix}\begin{bmatrix} \alpha \\ \beta \\ \gamma \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$\Rightarrow\quad 0\cdot\alpha + 2\beta + 2\gamma = 0$ and $2\alpha + \beta + \gamma = 0$

$\therefore\quad \frac{\alpha}{0} = \frac{\beta}{4} = \frac{\gamma}{-4}$

$\Rightarrow\quad \frac{\alpha}{0} = \frac{\beta}{-1} = \frac{\gamma}{1}$

So, $Y = \begin{bmatrix} 0 \\ -1 \\ 1 \end{bmatrix}$

If θ be the angle between X and Y, then

$$\cos\theta = \frac{0\cdot(-6) + (-1)\cdot 1 + 1\cdot 8}{\sqrt{(0+1+1)}\sqrt{36+1+64}} = \frac{7}{\sqrt{202}}$$

$\therefore\quad \theta = \cos^{-1}\left(\frac{7}{\sqrt{202}}\right)$

Matrices Exercise 1 :
Single Option Correct Type Questions

■ This section contains **30 multiple choice questions.** Each question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct

1. If $A^5 = O$ such that $A^n \neq I$ for $1 \leq n \leq 4$, then $(I - A)^{-1}$ is equal to
(a) A^4 (b) A^3
(c) $I + A$ (d) None of these

2. Let $A = \begin{bmatrix} a & b & c \\ p & q & r \\ x & y & z \end{bmatrix}$ and suppose that $\det(A) = 2$, then $\det(B)$ equals, where $B = \begin{bmatrix} 4x & 2a & -p \\ 4y & 2b & -q \\ 4z & 2c & -r \end{bmatrix}$
(a) -2 (b) -8 (c) -16 (d) 8

3. If both $A - \frac{1}{2}I$ and $A + \frac{1}{2}I$ are orthogonal matrices, then
(a) A is orthogonal
(b) A is skew-symmetric matrix of even order
(c) $A^2 = \frac{3}{4}I$
(d) None of the above

4. Let $a = \lim_{x \to 1}\left(\frac{x}{\ln x} - \frac{1}{x \ln x}\right)$, $b = \lim_{x \to 0}\left(\frac{x^3 - 16x}{4x + x^2}\right)$, $c = \lim_{x \to 0}\left(\frac{\ln(1 + \sin x)}{x}\right)$ and $d = \lim_{x \to -1} \frac{(x+1)^3}{3[\sin(x+1) - (x+1)]}$, then $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is
(a) idempotent (b) involutory
(c) non-singular (d) nilpotent

5. Let $A = \begin{bmatrix} 1 & 4 \\ 3 & 2 \end{bmatrix}$. If θ is the angle between the two non-zero column vectors X such that $AX = \lambda X$ for some scalar λ, then $\tan\theta$ is equal to
(a) 3 (b) 5
(c) 7 (d) 9

6. If a square matrix A is involutory, then A^{2n+1} is equal to
(a) I (b) A
(c) A^2 (d) $(2n + 1)A$

7. If $A = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$, then $\lim_{n \to \infty} \frac{A^n}{n}$ is (where $\theta \in R$)
(a) a zero matrix (b) an identity matrix
(c) $\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$ (d) $\begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix}$

8. The rank of the matrix $\begin{bmatrix} -1 & 2 & 5 \\ 2 & -4 & a-4 \\ 1 & -2 & a+1 \end{bmatrix}$ is (where $a = -6$)
(a) 1 (b) 2 (c) 3 (d) 4

9. A is an involutory matrix given by $A = \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix}$, the inverse of $\frac{A}{2}$ will be
(a) $2A$ (b) $\frac{A^{-1}}{2}$ (c) $\frac{A}{2}$ (d) A^2

10. Let A be a nth order square matrix and B be its adjoint, then $|AB + kI_n|$, is (where k is a scalar quantity)
(a) $(|A| + k)^{n-2}$ (b) $(|A| + k)^n$
(c) $(|A| + k)^{n-1}$ (d) $(|A| + k)^{n+1}$

11. If A and B are two square matrices such that $B = -A^{-1}BA$, then $(A + B)^2$ is equal to
(a) O (b) $A^2 + B^2$
(c) $A^2 + 2AB + B^2$ (d) $A + B$

12. If matrix $A = [a_{ij}]_{3\times 3}$, matrix $B = [b_{ij}]_{3\times 3}$, where $a_{ij} + a_{ji} = 0$ and $b_{ij} - b_{ji} = 0$, then $A^4 \cdot B^3$ is
(a) skew-symmetric matrix (b) singular
(c) symmetric (d) zero matrix

13. Let A be a $n \times n$ matrix such that $A^n = \alpha A$, where α is a real number different from 1 and -1. The matrix $A + I_n$ is
(a) singular (b) invertible
(c) scalar matrix (d) None of these

14. If $A = \begin{bmatrix} \frac{-1 + i\sqrt{3}}{2i} & \frac{-1 - i\sqrt{3}}{2i} \\ \frac{1 + i\sqrt{3}}{2i} & \frac{1 - i\sqrt{3}}{2i} \end{bmatrix}$, $i = \sqrt{-1}$ and $f(x) = x^2 + 2$, then $f(A)$ equals to
(a) $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ (b) $\left(\frac{3 - i\sqrt{3}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$
(c) $\left(\frac{5 - i\sqrt{3}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ (d) $(2 + i\sqrt{3})\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

15. The number of solutions of the matrix equation $X^2 = I$ other than I is
(a) 0 (b) 1
(c) 2 (d) more than 2

16. If A and B are square matrices such that $A^{2006} = 0$ and $AB = A + B$, then $\det(B)$ equals to
(a) -1 (b) 0
(c) 1 (d) None of these

17. If $P = \begin{bmatrix} \cos\frac{\pi}{6} & \sin\frac{\pi}{6} \\ -\sin\frac{\pi}{6} & \cos\frac{\pi}{6} \end{bmatrix}, A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ and $Q = PAP^T$, then $P^T Q^{2007} P$ is equal to
(a) $\begin{bmatrix} 1 & \sqrt{3}/2 \\ 0 & 2007 \end{bmatrix}$ (b) $\begin{bmatrix} 1 & 2007 \\ 0 & 1 \end{bmatrix}$
(c) $\begin{bmatrix} \sqrt{3}/2 & 2007 \\ 0 & 1 \end{bmatrix}$ (d) $\begin{bmatrix} \sqrt{3}/2 & -1/2 \\ 1 & 2007 \end{bmatrix}$

18. There are two possible values of A in the solution of the matrix equation $\begin{bmatrix} 2A+1 & -5 \\ -4 & A \end{bmatrix}^{-1} \begin{bmatrix} A-5 & B \\ 2A-2 & C \end{bmatrix} = \begin{bmatrix} 14 & D \\ E & F \end{bmatrix}$, where A, B, C, D, E, F are real numbers. The absolute value of the difference of these two solutions, is
(a) $\frac{8}{3}$ (b) $\frac{11}{3}$ (c) $\frac{1}{3}$ (d) $\frac{19}{3}$

19. If $f(\theta) = \begin{bmatrix} \cos^2\theta & \cos\theta\sin\theta & -\sin\theta \\ \cos\theta\sin\theta & \sin^2\theta & \cos\theta \\ \sin\theta & -\cos\theta & 0 \end{bmatrix}$, then $f\left(\frac{\pi}{7}\right)$ is
(a) symmetric (b) skew-symmetric
(c) singular (d) non-singular

20. In a square matrix A of order 3 the elements a_{ii}'s are the sum of the roots of the equation $x^2 - (a+b)x + ab = 0$; $a_{i,i+1}$'s are the product of the roots, $a_{i,i-1}$'s are all unity and the rest of the elements are all zero.

The value of the $\det(A)$ is equal to
(a) 0 (b) $(a+b)^3$
(c) $a^3 - b^3$ (d) $(a^2+b^2)(a+b)$

21. If A and B are two non-singular matrices of the same order such that $B^r = I$ for some positive integer $r > 1$. Then $A^{-1}B^{r-1}A - A^{-1}B^{-1}A$ is equal to
(a) I (b) $2I$ (c) 0 (d) $-I$

22. If $A = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix}, B = \begin{bmatrix} 1 & 0 \\ -1 & 1 \end{bmatrix}, C = ABA^T$, then $A^T C^n A, n \in I^+$ equals to
(a) $\begin{bmatrix} -n & 1 \\ 1 & 0 \end{bmatrix}$ (b) $\begin{bmatrix} 1 & -n \\ 0 & 1 \end{bmatrix}$ (c) $\begin{bmatrix} 0 & 1 \\ 1 & -n \end{bmatrix}$ (d) $\begin{bmatrix} 1 & 0 \\ -n & 1 \end{bmatrix}$

23. If A is a square matrix of order 3 such that $|A| = 2$, then $|(\text{adj } A^{-1})^{-1}|$ is
(a) 1 (b) 2 (c) 4 (d) 8

24. If A and B are different matrices satisfying $A^3 = B^3$ and $A^2B = B^2A$, then
(a) $\det(A^2 + B^2)$ must be zero
(b) $\det(A - B)$ must be zero
(c) $\det(A^2 + B^2)$ as well as $\det(A - B)$ must be zero
(d) atleast one of $\det(A^2 + B^2)$ or $\det(A - B)$ must be zero

25. If A is a skew-symmetric matrix of order 2 and B, C are matrices $\begin{bmatrix} 1 & 4 \\ 2 & 9 \end{bmatrix}, \begin{bmatrix} 9 & -4 \\ -2 & 1 \end{bmatrix}$ respectively, then
$A^3(BC) + A^5(B^2C^2) + A^7(B^3C^3) + \ldots + A^{2n+1}(B^nC^n)$, is
(a) a symmetric matrix (b) a skew-symmetric matrix
(c) an identity matrix (d) None of these

26. If $A = \begin{bmatrix} a & b & c \\ x & y & z \\ p & q & r \end{bmatrix}, B = \begin{bmatrix} q & -b & y \\ -p & a & -x \\ r & -c & z \end{bmatrix}$ and if A is invertible, then which of the following is not true?
(a) $|A| = |B|$
(b) $|A| = -|B|$
(c) $|\text{adj } A| = |\text{adj } B|$
(d) A is invertible $\Leftrightarrow B$ is invertible

27. Let three matrices $A = \begin{bmatrix} 2 & 1 \\ 4 & 1 \end{bmatrix}, B = \begin{bmatrix} 3 & 4 \\ 2 & 3 \end{bmatrix}$ and $C = \begin{bmatrix} 3 & -4 \\ -2 & 3 \end{bmatrix}$, then $\text{tr}(A) + \text{tr}\left(\frac{ABC}{2}\right) + \text{tr}\left(\frac{A(BC)^2}{4}\right) + \text{tr}\left(\frac{A(BC)^3}{8}\right) + \ldots + \infty$ equals to
(a) 4 (b) 9 (c) 12 (d) 6

28. If A is non-singular and $(A - 2I)(A - 4I) = O$, then $\frac{1}{6}A + \frac{4}{3}A^{-1}$ is equal to
(a) O (b) I
(c) $2I$ (d) $6I$

29. If $A = \begin{bmatrix} 0 & 1 & 2 \\ 1 & 2 & 3 \\ 3 & a & 1 \end{bmatrix}$ and $A^{-1} = \begin{bmatrix} 1/2 & -1/2 & 1/2 \\ -4 & 3 & b \\ 5/2 & -3/2 & 1/2 \end{bmatrix}$, then
(a) $a = 1, b = -1$ (b) $a = 2, b = -\frac{1}{2}$
(c) $a = -1, b = 1$ (d) $a = \frac{1}{2}, b = \frac{1}{2}$

30. Given the matrix $A = \begin{bmatrix} x & 3 & 2 \\ 1 & y & 4 \\ 2 & 2 & z \end{bmatrix}$. If $xyz = 60$ and $8x + 4y + 3z = 20$, then $A(\text{adj } A)$ is equal to
(a) $64I$ (b) $88I$ (c) $68I$ (d) $34I$

Matrices Exercise 2 :
More than One Correct Option Type Questions

- This section contains **15 multiple choice questions**. Each question has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

31. If $A=\begin{bmatrix}1&1&1\\1&1&1\\1&1&1\end{bmatrix}$, then

(a) $A^3=9A$ (b) $A^3=27A$

(c) $A+A=A^2$ (d) A^{-1} does not exist

32. A square matrix A with elements from the set of real numbers is said to be orthogonal if $A'=A^{-1}$. If A is an orthogonal matrix, then

(a) A' is orthogonal (b) A^{-1} is orthogonal

(c) adj $A=A'$ (d) $|A^{-1}|=1$

33. Let $A=\begin{bmatrix}1&2&2\\2&1&2\\2&2&1\end{bmatrix}$, then

(a) $A^2-4A-5I_3=O$ (b) $A^{-1}=\frac{1}{5}(A-4I_3)$

(c) A^3 is not invertible (d) A^2 is invertible

34. D is a 3×3 diagonal matrix. Which of the following statements are not true?

(a) $D^T=D$

(b) $AD=DA$ for every matrix A of order 3×3

(c) D^{-1} if exists is a scalar matrix

(d) None of the above

35. The rank of the matrix $\begin{bmatrix}-1&2&5\\2&-4&a-4\\1&-2&a+1\end{bmatrix}$, is

(a) 2, if $a=-6$ (b) 2, if $a=1$

(c) 1, if $a=2$ (d) 1, if $a=-6$

36. If $A=\begin{bmatrix}3&-3&4\\2&-3&4\\0&-1&1\end{bmatrix}$, then

(a) adj (adj A) $=A$ (b) $|$ adj (adj $(A)|=1$

(c) $|$ adj $(A)|=1$ (d) None of these

37. If B is an idempotent matrix and $A=I-B$, then

(a) $A^2=A$ (b) $A^2=I$

(c) $AB=O$ (d) $BA=O$

38. If A is a non-singular matrix, then

(a) A^{-1} is symmetric if A is symmetric

(b) A^{-1} is skew-symmetric if A is symmetric

(c) $|A^{-1}|=|A|$

(d) $|A^{-1}|=|A|^{-1}$

39. Let A and B are two matrices such that $AB=BA$, then for every $n\in N$

(a) $A^nB=BA^n$

(b) $(AB)^n=A^nB^n$

(c) $(A+B)^n={}^nC_0A^n+{}^nC_1A^{n-1}B+\ldots+{}^nC_nB^n$

(d) $A^{2n}-B^{2n}=(A^n-B^n)(A^n+B^n)$

40. If A and B are 3×3 matrices and $|A|\neq0$, which of the following are true?

(a) $|AB|=0\Rightarrow|B|=0$

(b) $|AB|=0\Rightarrow B=0$

(c) $|A^{-1}|=|A|^{-1}$

(d) $|A+A|=2|A|$

41. If A is a matrix of order $m\times m$ such that $A^2+A+2I=O$, then

(a) A is non-singular (b) A is symmetric

(c) $|A|\neq0$ (d) $A^{-1}=-\frac{1}{2}(A+I)$

42. If $A^2-3A+2I=0$, then A is equal to

(a) I (b) $2I$

(c) $\begin{bmatrix}3&-2\\1&0\end{bmatrix}$ (d) $\begin{bmatrix}3&1\\-2&0\end{bmatrix}$

43. If A and B are two matrices such that their product AB is a null matrix, then

(a) det $A\neq0\Rightarrow B$ must be a null matrix

(b) det $B\neq0\Rightarrow A$ must be a null matrix

(c) atleast one of the two matrices must be singular

(d) if neither det A nor det B is zero, then the given statement is not possible

44. If D_1 and D_2 are two 3×3 diagonal matrices where none of the diagonal elements is zero, then

(a) D_1D_2 is a diagonal matrix

(b) $D_1D_2=D_2D_1$

(c) $D_1^2+D_2^2$ is a diagonal matrix

(d) None of the above

45. Let, $C_k={}^nC_k$ for $0\le k\le n$ and $A_k=\begin{bmatrix}C_{k-1}^2&0\\0&C_k^2\end{bmatrix}$ for $k\ge1$ and

$A_1+A_2+A_3+\ldots+A_n=\begin{bmatrix}k_1&0\\0&k_2\end{bmatrix}$, then

(a) $k_1=k_2$ (b) $k_1+k_2=2$

(c) $k_1={}^{2n}C_n-1$ (d) $k_2={}^{2n}C_{n+1}$

Matrices Exercise 3 : Passage Based Questions

- This section contains **6 passages**. Based upon each of the passage **3 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I (Q. Nos. 46 to 48)

Suppose A and B be two non-singular matrices such that $AB = BA^m$, $B^n = I$ and $A^p = I$, where I is an identity matrix.

46. If $m = 2$ and $n = 5$, then p equals to
(a) 30 (b) 31
(c) 33 (d) 81

47. The relation between m, n and p, is
(a) $p = mn^2$ (b) $p = m^n - 1$
(c) $p = n^m - 1$ (d) $p = m^{n-1}$

48. Which of the following ordered triplet (m, n, p) is false?
(a) (3, 4, 80) (b) (6, 3, 215)
(c) (8, 3, 510) (d) (2, 8, 255)

Passage II (Q. Nos. 49 to 51)

Let $A = \begin{bmatrix} a & b & c \\ b & c & a \\ c & a & b \end{bmatrix}$ is an orthogonal matrix and $abc = \lambda\,(< 0)$.

49. The value of $a^2b^2 + b^2c^2 + c^2a^2$, is
(a) 2λ (b) -2λ
(c) λ^2 (d) $-\lambda$

50. The value of $a^3 + b^3 + c^3$, is
(a) λ (b) 2λ
(c) 3λ (d) None of these

51. The equation whose roots are a, b, c, is
(a) $x^3 - 2x^2 + \lambda = 0$ (b) $x^3 - \lambda x^2 + \lambda x + \lambda = 0$
(c) $x^3 - 2x^2 + 2\lambda x + \lambda = 0$ (d) $x^3 \pm x^2 - \lambda = 0$

Passage III (Q. Nos. 52 to 53)

Let $A = [a_{ij}]_{3\times 3}$. If tr is arithmetic mean of elements of rth row and $a_{ij} + a_{jk} + a_{ki} = 0$ holds for all $1 \le i, j, k \le 3$.

52. $\sum\limits_{1\le i}\sum\limits_{j\le 3} a_{ij}$ is not equal to
(a) $t_1 + t_2 + t_3$ (b) zero
(c) $(\det(A))^2$ (d) $t_1t_2t_3$

53. Matrix A is
(a) non-singular
(b) symmetric
(c) skew-symmetric
(d) neither symmetric nor skew-symmetric

Passage IV (Q. Nos. 54 to 56)

Let $A = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 3 & 2 & 1 \end{bmatrix}$ be a square matrix and C_1, C_2, C_3 be three column matrices satisfying $AC_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$, $AC_2 = \begin{bmatrix} 2 \\ 3 \\ 0 \end{bmatrix}$ and $AC_3 = \begin{bmatrix} 2 \\ 3 \\ 1 \end{bmatrix}$ of matrix B. If the matrix $C = \frac{1}{3}(A \cdot B)$.

54. The value of $\det(B^{-1})$, is
(a) 2 (b) $\frac{1}{2}$ (c) 3 (d) $\frac{1}{3}$

55. The ratio of the trace of the matrix B to the matrix C, is
(a) $-\frac{9}{5}$ (b) $-\frac{5}{9}$ (c) $-\frac{2}{3}$ (d) $-\frac{3}{2}$

56. The value of $\sin^{-1}(\det A) + \tan^{-1}(9 \det C)$, is
(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$ (c) $\frac{3\pi}{4}$ (d) π

Passage V (Q. Nos. 57 to 59)

If A is symmetric and B skew-symmetric matrix and $A + B$ is non-singular and $C = (A + B)^{-1}(A - B)$.

57. $C^T(A + B)C$ equals to
(a) $A + B$ (b) $A - B$
(c) A (d) B

58. $C^T(A - B)C$ equals to
(a) $A + B$ (b) $A - B$ (c) A (d) B

59. $C^T AC$ equals to
(a) $A + B$ (b) $A - B$
(c) A (d) B

Passage VI (Q. Nos. 60 to 61)

Let A be a square matrix of order 3 satisfies the matrix equation $A^3 - 6A^2 + 7A - 8I = O$ and $B = A - 2I$. Also, $\det A = 8$.

60. The value of $\det(\text{adj}(I - 2A^{-1}))$ is equal to
(a) $\frac{25}{16}$ (b) $\frac{125}{64}$
(c) $\frac{64}{125}$ (d) $\frac{16}{25}$

61. If $\text{adj}\left(\left(\frac{B}{2}\right)^{-1}\right) = \left(\frac{p}{q}\right)B$, where $p, q \in N$, the least value of $(p + q)$ is equal to
(a) 7 (b) 9 (c) 29 (d) 41

Matrices Exercise 4 :
Single Integer Answer Type Questions

- This section contains **10 questions**. The answer to each question is a **single digit integer**, ranging from 0 to 9 (both inclusive).

62. Let A, B, C, D be (not necessarily) real matrices such that $A^T = BCD; B^T = CDA; C^T = DAB$ and $D^T = ABC$ for the matrix $S = ABCD$, the least value of k such that $S^k = S$ is

63. If $A = \begin{bmatrix} 1 & \tan x \\ -\tan x & 1 \end{bmatrix}$ and a function $f(x)$ is defined as $f(x) = \det(A^T A^{-1})$ and if $f(f(f(f\ldots f(x))))$ is $(n \geq 2)\,\lambda$, the value of 2^{λ} is

64. If the matrix $A = \begin{bmatrix} \lambda_1^2 & \lambda_1\lambda_2 & \lambda_1\lambda_3 \\ \lambda_2\lambda_1 & \lambda_2^2 & \lambda_2\lambda_3 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 \end{bmatrix}$ is idempotent, the value of $\lambda_1^2 + \lambda_2^2 + \lambda_3^2$ is

65. Let A be a 3×3 matrix given by $A = [a_{ij}]$. If for every column vector X, $X^T AX = O$ and $a_{23} = -1008$, the sum of the digits of a_{32} is

66. Let X be the solution set of the equation $A^x = I$, where $A = \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix}$ and I is the corresponding unit matrix and $x \subseteq N$, the minimum value of $\Sigma(\cos^x\theta + \sin^x\theta)$, $\theta \in R - \left\{\frac{n\pi}{2}, n \in I\right\}$ is

67. If A is an idempotent matrix and I is an identity matrix of the same order, then the value of n, such that $(A + I)^n = I + 127\,A$ is

68. Suppose $a, b, c \in R$ and $abc = 1$, if $A = \begin{bmatrix} 3a & b & c \\ b & 3c & a \\ c & a & 3b \end{bmatrix}$ is such that $A^T A = 4^{1/3}\,I$ and $|A| > 0$, the value of $a^3 + b^3 + c^3$ is

69. If $A = \begin{bmatrix} 0 & 1 \\ 3 & 0 \end{bmatrix}$ and $(A^8 + A^6 + A^4 + A^2 + I)\,V = \begin{bmatrix} 0 \\ 11 \end{bmatrix}$, where V is a vertical vector and I is the 2×2 identity matrix and if λ is sum of all elements of vertical vector V, the value of 11λ is

70. Let the matrix A and B be defined as $A = \begin{bmatrix} 3 & 2 \\ 2 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & 1 \\ 7 & 3 \end{bmatrix}$, then the absolute value of $\det(2A^9 B^{-1})$ is

71. Let $A = \begin{bmatrix} 0 & \alpha \\ 0 & 0 \end{bmatrix}$ and $(A + I)^{70} - 70A = \begin{bmatrix} a-1 & b-1 \\ c-1 & d-1 \end{bmatrix}$, the value of $a + b + c + d$ is

Matrices Exercise 5 :
Matching Type Questions

- This section contains **4 questions**. Question 72 has four statements (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II** and questions 73 to 75 have four statements (A, B, C and D) given in **Column I** and five statements (p, q, r, s and t) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

72. Suppose a, b, c are three distinct real numbers and $f(x)$ is a real quadratic polynomial such that

$$\begin{bmatrix} 4a^2 & 4a & 1 \\ 4b^2 & 4b & 1 \\ 4c^2 & 4c & 1 \end{bmatrix}\begin{bmatrix} f(-1) \\ f(1) \\ f(2) \end{bmatrix} = \begin{bmatrix} 3a^2 + 3a \\ 3b^2 + 3b \\ 3c^2 + 3c \end{bmatrix}.$$

Column I		Column II	
(A)	x-coordinate(s) of the point of intersection of $y = f(x)$ with the X-axis is	(p)	–2
(B)	Area (in sq units) bounded by $y = \frac{3}{2} f(x)$ and the X-axis is	(q)	1
(C)	Maximum value of $f(x)$ is	(r)	2
(D)	Length (in unit) of the intercept made by $y = f(x)$ on the X-axis is	(s)	4

73. If A is non-singular matrix of order $n \times n$,

	Column I		Column II
(A)	adj (A^{-1}) is	(p)	$A\,(\det A)^{n-2}$
(B)	det (adj (A^{-1})) is	(q)	$(\det A)^{n-1}\,(\text{adj } A)$
(C)	adj (adj A) is	(r)	$\dfrac{\text{adj (adj } A)}{(\det A)^{n-1}}$
(D)	adj (A det (A)) is	(s)	$(\det A)^{1-n}$
		(t)	$\dfrac{A}{(\det A)}$

74.

	Column I		Column II
(A)	If A is a diagonal matrix of order 3×3 is commutative with every square matrix of order 3×3 under multiplication and tr $(A) = 12$, then $\lvert A \rvert$ is divisible by	(p)	3
		(q)	4
(B)	Let $a, b, c \in R^+$ and the system of equations $(1-a)x + y + z = 0$, $x + (1-b)y + z = 0$, $x + y + (1-c)z = 0$ has infinitely many solutions. If λ be the minimum value of $a\,b\,c$, then λ is divisible by	(r)	6
(C)	Let $A = [a_{ij}]_{3\times 3}$ be a matrix whose elements are distinct integers from 1, 2, 3, ..., 9. The matrix is formed so that the sum of the numbers is every row, column and each diagonal is a multiple of 9. If number of all such possible matrices is λ, then λ is divisible by	(s)	8
(D)	If the equations $x + y = 1$, $(c+2)x + (c+4)y = 6$, $(c+2)^2x + (c+4)^2 y = 36$ are consistent and c_1, c_2 $(c_1 > c_2)$ are two values of c, then $c_1\,c_2$ is divisible by	(t)	9

75.

	Column I		Column II
(A)	If C is skew-symmetric matrix of order n and X is $n \times 1$ column matrix, then X^TCX is	(p)	invertible
(B)	If A is skew - symmetric, then $I - A$ is, where I is an identity matrix of order A.	(q)	singular
(C)	If $S = \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$ and $A = \begin{bmatrix} b+c & c-a & b-a \\ c-b & c+a & a-b \\ b-c & a-c & a+b \end{bmatrix}$ $(a, b, c \neq 0)$, then SAS^{-1} is	(r)	symmetric
(D)	If A, B, C are the angles of a triangle, then the matrix $A = \begin{bmatrix} \sin 2A & \sin C & \sin B \\ \sin C & \sin 2B & \sin A \\ \sin B & \sin A & \sin 2C \end{bmatrix}$ is	(s)	non-singular
		(t)	non-invertible

Matrices Exercise 6 : Statement I and II Type Questions

■ **Directions** (Q. Nos. 76 to 85) are Assertion-Reason type questions. Each of these questions contains two statements:
Statement-1 (Assertion) and **Statement-2** (Reason)
Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

76. **Statement-1** If matrix $A = [a_{ij}]_{3\times 3}$, $B = [b_{ij}]_{3\times 3}$, where $a_{ij} + a_{ji} = 0$ and $b_{ij} - b_{ji} = 0$, then A^4B^5 is non-singular matrix.
Statement-2 If A is non-singular matrix, then $\lvert A \rvert \neq 0$.

77. **Statement-1** If A and B are two square matrices of order $n \times n$ which satisfy $AB = A$ and $BA = B$, then $(A + B)^7 = 2^6\,(A + B)$.
Statement-2 A and B are unit matrices.

78. **Statement-1** For a singular matrix A, if $AB = AC \Rightarrow B = C$
Statement-2 If $\lvert A \rvert = 0$, then A^{-1} does not exist.

79. **Statement-1** If A is skew-symmetric matrix of order 3, then its determinant should be zero.
Statement-2 If A is square matrix, $\det(A) = \det(A') = \det(-A')$.

80. Let A be a skew-symmetric matrix, $B = (I - A)(I + A)^{-1}$ and X and Y be column vectors conformable for multiplication with B.
Statement-1 $(BX)^T\,(BY) = X^TY$
Statement-2 If A is skew-symmetric, then $(I + A)$ is non-singular.

81. **Statement-1** Let a 2×2 matrix A has determinant 2. If $B = 9A^2$, the determinant of B^T is equal to 36.

Statement-2 If A, B and C are three square matrices such that $C = AB$, then $|C| = |A||B|$.

82. **Statement-1** If $A = \begin{bmatrix} 1 & -1 & -1 \\ 1 & -1 & 0 \\ 1 & 0 & -1 \end{bmatrix}$, then $A^3 + A^2 + A = I$.

Statement-2 If $\det(A - \lambda I) = C_0\lambda^3 + C_1\lambda^2 + C_2\lambda + C_3 = 0$, then $C_0A^3 + C_1A^2 + C_3A + C_3I = O$.

83. **Statement-1** $A = [a_{ij}]$ be a matrix of order 3×3, where $a_{ij} = \dfrac{i-j}{i+2j}$ cannot be expressed as a sum of symmetric and skew-symmetric matrix.

Statement-2 Matrix $A = [a_{ij}]_{n\times n}$, $a_{ij} = \dfrac{i-j}{i+2j}$ is neither symmetric nor skew-symmetric.

84. **Statement-1** If A, B, C are matrices such that $|A_{3\times 3}| = 3$, $|B_{3\times 3}| = -1$ and $|C_{2\times 2}| = 2$, $|2ABC| = -12$.

Statement-2 For matrices A, B, C of the same order $|ABC| = |A||B||C|$.

85. **Statement-1** The determinant of a matrix $A = [a_{ij}]_{n\times n}$, where $a_{ij} + a_{ji} = 0$ for all i and j is zero.

Statement-2 The determinant of a skew-symmetric matrix of odd order is zero.

Matrices Exercise 7 : Subjective Type Questions

- In this section, there are **12 subjective** questions.

86. If S is a real skew-symmetric matrix, the show that $I - S$ is non-singular and matrix $A = (I+S)(I-S)^{-1} = (I-S)^{-1}(I+S)$ is orthogonal.

87. If M is a 3×3 matrix, where $\det M = I$ and $MM^T = I$, where I is an identity matrix, prove that $\det(M - I) = 0$.

88. If $A = \begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix}$, $B = \begin{bmatrix} \cos 2\beta & \sin 2\beta \\ \sin 2\beta & -\cos 2\beta \end{bmatrix}$, where $0 < \beta < \dfrac{\pi}{2}$, then prove that $BAB = A^{-1}$. Also, find the least value of α for which $BA^4B = A^{-1}$.

89. Find the product of two matrices

$$A = \begin{bmatrix} \cos^2\theta & \cos\theta\sin\theta \\ \cos\theta\sin\theta & \sin^2\theta \end{bmatrix} B = \begin{bmatrix} \cos^2\phi & \cos\phi\sin\phi \\ \cos\phi\sin\phi & \sin^2\phi \end{bmatrix}$$

Show that, AB is the zero matrix if θ and ϕ differ by an odd multiple of $\dfrac{\pi}{2}$.

90. Show that the matrix $\begin{bmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{bmatrix}$ is orthogonal,

if $l_1^2 + m_1^2 + n_1^2 = \Sigma l_1^2 = 1 = \Sigma l_2^2 = \Sigma l_3^2$ and $l_1l_2 + m_1m_2 + n_1n_2 = \Sigma l_1l_2 = 0 = \Sigma\, l_2l_3 = \Sigma l_3l_1$.

91. A finance company has offices located in every division, every district and every taluka in a certain state in India. Assume that there are five divisions, thirty districts and 200 talukas in the state. Each office has one head clerk, one cashier, one clerk and one peon. A divisional office has, in addition, one office superintendent, two clerks, one typist and one poen. A district office, has in addition, one clerk and one peon. The basic monthly salaries are as follows:

Office superintendent ₹ 500, Head clerk ₹ 200, cashier ₹ 175, clerks and typist ₹ 150 and peon ₹ 100. Using matrix notation find

(i) the total number of posts of each kind in all the offices taken together,

(ii) the total basic monthly salary bill of each kind of office

(iii) the total basic monthly salary bill of all the offices taken together.

92. In a development plan of a city, a contractor has taken a contract to construct certain houses for which he needs building materials like stones, sand etc. There are three firms A, B, C that can supply him these materials. At one time these firms A, B, C supplied him 40, 35 and 25 truck loads of stones and 10, 5 and 8 truck loads of stone and sand, respectively. If the cost of one truck load of stone and sand are ₹ 1200 and 500 respectively, find the total amount paid by the contractor to each of these firms A, B, C separately.

93. Show that the matrix $A = \begin{bmatrix} 1 & a & \alpha & a\alpha \\ 1 & b & \beta & b\beta \\ 1 & c & \gamma & c\gamma \end{bmatrix}$ is of rank 3 provided no two of a, b, c are equal and no two of α, β, γ are equal.

94. By the method of matrix inversion, solve the system.

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 5 & 7 \\ 2 & 1 & -1 \end{bmatrix} \begin{bmatrix} x & u \\ y & v \\ z & w \end{bmatrix} = \begin{bmatrix} 9 & 2 \\ 52 & 15 \\ 0 & -1 \end{bmatrix}$$

95. If $x_1 = 3y_1 + 2y_2 - y_3$, $\quad y_1 = z_1 - z_2 + z_3$

$x_2 = -y_1 + 4y_2 + 5y_3$, $y_2 = z_2 + 3z_3$

$x_3 = y_1 - y_2 + 3y_3$, $\quad y_3 = 2z_1 + z_2$

express x_1, x_2, x_3 in terms of z_1, z_2, z_3.

96. For what values of k the set of equations
$2x-3y+6z-5t=3, y-4z+t=1,$
$4x-5y+8z-9t=k$ has
(i) no solution? (ii) infinite number of solutions?

97. Let A, B, U, V and X be the matrices defined as follows.

$$A=\begin{bmatrix}a & 1 & 0\\ 1 & b & d\\ 1 & b & c\end{bmatrix}, B=\begin{bmatrix}a & 1 & 1\\ 0 & d & c\\ f & g & h\end{bmatrix}, U=\begin{bmatrix}f\\ g\\ h\end{bmatrix}, V=\begin{bmatrix}a^2\\ 0\\ 0\end{bmatrix}, X=\begin{bmatrix}x\\ y\\ z\end{bmatrix}$$

If $AX=U$ has infinitely many solutions, show that $BX=V$ cannot have a unique solution. If $afd\neq 0$, show that $BX=V$ has no solution.

Matrices Exercise 8 :
Questions Asked in Previous 13 Year's Exam

■ This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to year **2017**.

98. $A=\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 1\\ 0 & -2 & 4\end{bmatrix}; I=\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}$ and

$A^{-1}=\frac{1}{6}[A^2+cA+dI]$ where $c, d\in R$, the pair of values (c, d) **[IIT- JEE 2005, 3M]**

(a) (6, 11) (b) (6, − 11) (c) (− 6, 11) (d) (− 6, − 11)

99. If $P=\begin{bmatrix}\frac{\sqrt{3}}{2} & \frac{1}{2}\\ -\frac{1}{2} & \frac{\sqrt{3}}{2}\end{bmatrix}, A=\begin{bmatrix}1 & 1\\ 0 & 1\end{bmatrix}$ and $Q=PAP^T$, the $P(Q^{2005})P^T$ equal to **[IIT- JEE 2005, 3M]**

(a) $\begin{bmatrix}1 & 2005\\ 0 & 1\end{bmatrix}$ (b) $\begin{bmatrix}\sqrt{3}/1 & 2005\\ 1 & 0\end{bmatrix}$

(c) $\begin{bmatrix}1 & 2005\\ \sqrt{3}/2 & 1\end{bmatrix}$ (d) $\begin{bmatrix}1 & \sqrt{3}/2\\ 0 & 2005\end{bmatrix}$

100. If $A=\begin{bmatrix}1 & 0\\ 1 & 1\end{bmatrix}$ and $I=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}$, which one of the following holds for all $n\geq 1$, (by the principal of mathematical induction) **[AIEEE 2005, 3M]**

(a) $A^n=nA+(n-1)I$ (b) $A^n=2^{n-1}A+(n-1)I$

(c) $A^n=nA-(n-1)I$ (d) $A^n=2^{n-1}A-(n-1)I$

101. If $A^2-A+I=0$, then A^{-1} is equal to **[AIEEE 2005, 3M]**

(a) A^{-2} (b) $A+I$ (c) $I-A$ (d) $A-I$

102. If $A=\begin{pmatrix}1 & 0 & 0\\ 2 & 1 & 0\\ 3 & 2 & 1\end{pmatrix}, U_1, U_2$ and U_3 are column matrices satisfying $AU_1=\begin{pmatrix}1\\ 0\\ 0\end{pmatrix}, AU_2=\begin{pmatrix}2\\ 3\\ 0\end{pmatrix}$ and $AU_3=\begin{pmatrix}2\\ 3\\ 1\end{pmatrix}$ and U is 3×3 matrix when columns are U_1, U_2, U_3, then answer the following questions

(i) The value of $|U|$ is
(a) 3 (b) − 3 (c) 3/2 (d) 2

(ii) The sum of the elements of U^{-1} is
(a) − 1 (b) 0 (c) 1 (d) 3

(iii) The value of $(3\ 2\ 0)\,U\begin{pmatrix}3\\ 2\\ 0\end{pmatrix}$ is **[IIT- JEE 2006, 5+5+5M]**

(a) 5 (b) 5/2 (c) 4 (d) 3/2

103. Let $A=\begin{pmatrix}1 & 2\\ 3 & 4\end{pmatrix}$ and $B=\begin{pmatrix}a & 0\\ 0 & b\end{pmatrix}, a, b\in N$. Then, **[AIEEE 2006, 4½M]**

(a) there cannot exist any B such that $AB=BA$
(b) there exist more than one but finite number of B's such that $AB=BA$
(c) there exists exactly one B such that $AB=BA$
(d) there exist infinitely among B's such that $AB=BA$

104. If A and B are square matrices of size $n\times n$ such that $A^2-B^2=(A-B)(A+B)$, which of the following will be always true? **[AIEEE 2006, 3M]**

(a) $A=B$ (b) $AB=BA$
(c) Either of A or B is a zero matrix
(d) Either of A or B is identity matrix

105. Let $A=\begin{bmatrix}5 & 5\alpha & \alpha\\ 0 & \alpha & 5\alpha\\ 0 & 0 & 5\end{bmatrix}$. If $|A^2|=25$, then $|\alpha|$ equals to **[AIEEE 2007, 3M]**

(a) 5^2 (b) 1 (c) 1/5 (d) 5

106. Let A and B be 3×3 matrices of real numbers, where A is symmetric, B is skew-symmetric and $(A+B)(A-B)=(A-B)(A+B)$. If $(AB)^t=(-1)^k AB$, where $(AB)^t$ is the transpose of matrix AB, the value of k is **[IIT- JEE 2008, 1½M]**

(a) 0 (b) 1 (c) 2 (d) 3

107. Let A be a square matrix all of whose entries are integers. Which one of the following is true? **[AIEEE 2008, 3M]**

(a) If det $A\neq\pm 1$, then A^{-1} exists and all its entries are non-integers
(b) If det $A=\pm 1$, then A^{-1} exists and all its entries are integers
(c) If det $A=\pm 1$, then A^{-1} need not exist
(d) If det $A=\pm 1$, then A^{-1} exists but all its entries are not necessarily integers

108. Let A be a 2×2 matrix with real entries. Let I be the 2×2 identity matrix. Denote by $\text{tr}(A)$, the sum of diagonal entries of A. Assume that $A^2 = I$. **[AIEEE 2008, 3M]**

Statement-1 If $A \neq I$ and $A \neq -I$, then $\det A = -1$.

Statement-2 If $A \neq I$ and $A \neq -1$, then $\text{tr}(A) \neq 0$.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(c) Statement-1 is true, Statement-2 is false

(d) Statement-1 is false, Statement-2 is true

109. Let A be the set of all 3×3 symmetric matrices all of whose entries are either 0 or 1. Five of these entries are 1 and four of them are 0. **[IIT- JEE 2009, 4+4+4M]**

(i) The number of matrices in A is

(a) 12 (b) 6

(c) 9 (d) 3

(ii) The number of matrices A for which the system of linear equations $A\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ has a unique solution, is

(a) less than 4 (b) atleast 4 but less than 7

(c) atleast 7 but less than 10

(d) atleast 10

(iii) The number of matrices A in which the system of linear equations $A\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ is inconsistent is

(a) 0 (b) more than 2

(c) 2 (d) 1

110. Let A be a 2×2 matrix

Statement-1 $\text{adj}\,(\text{adj}\,A) = A$

Statement-2 $|\text{adj}\,A| = |A|$ **[AIEEE 2009, 4M]**

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(c) Statement-1 is true, Statement-2 is false

(d) Statement-1 is false, Statement-2 is true

111. The number of 3×3 matrices A whose are either 0 or 1 and for which the system $A\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ has exactly two distinct solutions, is **[IIT- JEE 2010, 3M]**

(a) 0 (b) $2^9 - 1$

(c) 168 (d) 2

112. Let p be an odd prime number and T_p be the following set of 2×2 matrices.

$$T_p = \left\{ A = \begin{bmatrix} a & b \\ c & a \end{bmatrix};\ a, b, c, \in \{0, 1, 2, \ldots, p-1\} \right\}$$

[IIT- JEE 2010, 3+3+3M]

(i) The number of A in T_p such that A is either symmetric or skew-symmetric or both and $\det(A)$ divisible by p, is

(a) $(p-1)^2$ (b) $2(p-1)$

(c) $(p-1)^2 + 1$ (d) $2p - 1$

(ii) The number of A in T_p such that the trace of A is not divisible by p but $\det(A)$ is divisible by p, is

[**Note** The trace of a matrix is the sum of its diagonal entries]

(a) $(p-1)(p^2 - p + 1)$ (b) $p^3 - (p-1)^2$

(c) $(p-1)^2$ (d) $(p-1)(p^2 - 2)$

(iii) The number of A in T_p such that $\det(A)$ is not divisible by p, is

(a) $2p^2$ (b) $p^3 - 5p$ (c) $p^3 - 3p$ (d) $p^3 - p^2$

113. Let k be a positive real number and let

$$A = \begin{bmatrix} 2k-1 & 2\sqrt{k} & 2\sqrt{k} \\ 2\sqrt{k} & 1 & -2k \\ -2\sqrt{k} & 2k & -1 \end{bmatrix} \text{ and } \begin{bmatrix} 0 & 2k-1 & \sqrt{k} \\ 1-2k & 0 & 2\sqrt{k} \\ -\sqrt{k} & -2\sqrt{k} & 0 \end{bmatrix}.$$

If $\det(\text{adj}\,A) + \det(\text{adj}\,B) = 10^6$, then $[k]$ is equal to **[IIT- JEE 2010, 3M]**

Note adj M denotes the adjoint of a square matrix M and $[k]$ denotes the largest integer less than or equal to k}.

114. The number of 3×3 non-singular matrices, with four entries as 1 and all other entries as 0, is **[AIEEE 2010, 8M]**

(a) 5 (b) 6

(c) atleast 7 (d) less than 4

115. Let A be a 2×2 matrix with non-zero entries and let $A^2 = I$, where I is 2×2 identity matrix. Define $\text{Tr}(A)$ = sum of diagonal elements of A and $|A|$ = determinant of matrix A.

Statement-1 $\text{Tr}(A) = 0$

Statement-2 $|A| = 1$ **[AIEEE 2010, 4M]**

(a) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1.

(b) Statement-1 is true, Statement-2 is false.

(c) Statement-1 is false, Statement-2 is true.

(d) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1.

116. Let M and N be two 3×3 non-singular skew-symmetric matrices such that $MN = NM$. If P^T denotes the transpose of P, then $M^2N^2(M^TN)^{-1}(MN^{-1})^T$ is equal to **[IIT- JEE 2011, 4M]**

(a) M^2 (b) $-N^2$ (c) $-M^2$ (d) MN

117. Let a, b and c be three real numbers satisfying

$$[a\ b\ c]\begin{bmatrix}1 & 9 & 7\\ 8 & 2 & 7\\ 7 & 3 & 7\end{bmatrix} = [0\ 0\ 0]. \qquad \ldots(E)$$

(i) If the point $P(a, b, c)$, with reference to (E), lies on the plane $2x + y + z = 1$, then the value of $7a + b + c$ is

(a) 0 (b) 12 (c) 7 (d) 6

(ii) Let ω be a solution of $x^3 - 1 = 0$ with $\text{Im}(\omega) > 0$. If $a = 2$ with b and c satisfying (E), the value of $\frac{3}{\omega^a} + \frac{1}{\omega^b} + \frac{3}{\omega^c}$ is equal to

(a) -2 (b) 2 (c) 3 (d) -3

(iii) Let $b = 6$ with a and c satisfying (E). If α and β are the roots of the quadratic equation $ax^2 + bx + c = 0$, then $\sum_{n=0}^{\infty}\left(\frac{1}{\alpha} + \frac{1}{\beta}\right)^n$ is **[IIT- JEE 2011, 3+3+3M]**

(a) 6 (b) 7

(c) $\frac{6}{7}$ (d) ∞

118. Let $\omega \neq 1$ be a cube root of unity and S be the set of all non-singular matrices of the form $\begin{bmatrix}1 & a & b\\ \omega & 1 & c\\ \omega^2 & \omega & 1\end{bmatrix}$, where each of a, b and c is either ω or ω^2. The number of distinct matrices in the set S is **[IIT- JEE 2011, 3M]**

(a) 2 (b) 6

(c) 4 (d) 8

119. Let M be a 3×3 matrix satisfying $M\begin{bmatrix}0\\1\\0\end{bmatrix} = \begin{bmatrix}-1\\2\\3\end{bmatrix}$,

$$M\begin{bmatrix}1\\-1\\0\end{bmatrix} = \begin{bmatrix}1\\1\\-1\end{bmatrix} \text{ and } M\begin{bmatrix}1\\1\\1\end{bmatrix} = \begin{bmatrix}0\\0\\12\end{bmatrix}.$$

The sum of the diagonal entries of M is **[IIT- JEE 2011, 4M]**

120. Let A and B are symmetric matrices of order 3.

Statement-1 $A(BA)$ and $(AB)A$ are symmetric matrices.

Statement-2 AB is symmetric matrix, if matrix multiplication of A with B is commutative.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is false

(c) Statement-1 is false, Statement-2 is true

(d) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1 **[AIEEE 2011, 4M]**

121. Let $P = [a_{ij}]$ be a 3×3 matrix and $Q = [b_{ij}]$, where $b_{ij} = 2^{i+j}\ a_{ij}$ for $1 \le i, j \le 3$. If the determinant of P is 2, the determinant of the matrix Q is **[IIT- JEE 2012, 3M]**

(a) 2^{11} (b) 2^{12}

(c) 2^{13} (d) 2^{10}

122. If P is a 3×3 matrix such that $P^T = 2P + I$, where P^T is the transpose of P and I is the 3×3 identity matrix, then there exists a column matrix $X = \begin{bmatrix}x\\y\\z\end{bmatrix} \neq \begin{bmatrix}0\\0\\0\end{bmatrix}$ such that **[IIT- JEE 2012, 3M]**

(a) $PX = \begin{bmatrix}0\\0\\0\end{bmatrix}$ (b) $PX = X$ (c) $PX = 2X$ (d) $PX = -X$

123. If the adjoint of a 3×3 matrix P is $\begin{bmatrix}1 & 4 & 4\\ 2 & 1 & 7\\ 1 & 1 & 3\end{bmatrix}$, then the possible value(s) of the determinant of P is (are) **[IIT- JEE 2012, 4M]**

(a) -2 (b) -1 (c) 1 (d) 2

124. If $A = \begin{pmatrix}1 & 0 & 0\\ 2 & 1 & 0\\ 3 & 2 & 1\end{pmatrix}$, u_1 and u_2 are the column matrices such that $Au_1 = \begin{pmatrix}1\\0\\0\end{pmatrix}$ and $Au_2 = \begin{pmatrix}0\\1\\0\end{pmatrix}$, then $u_1 + u_2$ is equal to **[AIEEE 2012, 4M]**

(a) $\begin{pmatrix}-1\\-1\\0\end{pmatrix}$ (b) $\begin{pmatrix}1\\-1\\-1\end{pmatrix}$ (c) $\begin{pmatrix}-1\\1\\0\end{pmatrix}$ (d) $\begin{pmatrix}-1\\1\\-1\end{pmatrix}$

125. Let P and Q be 3×3 matrices with $P \neq Q$. If $P^3 = Q^3$ and $P^2Q = Q^2P$, the determinant of $(P^2 + Q^2)$ is equal to **[AIEEE 2012, 4M]**

(a) 0 (b) -1 (c) -2 (d) 1

126. If $P = \begin{bmatrix}1 & \alpha & 3\\ 1 & 3 & 3\\ 2 & 4 & 4\end{bmatrix}$ is the adjoint of a 3×3 matrix A and $|A| = 4$, then α is equal to **[JEE Main 2013, 4M]**

(a) 11 (b) 5 (c) 0 (d) 4

127. For 3×3 matrices M and N, which of the following statement(s) is (are) **not** correct?

(a) N^TMN is symmetric or skew-symmetric, according as M is symmetric or skew-symmetric

(b) $MN - NM$ is skew-symmetric for all symmetric matrices M and N

(c) MN is symmetric for all symmetric matrices M and N

(d) $(\text{adj}\,M)(\text{adj}\ N) = \text{adj}\,(MN)$ for all invertible matrices M and N **[JEE Advanced 2013, 4M]**

128. Let ω be a complex cube root of unity with $\omega \neq 1$ and $P = [p_{ij}]$ be a $n \times n$ matrix with $p_{ij} = \omega^{i+j}$. Then, $p^2 \neq 0$, when n is equal to **[JEE Advanced 2013, 3M]**

(a) 55 (b) 56 (c) 57 (d) 58

129. If A is a 3×3 non-singular matrix such that $AA' = A'A$ and $B = A^{-1}A'$, then BB' equals to **[JEE Main 2014, 4M]**

(a) B^{-1} (b) $(B^{-1})'$ (c) $I + B$ (d) I

130. Let M be a 2×2 symmetric matrix with integer entries. Then, M is invertible, if

(a) the first column of M is the transpose of the second row of M

(b) the second row of M is the transpose of the first column of M

(c) m is a diagonal matrix with non-zero entries in the main diagonal

(d) the product of entries in the main diagonal of M is not the square of an integer **[JEE Advanced 2014, 3M]**

131. Let M and N be two 3×3 matrices such that $MN = NM$. Further, if $M \neq N^2$ and $M^2 = N^4$, then

(a) determinant of $(M^2 + MN^2)$ is 0

(b) there is a 3×3 non-zero matrix U such that $(M^2 + MN^2)U$ is the zero matrix

(c) determinant of $(M^2 + MN^2) \geq 1$

(d) for a 3×3 matrix U, if $(M^2 + MN^2)U$ equals the zero matrix, then U is the zero matrix **[JEE Advanced 2014, 3M]**

132. If $A = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & -2 \\ a & 2 & b \end{bmatrix}$ is a matrix satisfying the equation $AA^T = 9I$, where I is 3×3 identity matrix, then the ordered pair (a, b) is equal to **[JEE Main 2015, 4M]**

(a) (2, 1) (b) (−2, −1) (c) (2, −1) (d) (−2, 1)

133. Let X and Y be two arbitrary 3×3 non-zero, skew-symmetric matrices and Z be an arbitrary 3×3 non-zero, symmetric matrix. Then, which of the following matrices is (are) skew-symmetric? **[JEE Advanced 2015, 4M]**

(a) $Y^3Z^4 - Z^4Y^3$ (b) $X^{44} + Y^{44}$

(c) $X^4Z^3 - Z^3X^4$ (d) $X^{23} + Y^{23}$

134. If $A = \begin{bmatrix} 5a & -b \\ 3 & 2 \end{bmatrix}$ and $A\,\text{adj}A = AA^T$, then $5a + b$ is equal to **[JEE Main 2016, 4M]**

(a) 5 (b) 13

(c) 4 (d) −1

135. Let $P = \begin{bmatrix} 3 & -1 & -2 \\ 2 & 0 & \alpha \\ 3 & -5 & 0 \end{bmatrix}$, where $\alpha \in R$. Suppose $Q = [q_{ij}]$ is a matrix such that $PQ = kI$, where $k \in R, k \neq 0$ and I is the identity matrix of order 3. If $q_{23} = -\frac{k}{8}$ and $\det.(Q) = \frac{k^2}{2}$, then **[JEE Advanced 2016, 4M]**

(a) $\alpha = 0, k = 8$ (b) $4\alpha - k + 8 = 0$

Solutions

1. $\because \quad A^4(I-A) = A^4I - A^5 = A^4 - 0 = A^4 \neq I$

$A^3(I-A) = A^3I - A^4 = A^3 - A^4 \neq I$

$(I+A)(I-A) = I^2 - A^2 = I - A^2 \neq I$

2. $\because \det(B) = \begin{vmatrix} 4x & 2a & -p \\ 4y & 2b & -q \\ 4z & 2c & -r \end{vmatrix} = -8 \begin{vmatrix} x & a & p \\ y & b & q \\ z & c & r \end{vmatrix}$

$= -8 \begin{vmatrix} x & y & z \\ a & b & c \\ p & q & r \end{vmatrix} = 8 \begin{vmatrix} a & b & c \\ x & y & z \\ p & q & r \end{vmatrix}$ [by property]

$= -8 \begin{vmatrix} a & b & c \\ p & q & r \\ x & y & z \end{vmatrix} = -8 \det(A) = -16$

3. $\because \quad \left(A - \frac{1}{2}I\right)\left(A - \frac{1}{2}I\right)^T = I$ ...(i)

and $\left(A + \frac{1}{2}I\right)\left(A + \frac{1}{2}I\right)^T = I$ ...(ii)

$\Rightarrow \quad \left(A - \frac{1}{2}I\right)\left(A^T - \frac{I}{2}\right) = I$

and $\left(A + \frac{1}{2}I\right)\left(A^T + \frac{1}{2}I\right) = I$

$\Rightarrow \quad A + A^T = 0$ [subtracting the two results]

$\Rightarrow \quad A^T = -A$

$\therefore$ A is skew-symmetric matrix.

From first result, we get

$AA^T = \frac{3}{4}I$

$\Rightarrow \quad A^2 = -\frac{3}{4}I$

$\therefore \quad |A^2| = \left|-\frac{3}{4}I\right|$

$\therefore \quad |A|^2 = \left(-\frac{3}{4}\right)^n$

$\Rightarrow$ n is even.

4. $\because \quad a = \lim_{x\to 1}\left(\frac{x}{\ln x} - \frac{1}{x \ln x}\right) = \lim_{x\to 1}\left(\frac{x^2-1}{x \ln x}\right)$

$= \lim_{x\to 1}\left(\frac{2x}{1 + \ln x}\right)$ [by L'Hospital's Rule]

$b = \lim_{x\to 0}\left(\frac{x^3 - 16x}{4x + x^2}\right)$

$= \lim_{x\to 0}\left(\frac{x(x+4)(x-4)}{x(x+4)}\right) = \lim_{x\to 0}(x-4) = -4$

$c = \lim_{x\to 0}\frac{\ln(1+\sin x)}{x}$

$= \lim_{x\to 0}\frac{\ln(1+\sin x)}{\sin x} \cdot \lim_{x\to 0}\frac{\sin x}{x} = 1 \cdot 1 = 1$

$d = \lim_{x\to -1}\frac{(x+1)^3}{3[\sin(x+1) - (x+1)]}$

$= \lim_{x\to -1}\frac{3(x+1)^2}{3[\cos(x+1) - 1]}$ [using L'Hospital's Rule]

$= -\lim_{x\to -1}\frac{1}{\frac{[1-\cos(x+1)]}{(x+1)^2}} = -2$

Let, $A = \begin{bmatrix} 2 & -4 \\ 1 & -2 \end{bmatrix} \Rightarrow A^2 = 0$

5. $\because \quad (A - \lambda I)X = 0$

$\therefore \quad |A - \lambda I| = 0$

$\Rightarrow \quad \begin{vmatrix} 1-\lambda & 4 \\ 3 & 2-\lambda \end{vmatrix} = 0$

$\Rightarrow \quad \lambda^2 - 3\lambda - 10 = 0$

$\therefore \quad \lambda = -2, 5$

For $\lambda = -2 \quad \Rightarrow \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 4 \\ -3 \end{bmatrix}$

For $\lambda = 5 \quad \Rightarrow \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$

$\therefore \cos\theta = \frac{4\cdot 1 + (-3)\cdot 1}{\sqrt{(16+9)}\sqrt{(1+1)}} = \frac{1}{5\sqrt{2}}$

$\therefore \tan\theta = \sqrt{(\sec^2\theta - 1)} = \sqrt{49} = 7$

6. $\because A^{2n+1} = (A^2)^n \cdot A = (I)^n \cdot A = IA = A$

7. $\because \quad A = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$

$\therefore \quad A^n = \begin{bmatrix} \cos n\theta & \sin n\theta \\ -\sin n\theta & \cos n\theta \end{bmatrix}$

$\Rightarrow \lim_{n\to\infty}\frac{A^n}{n} = \begin{bmatrix} \lim_{n\to\infty}\frac{\cos n\theta}{n} & \lim_{n\to\infty}\frac{\sin n\theta}{n} \\ -\lim_{n\to\infty}\frac{\sin n\theta}{n} & \lim_{n\to\infty}\frac{\cos n\theta}{n} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$

$=$ a zero matrix [$\because -1 < \sin\infty < 1$ and $-1 < \cos\infty < 1$]

8. Let $A = \begin{bmatrix} -1 & 2 & 5 \\ 2 & -4 & -10 \\ 1 & -2 & -5 \end{bmatrix}$ [$\because a = -6$]

Applying $R_2 \to R_2 + 2R_1$ and $R_3 \to R_3 + R_1$, then

$A = \begin{bmatrix} -1 & 2 & 5 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \Rightarrow \rho(A) = 1$

9. $\because$ A is involutory

$\therefore \quad A^2 = I \Rightarrow A = A^{-1}$

$\therefore \quad \left(\frac{A}{2}\right)^{-1} = 2A^{-1} = 2A$

10. $\because \quad B = \text{adj } A$

$\Rightarrow \quad AB = A(\text{adj } A) = |A| I_n$

$\therefore \quad AB + kI_n = |A| I_n + kI_n = (|A| + k) I_n$

$\Rightarrow \quad |AB + kI_n| = |(|A| + k) I_n| = (|A| + k)^n$

11. $\because \quad B = -A^{-1}BA$

$\Rightarrow \quad AB = -BA$

$\Rightarrow \quad AB + BA = 0$

Now, $(A + B)^2 = (A + B)(A + B)$

$= A^2 + AB + BA + B^2$

$= A^2 + 0 + B^2$

$= A^2 + B^2$

12. Since, A is skew-symmetric.

$\therefore \quad |A| = 0$

$\Rightarrow \quad |A^4 B^3| = |A^4||B^3| = |A|^4 |B|^3 = 0$

13. Let $B = A + I_n$

$\therefore \quad A = B - I_n$

Given, $A^n = \alpha A$

$\Rightarrow \quad (B - I_n)^n = \alpha (B - I_n)$

$\Rightarrow \quad B^n - {}^nC_1 B^{n-1} + {}^nC_2 B^{n-2} + \ldots + (-1)^n I_n$

$= \alpha B - \alpha I_n$

$\Rightarrow B(B^{n-1} - {}^nC_1 B^{n-2} + {}^nC_2 B^{n-3} + \ldots + (-1)^{n-1} I_n - \alpha I_n)$

$= [(-1)^{n+1} - \alpha] I_n \neq 0 \qquad [\because \alpha \neq \pm 1]$

Hence, B is invertible.

14. $\because \ \omega = \dfrac{-1 + i\sqrt{3}}{2}$ and $\omega^2 = \dfrac{-1 - i\sqrt{3}}{2}$

Also, $\omega^3 = 1$ and $\omega + \omega^2 = -1$

Thus, $A = \begin{bmatrix} -i\omega & -i\omega^2 \\ i\omega^2 & i\omega \end{bmatrix}$

$\therefore \quad A^2 = \begin{bmatrix} -i\omega & -i\omega^2 \\ i\omega^2 & i\omega \end{bmatrix}\begin{bmatrix} -i\omega & -i\omega^2 \\ i\omega^2 & i\omega \end{bmatrix} = \begin{bmatrix} -\omega^2 + \omega & 0 \\ 0 & -\omega^2 + \omega \end{bmatrix}$

Now, $f(A) = A^2 + 2I = \begin{bmatrix} -\omega^2 + \omega & 0 \\ 0 & -\omega^2 + \omega \end{bmatrix} + \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$

$= \begin{bmatrix} -\omega^2 + \omega + 2 & 0 \\ 0 & -\omega^2 + \omega + 2 \end{bmatrix}$

$= (-\omega^2 + \omega + 2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = (2 + i\sqrt{3})\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

15. $\because \quad X^2 = I \Rightarrow (X^{-1}X) X = X^{-1}I$

$\Rightarrow \quad IX = X^{-1}$

$\Rightarrow \quad X = X^{-1}$

which is self invertible involutory matrix.

There are many such matrices which are inverse of their own.

16. $\because \quad AB = A + B$

$\Rightarrow \quad B = AB - A = A(B - I)$

$\Rightarrow \quad \det(B) = \det(A) \cdot \det(B - I) = 0$

$[\because A^{2006} = 0 \Rightarrow \det A^{2006} = 0] \ [\therefore \det A = 0]$

17. We have, $P^T = P^{-1} \qquad [\because PP^T = I]$

Now, $Q = PAP^T = PAP^{-1}$

$\therefore \quad Q^{2007} = PA^{2007}P^{-1}$

$\therefore \quad P^T Q^{2007} P = P^{-1}(PA^{2007}P^{-1}) P$

$= A^{2007} = \begin{bmatrix} 1 & 2007 \\ 0 & 1 \end{bmatrix}$

$\left[\because A^2 = \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix}, A^3 = \begin{bmatrix} 1 & 3 \\ 0 & 1 \end{bmatrix}, \ldots\right]$

18. $\because \quad \begin{bmatrix} A - 5 & B \\ 2A - 2 & C \end{bmatrix} = \begin{bmatrix} 2A + 1 & -5 \\ -4 & A \end{bmatrix}\begin{bmatrix} 14 & D \\ E & F \end{bmatrix}$

$\Rightarrow \quad A - 5 = 28A + 14 - 5E$

$\Rightarrow \quad 5E = 27A + 19 \qquad \ldots(i)$

$2A - 2 = -56 + AE$

$\Rightarrow \quad AE = 2A + 54 \qquad \ldots(ii)$

From Eq. (i), we get

$5AE = 27A^2 + 19A$

$\Rightarrow \quad 5(2A + 54) = 27A^2 + 19A \qquad$ [from Eq. (ii)]

$\Rightarrow \quad 27A^2 + 9A - 270 = 0$

$\Rightarrow \quad 9(A - 3)(3A + 10) = 0$

$\therefore \quad A = 3, A = -\dfrac{10}{3}$

$\therefore$ Absolute value of difference

$= \left|3 + \dfrac{10}{3}\right| = \dfrac{19}{3}$

19. $\because |f(\theta)| = \begin{vmatrix} \cos^2\theta & \cos\theta \sin\theta & -\sin\theta \\ \cos\theta \sin\theta & \sin^2\theta & \cos\theta \\ \sin\theta & -\cos\theta & 0 \end{vmatrix}$

On multiplying in R_3 by $\cos\theta$ and then take common $\cos\theta$ from C_1, then

$$|f(\theta)| = \begin{vmatrix} \cos\theta & \cos\theta \sin\theta & -\sin\theta \\ \sin\theta & \sin^2\theta & \cos\theta \\ \sin\theta & -\cos^2\theta & 0 \end{vmatrix}$$

Applying $R_2 \to R_2 - R_3$, we get

$$|f(\theta)| = \begin{vmatrix} \cos\theta & \cos\theta\sin\theta & -\sin\theta \\ 0 & 1 & \cos\theta \\ \sin\theta & -\cos^2\theta & 0 \end{vmatrix} = 1$$

Applying $C_2 \to C_2 - \sin\theta\, C_1$, then

$$|f(\theta)| = \begin{vmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & \cos\theta \\ \sin\theta & -1 & 0 \end{vmatrix} = 1$$

$\therefore \quad f\left(\dfrac{\pi}{7}\right)$ is non-singular matrix.

20. $\because\ a_{11} = a_{22} = a_{33} = a + b,$

$a_{12} = a_{23} = ab,\ a_{21} = a_{32} = 1,\ a_{13} = a_{31} = 0$

$$\therefore \quad A = \begin{bmatrix} a+b & ab & 0 \\ 1 & a+b & ab \\ 0 & 1 & a+b \end{bmatrix}$$

$$\Rightarrow |A| = \begin{vmatrix} a+b & ab & 0 \\ 1 & a+b & ab \\ 0 & 1 & a+b \end{vmatrix}$$

$$= (a+b)[(a+b)^2 - ab] - ab(a+b) = (a+b)(a^2+b^2)$$

21. Given, $B^r = I \Rightarrow B^r B^{-1} = IB^{-1}$

$$\Rightarrow \quad B^{r-1} = B^{-1}$$

$$\therefore \quad A^{-1}B^{r-1}A = A^{-1}B^{-1}A$$

$$\Rightarrow \quad A^{-1}B^{r-1}A - A^{-1}B^{-1}A = 0$$

22. Here, $A = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix}$

$$\Rightarrow \quad AA^T = I$$

$\because \quad C = ABA^T \Rightarrow A^TC = BA^T$

Now, $A^TC^nA = A^TC \cdot C^{n-1}A$

$$= BA^TC^{n-1}A = BA^TC\,C^{n-2}A$$

$$= B^2A^TC^{n-2}A$$

$$\ldots \quad \ldots \quad \ldots$$

$$= B^{n-1}A^TCA = B^{n-1}(BA^T)\,A$$

$$= B^nA^TA = B^nI = B^n = \begin{bmatrix} 1 & 0 \\ -n & 1 \end{bmatrix}$$

23. $\because\ |\text{adj}\,A^{-1}| = |A^{-1}|^2 = \dfrac{1}{|A|^2}$

$$\therefore\ |(\text{adj}\,A^{-1})^{-1}| = \frac{1}{|\text{adj}\,A^{-1}|} = |A|^2 = 2^2 = 4$$

24. $\because\ A^3 - A^2B = B^3 - B^2A$

$$\Rightarrow \quad A^2(A-B) = B^2(B-A)$$

or $\quad (A^2 + B^2)(A-B) = 0$

or $\det(A^2+B^2)\cdot\det(A-B) = 0$

Either $\det(A^2+B^2) = 0$ or $\det(A-B) = 0$

25. Let, $A = \begin{bmatrix} 0 & a \\ -a & 0 \end{bmatrix}$,

$$BC = \begin{bmatrix} 1 & 4 \\ 2 & 9 \end{bmatrix}\begin{bmatrix} 9 & -4 \\ -2 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I$$

$$\therefore\ B^2C^2 = (BC)^2 = I^2 = I$$

Similarly, $B^2C^2 = B^3C^3 = \ldots = B^nC^n = I$

Let, $\quad D = A^3(BC) + A^5(B^2C^2) + A^7(B^3C^3)$

$$+ \ldots + A^{2n+1}(B^nC^n)$$

$$= A^3 + A^5 + A^7 + \ldots + A^{2n+1}$$

$$= A(A^2 + A^4 + A^6 + \ldots + A^{2n})$$

Let, $\quad A = \begin{bmatrix} 0 & a \\ -a & 0 \end{bmatrix}$

$$\Rightarrow \quad A^2 = \begin{bmatrix} -a^2 & 0 \\ 0 & -a^2 \end{bmatrix} = -a^2I$$

$$\therefore \quad D = IA(-a^2 + a^4 - a^6 + \ldots + (-1)^n a^{2n}) \qquad [a > 0]$$

$$= A(-a^2 + a^4 - a^6 + \ldots + (-1)^n a^{2n})$$

Hence, D is skew-symmetric.

26. $\because \quad |B| = \begin{vmatrix} q & -b & y \\ -p & a & -x \\ r & -c & z \end{vmatrix}$

Applying $R_2 \to (-1)\,R_2$, then

$$|B| = \begin{vmatrix} q & -b & y \\ p & -a & x \\ r & -c & z \end{vmatrix}$$

Applying $C_2 \to (-1)\,C_2$, then

$$|B| = \begin{vmatrix} q & b & y \\ p & a & x \\ r & c & z \end{vmatrix} = |B^T| = \begin{vmatrix} q & p & r \\ b & a & c \\ y & x & z \end{vmatrix}$$

$$= -\begin{vmatrix} b & a & c \\ q & p & r \\ y & x & z \end{vmatrix} \qquad [R_1 \leftrightarrow R_2]$$

$$= \begin{vmatrix} b & a & c \\ y & x & z \\ q & p & r \end{vmatrix} \qquad [R_2 \leftrightarrow R_30]$$

$$= -\begin{vmatrix} a & b & c \\ x & y & z \\ p & q & r \end{vmatrix} = -|A|$$

$$\Rightarrow \quad |B| = -|A|$$

Also, $|\text{adj}\,B| = |B|^2$

$$= |A|^2 = |\text{adj}\,A| \qquad [\because |A| \neq 0, \text{ then } |B| \neq 0]$$

27. $\because \quad BC = \begin{bmatrix} 3 & 4 \\ 2 & 3 \end{bmatrix}\begin{bmatrix} 3 & -4 \\ -2 & 3 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I$

$$\therefore \quad \text{tr}(A) + \text{tr}\left(\frac{ABC}{2}\right) + \text{tr}\left(\frac{A(BC)^2}{4}\right) + \text{tr}\left(\frac{A(BC)^3}{8}\right) + \ldots$$

$$= \text{tr}(A) + \text{tr}\left(\frac{A}{2}\right) + \text{tr}\left(\frac{A}{2^2}\right) + \text{tr}\left(\frac{A}{2^3}\right) + \ldots \text{ upto } \infty$$

$$= \text{tr}(A) + \frac{1}{2}\text{tr}(A) + \frac{1}{2^2}\text{tr}(A) + \ldots \text{ upto } \infty$$

$$= \frac{\text{tr}(A)}{1 - \left(\frac{1}{2}\right)} = 2\,\text{tr}(A) = 2(2+1) = 6$$

28. We have, $\quad (A - 2I)(A - 4I) = 0$

$$\Rightarrow \quad A^2 - 4A - 2A + 8I^2 = 0$$

$$\Rightarrow \quad A^2 - 6A + 8I = 0$$

$$\Rightarrow \quad A^{-1}(A^2 - 6A + 8I) = A^{-1}0$$

$$\Rightarrow \quad A - 6I + 8A^{-1} = 0$$

$$\Rightarrow \quad \frac{1}{6}A + \frac{4}{3}A^{-1} = I$$

29. We have, $AA^{-1} = I$

$$\Rightarrow \begin{bmatrix} 0 & 1 & 2 \\ 1 & 2 & 3 \\ 3 & a & 1 \end{bmatrix}\begin{bmatrix} \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \\ -4 & 3 & 6 \\ \frac{5}{2} & -\frac{3}{2} & \frac{1}{2} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 1 & 0 & b+1 \\ 0 & 1 & 2(b+1) \\ 4(1-a) & 3(a-1) & ab+2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

On comparing, we get

$$b + 1 = 0, ab + 2 = 1, a - 1 = 0$$

$$\therefore \quad a = 1, b = -1$$

30. $\because \quad A(\text{adj } A) = |A| I$ ...(i)

Now, $$|A| = \begin{vmatrix} x & 3 & 2 \\ 1 & y & 4 \\ 2 & 2 & z \end{vmatrix}$$

$$= x(yz - 8) - 3(z - 8) + 2(2 - 2y)$$

$$= xyz - (8x + 4y + 3z) + 28$$

$$= 60 - 20 + 28 = 68$$

From Eq. (i), $A(\text{adj } A) = 68I$

31. Here, $|A| = 0$

$\therefore A^{-1}$ does not exist.

Now, $$A^2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix} = 3A$$

$$\therefore \quad A^3 = A^2 \cdot 2 = 3A \cdot A = 3A^2 = 3(3A) = 9A$$

32. $\because \quad A' = A^{-1} \Rightarrow AA' = I$ ...(i)

Now, $(A')' A' = I$

$\therefore A'$ is orthogonal

From Eq. (i), $(AA')^{-1} = I^{-1}$

$$\Rightarrow \quad (A')^{-1} A^{-1} = I$$

$$\Rightarrow \quad (A^{-1})'(A^{-1}) = I$$

$\therefore A^{-1}$ is orthogonal

Since, $\text{adj } A = A^{-1}|A| \neq A'$

and $$|A^{-1}| = \frac{1}{|A|} = \pm 1 \qquad [\text{for orthogonal } |A| = \pm 1]$$

33. $\because$ $$A^2 = \begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix}\begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix} = \begin{bmatrix} 9 & 8 & 8 \\ 8 & 9 & 8 \\ 8 & 8 & 9 \end{bmatrix}$$

We have, $A^2 - 4A - 5I_3$

$$= \begin{bmatrix} 9 & 8 & 8 \\ 8 & 9 & 8 \\ 8 & 8 & 9 \end{bmatrix} - 4\begin{bmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 1 \end{bmatrix} - 5\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = 0$$

$$\Rightarrow \quad 5I_3 = A^2 - 4A = A(A - 4I_3)$$

$$\Rightarrow \quad I_3 = \frac{1}{5}A(A - 4I_3)$$

$$\therefore \quad A^{-1} = \frac{1}{5}(A - 4I_3)$$

Since, $|A| = 5$

$$\therefore \quad |A^3| = |A|^3 = 125 \neq 0$$

$\Rightarrow A^3$ is invertible

Similarly, A^2 is invertible.

34. Let, $D = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix} = D^T$ and let $A = \begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix}$

$$\therefore \quad DA = \begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix}\begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix} = \begin{bmatrix} aa_1 & aa_2 & aa_3 \\ bb_1 & bb_2 & bb_3 \\ cc_1 & cc_2 & cc_3 \end{bmatrix}$$

$$AD = \begin{bmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{bmatrix}\begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{bmatrix} = \begin{bmatrix} a_1a & a_2b & a_3c \\ b_1a & b_2b & b_3c \\ c_1a & c_2b & c_3c \end{bmatrix} \neq DA$$

and $$D^{-1} = \begin{bmatrix} \frac{1}{a} & 0 & 0 \\ 0 & \frac{1}{b} & 0 \\ 0 & 0 & \frac{1}{c} \end{bmatrix}$$

$$|D^{-1}| = \frac{1}{abc} \neq 0 \qquad [\because a \neq 0, b \neq 0, c \neq 0]$$

35. Let $$A = \begin{bmatrix} -1 & 2 & 5 \\ 2 & -4 & a-4 \\ 1 & -2 & a+1 \end{bmatrix}$$

Applying $R_2 \to R_2 + 2R_1$ and $R_3 \to R_3 + R_1$, then

$$A = \begin{bmatrix} -1 & 2 & 5 \\ 0 & 0 & a+6 \\ 0 & 0 & a+6 \end{bmatrix}$$

Applying $R_3 \to R_3 - R_2$, then

$$A = \begin{bmatrix} -1 & 2 & 5 \\ 0 & 0 & a+6 \\ 0 & 0 & 0 \end{bmatrix}$$

For $a = -6$, $\rho(A) = 1$

For $a = 1, 2$, $\rho(A) = 2$

36. Here, $|A| = \begin{vmatrix} 3 & -3 & 4 \\ 2 & -3 & 4 \\ 0 & -1 & 1 \end{vmatrix}$

$= 3(-3+4) + 3(2-0) + 4(-2+0) = 1 \neq 0$

$\because \quad \text{adj}(\text{adj}\, A) = |A|^{3-2} A = A$ ...(i)

and $\quad |\text{adj}(A)| = |A|^{3-1} = |A|^2 = 1^2 = 1$

Also, $|\text{adj}(\text{adj}(A))| = |A| = 1$ [from Eq. (i)]

37. $\because \quad A = I - B$

$\Rightarrow \quad A^2 = I^2 + B^2 - 2B = I - B = A$ [$\because B$ is idempotent]

and $\quad AB = B - B^2 = B - B = 0$ [null matrix]

and $\quad BA = B - B^2 = B - B = 0$ [null matrix]

38. $\because \quad |A| \neq 0 \Rightarrow A^{-1}$ is also symmetric, if A is symmetric

and $|A^{-1}| = \dfrac{1}{|A|} = |A|^{-1}$

39. $\because \quad A^2B = A(AB) = A(BA) = (AB)A = (BA)A = BA^2$

Similarly, $A^3B = BA^3$

In general, $A^nB = BA^n, \forall\, n \geq 1$

and $\quad (A+B)^n = {}^nC_0A^n + {}^nC_1A^{n-1}B + {}^nC_2A^{n-2}B^2 + \ldots + {}^nC_nB^n$

Also, $(A^n - B^n)(A^n + B^n) = A^nA^n + A^nB^n - B^nA^n - B^nB^n$

$= A^{2n} - B^{2n}$ [$\because AB = BA$]

40. $|AB| = 0 \Rightarrow |A||B| = 0$

$\therefore \quad |B| = 0$ as $|A| \neq 0$

Also, $\quad |A^{-1}| = |A|^{-1}$

41. Here, $A(A+I) = -2I$ ...(i)

$\Rightarrow \quad |A(A+I)| = |-2I| = (-2)^m \neq 0$

Thus, $\quad |A| \neq 0,$

also, $\quad I = -\dfrac{1}{2}A(A+I)$ [from Eq. (i)]

$\therefore \quad A^{-1} = -\dfrac{1}{2}(A+I)$

42. $\because \quad A^2 - 3A + 2I = 0$ ...(i)

$\Rightarrow \quad A^2 - 3AI + 2I^2 = 0$

$\Rightarrow \quad (A-I)(A-2I) = 0$

$\therefore \quad A = I$ or $A = 2I$

Characteristic Eq. (i) is

$\lambda^2 - 3\lambda + 2 = 0 \Rightarrow \lambda = 1, 2$

It is clear that alternate (c) and (d) have the characteristic equation $\lambda^2 - 3\lambda + 2 = 0$.

43. $\because \quad AB = 0$

$\Rightarrow \quad |AB| = 0 \Rightarrow |A||B| = 0$

or $\quad (\det A)(\det B) = 0$

$\Rightarrow$ Either $\det A = 0$ or $\det B = 0$

Hence, atleast one of the two matrices must be singular otherwise this statement is not possible.

44. Let $D_1 = \begin{bmatrix} d_1 & 0 & 0 \\ 0 & d_2 & 0 \\ 0 & 0 & d_3 \end{bmatrix}$ and $D_2 = \begin{bmatrix} d_4 & 0 & 0 \\ 0 & d_5 & 0 \\ 0 & 0 & d_6 \end{bmatrix}$

$\therefore D_1D_2 = \begin{bmatrix} d_1d_4 & 0 & 0 \\ 0 & d_2d_5 & 0 \\ 0 & 0 & d_3d_6 \end{bmatrix} = D_2D_1$

and $\quad D_1^2 + D_2^2 = \begin{bmatrix} d_1^2 & 0 & 0 \\ 0 & d_2^2 & 0 \\ 0 & 0 & d_3^2 \end{bmatrix} + \begin{bmatrix} d_4^2 & 0 & 0 \\ 0 & d_5^2 & 0 \\ 0 & 0 & d_6^2 \end{bmatrix}$

$= \begin{bmatrix} d_1^2 + d_4^2 & 0 & 0 \\ 0 & d_2^2 + d_5^2 & 0 \\ 0 & 0 & d_3^2 + d_6^2 \end{bmatrix}$

45. $A_1 + A_2 + A_3 + \ldots + A_n = \begin{bmatrix} C_0^2 & 0 \\ 0 & C_1^2 \end{bmatrix} + \begin{bmatrix} C_1^2 & 0 \\ 0 & C_2^2 \end{bmatrix} + \begin{bmatrix} C_2^2 & 0 \\ 0 & C_3^2 \end{bmatrix} + \ldots + \begin{bmatrix} C_{n-1}^2 & 0 \\ 0 & C_n^2 \end{bmatrix}$

$= \begin{bmatrix} C_0^2 + C_1^2 + C_2^2 + \ldots + C_{n-1}^2 & 0 \\ 0 & C_1^2 + C_2^2 + C_3^2 + \ldots + C_n^2 \end{bmatrix}$

$= \begin{bmatrix} {}^{2n}C_n - 1 & 0 \\ 0 & {}^{2n}C_n - 1 \end{bmatrix} = \begin{bmatrix} k_1 & 0 \\ 0 & k_2 \end{bmatrix}$ [given]

$\therefore \quad k_1 = k_2 = {}^{2n}C_n - 1$

Passage (Q. Nos. 46 to 48)

$\because \quad AB = BA^m$

$\Rightarrow \quad B = A^{-1}BA^m$

$\therefore \quad B^n = \underbrace{(A^{-1}BA^m)(A^{-1}BA^m)\ldots(A^{-1}BA^m)}_{n \text{ times}}$

$= A^{-1}\underbrace{BA^{m-1}BA^{m-1}\ldots BA^{m-1}BA^{m-1}}_{n \text{ times}}A$ ...(i)

Given, $\quad AB = BA^m$

$\Rightarrow \quad AAB = ABA^m = BA^{2m} \Rightarrow AAAB = BA^{3m}$

Similarly, $\quad A^xB = BA^{mx}\ \forall m \in N$

From Eq. (i), we get

$B^n = A^{-1}BA^{m-1}\underbrace{BA^{m-1}BA^{m-1}\ldots BA^{m-1}BA^{m-1}}_{(n-1) \text{ times}}A$

$= A^{-1}B(A^{m-1}B)A^{m-1}\underbrace{BA^{m-1}\ldots BA^{m-1}BA^{m-1}}_{(n-2) \text{ times}}A$

$= A^{-1}BBA^{(m-1)m}A^{m-1}\underbrace{BA^{m-1}\ldots BA^{m-1}BA^{m-1}}_{(n-2) \text{ times}}A$

$= A^{-1}B^2A^{(m^2-1)}\underbrace{BA^{m-1}\ldots BA^{m-1}BA^{m-1}}_{(n-2) \text{ times}}A$

$\ldots \qquad \ldots \qquad \ldots \quad \ldots$

$= A^{-1}B^m(A)^{(m^n-1)}A$

$I = A^{-1}IA^{(m^n-1)}A$ [$\because B^n = I$]

$I = A^{-1}A^{(m^n-1)}A = A^{-1}A^{m^n}$

$\Rightarrow \quad I = A^{(m^n-1)}$

$\therefore \quad p = m^n - 1$ ...(ii) [$\because A^p = I$]

46. Put $m = 2, n = 5$ in Eq. (ii), we get

$$p = 2^5 - 1 = 31$$

47. From Eq. (ii), we get

$$p = m^n - 1$$

48. From Eq. (ii), we get

$$510 \neq 8^3 - 1$$

Passage (Q. Nos. 49 to 51)

$\because$ A is an orthogonal matrix

$\therefore$ $AA^T = I$

$$\begin{bmatrix} a & b & c \\ b & c & a \\ c & a & b \end{bmatrix}\begin{bmatrix} a & b & c \\ b & c & a \\ c & a & b \end{bmatrix} = 1\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\begin{bmatrix} a^2+b^2+c^2 & ab+bc+ca & ab+bc+ca \\ ab+bc+ca & a^2+b^2+c^2 & ab+bc+ca \\ ab+bc+ca & ab+bc+ca & a^2+b^2+c^2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

By equality of matrices, we get

$$a^2 + b^2 + c^2 = 1 \quad \text{...(i)}$$

$$ab + bc + ca = 0 \quad \text{...(ii)}$$

$$(a + b + c)^2 + a^2 = b^2 + c^2 + 2(ab + bc + ca)$$

$$= 1 + 0 = 1$$

$\therefore$ $a + b + c = \pm 1$ ...(iii)

49. $\because a^2b^2 + b^2c^2 + c^2a^2 = (ab + bc + ca)^2 - 2abc(a + b + c)$

$$= 0 - 2abc(\pm 1) = \mp 2\lambda \qquad [\because abc = \lambda]$$

$$= -2\lambda \qquad [\because \lambda < 0]$$

50. $\because$ $a^3 + b^3 + c^3 - 3abc = (a + b + c)$

$$(a^2 + b^2 + c^2 - ab - bc - ca)$$

$\Rightarrow$ $a^3 + b^3 + c^3 - 3\lambda = (\pm 1)(1 - 0)$

[from Eqs. (i), (ii) and (iii) and $abc = \lambda$]

$\Rightarrow$ $a^3 + b^3 + c^3 = 3\lambda \pm 1$

51. Equation whose roots are a, b, c is

$$x^3 - (a + b + c)x^2 + (ab + bc + ca)x - abc = 0$$

$\Rightarrow$ $x^3 - (\pm 1)x^2 + 0 - \lambda = 0$

$\therefore$ $x^3 \pm x^2 - \lambda = 0$

Passage (Q. Nos. 52 to 53)

$\therefore$ $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$

$\Rightarrow$ $t_1 = \dfrac{a_{11} + a_{12} + a_{13}}{3} = 0, \qquad [\because a_{ij} + a_{jk} + a_{ki} = 0]$

$$t_2 = \frac{a_{21} + a_{22} + a_{23}}{3} = 0$$

and $t_3 = \dfrac{a_{31} + a_{32} + a_{33}}{3} = 0$

52. $\sum\limits_{1 \le i,\ j \le 3} a_{ij} = 3(t_1 + t_2 + t_3) = 0 = t_1 + t_2 + t_3$

$$\neq t_1t_2t_3 \qquad [\because t_1 = 0, t_2 = 0, t_3 = 0]$$

and $\det A = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$

Applying $C_1 \to C_1 + C_2 + C_3$, we get

$$= \begin{vmatrix} 0 & a_{12} & a_{13} \\ 0 & a_{22} & a_{23} \\ 0 & a_{32} & a_{33} \end{vmatrix} = 0$$

$\therefore$ $(\det A)^2 = 0$

53. $\because$ $a_{11} + a_{11} + a_{11} = 0, a_{11} + a_{12} + a_{21} = 0,$

$a_{11} + a_{13} + a_{31} = 0, a_{22} + a_{22} + a_{22} = 0,$

$a_{22} + a_{12} + a_{21} = 0, a_{22} + a_{23} + a_{32} = 0,$

$a_{33} + a_{13} + a_{31} = 0, a_{33} + a_{23} + a_{32} = 0$

and $a_{33} + a_{12} + a_{21} = 0$, we get

$a_{11} = a_{22} = a_{33} = 0$

and $a_{12} = -a_{21}, a_{23} = -a_{32}, a_{13} = -a_{31}$

Hence, A is skew-symmetric matrix.

Passage (Q. Nos. 54 to 56)

Let $B = \begin{bmatrix} \alpha_1 & \beta_1 & \gamma_1 \\ \alpha_2 & \beta_2 & \gamma_2 \\ \alpha_3 & \beta_3 & \gamma_3 \end{bmatrix}$

$\therefore$ $C_1 = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix}, C_2 = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix}$ and $C_3 = \begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \end{bmatrix}$

$\Rightarrow$ $AC_1 = \begin{bmatrix} \alpha_1 \\ 2\alpha_1 + \alpha_2 \\ 3\alpha_1 + 2\alpha_2 + \alpha_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$

$\Rightarrow$ $\alpha_1 = 1, \alpha_2 = -2, \alpha_3 = 1$

$\Rightarrow$ $AC_2 = \begin{bmatrix} \beta_1 \\ 2\beta_1 + \beta_2 \\ 3\beta_1 + 2\beta_2 + \beta_3 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \\ 0 \end{bmatrix}$

$\Rightarrow$ $\beta_1 = 2, \beta_2 = -1, \beta_3 = -4$

and $AC_3 = \begin{bmatrix} \gamma_1 \\ 2\gamma_1 + \gamma_2 \\ 3\gamma_1 + 2\gamma_2 + \gamma_3 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \\ 1 \end{bmatrix}$

$\Rightarrow$ $\gamma_1 = 2, \gamma_2 = -1, \gamma_3 = -3$

$\therefore$ $B = \begin{bmatrix} 1 & 2 & 2 \\ -2 & -1 & -1 \\ 1 & -4 & -3 \end{bmatrix}$

$\Rightarrow$ $\det B = \begin{vmatrix} 1 & 2 & 2 \\ -2 & -1 & -1 \\ 1 & -4 & -3 \end{vmatrix}$

$$= 1(3 - 4) - 2(6 + 1) + 2(8 + 1) = 3$$

and $C = \dfrac{1}{3}\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 3 & 2 & 1 \end{bmatrix}\begin{bmatrix} 1 & 2 & 2 \\ -2 & -1 & -1 \\ 1 & -4 & -3 \end{bmatrix}$

$$= \frac{1}{3}\begin{bmatrix} 1 & 2 & 2 \\ 0 & 3 & 3 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\therefore \quad \det C = \begin{vmatrix} \frac{1}{3} & \frac{2}{3} & \frac{2}{3} \\ 0 & 1 & 1 \\ 0 & 0 & \frac{1}{3} \end{vmatrix} = \frac{1}{9}$$

54. $\det(B^{-1}) = \dfrac{1}{\det B} = \dfrac{1}{3}$

55. $\dfrac{\text{Trace of } B}{\text{Trace of } C} = \dfrac{(-3)}{\left(\frac{5}{3}\right)} = -\dfrac{9}{5}$

56. $\sin^{-1}(\det A) + \tan^{-1}(9 \det C) = \sin^{-1}(1) + \tan^{-1}(1)$

$$= \frac{\pi}{2} + \frac{\pi}{4} = \frac{3\pi}{4}$$

Passage (Q. Nos. 57 to 59)

Given, $A^T = A$, $B^T = -B$, $\det(A + B) \neq 0$

and $C = (A + B)^{-1}(A - B)$

$\Rightarrow \quad (A + B)C = A - B$ ...(i)

Also, $(A + B)^T = A - B$ ...(ii)

and $(A - B)^T = A + B$ ...(iii)

57. $C^T(A + B)C = C^T[(A + B)C]$

$= C^T(A - B)$ [from Eq. (i)]

$= C^T(A + B)^T$ [from Eq. (ii)]

$= [(A + B)C]^T$

$= (A - B)^T$ [from Eq. (i)]

$= A + B$ [from Eq. (iii)]

58. $C^T(A - B)C = [C^T(A + B)^T]C$ [from Eq. (ii)]

$= [(A + B)C]^T C$

$= (A - B)^T C$ [from Eq. (i)]

$= (A + B)C$ [from Eq. (iii)]

$= A - B$ [from Eq. (i)]

59. $C^T AC = C^T\left(\dfrac{A + B + A - B}{2}\right)C$

$= \dfrac{1}{2}C^T(A + B)C + \dfrac{1}{2}C^T(A - B)C$

$= \dfrac{1}{2}(A + B) + \dfrac{1}{2}(A - B)$ [from Q13 and Q15]

$= A$

Passage (Q. Nos. 60 to 61)

$\because \quad B = A - 2I$

$\therefore \quad A^{-1}B = I - 2A^{-1}$ ...(i)

60. $\det[\text{adj}\,(I - 2A^{-1})] = \det[\text{adj}(A^{-1}B)]$ [from Eq. (i)]

$= |\text{adj}(A^{-1}B)|$

$= |A^{-1}B|^2 = (|A^{-1}||B|)^2 = \left(\dfrac{|B|}{|A|}\right)^2$ ...(ii)

From Eq. (i), we get $B = A - 2I$

$\therefore \quad B^3 = (A - 2I)^3 = A^3 - 6A^2 + 12A - 8I$

$= 5A \qquad [\because A^3 - 6A^2 + 7A - 8I = 0]$

$\Rightarrow \quad |B^3| = |5A|$

$\Rightarrow \quad |B|^3 = 5^3|A|$

$\Rightarrow \quad |B|^3 = 5^3 \times 8$

$\Rightarrow \quad |B|^3 = (10)^3$

$\therefore \quad |B| = 10$

From Eq. (ii), we get

$$\det[\text{adj}(I - 2A^{-1})] = \left(\frac{|B|}{|A|}\right)^2 = \left(\frac{10}{8}\right)^2 = \frac{25}{16}$$

61. $\text{adj}\left[\left(\dfrac{B}{2}\right)^{-1}\right] = \dfrac{\frac{B}{2}}{\left|\frac{B}{2}\right|} = \dfrac{\frac{B}{2}}{\frac{1}{8}|B|} = \dfrac{4B}{|B|} = \dfrac{4}{10}B \qquad [\because |B| = 10]$

$= \dfrac{2}{5}B = \dfrac{p}{q}B$ [given]

$\therefore \quad p = 2$ and $q = 5$

Hence, $p + q = 7$

62. $S = ABCD = A(BCD) = AA^T$ ...(i)

$\therefore \quad S^3 = (ABCD)(ABCD)(ABCD)$

$= (ABC)(DAB)(CDA)(BCD)$

$= D^T C^T B^T A^T = (BCD)^T A^T$

$= (A^T)^T A^T = AA^T = S$

$\Rightarrow \quad S^3 = S$

Hence, least value of k is 3.

63. $\because \quad A = \begin{bmatrix} 1 & \tan x \\ -\tan x & 1 \end{bmatrix}$

$\therefore \quad \det A = \begin{vmatrix} 1 & \tan x \\ -\tan x & 1 \end{vmatrix} = (1 + \tan^2 x) = \sec^2 x$

$\Rightarrow \quad \det A^T = \det A = \sec^2 x$

Now, $f(x) = \det(A^T A^{-1}) = (\det A^T)(\det A^{-1})$

$= (\det A^T)(\det A)^{-1} = \dfrac{\det A^T}{\det A} = 1$

$\therefore \quad \underbrace{\lambda = f(f(f(f \ldots f(x))))}_{n \text{ times}} = 1 \qquad [\because f(x) = 1]$

Hence, $2^\lambda = 2^1 = 2$

64. $\because A^2 = A \cdot A = \begin{bmatrix} \lambda_1^2 & \lambda_1\lambda_2 & \lambda_1\lambda_3 \\ \lambda_2\lambda_1 & \lambda_2^2 & \lambda_2\lambda_3 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 \end{bmatrix}\begin{bmatrix} \lambda_1^2 & \lambda_1\lambda_2 & \lambda_1\lambda_3 \\ \lambda_2\lambda_1 & \lambda_2^2 & \lambda_2\lambda_3 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 \end{bmatrix}$

$$= \begin{bmatrix} \lambda_1^2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_1\lambda_2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_1\lambda_3(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) \\ \lambda_1\lambda_2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_2^2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_2\lambda_3(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) \\ \lambda_1\lambda_3(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_3\lambda_2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) & \lambda_3^2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) \end{bmatrix}$$

$$= (\lambda_1^2 + \lambda_2^2 + \lambda_3^2)\, A$$

Given, A is idempotent

$\Rightarrow \quad A^2 = A$

$\therefore \quad \lambda_1^2 + \lambda_2^2 + \lambda_3^2 = 1$

65. Let $X = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$ and given $X^T AX = O$

$$\Rightarrow \quad [x_1\ x_2\ x_3] \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = O$$

$$\Rightarrow \quad [x_1\ x_2\ x_3] \begin{bmatrix} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 \end{bmatrix} = O$$

$$\Rightarrow \quad a_{11}x_1^2 + a_{12}x_1x_2 + a_{13}x_1x_3 + a_{21}x_1x_2 + a_{22}x_2^2 + a_{23}x_2x_3 + a_{31}x_1x_3 + a_{32}x_2x_3 + a_{33}x_3^2 = 0$$

$$\Rightarrow \quad a_{11}x_1^2 + a_{22}x_2^2 + a_{33}x_3^2 + (a_{12} + a_{21})\, x_1x_2 + (a_{23} + a_{32})\, x_2x_3 + (a_{31} + a_{13})\, x_3x_1 = 0$$

it is true for every x_1, x_2, x_3, then

$$a_{11} = a_{22} = a_{33} = 0 \text{ and } a_{12} = -a_{21},\ a_{23} = -a_{32},\ a_{13} = -a_{31}$$

Now, as $a_{23} = -1008 \Rightarrow a_{32} = 1008$

$\therefore$ Sum of digits $= 1 + 0 + 0 + 8 = 9$

66. $\because A = \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix}$

$$\therefore \quad A^2 = A \cdot A = \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix} \begin{bmatrix} 0 & 1 & -1 \\ 4 & -3 & 4 \\ 3 & -3 & 4 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$$

$\Rightarrow A^2 = I \Rightarrow A^4 = A^6 = A^8 = \ldots = I$

Now, $\quad A^x = I$

$\Rightarrow \quad x = 2, 4, 6, 8, \ldots$

$$\therefore \sum (\cos^x \theta + \sin^x \theta) = (\cos^2 \theta + \sin^2 \theta) + (\cos^4 \theta + \sin^4 \theta) + (\cos^6 \theta + \sin^6 \theta) + \ldots$$

$$= (\cos^2 \theta + \cos^4 \theta + \cos^6 \theta + \ldots) + (\sin^2 \theta + \sin^4 \theta + \sin^6 \theta + \ldots)$$

$$= \frac{\cos^2 \theta}{1 - \cos^2 \theta} + \frac{\sin^2 \theta}{1 - \sin^2 \theta}$$

$$= \cot^2 \theta + \tan^2 \theta \geq 2$$

Hence, minimum value of $\sum (\cos^x \theta + \sin^x \theta)$ is 2.

67. $\because A$ is idempotent matrix

$\therefore \quad A^2 = A$

$\Rightarrow \quad A = A^2 = A^3 = A^4 = A^5 = \ldots$ ...(i)

Now, $(A + I)^n = (I + A)^n$

$$= I + {}^nC_1\, A + {}^nC_2\, A^2 + {}^nC_3\, A^3 + \ldots + {}^nC_n A^n$$

$$= I + ({}^nC_1 + {}^nC_2 + {}^nC_3 + \ldots + {}^nC_n)\, A$$

[from Eq.(i)]

$\Rightarrow \quad (A + I)^n = I + (2^n - 1)A$ ...(ii)

Given, we get

$(A + I)^n = I + 127\, A$ ...(iii)

From Eqs (ii) and (iii), we get

$$2^n - 1 = 127$$

$\Rightarrow \quad 2^n = 128 = 2^7$

$\therefore \quad n = 7$

68. $\because \quad A = \begin{bmatrix} 3a & b & c \\ b & 3c & a \\ c & a & 3b \end{bmatrix}$

$$\therefore \det(A) = \begin{vmatrix} 3a & b & c \\ b & 3c & a \\ c & a & 3b \end{vmatrix} = 29abc - 3(a^3 + b^3 + c^3)$$

Or

$$|A| = 29abc - 3(a^3 + b^3 + c^3) \quad \ldots(i)$$

Given, $\quad A^TA = 4^{1/3}\, I$

$\Rightarrow \quad |A^T\, A| = |4^{1/3}\, I|$

$\Rightarrow \quad |A^T|\,|A| = (4^{1/3})^3\, |I|$

$\Rightarrow \quad |A|\,|A| = 4 \cdot 1$

$\Rightarrow \quad |A|^2 = 4$

$\therefore \quad |A| = 2 \quad [\because |A| > 0]$

From Eq.(i), we get

$$2 = 29abc - 3(a^3 + b^3 + c^3)$$

$\Rightarrow \quad 2 = 29 - 3(a^3 + b^3 + c^3) \quad [\because abc = 1]$

$\therefore \ a^3 + b^3 + c^3 = 9$

69. $\because \quad A = \begin{bmatrix} 0 & 1 \\ 3 & 0 \end{bmatrix}$

$$\therefore A^2 = A \cdot A = \begin{bmatrix} 0 & 1 \\ 3 & 0 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 3 & 0 \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ 0 & 3 \end{bmatrix} = 3I$$

$\Rightarrow \quad A^4 = (A^2)^2 = 9I,\ A^6 = 27I,\ A^8 = 81I$

Now, $\quad (A^8 + A^6 + A^4 + A^2 + I)\, V = (121)\, IV = (121)\, V$ ...(i)

Given, $(A^8 + A^6 + A^4 + A^2 + I)\, V = \begin{bmatrix} 0 \\ 11 \end{bmatrix}$ ...(ii)

From Eqs.(i) and (ii), $(121)\, V = \begin{bmatrix} 0 \\ 11 \end{bmatrix} \Rightarrow V = \begin{bmatrix} 0 \\ \frac{1}{11} \end{bmatrix}$

$\therefore$ Sum of elements of $V = 0 + \frac{1}{11} = \frac{1}{11} = \lambda$ [given]

$\therefore \quad 11\, \lambda = 1$

70. $\because A = \begin{bmatrix} 3 & 2 \\ 2 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 3 & 1 \\ 7 & 3 \end{bmatrix}$

$\therefore \quad \det A = -1$ and $\det B = 2$

Now, $\det(2A^9\, B^{-1}) = 2^2 \cdot \det(A^9) \cdot \det(B^{-1})$

$$= 2^2 \cdot (\det A)^9 \cdot (\det B)^{-1}$$

$$= 2^2 \cdot (-1)^9 \cdot (2)^{-1} = -2$$

Hence, absolute value of $\det(2A^9B^{-1}) = 2$

71. $\because \quad A=\begin{bmatrix}0 & \alpha\\ 0 & 0\end{bmatrix}$

$\therefore \quad A^2=A\cdot A=\begin{bmatrix}0 & \alpha\\ 0 & 0\end{bmatrix}\begin{bmatrix}0 & \alpha\\ 0 & 0\end{bmatrix}=\begin{bmatrix}0 & 0\\ 0 & 0\end{bmatrix}=0$

$\Rightarrow \quad A^2=A^3=A^4=A^5=\ldots=0$

Now, $(A+I)^{70}=(I+A)^{70}$

$=I+{}^{70}C_1\,A+{}^{70}C_2\,A^2+{}^{70}C_3\,A^3+..+{}^{70}C_{70}\,A^{70}$

$=I+70\,A+0+0+\ldots=I+70A$

$\Rightarrow (A+I)^{70}-70A=I=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}=\begin{bmatrix}a-1 & b-1\\ c-1 & d-1\end{bmatrix}$ [given]

$\therefore \quad a-1=1, b-1=0, c-1=0, d-1=1$

$\Rightarrow \quad a=2, b=1, c=1, d=2$

Hence, $a+b+c+d=6$

72. (A) → (p, r); (B) → (s); (C) → (q); (D) → (s)

On comparing, we get

$\{4f(-1)-3\}a^2+\{4f(1)-3\}a+f(2)=0$

$\{4f(-1)-3\}b^2+\{4f(1)-3\}b+f(2)=0,$

and $\{4f(-1)-3\}c^2+\{4f(1)-3\}C+f(2)=0$

It is clear that a, b, c are the roots of

$\{4f(-1)-3\}x^2+\{4f(1)-3\}x+f(2)=0$, then

$4f(-1)-3=0, 4f(1)-3=0, f(2)=0$

$\Rightarrow \quad f(-1)=\frac{3}{4}, f(1)=\frac{3}{4}, f(2)=0$

Let $f(x)=(x-2)(ax+b)$

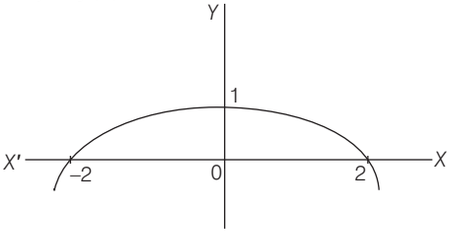
Now, $f(-1)=\frac{3}{4} \Rightarrow (-3)(-a+b)=\frac{3}{4} \Rightarrow a-b=\frac{1}{4}$

$f(1)=\frac{3}{4} \Rightarrow (-1)(a+b)=\frac{3}{4} \Rightarrow a+b=-\frac{3}{4}$

$\therefore \quad a=-\frac{1}{4}, b=-\frac{1}{2}$

$\Rightarrow \quad f(x)=\frac{1}{4}(4-x^2)$

Graph of $y=f(x)$



(A) x-coordinates of the point intersection of $y=f(x)$ with the X-axis are -2 and 2.

(B) Area $=\frac{3}{2}\int_{-2}^{2}\frac{1}{4}(4-x^2)dx=\frac{3}{4}\int_0^2(4-x^2)dx$

$=\frac{3}{4}\left[4x-\frac{x^3}{3}\right]_0^2=\frac{3}{4}\times\frac{16}{3}=4$

(C) Maximum value of $f(x)$ is 1.

(D) Length of intercept on the X-axis is 4.

73. (A) → (r, t); (B) → (s); (C) → (p); (D) → (q)

(A) $\text{adj}\,(A^{-1})=(A^{-1})^{-1}\det(A^{-1})=\frac{A}{\det(A)}$

Also, $\frac{\text{adj}\,(\text{adj}\,A)}{(\text{adj}\,A)^{n-1}}=\frac{A[\det(A)]^{n-2}}{(\det A)^{n-1}}=\frac{A}{\det(A)}$

(B) $\det(\text{adj}\,(A^{-1}))=(\det A^{-1})^{n-1}$

$=\frac{1}{(\det A)^{n-1}}=(\det A)^{1-n}$

(C) $\text{adj}\,[\text{adj}\,A]=A(\det A)^{n-2}$

(D) $\text{adj}\,(A\det A)=(\det A)^{n-1}(\text{adj}\,A)$

74. (A)→(q, s); (B)→(p, t); (C)→(p, q, r, s); (D)→(q, s)

(A) A diagonal matrix is commutative with every square matrix, if it is scalar matrix, so every diagonal element is 4.

Therefore, $|A|=\begin{vmatrix}4 & 0 & 0\\ 0 & 4 & 0\\ 0 & 0 & 4\end{vmatrix}=64$

(B) $\begin{vmatrix}1-a & 1 & 1\\ 1 & 1-b & 1\\ 1 & 1 & 1-c\end{vmatrix}=0$

Applying $R_1\to R_1-R_3$ and $R_2\to R_2-R_3$, then

$\begin{vmatrix}-a & 0 & c\\ 0 & -b & c\\ 1 & 1 & 1-c\end{vmatrix}=0$

$\Rightarrow \quad -a(-b+bc-c)-0+c(b)=0$

$ab+bc+ca=abc$ ...(i)

Now, $AM\geq GM$

$\Rightarrow \quad \frac{ab+bc+ca}{3}\geq(ab\cdot bc\cdot ca)^{\frac{1}{3}}$

$\Rightarrow \quad \frac{abc}{3}\geq(abc)^{\frac{2}{3}}$ [from Eq. (i)]

$\Rightarrow \quad (abc)^{\frac{1}{3}}\geq 3$

$\therefore \quad abc\geq 27$

Hence, $\lambda=27$

(C) $\because \quad A=\begin{bmatrix}a_{11} & a_{12} & a_{13}\\ a_{21} & a_{22} & a_{23}\\ a_{31} & a_{32} & a_{33}\end{bmatrix}$

Given, $\sum_{k=1}^{3}a_{ik}=9\lambda_i, \forall\, i\in\{1,2,3\};$

$\sum_{k=1}^{3}a_{kj}=9\mu_j, \forall\, j\in\{1,2,3\}$ and

$a_{11}+a_{22}+a_{33}=9\upsilon$; where $\lambda_i, \mu_j, \nu\in\{1,2\}$

Following types of matrices are possible:

$A=\begin{bmatrix}1 & & \\ & 3 & \\ & & 5\end{bmatrix}; B=\begin{bmatrix}2 & & \\ & 3 & \\ & & 4\end{bmatrix}; C=\begin{bmatrix}7 & & \\ & 3 & \\ & & 8\end{bmatrix};$

$D=\begin{bmatrix}6 & & \\ & 3 & \\ & & 9\end{bmatrix}; E=\begin{bmatrix}1 & & \\ & 6 & \\ & & 2\end{bmatrix}; F=\begin{bmatrix}3 & & \\ & 6 & \\ & & 9\end{bmatrix};$

$$G=\begin{bmatrix}4&&\\&6&\\&&8\end{bmatrix};\ H=\begin{bmatrix}5&&\\&6&\\&&7\end{bmatrix};\ I=\begin{bmatrix}1&&\\&9&\\&&8\end{bmatrix};$$

$$\mathcal{J}=\begin{bmatrix}2&&\\&9&\\&&7\end{bmatrix};\ K=\begin{bmatrix}3&&\\&9&\\&&6\end{bmatrix};\ L=\begin{bmatrix}4&&\\&9&\\&&5\end{bmatrix}$$

Now, if we interchange 1 and 5 to obtain

$$A_1=\begin{bmatrix}5&4&9\\7&3&8\\6&2&1\end{bmatrix}$$

Also, $$A^T=\begin{bmatrix}1&8&9\\2&3&4\\6&7&5\end{bmatrix}$$

and $$A_1^T=\begin{bmatrix}5&7&6\\4&3&2\\9&8&1\end{bmatrix}$$

Then, from A we get four matrices A, A_1, A^T, A_1^T.

Similarly, from $B, C, D, \ldots, K, L$ we get 4 matrices.

Thus, total $12\times 4=48$ matrices. Hence, $\lambda=48$.

(D) For consistent, $\begin{vmatrix}1&1&1\\c+2&c+4&6\\(c+2)^2&(c+4)^2&36\end{vmatrix}=0$

Applying $C_2\to C_2-C_1$, we get

$$\begin{vmatrix}1&0&1\\c+2&2&6\\(c+2)^2&4c+12&36\end{vmatrix}=0$$

$$\Rightarrow\quad 2\begin{vmatrix}1&0&1\\c+2&1&6\\(c+2)^2&2c+6&36\end{vmatrix}=0$$

$$\Rightarrow\quad -12c-0+1[(c+2)(2c+6)-(c+2)^2]=0$$

$$\Rightarrow\quad c^2-6c+8=0$$

$$\Rightarrow\quad c=2,4$$

$$\therefore\quad c_1=4,\ c_2=2$$

$$\Rightarrow\quad c_1^{c_2}=4^2=16$$

75. (A) $\to$(q, t); (B) $\to$(p, s); (C) $\to$(p, r, s); (D) $\to$(q, r, t)

(A) Here, X is a $n\times 1$ matrix, C is $n\times n$ matrix and X^T is a $1\times n$ matrix.

Hence, X^TCX is a 1×1 matrix.

Let $X^TCX=[\lambda]$, then

$$(X^TCX)^T=X^TC^T(X^T)^T=X^T(-C)X=-X^TCX$$

$$\therefore\quad [\lambda]=-[\lambda]$$

$$\Rightarrow\quad \lambda=0$$

$$\Rightarrow\quad X^TCX=O$$

i.e., X^TCX is null matrix.

(B) Consider the homogeneous system

$$(I-A)X=O$$

$$\Rightarrow\quad AX=IX=X \qquad \ldots(i)$$

Now, $$(AX)^T=X^TA^T\Rightarrow X^T=-X^TA$$

$$\Rightarrow\quad X^TX=-X^TAX=-X^TX \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow\quad 2X^TX=O\quad\Rightarrow\quad |X|=O$$

$(I-A)X=O$ has only trivial solution

$\therefore$ $I-A$ is non-singular

$\Rightarrow$ $(I-A)$ is invertible

(C) $\because$ $$S=\begin{bmatrix}0&1&1\\1&0&1\\1&1&0\end{bmatrix}$$

$$\Rightarrow\quad S^{-1}=\frac{1}{2}\begin{bmatrix}-1&1&1\\1&-1&1\\1&1&-1\end{bmatrix}$$

We have, $$SA=\begin{bmatrix}0&1&1\\1&0&1\\1&1&0\end{bmatrix}\begin{bmatrix}b+c&c-a&b-a\\c-b&c+a&a-b\\b-c&a-c&a+b\end{bmatrix}$$

$$=\begin{bmatrix}0&2a&2a\\2b&0&2b\\2c&2c&0\end{bmatrix}$$

$$\therefore\quad SAS^{-1}=\begin{bmatrix}0&2a&2a\\2b&0&2b\\2c&2c&0\end{bmatrix}\frac{1}{2}\begin{bmatrix}-1&1&1\\1&-1&1\\1&1&-1\end{bmatrix}$$

$$=\begin{bmatrix}0&a&a\\b&0&b\\c&c&0\end{bmatrix}\begin{bmatrix}-1&1&1\\1&-1&1\\1&1&-1\end{bmatrix}=\begin{bmatrix}2a&0&0\\0&2b&0\\0&0&2c\end{bmatrix}$$

$$\therefore\quad |SAS^{-1}|=8abc\neq 0$$

(D) $\because$ $$A=\begin{bmatrix}\sin 2A&\sin C&\sin B\\\sin C&\sin 2B&\sin A\\\sin B&\sin A&\sin 2C\end{bmatrix}$$

$$|A|=\begin{bmatrix}2ak\cos A&ck&bk\\ck&2bk\cos B&ak\\bk&ak&2ck\cos C\end{bmatrix}$$

$$=k^3\begin{bmatrix}a\cos A+a\cos A&a\cos B+b\cos A&a\cos C+c\cos A\\a\cos B+b\cos A&b\cos B+b\cos B&b\cos C+c\cos B\\a\cos C+c\cos A&b\cos C+c\cos B&c\cos C+c\cos C\end{bmatrix}$$

$$=k^3\begin{vmatrix}a&\cos A&0\\b&\cos B&0\\c&\cos C&0\end{vmatrix}\times\begin{vmatrix}\cos A&a&0\\\cos B&b&0\\\cos C&c&0\end{vmatrix}=k^3\cdot 0\cdot 0=0$$

76. Since, matrix A is skew-symmetric

$$\therefore\quad |A|=0$$

$$\therefore\quad |A^4B^5|=0$$

$\Rightarrow A^4B^5$ is singular matrix.

Statement-1 is false and Statement-2 is true.

77. $\because \quad AB = A,\ BA = B \Rightarrow A^2 = A$ and $B^2 = B$

$\therefore \quad (A+B)^2 = A^2 + B^2 + AB + BA = A + B + A + B$

$= 2(A+B)$

$(A+B)^3 = (A+B)^2 . (A+B)$

$= 2(A+B)^2 = 2^2 (A+B)$

$\therefore \quad (A+B)^7 = 2^6 (A+B)$

Statement-1 is true and Statement-2 is false.

78. A^{-1}exists only for non-singular matrix

$AB = AC \Rightarrow A^{-1}(AB) = A^{-1}(AC)$

$\Rightarrow \quad (A^{-1}\ A)\ B = (A^{-1}\ A)\ C$

$\Rightarrow \quad IB = IC$

$\Rightarrow \quad B = C$, if A^{-1} exist

$\therefore \quad |A| \neq 0$

Statement-1 is false and Statement-2 is true.

79. Statement-2 is false

$\because \quad \det(A^{-1}) \neq \det(-A')$

$[\because \det(-A') = (-1)^3 \det(A') = -\det(A')]$

but in Statement-1

$A' = -A \Rightarrow A = -A'$

$\therefore \quad \det(A) = \det(-A')$

$= -\det A' = -\det(A)$

$\Rightarrow \quad 2\det(A) = 0$

$\therefore \quad \det(A) = 0$

Then, Statement-1 is true.

80. $\because (BX)^T (BY) = \{(I-A)(I+A)^{-1} X\}^T (I-A)(I+A)^{-1} Y$

$= X^T \{(I+A)^{-1}\}^T (I-A)^T (I-A)(I+A)^{-1} Y$

$= X^T (I+A^T)^{-1} (I-A^T)(I-A)(I+A)^{-1} Y$

$= X^T (I-A)^{-1} (I+A)(I-A)(I+A)^{-1} Y$

$= X^T (I-A)^{-1} (I-A)(I+A)(I+A)^{-1} Y$

$[\because A^T = -A$ and $(I-A)(I+A) = (I+A)(I-A)]$

$= X^T \cdot I \cdot I \cdot Y = X^T Y$

Both Statements are true; Statement-2 is correct explanation for Statement-1.

81. $\because \quad |A| = 2$

and $\quad B = 9A^2$ (given)

$\therefore \quad |B| = |9A^2| = 9^2 |A|^2$

$= 81 \times 4 = 324 \Rightarrow |B^T| = |B| = 324$

Hence, Statement-1 is false but Statement-2 is true.

82. $\therefore \det(A - \lambda I) = \begin{vmatrix} 1-\lambda & -1 & -1 \\ 1 & -1-\lambda & 0 \\ 1 & 0 & -1-\lambda \end{vmatrix} = 0$

$\Rightarrow \quad (1-\lambda)(1+\lambda)^2 - 1 - \lambda - 1 - \lambda = 0$

$\Rightarrow \quad \lambda^3 + \lambda^2 + \lambda + 1 = 0$

$\Rightarrow \quad A^3 + A^2 + A + I = 0$

$\Rightarrow \quad A^3 + A^2 + A = -I$

Statement-1 is false but Statement-2 is true.

83. $A = \begin{bmatrix} 0 & -\frac{1}{5} & -\frac{2}{7} \\ \frac{1}{4} & 0 & -\frac{1}{8} \\ \frac{2}{5} & \frac{1}{7} & 0 \end{bmatrix}$

which is neither symmetric nor skew-symmetric. Infact every square matrix can be expressed as a sum of symmetric and skew-symmetric matrix. Hence, Statement-1 is false and Statement-2 is true.

84. ABC is not defined, as order of A, B and C are such that they are not conformable for multiplication.

Hence, Statement-1 is false and Statement-2 is true.

85. $\because \quad A^T = -A$

$\Rightarrow \quad |A^T| = |-A|$

$= (-1)^5 |A| = -|A|$

$\Rightarrow \quad |A| = -|A|$

$\Rightarrow \quad 2|A| = 0$

$\therefore \quad |A| = 0$

Both Statements are true but Statement-2 is a correct explanation of Statement-1.

86. $\because S$ is skew-symmetric matrix

$\therefore \quad S^T = -S$ ...(i)

First we will show that $I - S$ is non-singular. The equality $|I - S| = 0 \Rightarrow I$ is a characteristic root of the matrix S but this is not possible, for a real skew-symmetric matrix can have zero or purely imaginary numbers as its characteristic roots. Thus, $|I - S| \neq 0$ i.e., $I - S$ is non-singular.

We have,

$A^T = \{(I+S)(I-S)^{-1}\}^T = \{(I-S)^{-1}(I+S)\}^T$

$= ((I-S)^{-1})^T (I+S)^T = (I+S)^T \{(I-S)^{-1}\}^T$

$= ((I-S)^T)^{-1}(I+S)^T = (I+S)^T ((I-S)^T)^{-1}$

$= (I^T - S^T)^{-1}(I^T + S^T) = (I^T + S^T)(I^T - S^T)^{-1}$

$= (I+S)^{-1}(I-S) = (I-S)(I+S)^{-1}$ [from Eq. (i)]

$\therefore \quad A^T A = (I+S)^{-1}(I-S)(I+S)(I-S)^{-1}$

$= (I-S)(I+S)^{-1}(I-S)^{-1}(I+S)$

$= (I+S)^{-1}(I+S)(I-S)(I-S)^{-1}$

$= (I-S)(I-S)^{-1}(I+S)^{-1}(I+S)$

$= I \cdot I = I \cdot I = I = I$

Hence, A is orthogonal.

87. $\because \quad MM^T = I$ ...(i)

Let $\quad B = M - I$ ...(ii)

$\therefore \quad B^T = M^T - I^T = M^T - M^T M$ [from Eq. (i)]

$= M^T (I - M) = -M^T B$ [from Eq. (ii)]

Now, $\det(B^T) = \det(-M^T B)$

$= (-1)^3 \det(M^T)\det(B) = -\det(M^T)\det(B)$

$\Rightarrow \quad \det(B) = -\det(M)\det(B) = -\det(B)$

$\therefore \quad \det(B) = 0$

$\Rightarrow \quad \det(M - I) = 0$

88. $\because \quad BAB = A^{-1}$

$\Rightarrow \quad ABAB = I$

$\Rightarrow \quad (AB)^2 = I$

Now, $AB = \begin{bmatrix} \cos(\alpha + 2\beta) & \sin(\alpha + 2\beta) \\ \sin(\alpha + 2\beta) & -\cos(\alpha + 2\beta) \end{bmatrix}$

and $(AB)^2 = (AB)(AB) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = I \quad [\because (AB)(AB) = I\,]$

Also, $BA^4B = A^{-1}$

or $A^4B = B^{-1}A^{-1} = (AB)^{-1} = AB$

or $A^4 = A \qquad \ldots(i)$

Now, $A^2 = \begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix}\begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix}$

$= \begin{bmatrix} \cos 2\alpha & -\sin 2\alpha \\ \sin 2\alpha & \cos 2\alpha \end{bmatrix}$

Similarly, $A^4 = \begin{bmatrix} \cos 4\alpha & -\sin 4\alpha \\ \sin 4\alpha & \cos 4\alpha \end{bmatrix}$

Hence, from Eq. (i)

$$\begin{bmatrix} \cos 4\alpha & -\sin 4\alpha \\ \sin 4\alpha & \cos 4\alpha \end{bmatrix} = \begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix}$$

or $4\alpha = 2\pi + \alpha$

$\therefore \quad \alpha = \dfrac{2\pi}{3}$

89. $AB = \begin{bmatrix} \cos^2\theta & \cos\theta\sin\theta \\ \cos\theta\sin\theta & \sin^2\theta \end{bmatrix}\begin{bmatrix} \cos^2\phi & \cos\phi\sin\phi \\ \cos\phi\sin\phi & \sin^2\phi \end{bmatrix}$

$= \begin{bmatrix} \cos^2\theta\cos^2\phi + \cos\theta\cos\phi\sin\theta\sin\phi & \cos^2\theta\cos\phi\sin\phi + \sin^2\phi\sin\theta\cos\theta \\ \cos^2\phi\cos\theta\sin\theta + \sin^2\theta\sin\phi\cos\phi & \cos\theta\cos\phi\sin\theta\sin\phi + \sin^2\theta\sin^2\phi \end{bmatrix}$

$= \begin{bmatrix} \cos\theta\cos\phi(\cos\theta\cos\phi + \sin\theta\sin\phi) & \cos\phi\sin\phi(\cos\theta\cos\phi + \sin\theta\sin\phi) \\ \sin\theta\cos\phi(\cos\theta\cos\phi + \sin\theta\sin\phi) & \sin\theta\sin\phi(\cos\theta\cos\phi + \sin\theta\sin\phi) \end{bmatrix}$

$= \begin{bmatrix} \cos\theta\cos\phi\cos(\theta - \phi) & \cos\theta\sin\phi\cos(\theta - \phi) \\ \sin\theta\cos\phi\cos(\theta - \phi) & \sin\theta\sin\phi\cos(\theta - \phi) \end{bmatrix}$

Clearly, AB is the zero matrix, if $\cos(\theta \sim \phi) = 0$ i.e., $\theta - \phi$ is an odd multiple of $\dfrac{\pi}{2}$.

90. Let $A = \begin{bmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{bmatrix}$

$\therefore \quad A^T = \begin{bmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \\ n_1 & n_2 & n_3 \end{bmatrix}$

Now, $AA^T = \begin{bmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{bmatrix} \times \begin{bmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \\ n_1 & n_2 & n_3 \end{bmatrix}$

$= \begin{bmatrix} \Sigma l_1^2 & \Sigma l_1 l_2 & \Sigma l_3 l_1 \\ \Sigma l_1 l_2 & \Sigma l_2^2 & \Sigma l_2 l_3 \\ \Sigma l_3 l_1 & \Sigma l_2 l_3 & \Sigma l_3^2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$

Hence, matrix A is orthogonal.

91. Let us use the symbols Div, Dis, Tal for division, district, taluka respectively and O, H, C, Cl, T and P for office superintendent, Head clerk, Cashier, Clerk, Typist and Peon respectively.

Then, the number of offices can be arranged as elements of a row matrix A and the composition of staff in various offices can be arranged in a 3×6 matrix B (say).

$\therefore \quad A = \begin{matrix} \text{Div} & \text{Dis} & \text{Tal} \end{matrix}$

$\begin{bmatrix} 5 & 30 & 200 \end{bmatrix}$

and $B = \begin{matrix} \text{O} & \text{H} & \text{C} & \text{Cl} & \text{T} & \text{P} \end{matrix}$

$\begin{bmatrix} 1 & 1 & 1 & 2+1 & 1 & 1+1 \\ 0 & 1 & 1 & 1+1 & 0 & 1+1 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{bmatrix}$

or $B = \begin{matrix} \text{O} & \text{H} & \text{C} & \text{Cl} & \text{T} & \text{P} \end{matrix}$

$\begin{bmatrix} 1 & 1 & 1 & 3 & 1 & 2 \\ 0 & 1 & 1 & 2 & 0 & 2 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{bmatrix}$

The basic monthly salaries of various types of employees of these offices correspond to the elements of the column matrix C.

$\therefore \quad C = \begin{matrix} \text{O} \\ \text{H} \\ \text{C} \\ \text{Cl} \\ \text{T} \\ \text{P} \end{matrix} \begin{bmatrix} 500 \\ 200 \\ 175 \\ 150 \\ 150 \\ 100 \end{bmatrix}$

(i) Total number of Posts = AB

$$= \begin{matrix} & \text{O} & \text{H} & \text{C} & \text{Cl} & \text{T} & \text{P} \\ \text{Div}\ \ \text{Dis}\ \ \text{Tal} & & & & & & \end{matrix} \begin{bmatrix} 1 & 1 & 1 & 3 & 1 & 2 \\ 0 & 1 & 1 & 2 & 0 & 2 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{bmatrix}$$

$$= \begin{matrix} \text{O} & \text{H} & \text{C} & \text{Cl} & \text{T} & \text{P} \end{matrix}$$

$$[5 \quad 235 \quad 235 \quad 275 \quad 5 \quad 270]$$

i.e., Required number of posts in all the offices taken together are 5 office Suprintendents, 235 Head Clerks, 235 Cashiers, 275 Clerks, 5 Typists and 270 Peons.

(ii) The total basic monthly salary bill of each kind of office = BC

$$= \begin{bmatrix} \text{O} & \text{H} & \text{C} & \text{Cl} & \text{T} & \text{P} \\ 1 & 1 & 1 & 3 & 1 & 2 \\ 0 & 1 & 1 & 2 & 0 & 2 \\ 0 & 1 & 1 & 1 & 0 & 1 \end{bmatrix} \times \begin{matrix} \begin{bmatrix} 500 \\ 200 \\ 175 \\ 150 \\ 150 \\ 100 \end{bmatrix} \end{matrix} \begin{matrix} \text{O} \\ \text{H} \\ \text{C} \\ \text{Cl} \\ \text{T} \\ \text{P} \end{matrix}$$

$$= \begin{bmatrix} 500 + 200 + 175 + 3 \times 150 + 1 \times 150 + 2 \times 100 \\ 0 + 1 \times 200 + 1 \times 175 + 2 \times 150 + 0 + 2 \times 100 \\ 0 + 1 \times 200 + 1 \times 175 + 1 \times 150 + 0 + 1 \times 100 \end{bmatrix}$$

$$= \begin{bmatrix} 1675 \\ 875 \\ 625 \end{bmatrix}$$

i.e., The total basic monthly salary bill of each divisional, district and taluka offices are ₹ 1675, ₹ 875 and ₹ 625, respectively.

(iii) The total basic monthly salary bill of all the offices taken together

$$= ABC = A(BC)$$

$$= [5 \quad 30 \quad 200] \times \begin{bmatrix} 1675 \\ 875 \\ 625 \end{bmatrix}$$

$$= [5 \times 1675 + 30 \times 875 + 200 \times 625]$$

$$= [159625]$$

Hence, total basic monthly salary bill of all the offices taken together is ₹ 159625.

92. The total load of stone and sand supplied by A can be represented by row matrix X_1 and cost of one truck load of stone and sand can be represented by column matrix Y_1.

$$\therefore \quad X_1 = [40 \quad 10], \; Y_1 = \begin{bmatrix} 1200 \\ 500 \end{bmatrix}$$

Total amount paid by contractor to $A = X_1 Y_1$

$$= [40 \quad 10] \begin{bmatrix} 1200 \\ 500 \end{bmatrix}$$

$$= [48000 + 5000]$$

$$= [53000]$$

$\therefore$ Amount paid by contractor to A is ₹ 53000.

Similarly for B, $X_2 = [35 \quad 5]$, $Y_2 = \begin{bmatrix} 1200 \\ 500 \end{bmatrix}$

Total amount paid by contractor to $B = X_2 Y_2$

$$= [35 \quad 5] \begin{bmatrix} 1200 \\ 500 \end{bmatrix} = [42000 + 2500]$$

$$= [44500]$$

$\therefore$ Amount paid by contractor to B is ₹ 44500.

Similarly for C,

$$X_3 = [25 \quad 8], \; Y_3 = \begin{bmatrix} 1200 \\ 500 \end{bmatrix}$$

Total amount paid by contractor to $C = X_3 Y_3$

$$= [25 \quad 8] \begin{bmatrix} 1200 \\ 500 \end{bmatrix}$$

$$= [30000 + 4000] = [34000]$$

$\therefore$ Amount paid by contractor to C is ₹ 34000.

93. We have, $A = \begin{bmatrix} 1 & a & \alpha & a\alpha \\ 1 & b & \beta & b\beta \\ 1 & c & \gamma & c\gamma \end{bmatrix}$

Applying $R_2 \to R_2 - R_1$ and $R_3 \to R_3 - R_1$, we get

$$A = \begin{bmatrix} 1 & a & \alpha & a\alpha \\ 0 & b-a & \beta-\alpha & b\beta - a\alpha \\ 0 & c-a & \gamma-\alpha & c\gamma - a\alpha \end{bmatrix}$$

Applying $C_2 \to C_2 - aC_1$, $C_3 \to C_3 - \alpha C_1$ and $C_4 \to C_4 - a\alpha C_1$, we get

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & b-a & \beta-\alpha & b\beta - a\alpha \\ 0 & c-a & \gamma-\alpha & c\gamma - a\alpha \end{bmatrix}$$

Applying $C_4 \to C_4 - \alpha C_2 - bC_3$, we get

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & b-a & \beta-\alpha & 0 \\ 0 & c-a & \gamma-\alpha & (c-b)(\gamma-\alpha) \end{bmatrix}$$

For $\rho(A) = 3$

$c - a \neq 0, \gamma - \alpha \neq 0, c - b \neq 0, b - a \neq 0, \beta - \alpha \neq 0$

i.e., $a \neq b, b \neq c, c \neq a$ and $\alpha \neq \beta, \beta \neq \gamma, \gamma \neq \alpha$

94. We have, $\begin{bmatrix} 1 & 1 & 1 \\ 2 & 5 & 7 \\ 2 & 1 & -1 \end{bmatrix} \begin{bmatrix} x & u \\ y & v \\ z & w \end{bmatrix} = \begin{bmatrix} 9 & 2 \\ 52 & 15 \\ 0 & -1 \end{bmatrix}$

or $AX = B$

or $X = A^{-1}B$ ...(i)

Where, $A = \begin{bmatrix} 1 & 1 & 1 \\ 2 & 5 & 7 \\ 2 & 1 & -1 \end{bmatrix}$, $X = \begin{bmatrix} x & u \\ y & v \\ z & \omega \end{bmatrix}$ and $B = \begin{bmatrix} 9 & 2 \\ 52 & 15 \\ 0 & -1 \end{bmatrix}$

$$\therefore \quad |A| = 1(-5-7) - 1(-2-14) + 1(2-10)$$

$$= -12 + 16 - 8 = -4 \neq 0$$

Let C be the matrix of cofactors of elements of $|A|$.

$$\therefore \quad C = \begin{bmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{bmatrix}$$

$$= \begin{bmatrix} \begin{vmatrix} 5 & 7 \\ 1 & -1 \end{vmatrix} & -\begin{vmatrix} 2 & 7 \\ 2 & -1 \end{vmatrix} & \begin{vmatrix} 2 & 5 \\ 2 & 1 \end{vmatrix} \\ -\begin{vmatrix} 1 & 1 \\ 1 & -1 \end{vmatrix} & \begin{vmatrix} 1 & 1 \\ 2 & -1 \end{vmatrix} & -\begin{vmatrix} 1 & 1 \\ 2 & 1 \end{vmatrix} \\ \begin{vmatrix} 1 & 1 \\ 5 & 7 \end{vmatrix} & -\begin{vmatrix} 1 & 1 \\ 2 & 7 \end{vmatrix} & \begin{vmatrix} 1 & 1 \\ 2 & 5 \end{vmatrix} \end{bmatrix}$$

$$= \begin{bmatrix} -12 & 16 & -8 \\ 2 & -3 & 1 \\ 2 & -5 & 3 \end{bmatrix}$$

$$\therefore \quad \text{adj } A = C' = \begin{bmatrix} -12 & 2 & 2 \\ 16 & -3 & -5 \\ -8 & 1 & 3 \end{bmatrix}$$

$$\therefore \quad A^{-1} = \frac{\text{adj } A}{|A|} = -\frac{1}{4} \begin{bmatrix} -12 & 2 & 2 \\ 16 & -3 & -5 \\ -8 & 1 & 3 \end{bmatrix}$$

Now, $A^{-1}B = -\frac{1}{4} \begin{bmatrix} -12 & 2 & 2 \\ 16 & -3 & -5 \\ -8 & 1 & 3 \end{bmatrix} \times \begin{bmatrix} 9 & 2 \\ 52 & 15 \\ 0 & -1 \end{bmatrix}$

$$= -\frac{1}{4}\begin{bmatrix} -4 & 4 \\ -12 & -8 \\ -20 & -4 \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ 3 & 2 \\ 5 & 1 \end{bmatrix}$$

From Eq. (i) $X = A^{-1}B$

$$\Rightarrow \quad \begin{bmatrix} x & u \\ y & v \\ z & w \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ 3 & 2 \\ 5 & 1 \end{bmatrix}$$

On equating the corresponding elements, we have

$x = 1, u = -1$

$y = 3, v = 2$

$z = 5, w = 1$

95. Since, $x_1 = 3y_1 + 2y_2 - y_3$

$$\Rightarrow \quad [x_1] = [3 \quad 2 \quad -1]\begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix}$$

Putting the values of y_1, y_2, y_3, we get

$$[x_1] = [3 \quad 2 \quad -1]\begin{bmatrix} z_1 - z_2 + z_3 \\ 0 + z_2 + 3z_3 \\ 2z_1 + z_2 + 0 \end{bmatrix}$$

$$= [3 \quad 2 \quad -1]\begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 3 \\ 2 & 1 & 0 \end{bmatrix}\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [3 + 0 - 2 \quad -3 + 2 - 1 \quad 3 + 6 + 0]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [1 \quad -2 \quad 9]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$[x_1] = [z_1 - 2z_2 + 9z_3]$$

$\therefore \quad x_1 = z_1 - 2z_2 + 9z_3$ ...(i)

Further, $x_2 = -y_1 + 4y_2 + 5y_3$

$$\Rightarrow \quad [x_2] = [-1 \quad 4 \quad 5]\begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix}$$

Putting the values of y_1, y_2, y_3, we get

$$[x_2] = [-1 \quad 4 \quad 5]\begin{bmatrix} z_1 - z_2 + z_3 \\ 0 + z_2 + 3z_3 \\ 2z_1 + z_2 + 0 \end{bmatrix}$$

$$= [-1 \quad 4 \quad 5]\begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 3 \\ 2 & 1 & 0 \end{bmatrix}\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [-1 + 0 + 10 \quad 1 + 4 + 5 \quad -1 + 12 + 0]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [9 \quad 10 \quad 11]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix} = [9z_1 + 10z_2 + 11z_3]$$

Hence, $x_2 = 9z_1 + 10z_2 + 11z_3$ ...(ii)

Further, $x_3 = y_1 - y_2 + 3y_3$

$$\therefore \quad [x_3] = [1 \quad -1 \quad 3]\begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix}$$

Putting the values of y_1, y_2, y_3, we get

$$\Rightarrow \quad [x_3] = [1 \quad -1 \quad 3]\begin{bmatrix} z_1 - z_2 + z_3 \\ 0 + z_2 + 3z_3 \\ 2z_1 + z_2 + 0 \end{bmatrix}$$

$$= [1 \quad -1 \quad 3]\begin{bmatrix} 1 & -1 & 1 \\ 0 & 1 & 3 \\ 2 & 1 & 0 \end{bmatrix}\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [1 - 0 + 6 \quad -1 - 1 + 3 \quad 1 - 3 + 0]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix}$$

$$= [7 \quad 1 \quad -2]\begin{bmatrix} z_1 \\ z_2 \\ z_3 \end{bmatrix} = [7z_1 + z_2 - 2z_3]$$

$\therefore \quad x_3 = 7z_1 + z_2 - 2z_3$ ...(iii)

Hence, from Eqs. (i), (ii) and (iii), we get

$x_1 = z_1 - 2z_2 + 9z_3,\ x_2 = 9z_1 + 10z_2 + 11z_3,\ x_3 = 7z_1 + z_2 - 2z_3$

96. Given equations can be written as,

$2x - 3y + 6z = 5t + 3$

$y - 4z = 1 - t$

$4x - 5y + 8z = 9t + k$

which is of the form $AX = B$.

Let C be the augmented matrix, then

$$C = [A : B] = \begin{bmatrix} 2 & -3 & 6 & \vdots & 5t + 3 \\ 0 & 1 & -4 & \vdots & 1 - t \\ 4 & -5 & 8 & \vdots & 9t + k \end{bmatrix}$$

Applying $R_3 \to R_3 - 2R_1$, then

$$C = \begin{bmatrix} 2 & -3 & 6 & \vdots & 5t + 3 \\ 0 & 1 & -4 & \vdots & 1 - t \\ 0 & 1 & -4 & \vdots & -t + k - 6 \end{bmatrix}$$

Applying $R_3 \to R_3 - R_2$, then

$$C = \begin{bmatrix} 2 & -3 & 6 & \vdots & 5t + 3 \\ 0 & 1 & -4 & \vdots & 1 - t \\ 0 & 0 & 0 & \vdots & k - 7 \end{bmatrix}$$

(i) For no solution

$R_A \neq R_C$

$\therefore \quad k \neq 7$

(ii) For infinite number of solutions

$R_A = R_C$

$\therefore \quad k = 7$

97. $AX = U$ has infinite many solutions

$\Rightarrow \quad |A| = 0 = |A_1| = |A_2| = |A_3|$

Now, $|A| = 0$

$$\Rightarrow \quad \begin{vmatrix} a & 1 & 0 \\ 1 & b & d \\ 1 & b & c \end{vmatrix} = 0 \Rightarrow (ab - 1)(c - d) = 0$$

$\Rightarrow \quad ab = 1$ or $c = d$ ...(i)

and $|A_1| = 0$

$\Rightarrow \begin{vmatrix} f & 1 & 0 \\ g & b & d \\ h & b & c \end{vmatrix} = 0$

$\Rightarrow fb(c-d) - gc + hd = 0$

$\Rightarrow fb(c-d) = gc - hd$ ...(ii)

$\Rightarrow |A_2| = 0$

$\Rightarrow \begin{vmatrix} a & f & 0 \\ 1 & g & d \\ 1 & h & c \end{vmatrix} = 0$

$\Rightarrow a(gc-dh) - f(c-d) = 0$

$\Rightarrow a(gc-dh) = f(c-d)$ ...(iii)

$|A_3| = 0$

$\Rightarrow \begin{vmatrix} a & 1 & f \\ 1 & b & g \\ 1 & b & h \end{vmatrix} = 0$

$\Rightarrow (h-g)(ab-1) = 0$

$\Rightarrow h = g$ or $ab = 1$ ...(iv)

Taking $c = d \Rightarrow h = g$ and $ab \neq 1$ (from Eqs. (i), (ii) and (iv))

Now, taking $BX = V$,

Then, $|B| = \begin{vmatrix} a & 1 & 1 \\ 0 & d & c \\ f & g & h \end{vmatrix} = 0$

[$\because$ In view of $c = d$ and $g = h$, c_2 and c_3 are identical]

$\Rightarrow$ $BX = V$ has no unique solution.

and $|B_1| = \begin{vmatrix} a^2 & 1 & 1 \\ 0 & d & c \\ 0 & g & h \end{vmatrix} = 0$ [$\because c = d, g = h$]

$|B_2| = \begin{vmatrix} a & a^2 & 1 \\ 0 & 0 & c \\ f & 0 & h \end{vmatrix} = a^2 fc = a^2 df$ [$\because c = d$]

and $|B_3| = \begin{vmatrix} a & 1 & a^2 \\ 0 & d & 0 \\ f & g & 0 \end{vmatrix} = -a^2 df$

If $a^2 df \neq 0$, then $|B_2| = |B_3| \neq 0$

Hence, no solution exist.

98. Given, $A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & -2 & 4 \end{bmatrix}$, $A^{-1} = \frac{1}{6}\begin{bmatrix} 6 & 0 & 0 \\ 0 & 4 & -1 \\ 0 & 2 & 1 \end{bmatrix}$

$$A^2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & -2 & 4 \end{bmatrix}\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & -2 & 4 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 5 \\ 0 & -10 & 14 \end{bmatrix}$$

$$cA = \begin{bmatrix} c & 0 & 0 \\ 0 & c & c \\ 0 & -2c & 4c \end{bmatrix}; dI = \begin{bmatrix} d & 0 & 0 \\ 0 & d & 0 \\ 0 & 0 & d \end{bmatrix}$$

$\therefore$ By $A^{-1} = \frac{1}{6}[A^2 + cA + dI]$

$\Rightarrow 6 = 1 + c + d$ [By equality of matrices]

$\therefore (-6, 11)$ satisfy the relation.

99. If $Q = PAP^T$

then $P^T Q = AP^T$ [$\because PP^T = I$]

$\Rightarrow P^T Q^{2005} P = AP^T Q^{2004} P$

$= A^2 P^T Q^{2003} P = A^3 P^T Q^{2002} P$

$= A^{2004} P^T (QP)$

$= A^{2004} P^T (PA)$ [$Q = PAP^T \Rightarrow QP = PA$]

$= A^{2005}$

$\therefore A^{2005} = \begin{bmatrix} 1 & 2005 \\ 0 & 1 \end{bmatrix}$

100. $A^2 = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}$

$A^3 = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 3 & 1 \end{bmatrix}$

$\therefore A^n = \begin{bmatrix} 1 & 0 \\ n & 1 \end{bmatrix}$

$nA = \begin{bmatrix} n & 0 \\ n & n \end{bmatrix}, (n-1)\, I = \begin{bmatrix} n-1 & 0 \\ 0 & n-1 \end{bmatrix}$

$nA - (n-1)\, I = \begin{bmatrix} 1 & 0 \\ n & 1 \end{bmatrix} = A^n$

101. $A^2 - A + I = 0$

$\Rightarrow I = A - A^2 \Rightarrow I = A(I - A)$

$\Rightarrow A^{-1} I = A^{-1}(A(I - A)) \Rightarrow A^{-1} = I - A$

102. (i) Let U_1 be $\begin{pmatrix} x \\ y \\ z \end{pmatrix}$ so that $\begin{pmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 3 & 2 & 1 \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$

$\Rightarrow \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 1 \\ -2 \\ 1 \end{pmatrix}$

Similarly, $U_2 = \begin{pmatrix} 2 \\ -1 \\ -4 \end{pmatrix}, U_3 = \begin{pmatrix} 2 \\ -1 \\ -3 \end{pmatrix}$

Hence, $U = \begin{pmatrix} 1 & 2 & 2 \\ -2 & -1 & -1 \\ 1 & -4 & -3 \end{pmatrix}$

$\therefore |U| = 3$

(ii) $\because \quad \text{Adj}U = \begin{pmatrix} -1 & -2 & 0 \\ -7 & -5 & -3 \\ 9 & -6 & 3 \end{pmatrix}$

$\therefore \quad U^{-1} = \dfrac{\text{Adj}U}{|U|} = \dfrac{\text{Adj}U}{3}$

$\Rightarrow$ sum of the elements of

$$U^{-1} = \frac{1}{3}(-1-2+0-7-5-3+9+6+3) = 0$$

(iii) The value of

$$(3\ 2\ 0)\, U \begin{pmatrix} 3 \\ 2 \\ 0 \end{pmatrix} = (3\ 2\ 0) \begin{pmatrix} 1 & 2 & 2 \\ -2 & -1 & -1 \\ 1 & -6 & -3 \end{pmatrix} \begin{pmatrix} 3 \\ 2 \\ 0 \end{pmatrix}$$

$$= (-1\ \ 4\ \ 4) \begin{pmatrix} 3 \\ 2 \\ 0 \end{pmatrix}$$

$$= (-3+8+0) = 5$$

103. $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}, B = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$

$\Rightarrow \quad AB = \begin{pmatrix} a & 2b \\ 3a & 4b \end{pmatrix}$

and $\quad BA = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix} \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} = \begin{pmatrix} a & 2a \\ 3b & 4b \end{pmatrix}$

Hence, $AB = BA$ only when $a = b$.

104. $A^2 - B^2 = (A-B)(A+B)$

$\Rightarrow \quad A^2 - B^2 = A^2 + AB - BA - B^2$

$\Rightarrow \quad AB = BA$

105. $A = \begin{bmatrix} 5 & 5\alpha & \alpha \\ 0 & \alpha & 5\alpha \\ 0 & 0 & 5 \end{bmatrix} \Rightarrow |A \cdot A| = |A||A| = (25\alpha)^2 = 25$

$\Rightarrow \quad \alpha^2 = \dfrac{1}{25}$

$\Rightarrow \quad \alpha = \pm \dfrac{1}{5}$

106. $\because \quad A^t = A, B^t = -B$

Given, $\quad (A+B)(A-B) = (A-B)(A+B)$

$\Rightarrow \quad A^2 - AB + BA - B^2 = A^2 + AB - BA - B^2$

$\Rightarrow \quad AB = BA$

Also, given $\quad (AB)^t = (-1)^k\, AB$

$\Rightarrow \quad B^t A^t = (-1)^k\, AB$

$\Rightarrow \quad -BA = (-1)^k\, AB$

$\Rightarrow \quad (-1) = (-1)^k \qquad [\because AB = BA]$

$\therefore \quad k = 1, 3, 5, \ldots$

107. Let $A = \begin{bmatrix} 2 & 1 \\ 0 & 1/2 \end{bmatrix}$

$$\det A = \begin{vmatrix} 2 & 1 \\ 0 & 1/2 \end{vmatrix} = 1$$

and $\quad A^{-1} = \begin{bmatrix} 1/2 & -1 \\ 0 & 2 \end{bmatrix}$

and let $\quad A = \begin{bmatrix} 3 & 0 \\ -3 & -1/3 \end{bmatrix},$

$$\det A = \begin{vmatrix} 3 & 0 \\ -3 & -1/3 \end{vmatrix} = -1$$

and $\quad A^{-1} = \begin{bmatrix} 1/3 & 0 \\ -3 & -3 \end{bmatrix}$

108. Let $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ or $\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$

Then, $A^2 = I$

$\therefore \quad \det A = \begin{vmatrix} 1 & 0 \\ 0 & -1 \end{vmatrix} = -1$ and $\text{tr}(A) = 0$

109. (i) If two zero's are the entries in the diagonal, then

$${}^3C_2 \times {}^3C_1 = 9$$

If the entries in the principal diagonal is1, then

$${}^3C_1 = 3$$

$\Rightarrow$ Total matrix $= 9 + 3 = 12$

(ii) $\begin{bmatrix} 0 & a & b \\ a & 0 & c \\ b & c & 1 \end{bmatrix}$ either $b = 0$ or $c = 0 \Rightarrow |A| \neq 0$

$\Rightarrow$ 2 matrices

$\begin{bmatrix} 0 & a & b \\ a & 1 & c \\ b & c & 0 \end{bmatrix}$ either $a = 0$ or $c = 0 \Rightarrow |A| \neq 0$

$\Rightarrow$ 2 matrices

$\begin{bmatrix} 1 & a & b \\ a & 0 & c \\ b & c & 0 \end{bmatrix}$ either $a = 0$ or $b = 0 \Rightarrow |A| \neq 0$

$\Rightarrow$ 2 matrices

$$\begin{bmatrix} 1 & a & b \\ a & 1 & c \\ b & c & 1 \end{bmatrix}$$

If $a = b = 0 \Rightarrow |A| = 0$

If $a = c = 0 \Rightarrow |A| = 0$

If $b = c = 0 \Rightarrow |A| = 0$

$\Rightarrow$ There will be only 6 matrices.

(iii) The six matrix A for which $|A| = 0$ are

$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & 1 \end{bmatrix} \Rightarrow$ inconsistent

$\begin{bmatrix} 0 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 0 \end{bmatrix} \Rightarrow$ inconsistent

$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \Rightarrow$ infinite solutions

$$\begin{bmatrix}1 & 1 & 0\\ 1 & 1 & 0\\ 0 & 0 & 1\end{bmatrix} \Rightarrow \text{inconsistent}$$

$$\begin{bmatrix}1 & 0 & 1\\ 0 & 1 & 0\\ 1 & 0 & 1\end{bmatrix} \Rightarrow \text{inconsistent}$$

$$\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 1\\ 0 & 1 & 1\end{bmatrix} \Rightarrow \text{infinite solutions}$$

110. $|\text{adj } A| = |A|^{n-1} = |A|^{2-1} = |A|$

$$\text{adj}(\text{adj } A) = |A|^{n-2} A$$

$$= |A|^{2-2} A = |A|^0 A = A$$

111. Three planes cannot meet only at two distinct points.

Hence, number of matrices = 0

112. If A is symmetric matrix, then $b = c$

$$\therefore \quad \det(A) = \begin{vmatrix} a & b \\ b & a \end{vmatrix} = a^2 - b^2 = (a+b)(a-b)$$

$a, b, c \in \{0, 1, 2, 3, \ldots, p-1\}$

Number of numbers of type

$$np = 1$$
$$np + 1 = 1$$
$$np + 2 = 1$$
$$\ldots\ldots\ldots\ldots$$
$$\ldots\ldots\ldots\ldots$$
$$np + (p-1) = 1 \ \forall\ n \in I$$

(i) as $\det(A)$ is divisible by $p \Rightarrow$ either $a + b$ divisible by p corresponding number of ways $= (p-1)$ [excluding zero] or $(a - b)$ is divisible by p corresponding number of ways $= p$
Total Number of ways $= 2p - 1$

(ii) as $\text{Tr}(A)$ not divisible by $p \Rightarrow a \neq 0$
$\det(A)$ is divisible by $p \Rightarrow a^2 - bc$ divisible by p
Number of ways of selection of a, b, c

$$= (p-1)[(p-1) \times 1] = (p-1)^2$$

(iii) Total number of $A = p \times p \times p = p^3$
Number of A such that $\det(A)$ divisible by p

$$= (p-1)^2 + \text{ number of } A \text{ in which } a = 0$$
$$= (p-1)^2 + p + p - 1 = p^2$$

Required number $= p^3 - p^2$

113. $|A| = (2k-1)(-1 + 4k^2) + 2\sqrt{k}(2\sqrt{k} + 4k\sqrt{k})$

$$+ 2\sqrt{k}(4k\sqrt{k} + 2\sqrt{k})(2k-1)(4k^2-1)$$
$$+ 4k + 8k^2 + 8k^2 + 4k$$

$$= (2k-1)(4k^2-1) + 8k + 16k^2$$
$$= 8k^3 - 4k^2 - 2k + 1 + 8k + 16k^2$$
$$= 8k^3 + 12k^2 + 6k + 1$$

$|B| = 0$ as B is skew-symmetric matrix of odd order.

$$\Rightarrow \quad (8k^3 + 12k^2 + 6k + 1)^2 = (10^3)^2$$
$$\Rightarrow \quad (2k+1)^3 = 10^3$$
$$\Rightarrow \quad 2k + 1 = 10$$
$$\Rightarrow \quad k = 4.5$$
$$\Rightarrow \quad [k] = 4$$

114. First row with exactly one zero

$\therefore$ Total number of cases = 6

First row 2 zeroes, we get more cases.

$\therefore$ Total we get more than 7.

115. Let $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, $abcd \neq 0$

$$A^2 = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

$$\Rightarrow \quad A^2 = \begin{pmatrix} a^2 + bc & ab + bd \\ ac + cd & bc + d^2 \end{pmatrix}$$

$$\Rightarrow \quad a^2 + bc = 1, \ bc + d^2 = 1$$
$$ab + bd = ac + cd = 0$$
$$c \neq 0 \text{ and } b \neq 0$$

and $\quad a + d = 0$

Trace $\quad A = a + d = 0$

$$|A| = ad - bc = -a^2 - bc = 1$$

116. $MN = NM$

$$M^2N^2(M^TN)^{-1}(MN^{-1})^T M^2N^2N^{-1}(M^T)^{-1}(N^{-1})^T \cdot M^T$$
$$= M^2N \cdot (M^T)^{-1}(N^{-1})^T M^T = -M^2 \cdot N(M)^{-1}(N^T)^{-1} M^T$$
$$= +M^2NM^{-1}N^{-1}M^T = -M \cdot NMM^{-1}N^{-1} M$$
$$= -MNN^{-1}M = -M^2$$

Note

A skew-symmetric matrix of order 3 cannot be non-singular hence the question is wrong.

117. (i) $a + 8b + 7c = 0; \quad 9a + 2b + 3c = 0$

$$7a + 7b + 7c = 0$$

Solving these equations, we get

$$b = 6a$$
$$\Rightarrow \quad c = -7a$$

Now, $\quad 2x + y + z = 0$

$$\Rightarrow \quad 2a + 6a + (-7a) = 1$$
$$\Rightarrow \quad a = 1, b = 6, c = -7$$
$$\therefore \quad 7a + b + c = 7 + 6 - 7 = 6$$

(ii) $\because a = 2$ with b and c satisfying (E)

$\therefore \quad 2 + 8b + 7c = 0, 18 + 2b + 3c = 0$

and $\quad 2 + b + c = 0$

we get $\quad b = 12$ and $c = -14$

Hence, $\dfrac{3}{\omega^a} + \dfrac{1}{\omega^b} + \dfrac{3}{\omega^c} = \dfrac{3}{\omega^2} + \dfrac{1}{\omega^{12}} + \dfrac{3}{\omega^{-14}}$

$$= \frac{3\omega}{\omega^3} + \frac{1}{1} + 3\omega^{14}$$
$$= 3\omega + 1 + 3\omega^2$$
$$= 1 + 3(\omega + \omega^2)$$
$$= 1 + 3(-1) = -2$$

(iii) $\because b = 6$, with a and c satisfying (E)

$\therefore \quad a + 48 + 7c = 0, 9a + 12 + 3c = 0, a + 6 + c = 0$

we get $\quad a = 1, c = -7$

Given, α, β are the roots of $ax^2 + bx + c = 0$

$$\therefore \quad \alpha + \beta = -\frac{b}{a} = -6,$$

$$\alpha\beta = \frac{c}{a} = -7$$

Now, $\dfrac{1}{\alpha} + \dfrac{1}{\beta} = \dfrac{\alpha + \beta}{\alpha\beta} = \dfrac{-6}{-7} = \dfrac{6}{7}$

$$\therefore \quad \sum_{n=0}^{\infty} \left(\frac{1}{\alpha} + \frac{1}{\beta}\right)^n = \sum_{n=0}^{\infty} \left(\frac{6}{7}\right)^n$$

$$= 1 + \left(\frac{6}{7}\right) + \left(\frac{6}{7}\right)^2 + \ldots \infty$$

$$= \frac{1}{1 - 6/7} = 7$$

118. For the given matrix to be non singular

$$\therefore \quad \begin{vmatrix} 1 & a & b \\ \omega & 1 & c \\ \omega^2 & \omega & 1 \end{vmatrix} \neq 0$$

$$\Rightarrow \quad 1 - (a + c)\,\omega + ac\omega^2 \neq 0$$

$$\Rightarrow \quad (1 - a\omega)(1 - c\omega) \neq 0$$

$$\Rightarrow \quad a \neq \omega^2 \text{ and } c \neq \omega^2$$

$\because a, b$ and c are complex cube roots of unity.

$\therefore a$ and c can take only one value i.e., ω while b can take two values i.e., ω and ω^2.

$\therefore$ Total number of distinct = 2

119. Let $M = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$

$$M\begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \\ 3 \end{bmatrix} \Rightarrow b = -1, e = 2, h = 3$$

$$M\begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ -1 \end{bmatrix} \Rightarrow a = 0, d = 3, g = 2$$

$$M\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 12 \end{bmatrix} \Rightarrow g + h + i = 12 \Rightarrow i = 7$$

$\therefore$ Sum of diagonal elements $= a + e + i = 0 + 2 + 7 = 9$

120. Since, A and B are symmetric matrices

$\therefore \quad A' = A$ and $B' = B$

Statement-1 Let $P = A(BA)$

$\therefore \quad P' = (A(BA))' = (BA)'\,A'$

$= (A'\,B')\,A'$

$= (AB)\,A \qquad [\because A' = A, B' = B]$

$= A(BA) \qquad$ [By associative law]

$= P$

$\Rightarrow A(BA)$ is symmetric

Now, let $\quad Q = (AB)\,A$

$Q' = ((AB)\,A)'$

$= A'(AB)' = A'(B'\,A')$

$= A(BA) \qquad [\because A' = A, B' = B]$

$= (AB)\,A \qquad$ [By associative law]

$= Q$

$\Rightarrow (AB)\,A$ is symmetric.

$\therefore$ Statement-1 is true.

Statement - 2 $(AB)' = B'\,A' = BA \qquad [\because A' = A, B' = B]$

$= AB \qquad [\because AB = BA]$

$\Rightarrow AB$ is symmetric matrix

$\therefore$Statement-2 is true.

Hence, both Statements are true, Statement-2 is not a correct explanation for Statement-1.

121. We have, $|Q| = \begin{vmatrix} 2^2a_{11} & 2^3a_{12} & 2^4a_{13} \\ 2^3a_{21} & 2^4a_{22} & 2^5a_{23} \\ 2^4a_{31} & 2^5a_{32} & 2^6a_{33} \end{vmatrix}$

$$= 2^2 \cdot 2^3 \cdot 2^4 \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ 2a_{21} & 2a_{22} & 2a_{23} \\ 2^2a_{31} & 2^2a_{32} & 2^2a_{33} \end{vmatrix}$$

$$= 2^9 \cdot 2 \cdot 2^2 \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = 2^{12}\,|P|$$

$\therefore \quad |Q| = 2^{12} \times 2 = 2^{13}$

122. $\because \quad P^T = 2P + I \qquad \ldots$ (i)

$\therefore \quad (P^T)^T = (2P + I)^T$

$\Rightarrow \quad P = 2\,P^T + I \qquad \ldots$ (ii)

From Eqs. (i) and (ii), we get

$P = 2(2P + I) + I$

$\Rightarrow \quad P = -I$

$\therefore \quad PX = -IX = -X$

123. Given, adj $P = \begin{bmatrix} 1 & 4 & 4 \\ 2 & 1 & 7 \\ 1 & 1 & 3 \end{bmatrix}$

$$\Rightarrow \quad |\text{adj}P| = \begin{vmatrix} 1 & 4 & 4 \\ 2 & 1 & 7 \\ 1 & 1 & 3 \end{vmatrix}$$

$= 1(-4) - 4(-1) + 4(1) = 4$

$\Rightarrow \quad |P|^{3-1} = 4$

$\Rightarrow \quad |P| = \pm 2$

124. Let $u_1 + u_2 = \begin{pmatrix} x \\ y \\ z \end{pmatrix}$

Now, $\quad Au_1 + Au_2 = \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$

$$\Rightarrow \quad A(u_1+u_2)=\begin{pmatrix}1\\1\\0\end{pmatrix}$$

$$\Rightarrow \begin{pmatrix}1&0&0\\2&1&0\\3&2&1\end{pmatrix}\begin{pmatrix}x\\y\\z\end{pmatrix}=\begin{pmatrix}1\\1\\0\end{pmatrix}$$

$$\Rightarrow \begin{pmatrix}x\\2x+y\\3x+2y+z\end{pmatrix}=\begin{pmatrix}1\\1\\0\end{pmatrix}$$

$\therefore \quad x=1, 2x+y=1$

and $\quad 3x+2y+z=0$

$\Rightarrow \quad x=1, y=-1, z=-1$

Hence, $u_1+u_2=\begin{pmatrix}1\\-1\\-1\end{pmatrix}$.

125. Given, $P^3=Q^3$ ...(i)

and $P^2Q=Q^2P$ ... (ii)

Subtracting Eq. (i) and (ii), we get

$$P^3-P^2Q=Q^3-Q^2P$$

$$P^2(P-Q)=-Q^2(P-Q)$$

$$\Rightarrow \quad (P^2+Q^2)(P-Q)=O$$

$$\Rightarrow \quad |(P^2+Q^2)(P-Q)|=|O|$$

$$\Rightarrow \quad |P^2+Q^2||P-Q|=0$$

$\therefore \quad |P^2+Q^2|=0 \quad [\because P\neq Q]$

126. Given, adj $A=P$

$\therefore \quad |\text{adj } A|=|P|$

$\Rightarrow \quad |A|^{3-1}=|P| \quad [\because |A|=4]$

$\Rightarrow \quad 16=|P|$

$$\Rightarrow \quad 16=\begin{vmatrix}1&\alpha&3\\1&3&3\\2&4&4\end{vmatrix}$$

$\Rightarrow \quad 16=1(0)-\alpha(4-6)+3(4-6)$

$\Rightarrow \quad 16=2\alpha-6$

$\Rightarrow \quad 2\alpha=22$

$\therefore \quad \alpha=11$

127. (*a*) $(N^TMN)^T=N^TM^T(N^T)^T=N^TM^TN=N^TMN$

or $-N^TMN$ According as M is symmetric or skew-symmetric.

$\therefore$ Correct.

(b) $(MN-NM)^T=(MN)^T-(NM)^T=N^TM^T-M^TN^T$

$=NM-MN \quad [\because M, N \text{ are symmetric}]$

$=-(MN-NM)$

$\therefore$ correct

(c) $(MN)^T=N^TM^T=NM\neq MN \quad [\because M, N \text{ are symmetric}]$

$\therefore$ Incorrect.

(d) $(\text{adj}M)(\text{adj}N)=\text{adj}(NM)\neq\text{adj}(MN)$

$\therefore$ Incorrect.

128. $P=[p_{ij}]_{n\times n}=[\omega^{i+j}]_{n\times n}=\begin{bmatrix}\omega^2&\omega^3&\omega^4&\dots&\omega^{1+n}\\\omega^3&\omega^4&\omega^5&\dots&\omega^{2+n}\\\omega^4&\omega^5&\omega^6&\dots&\omega^{3+n}\\\vdots&\vdots&\vdots&&\vdots\\\omega^{n+1}&\omega^{n+2}&\omega^{n+3}&\dots&\omega^{2n}\end{bmatrix}$

$$\therefore \quad P^2=\begin{bmatrix}0&0&0&\dots&0\\0&0&0&\dots&0\\0&0&0&\dots&0\\\vdots&\vdots&\vdots&&\vdots\\0&0&0&\dots&0\end{bmatrix}=0$$

If n is multiple of 3, so for $P^2\neq 0$, n should not be a multiple of 3, i.e. n can take values 55, 56 and 58.

129. $B=A^{-1}A'$

$B'=(A^{-1}A')'=A(A^{-1})'$

Now, $BB'=(A^{-1}A')A(A^{-1})'=A^{-1}(A'A)(A^{-1})'$

$=A^{-1}(AA')(A^{-1})' \quad [\because A'A=AA']$

$=(A^{-1}A)A'(A^{-1})'$

$=(IA')(A^{-1})'=A'(A^{-1})'=(A^{-1}A)'=I'=I$

130. Let $M=\begin{bmatrix}a&b\\b&c\end{bmatrix}$, where $a, b, c\in I$

M is invertible if $\begin{vmatrix}a&b\\b&c\end{vmatrix}\neq 0$

$\Rightarrow \quad ac-b^2\neq 0$

(a) $\begin{bmatrix}a\\b\end{bmatrix}=\begin{bmatrix}b\\c\end{bmatrix}\Rightarrow a=b=c \Rightarrow ac-b^2=0$

$\therefore$ Option (a) is incorrect

(b) $[b\ c]=[a\ b]\Rightarrow a=b=c\Rightarrow ac-b^2=0$

$\therefore$ Option (b) is incorrect

(c) $M=\begin{bmatrix}a&0\\0&c\end{bmatrix}$, then $|M|=ac\neq 0$

$\therefore$ M is invertible

$\therefore$ Option (c) is correct.

(d) As $ac\neq(\text{Integer})^2 \Rightarrow ac\neq b^2$

$\therefore$ Option (d) is correct.

131. Given, $MN=NM$, $M\neq N^2$ and $M^2=N^4$

Then, $\quad M^2=N^4$

$\Rightarrow \quad (M+N^2)(M-N^2)=0$

$\therefore \quad M+N^2=0 \quad [\because M\neq N^2]$

$\Rightarrow \quad |M+N^2|=0$

(a) $|M^2+MN^2|=|M||M+N^2|=0$

$\therefore$ Option (a) is correct.

(b) $(M^2+MN^2)U=M(M+N^2)U=0$

$\therefore$ Option (b) is correct.

(c) $\because\ |M^2 + MN^2| = 0$ from option (a)

$\therefore \quad |M^2 + MN^2| \neq 1$

$\therefore$ Option (c) is incorrect.

(d) If $AX = 0$ and $|A| = 0$, then X can be non-zero.

132. $\because\ AA^T = 9I$

$$\begin{bmatrix}1 & 2 & 2\\ 2 & 1 & -2\\ a & 2 & b\end{bmatrix}\begin{bmatrix}1 & 2 & a\\ 2 & 1 & 2\\ 2 & -2 & b\end{bmatrix} = 9\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{bmatrix}$$

$$\Rightarrow \begin{bmatrix}9 & 0 & a+4+2b\\ 0 & 9 & 2a+2-2b\\ a+4+2b & 2a+2-2b & a^2+4+b^2\end{bmatrix} = \begin{bmatrix}9 & 0 & 0\\ 0 & 9 & 0\\ 0 & 0 & 9\end{bmatrix}$$

On comparing, we get

$$a + 2b + 4 = 0 \quad \text{... (i)}$$
$$2a - 2b + 2 = 0 \quad \text{... (ii)}$$

From Eqs. (i) and (ii), we get

$$a = -2,$$
$$b = -1$$

$\therefore$ Ordered pair is $(-2, -1)$.

133. $\because\ X^T = -X, Y^T = -Y, Z^T = Z$

(a) $(Y^3 Z^4 - Z^4 Y^3)^T = (Y^3 Z^4)^T - (Z^4 Y^3)^T$

$= (Z^4)^T (Y^3)^T - (Y^3)^T (Z^4)^T$

$= (Z^T)^4 (Y^T)^3 - (Y^T)^3 (Z^T)^4$

$= -Z^4 Y^3 + Y^3 Z^4$

$= Y^3 Z^4 - Z^4 Y^3$

Option (a) is incorrect.

(b) $X^{44} + Y^{44}$ is symmetric matrix. Option b is incorrect.

(c) $(X^4 Z^3 - Z^3 X^4)^T = (X^4 Z^3)^T - (Z^3 X^4)^T$

$= (Z^3)^T (X^4)^T - (X^4)^T (Z^3)^T$

$= (Z^T)^3 (X^T)^4 - (X^T)^4 (Z^T)^3$

$= Z^3 X^4 - X^4 Z^3$

$= -(X^4 Z^3 - Z^3 X^4)$

$\therefore$ Option (c) is correct.

(d) $X^{23} + Y^{23}$ is skew-symmetric matrix. Option (d) is correct.

134. $\because \quad A \text{ adj } A = AA^T$

$\Rightarrow \quad A^{-1}(A \text{ adj } A) = A^{-1}(AA^T)$

$\Rightarrow \quad (A^{-1}A) \text{ adj } A = (A^{-1}A)A^T$

$\Rightarrow \quad I(\text{adj } A) = IA^T$

or $\quad \text{adj } A = A^T$

or $\quad \begin{bmatrix}2 & b\\ -3 & 5a\end{bmatrix} = \begin{bmatrix}5a & 3\\ -b & 2\end{bmatrix}$

$\Rightarrow \quad 5a = 2 \text{ and } b = 3$

$\therefore \quad 5a + b = 5$

135. $\because PQ = kI \Rightarrow \dfrac{P.Q}{k} = I \Rightarrow P^{-1} = \dfrac{Q}{k}$ ...(i)

Also $\quad |P| = 12\alpha + 20$ ...(ii)

and $\quad \text{given } q_{23} = \dfrac{-k}{8}$

Comparing the third element of 2^{nd} row on both sides,

we get $\quad \dfrac{1}{(12\alpha + 20)}(-(3\alpha + 4)) = \dfrac{1}{k} \times \dfrac{-k}{8}$

$\Rightarrow \quad 24\alpha + 32 = 12\alpha + 20$

$\alpha = -1$ ...(iii)

From (ii), $\quad |P| = 8$ ...(iv)

Also $\quad PQ = kI$

$\Rightarrow \quad |PQ| = |kI|$

$\Rightarrow \quad |P||Q| = k^3$

$\Rightarrow \quad 8 \times \dfrac{k^2}{2} = k^3 \qquad \left(\because |P| = 8, |Q| = \dfrac{k^2}{2}\right)$

$\therefore \quad k = 4$ ...(v)

(b) $4\alpha - k + 8 = -4 - 4 + 8 = 0$

(c) $\det(P \text{ adj } (Q)) = |P|\,|\text{adj } Q| = |P||Q|^2 = 8 \times 8^2 = 2^9$

(d) $\det(Q \text{adj } (P)) = |Q|\,|\text{adj } P| = |Q||P|^2 = 8 \times 8^2 = 2^9$

136. $\because Z = \dfrac{-1 + \sqrt{3}i}{2} = \omega$ ...(i)

$\Rightarrow \quad \omega^3 = 1 \text{ and } 1 + \omega + \omega^2 = 0$

Now, $\quad P = \begin{bmatrix}(-\omega)^r & \omega^{2s}\\ \omega^{2s} & \omega^r\end{bmatrix}$

$\therefore \quad P^2 = \begin{bmatrix}(-\omega)^r & \omega^{2s}\\ \omega^{2s} & \omega^r\end{bmatrix}\begin{bmatrix}(-\omega)^r & \omega^{2s}\\ \omega^{2s} & \omega^r\end{bmatrix}$

$= \begin{bmatrix}\omega^{2r} + \omega^{4s} & \omega^{2r}((-\omega)^r + \omega^r)\\ \omega^{2s}((-\omega)^r + \omega^r) & \omega^{4s} + \omega^{2r}\end{bmatrix}$

$= \begin{bmatrix}\omega^{2r} + \omega^s & \omega^{2s}((-\omega)^r + \omega^r)\\ \omega^{2s}((-\omega)^r + \omega^s) & \omega^s + \omega^{2r}\end{bmatrix} (\because \omega^3 = 1)$

$\because \quad P^2 = -I = \begin{bmatrix}-1 & 0\\ 0 & -1\end{bmatrix}$ ...(ii)

Form Eqs. (i) and (ii), we get

$$\omega^{2r} + \omega^s = -1$$

and $\quad \omega^{2s}((-\omega)^r + \omega^r) = 0$

$\Rightarrow r$ is odd and $s = r$ but not a multiple of 3. Which is possible when $r = s = 1$

$\therefore$ Only one pair is there.

137. $P=\begin{bmatrix}1&0&0\\4&1&0\\16&4&1\end{bmatrix}=I+\begin{bmatrix}0&0&0\\4&0&0\\16&4&0\end{bmatrix}=I+A$

Let $A=\begin{bmatrix}0&0&0\\4&0&0\\16&4&0\end{bmatrix}$

$\Rightarrow A^2=\begin{bmatrix}0&0&0\\0&0&0\\16&0&0\end{bmatrix}$ and $A^3=\begin{bmatrix}0&0&0\\0&0&0\\0&0&0\end{bmatrix}$

$\Rightarrow A^n$ is a null matrix $\forall n\geq 3$

$\therefore \quad P^{50}=(I+A)^{50}=I+50A+\frac{50\times 49}{2}A^2$

$\Rightarrow \quad Q+\mathcal{J}=I+50A+25\times 49A^2$

or $\quad Q=50A+25\times 49A^2$

$$=\begin{bmatrix}0&0&0\\200&0&0\\800&200&0\end{bmatrix}+\begin{bmatrix}0&0&0\\0&0&0\\19600&0&0\end{bmatrix}$$

$\therefore \quad \begin{bmatrix}q_{11}&q_{12}&q_{13}\\q_{21}&q_{22}&q_{23}\\q_{31}&q_{32}&q_{33}\end{bmatrix}=\begin{bmatrix}0&0&0\\200&0&0\\20400&200&0\end{bmatrix}$

On comparing, we get

$q_{21}=q_{32}=200,\ q_{31}=20400$

$\therefore \quad \frac{q_{31}+q_{32}}{q_{21}}=\frac{20400+200}{200}$

$=102+1=103$

138. $\because A^2=\begin{bmatrix}2&-3\\-4&1\end{bmatrix}\begin{bmatrix}2&-3\\-4&1\end{bmatrix}=\begin{bmatrix}16&-9\\-12&13\end{bmatrix}$

$\therefore \quad 3A^2+12A=3\begin{bmatrix}16&-9\\-12&13\end{bmatrix}+12\begin{bmatrix}2&-3\\-4&1\end{bmatrix}$

$=\begin{bmatrix}72&-63\\-84&51\end{bmatrix}$

$\Rightarrow \quad \text{adj}\,(3A^2+12A)=\begin{bmatrix}51&63\\84&72\end{bmatrix}$

Session 1

Some Basic Definitions, Mathematical or Priori or Classical Definition of Probability, Odds in Favour and Odds Against the Event

Some Basic Definitions

1. Random Experiment

An experiment whose outcome cannot be predicted with certainty, is called a random experiment.

Or

If in each trial of an experiment, which when repeated under identical conditions, the outcome is not unique but the outcome in a trial is one of the several possible outcomes, then such an experiment is known as a random experiment.

For example,

(i) "Throwing an unbiased die" is a random experiment because when a die is thrown, we cannot say with certainty which one of the numbers 1, 2, 3, 4, 5 and 6 will come up.

(ii) "Tossing of a fair coin" is a random experiment because when a coin is tossed, we cannot say with certainty whether either a head or a tail will come up.

(iii) "Drawing a card from a well-shuffled pack of cards'' is a random experiment.

Remark

1. A die is a solid cube which has six faces and numbers 1, 2, 3, 4, 5 and 6 marked on the faces, respectively. In throwing or rolling a die, then any one number can be on the uppermost face.
2. (i) A pack of cards consists of 52 cards in 4 suits, i.e (a) Spades (♠) (b) Clubs (♣) (c) Hearts (♥) (d) Diamonds (♦). Each suit consists of 13 cards. Out of these, spades and clubs are black faced cards, while hearts and diamonds are red faced cards. The King, Queen, Jack (or Knave) are called face cards or honour cards.
   (ii) **Game of bridge** It is played by 4 players, each player is given 13 cards.
   (iii) **Game of whist** It is played by two pairs of persons.

2. Sample Space

The set of all possible results of a random experiment is called the sample space of that experiment and it is generally denoted by S.

Each element of a sample space is called a **sample point.**

For example,

(i) If we toss a coin, there are two possible results, namely a head (H) or a tail (T).
So, the sample space in this experiment is given by
$$S = \{H, T\}.$$

(ii) When two coins are tossed, the sample space
$$S = \{HH, HT, TH, TT\}$$o
where, HH denotes the head on the first coin and head on the second coin. Similarly, HT denotes the head on the first coin and tail on the second coin.

(iii) When we throw a die, then any one of the numbers 1, 2, 3, 4, 5 and 6 will come up. So, the sample space
$$S = \{1, 2, 3, 4, 5, 6\}.$$

3. Elementary Event

An event having only a single sample point is called an elementary or simple event.

For example, When two coins are tossed, the sample space, $S = \{HH, HT, TH, TT\}$, then the event, $E_1 = \{HH\}$ of getting both the heads is a simple event.

4. Mixed Event or Compound Event or Composite Event

An event other than elementary or simple event is called mixed event.

For example,

(i) When two coins are tossed, the sample space
$$S = \{HH, HT, TH, TT\}$$
Then, the event $E = \{HH, HT, TH\}$ of getting atleast one head, is a mixed event.

(ii) When a die is thrown, the sample space
$$S = \{1, 2, 3, 4, 5, 6\}$$
Let $A = \{2, 4, 6\}$ = the event of occurrence of an even number
and $B = \{3, 6\}$ = the event of occurrence of a number divisible by 3.
Here, A and B are mixed events.

5. Equally likely Events

The given events are said to be equally likely, if none of them is expected to occur in preference to the other.

For example,

(i) When an unbiased coin is tossed, then occurrence of head or tail are equally likely cases and there is no reason to expect a 'head' or a 'tail' in preference to the other.

(ii) When an unbiased die is thrown, all the six faces 1, 2, 3, 4, 5 and 6 are equally likely to come up. There is no reason to expect 1 or 2 or 3 or 4 or 5 or 6 in preference to the other.

6. Independent Events

Two events are said to be independent, if the occurrence of one does not depend on the occurrence of the other.

For example, When an unbiased die is thrown, then the sample space $S = \{1, 2, 3, 4, 5, 6\}$

Let $E_1 = \{1, 3, 5\}$ = the event of occurrence of an odd number and $E_2 = \{2, 4, 6\}$ = the event of occurrence of an even number. Clearly, the occurrence of odd number does not depend on the occurrence of even number. So, E_1 and E_2 are independent events.

7. Complementary Event

Let E be an event and S be the sample space for a random experiment, then complement of E is denoted by E' or E^c or $\bar{E}$. Clearly, E' means E does not occur.

Thus, E' occurs $\Leftrightarrow$ E does not occur.

For example, When an unbiased die is thrown, then the sample space $S = \{1, 2, 3, 4, 5, 6\}$.

If $E = \{1, 4, 6\}$, then $E' = \{2, 3, 5\}$

8. Mutually Exclusive Events

A set of events is said to be mutually exclusive, if occurrence of one of them precludes the occurrence of any of the remaining events. If a set of events $E_1, E_2, ..., E_n$ for mutually exclusive events.

Then, $E_1 \cap E_2 \cap \ldots \cap E_n = \phi$

For example, If we thrown an unbiased die, then the sample space $S = \{1, 2, 3, 4, 5, 6\}$ in which

$E_1 = \{1, 2, 3\}$ = the event of occurrence of a number less than 4 and $E_2 = \{5, 6\}$ = the event of occurrence of a number greater than 4. Clearly, $E_1 \cap E_2 = \phi$

So, E_1 and E_2 are mutually exclusive.

9. Exhaustive Events

A set of events is said to be exhaustive, if the performance of the experiment results in the occurrence of atleast one of them. If a set of events $E_1, E_2, ..., E_n$ for exhaustive events.

Then, $E_1 \cup E_2 \cup \ldots \cup E_n = S$

For example, If we thrown an unbiased die, then sample space $S = \{1, 2, 3, 4, 5, 6\}$ in which

$E_1 = \{1, 2, 3, 4\}$ = the event of occurrence of a number less than 5 and $E_2 = \{3, 4, 5, 6\}$ = the event of occurrence of a number greater than 2.

Then, $E_1 \cup E_2 = \{1, 2, 3, 4, 5, 6\}$ and $E_1 \cap E_2 = \{3, 4\}$

So, $E_1 \cup E_2 = S$ and $E_1 \cap E_2 \neq \phi$

Hence, E_1 and E_2 are exhaustive events.

10. Mutually Exclusive and Exhaustive Events

A set of events is said to be mutually exclusive and exhaustive, if above two conditions are satisfied. If a set of events $E_1, E_2, \ldots, E_n$ for mutually exclusive and exhaustive events.

Then, $E_1 \cup E_2 \cup \ldots \cup E_n = S$ and $E_1 \cap E_2 \cap \ldots \cap E_n = \phi$

For example, If we thrown an unbiased die, then sample space

$S = \{1, 2, 3, 4, 5, 6\}$ in which

$E_1 = \{1, 3, 5\}$ = the event of occurrence of an odd number and $E_2 = \{2, 4, 6\}$ = the event of occurrence of an even number.

Then, $E_1 \cup E_2 = \{1, 2, 3, 4, 5, 6\}$ and $E_1 \cap E_2 = \phi$

So, $E_1 \cup E_2 = S$ and $E_1 \cap E_2 = \phi$.

Hence, E_1 and E_2 are mutually exclusive and exhaustive events.

Mathematical or Priori
or Classical Definition of Probability

The probability of an event E to occur is the ratio of the number of cases in its favour to the total number of cases (equally likely).

$$\therefore \quad P(E) = \frac{n(E)}{n(S)} = \frac{\text{Number of cases favourable to event E}}{\text{Total number of cases}}$$

Range of Value of $P(E)$

Probability of occurrence of an event is a number lying between 0 and 1.

Proof Let S be the sample space and E be an event. Then,

$$E \subseteq S \qquad \ldots(i)$$

Also, $$\phi \subseteq S \qquad \ldots(ii)$$

where ϕ is a null set. From Eqs. (i) and (ii), we get

$$\phi \subseteq S \supseteq E \Rightarrow \; n(\phi) \leq n(E) \leq n(S)$$

$$\Rightarrow \qquad 0 \leq \frac{n(E)}{n(S)} \leq 1 \qquad [\because \; n(\phi) = 0]$$

$$\Rightarrow \qquad 0 \leq P(E) \leq 1$$

Remark

1. For impossible event ϕ; $P(\phi) = 0$
2. For sure event S, $P(S) = 1$

Relationship between $P(E)$ and $P(E')$

If E is any event and E' be the complement of event E, then

$$P(E) + P(E') = 1$$

Proof Let S be the sample space, then

$$E' = S - E$$

$$\Rightarrow \quad n(E') = n(S) - n(E)$$

$$\Rightarrow \quad \frac{n(E')}{n(S)} = 1 - \frac{n(E)}{n(S)}$$

$$\Rightarrow \quad P(E') = 1 - P(E)$$

$$\text{i.e.} \quad P(E) + P(E') = 1$$

Odds in Favour and Odds Against the Event

Let S be the sample space. If a is the number of cases favourable to the event E, b is the number of cases favourable to the event E', the **odds in favour** of E are defined by $a : b$ and **odds against** of E are $b : a$.

i.e. odds in favour of event E is

$$\frac{a}{b} = \frac{n(E)}{n(E')} = \frac{\frac{n(E)}{n(S)}}{\frac{n(E')}{n(S)}} = \frac{P(E)}{P(E')} \Rightarrow \frac{P(E')}{P(E)} = \frac{b}{a}$$

$$\Rightarrow \quad \frac{P(E') + P(E)}{P(E)} = \frac{b + a}{a}$$

$$\Rightarrow \quad \frac{1}{P(E)} = \frac{b + a}{a}$$

$$\Rightarrow \quad P(E) = \frac{a}{a + b} \text{ and } P(E') = \frac{b}{a + b}$$

Remark

We use the sign '+' for the operation 'or' and '×' for the operation 'and' in order to solve the problems on definition of probability.

Example 1. If three coins are tossed, represent the sample space and the event of getting atleast two heads, then find the number of elements in them.

Sol. Let S be the sample space and E be the event of occurrence of atleast two heads and let H denote the occurrence of head and T denote the occurrence of tail, when one coin is tossed.

Then, $S = \{H, T\} \times \{H, T\} \times \{H, T\}$

$$S = \{(H, H, H), (H, H, T), (H, T, H), (T, H, H), (T, T, H), (T, H, T), (H, T, T), (T, T, T)\}$$

and $E = \{(H, H, H), (H, H, T), (H, T, H), (T, H, H)\}$

Also, $n(S) = 8$ and $n(E) = 4$

Example 2. One ticket is drawn at random from a bag containing 24 tickets numbered 1 to 24. Represent the sample space and the event of drawing a ticket containing number which is a prime. Also, find the number of elements in them.

Sol. Let S be the sample space and E be the event of occurrence a prime number.

Then, $S = \{1, 2, 3, 4, 5, ..., 24\}$

and $E = \{2, 3, 5, 7, 11, 13, 17, 19, 23\}$

Also, $n(S) = 24$ and $n(E) = 9$

Example 3. Two dice are thrown simultaneously. What is the probability obtaining a total score less than 11?

Sol. Let S be the sample space and E be the event of obtaining a total less than 11.

Then, $S = \{1, 2, 3, 4, 5, 6\} \times \{1, 2, 3, 4, 5, 6\} \Rightarrow n(S) = 6 \times 6 = 36$

Let E' be the event of obtaining a total score greater than or equal to 11.

Also, $E' = \{(5, 6), (6, 5), (6, 6)\}$; $\therefore\ n(E') = 3$

Then, probability of obtaining a total score greater than or equal to 11,

$$P(E') = \frac{n(E')}{n(S)} = \frac{3}{36} = \frac{1}{12}$$

$$\therefore \quad P(E) = 1 - P(E') = 1 - \frac{1}{12} = \frac{11}{12}$$

Hence, required probability is $\frac{11}{12}$.

Example 4. ***If a leap-leap year is selected at random, then what is the chance it will contain 53 Sunday?***

Sol. A leap-leap year has 367 days i.e., 52 complete week and three days more. These three days will be three consecutive days of a week. A leap-leap year will have 53 Sundays, if out of the three consecutive days of a week selected at random one is a Sunday.

Let be the sample space and E be the event that out of the three consecutive days of a week one is Sunday, then

S = {(Sunday, Monday, Tuesday), (Monday, Tuesday, Wednesday), (Tuesday, Wednesday, Thursday), (Wednesday, Thursday, Friday), (Thursday, Friday, Saturday), (Friday, Saturday, Sunday), (Saturday, Sunday, Monday)}; $n(S) = 7$

and E = {(Sunday, Monday, Tuesday), (Friday, Saturday, Sunday), (Saturday, Sunday, Monday)}

$$\therefore \quad n(E) = 3$$

Now, required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{3}{7}$

Example 5. ***From a pack of 52 playing cards, three cards are drawn at random. Find the probability of drawing a King, a Queen and a Knave.***

Sol. Let S be the sample space and E be the event that out of the three cards drawn one is a King, one is a Queen and one is a Knave.

$\therefore$ $n(S)$ = Total number of selecting 3 cards out of 52 cards
$= {}^{52}C_3$

and $n(E)$ = Number of selecting 3 cards out of one is King, one is Queen and one is Knave $= {}^4C_1 \cdot {}^4C_1 \cdot {}^4C_1 = 64$

$\therefore$ Required probability, $P(E) = \dfrac{n(E)}{n(S)} = \dfrac{64}{{}^{52}C_3} = \dfrac{64}{\dfrac{52 \cdot 51 \cdot 50}{1 \cdot 2 \cdot 3}} = \dfrac{16}{5525}$

Example 6. ***A bag contains 8 red and 5 white balls. Three balls are drawn at random. Find the probability that***

(i) all the three balls are white.
(ii) all the three balls are red.
(iii) one ball is red and two balls are white.

Sol. Let S be the sample space, E_1 be the event of getting 3 white balls, E_2 be the event of getting 3 red balls and E_3 be the event of getting one red ball and two white balls.

$\therefore$ $n(S)$ = Number of ways of selecting 3 balls out of $13(8+5) = {}^{13}C_3 = \dfrac{13 \cdot 12 \cdot 11}{1 \cdot 2 \cdot 3} = 286$

(i) $n(E_1)$ = Number of ways of selecting 3 white balls out of 5
$= {}^5C_3 = {}^5C_2 = \dfrac{5 \cdot 4}{1 \cdot 2} = 10$

$\therefore$ P (getting 3 white balls) $= \dfrac{n(E_1)}{n(S)} = \dfrac{10}{286} = \dfrac{5}{143}$

(ii) $n(E_2)$ = Number of ways of selecting 3 red balls out of 8
$= {}^8C_3 = \dfrac{8 \cdot 7 \cdot 6}{1 \cdot 2 \cdot 3} = 56$

$\therefore$ P (getting 3 red balls) $= \dfrac{n(E_2)}{n(S)}$
$= \dfrac{56}{286} = \dfrac{28}{143}$

(iii) $n(E_3)$ = Number of ways of selecting 1 red ball out of 8 and 2 black balls out of 5 $= {}^8C_1 \cdot {}^5C_2 = 8 \cdot 10 = 80$

$\therefore$ P (getting 1 red and 2 black balls)
$= \dfrac{n(E_3)}{n(S)} = \dfrac{80}{286} = \dfrac{40}{143}$

Exercise for Session 1

1. A problem in mathematics is given to three students and their respective probabilities of solving the problem are $\frac{1}{2}$, $\frac{1}{3}$ and $\frac{1}{4}$. The probability that the problem is solved, is

(a) $\frac{3}{4}$ (b) $\frac{1}{2}$ (c) $\frac{2}{3}$ (d) $\frac{1}{3}$

2. A dice is thrown 3 times and the sum of the 3 numbers thrown is 15. The probability that the first throw was a four, is

(a) $\frac{1}{5}$ (b) $\frac{1}{4}$ (c) $\frac{1}{6}$ (d) $\frac{2}{5}$

3. Three faces of a fair dice are yellow, two faces red and one blue. The dice is tossed three times. The probability that the colours yellow, red and blue appear in the first, second and third toss respectively, is

(a) $\frac{1}{6}$ (b) $\frac{1}{12}$ (c) $\frac{1}{24}$ (d) $\frac{1}{36}$

4. *A* speaks truth in 75% of cases and *B* in 80% of cases. The percentage of cases they are likely to contradict each other in stating the same fact, is

(a) 30% (b) 35% (c) 45% (d) 25%

5. An unbiased dice with faces marked 1, 2, 3, 4, 5, 6 is rolled four times. Out of four face values obtained the probability that the minimum face value is not less than 2 and the maximum face value is not greater than 5, is

(a) $\frac{16}{81}$ (b) $\frac{1}{81}$ (c) $\frac{80}{81}$ (d) $\frac{65}{81}$

6. Three numbers are chosen at random without replacement from {1, 2, 3, ..., 10}. The probability that the minimum of the chosen number is 3 or their maximum is 7, is

(a) $\frac{11}{20}$ (b) $\frac{7}{20}$ (c) $\frac{11}{40}$ (d) $\frac{7}{40}$

7. Seven white balls and three black balls are randomly placed in a row. The probability that no two black balls are placed adjacently, is

(a) $\frac{1}{2}$ (b) $\frac{7}{15}$ (c) $\frac{2}{15}$ (d) $\frac{1}{3}$

8. Two numbers are selected randomly from the set $S = \{1, 2, 3, 4, 5, 6\}$ without replacement. The probability that minimum of the two numbers is less than 4, is

(a) $\frac{1}{15}$ (b) $\frac{14}{15}$ (c) $\frac{1}{5}$ (d) $\frac{4}{5}$

9. If $\frac{1+3p}{3}, \frac{1-p}{4}$ and $\frac{1-2p}{2}$ are the probabilities of the three mutually exclusive events, then $p \in$

(a) $[0, 1]$ (b) $\left[0, \frac{1}{2}\right]$ (c) $\left[\frac{1}{3}, 1\right]$ (d) $\left[\frac{1}{3}, \frac{1}{2}\right]$

10. Three identical dice are rolled once. The probability that the same number will appear on each of them, is

(a) $\frac{1}{6}$ (b) $\frac{1}{36}$ (c) $\frac{1}{18}$ (d) $\frac{3}{28}$

11. If the letters of the word ASSASSIN are written down in a row, the probability that no two S's occur together, is

(a) $\frac{1}{35}$ (b) $\frac{1}{21}$ (c) $\frac{1}{14}$ (d) $\frac{1}{28}$

12. A box contains 2 black, 4 white and 3 red balls. One ball is drawn at random from the box and kept aside. From the remaining balls in the box another ball is drawn and kept beside the first. This process is repeated till all the balls are drawn from the box. The probability that the balls drawn from the box are in the sequence 2 black, 4 white and 3 red, is

(a) $\frac{1}{126}$ (b) $\frac{1}{630}$ (c) $\frac{1}{1260}$ (d) $\frac{1}{2520}$

13. If three distinct numbers are chosen randomly from the first 100 natural numbers, then the probability that all three of them are divisible by both 2 and 3, is

(a) $\frac{4}{55}$ (b) $\frac{4}{35}$ (c) $\frac{4}{33}$ (d) $\frac{4}{1155}$

14. There are 2 vans each having numbered seats, 3 in the front and 4 at the back. There are 3 girls and 9 boys to be seated in the vans. The probability of 3 girls sitting together in a back row on adjacent seats, is

(a) $\frac{1}{13}$ (b) $\frac{1}{39}$ (c) $\frac{1}{65}$ (d) $\frac{1}{91}$

15. *A* and *B* stand in a ring along with 10 other persons. If the arrangement is at random, then the probability that there are exactly 3 persons between *A* and *B*, is

(a) $\frac{1}{11}$ (b) $\frac{2}{11}$ (c) $\frac{3}{11}$ (d) $\frac{4}{11}$

16. The first 12 letters of English alphabet are written down at random in a row. The probability that there are exactly 4 letters between *A* and *B*, is

(a) $\frac{7}{33}$ (b) $\frac{7}{66}$ (c) $\frac{7}{99}$ (d) $\frac{5}{33}$

17. Six boys and six girls sit in a row randomly. The probability that the six girls sit together or the boys and girls sit alternately, is

(a) $\frac{3}{308}$ (b) $\frac{1}{100}$ (c) $\frac{2}{205}$ (d) $\frac{4}{407}$

18. If from each of three boxes containing 3 white and 1 black, 2 white and 2 black, 1 white and 3 black balls, one ball is drawn, the probability of drawing 2 white and 1 black ball, is

(a) $\frac{13}{32}$ (b) $\frac{1}{4}$ (c) $\frac{1}{32}$ (d) $\frac{3}{16}$

19. The probability that a year chosen at random has 53 Sundays, is

(a) $\frac{5}{7}$ (b) $\frac{3}{7}$ (c) $\frac{5}{28}$ (d) $\frac{3}{28}$

20. If the letters of the word MATHEMATICS are arranged arbitrarily, the probability that C comes before E, E before H, H before I and I before S, is

(a) $\frac{3}{10}$ (b) $\frac{1}{20}$ (c) $\frac{1}{120}$ (d) $\frac{1}{720}$

Session 2

Some Important Symbols, Conditional Probability

Some Important Symbols

If A, B and C are any three events, then

(i) $A \cap B$ or AB denotes the event of simultaneous occurrence of both the events A and B.

(ii) $A \cup B$ or $A + B$ denotes the event of occurrence of atleast one of the events A or B.

(iii) $A - B$ denotes the occurrence of event A but not B.

(iv) $\overline{A}$ denotes the not occurrence of event A.

(v) $A \cap \overline{B}$ denotes the occurrence of event A but not B.

(vi) $\overline{A} \cap \overline{B} = (\overline{A \cup B})$ denotes the occurrence of neither A nor B.

(vii) $A \cup B \cup C$ denotes the occurrence of atleast one event A, B or C.

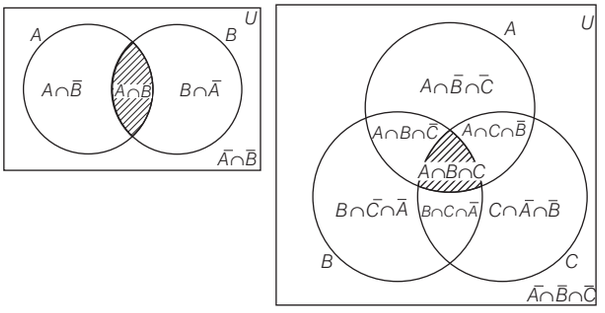
(viii) $(A \cap \overline{B}) \cup (\overline{A} \cap B)$ denotes the occurrence of exactly one of A and B.

(ix) $A \cap B \cap C$ denotes the occurrence of all three A, B and C.

(x) $(A \cap B \cap \overline{C}) \cup (A \cap \overline{B} \cap C) \cup (\overline{A} \cap B \cap C)$ denotes the occurrence of exactly two of A, B and C.

Remark

Remember with the help of figures



Important Results

1. If A and B are arbitrary events, then

(a) $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

Proof Let S be the sample space. Since, we know that

$$n(A \cup B) = n(A) + n(B) - n(A \cap B)$$

$$\Rightarrow \quad \frac{n(A \cup B)}{n(S)} = \frac{n(A)}{n(S)} + \frac{n(B)}{n(S)} - \frac{n(A \cap B)}{n(S)}$$

$$\Rightarrow \quad P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

Remark

If A and B are mutually exclusive events, then $A \cap B = \phi$.
Hence, $P(A \cap B) = 0$.
$\therefore P(A \cup B) = P(A) + P(B)$

(b) P (exactly one of A, B occurs)

$$= P(A \cap \overline{B}) + P(\overline{A} \cap B)$$
$$= P(A) - P(A \cap B) + P(B) - P(A \cap B)$$
$$= P(A) + P(B) - 2P(A \cap B)$$
$$= P(A \cup B) - P(A \cap B)$$

(c) P (neither A nor B)

$$= P(\overline{A} \cap \overline{B}) = P(\overline{A \cup B}) = 1 - P(A \cup B)$$

Remark

$P(\overline{A} \cup \overline{B}) = 1 - P(A \cap B)$

2. If A, B and C are three events, then

(a) $P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(A \cap B)$
$- P(B \cap C) - P(C \cap A) + P(A \cap B \cap C)$

Remark

If A, B and C are mutually exclusive events, then

$$A \cap B = \phi,\ B \cap C = \phi,\ C \cap A = \phi,\ A \cap B \cap C = \phi$$
$$\Rightarrow P(A \cap B) = 0, P(B \cap C) = 0, P(C \cap A) = 0, P(A \cap B \cap C) = 0$$
$$\therefore \quad P(A \cup B \cup C) = P(A) + P(B) + P(C)$$

General form of Addition Theorem of Probability

$$P(A_1 \cup A_2 \cup \ldots \cup A_n) = \sum_{i=1}^{n} P(A_i) - \sum_{i<j} P(A_i \cap A_j) + \sum_{i<j<k} P(A_i \cap A_j \cap A_k) - \ldots + (-1)^{n-1} P(A_1 \cap A_2 \cap \ldots \cap A_n)$$

Remark

If $A_1, A_2, \ldots, A_n$ are mutually exclusive events, then

$$\sum_{i<j} P(A_i \cap A_j) = 0, \quad \sum_{i<j<k} P(A_i \cap A_j \cap A_k) = 0$$

and $\quad P(A_1 \cap A_2 \cap \ldots \cap A_n) = 0$

$$\therefore \quad P(A_1 \cup A_2 \cup \ldots \cup A_n) = \sum_{i=1}^{n} P(A_i)$$

(b) P (atleast two of A, B, C occur)
$= P(A \cap B) + P(B \cap C) + P(C \cap A) - 2P(A \cap B \cap C)$

(c) P (exactly two of A, B, C occur)
$= P(A \cap B) + P(B \cap C) + P(C \cap A) - 3P(A \cap B \cap C)$

(d) P (exactly one of A, B, C occur)
$= P(A) + P(B) + P(C) - 2P(A \cap B) - 2P(B \cap C) - 2P(C \cap A) + 3P(A \cap B \cap C)$

3. (a) If $A_1, A_2, ..., A_n$ are independent events, then
$P(A_1 \cap A_2 \cap ... \cap A_n) = P(A_1)\, P(A_2) ... P(A_n)$

(b) If $A_1, A_2, ..., A_n$ are mutually exclusive events, then
$P(A_1 \cup A_2 \cup ... \cup A_n) = P(A_1) + P(A_2) + ... + P(A_n)$

(c) If $A_1, A_2, ..., A_n$ are exhaustive events, then
$P(A_1 \cup A_2 \cup ... \cup A_n) = 1$

(d) If $A_1, A_2, ..., A_n$ are mutually exclusive and exhaustive events, then
$P(A_1 \cup A_2 \cap ... \cap A_n) = P(A_1) + P(A_2) + ... + P(A_n) = 1$

4. If $A_1, A_2, ..., A_n$ are n events, then

(a) $P(A_1 \cup A_2 \cup ... \cup A_n) \le P(A_1) + P(A_2) + ... + P(A_n)$

(b) $P(A_1 \cap A_2 \cap ... \cap A_n) \ge 1 - P(\overline{A}_1) - P(\overline{A}_2) - ... - P(\overline{A}_n)$

Important Result

If E_1 and E_2 are independent events, then

(a) E_1 and $\overline{E}_2$ are independent events.

(b) $\overline{E}_1$ and E_2 are independent events.

(c) $\overline{E}_1$ and $\overline{E}_2$ are independent events.

Proof Given, E_1 and E_2 are independent events, then
$P(E_1 \cap E_2) = P(E_1) \cdot P(E_2)$

(a) $P(E_1 \cap \overline{E}_2) = P(E_1) - P(E_1 \cap E_2)$
$= P(E_1) - P(E_1) \cdot P(E_2)$
$= P(E_1)[1 - P(E_2)] = P(E_1) \cdot P(\overline{E}_2)$

So, E_1 and $\overline{E}_2$ are independent events.

(b) Same as in part (i).

(c) $P(\overline{E}_1 \cap \overline{E}_2) = P(\overline{E_1 \cup E_2})$
$= 1 - P(E_1 \cup E_2) = 1 - [P(E_1) + P(E_2) - P(E_1 \cap E_2)]$
$= 1 - P(E_1) - P(E_2) + P(E_1) \cdot P(E_2)$
$= P(\overline{E}_1) - P(E_2)[1 - P(E_1)]$
$= P(\overline{E}_1) - P(E_2) \cdot P(\overline{E}_1) = P(\overline{E}_1)[1 - P(E_2)]$
$= P(\overline{E}_1)\, P(\overline{E}_2)$

Remark

If $E_1, E_2, ..., E_n$ are independent events,
then $P(E_1 \cup E_2 \cup ... \cup E_n)$
$= 1 - P(E_1 \cup E_2 \cup ... \cup E_n)' = 1 - P(E_1' \cap E_2' \cap ... \cap E_n')$
$= 1 - P(E_1') \cdot P(E_2') ... P(E_n')$

Example 7. For a post, three persons A, B and C appear in the interiew. The probability of A being selected is twice that of B and the probability of B being selected is thrice that of C. What are the individual probabilities of A, B and C being selected?

Sol. Let E_1, E_2 and E_3 be the events of selection of A, B and C respectively.

Let $P(E_3) = x$.

Then, $P(E_2) = 3P(E_3) = 3x$ and $P(E_1) = 2P(E_2) = 6x$

Since, E_1, E_2 and E_3 are mutually exclusive and exhaustive events.

$\therefore \quad P(E_1 \cup E_2 \cup E_3) = P(E_1) + P(E_2) + P(E_3) = 1$

$\therefore \quad P(E_1) + P(E_2) + P(E_3) = 1$

$\Rightarrow \quad 6x + 3x + x = 1$

$\therefore \quad x = \frac{1}{10}$

Hence, $P(E_1) = 6x = \frac{6}{10} = \frac{3}{5}$

$P(E_2) = 3x = \frac{3}{10}$ and $P(E_3) = x = \frac{1}{10}$

Example 8. If A and B are independent events, the probability that both A and B occur is $\frac{1}{8}$ and the probability that none of them occurs is $\frac{3}{8}$. Find the probability of the occurrence of A.

Sol. We have,

$$P(A \cap B) = \frac{1}{8} \Rightarrow P(A)\, P(B) = \frac{1}{8} \quad ...(i)$$

[$\because A$ and B are independent]

and $P(\overline{A} \cap \overline{B}) = \frac{3}{8} \Rightarrow P(\overline{A})\, P(\overline{B}) = \frac{3}{8}$

$\Rightarrow \quad (1 - P(A))(1 - P(B)) = \frac{3}{8}$

$\Rightarrow \quad 1 - P(A) - P(B) + \frac{1}{8} = \frac{3}{8}$ [from Eq. (i)]

$\Rightarrow \quad P(A) + P(B) = \frac{3}{4} \quad ...(ii)$

The quadratic equation whose roots are $P(A)$ and $P(B)$ is
$x^2 - [P(A) + P(B)]x + P(A) \cdot P(B) = 0$

$\Rightarrow \quad x^2 - \frac{3}{4}x + \frac{1}{8} = 0$ [from Eqs. (i) and (ii)]

or $8x^2 - 6x + 1 = 0$ or $x = \frac{1}{2}, \frac{1}{4}$

Hence, $P(A) = \frac{1}{2}$ or $\frac{1}{4}$

Example 9. A and B are two candidates seeking admission in IIT. The probability that A is selected is 0.5 and the probability that both A and B are selected is atmost 0.3. Is it possible that the probability of B getting selected is 0.9?

Sol. Let E_1 and E_2 are the events of A and B selected, respectively.

Given, $P(E_1 \cap E_2) \le 0.3$ and $P(E_1) = 0.5$

Since, $P(E_1 \cup E_2) = P(E_1) + P(E_2) - P(E_1 \cap E_2)$

$\because \quad P(E_1 \cup E_2) \le 1$

$\therefore \quad P(E_1) + P(E_2) - P(E_1 \cap E_2) \le 1$

$\Rightarrow \quad P(E_1) + P(E_2) \le 1 + P(E_1 \cap E_2)$

$\Rightarrow \quad 0.5 + P(E_2) \le 1 + 0.3 \Rightarrow P(E_2) \le 0.8$

Hence, $P(E_2) \ne 0.9$

Example 10. Let A, B and C be three events. If the probability of occurring exactly one event out of A and B is $1 - a$, out of B and C is $1 - 2a$, out of C and A is $1 - a$ and that of occurring three events simultaneously is a^2, then prove that the probability that atleast one out of A, B and C will occur is greater than $\frac{1}{2}$.

Sol. Given,

$$P(A) + P(B) - 2P(A \cap B) = 1 - a \quad \text{...(i)}$$

$$P(B) + P(C) - 2P(B \cap C) = 1 - 2a \quad \text{...(ii)}$$

and $P(C) + P(A) - 2P(C \cap A) = 1 - a$ ...(iii)

$\therefore \quad P(A \cap B \cap C) = a^2$ ...(iv)

$$\therefore P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(C \cap A) + P(A \cap B \cap C)$$

$$= \frac{1}{2}\{P(A) + P(B) - 2P(A \cap B) + P(B) + P(C) - 2P(B \cap C) + P(C) + P(A) - 2P(C \cap A)\} + P(A \cap B \cap C)$$

$$= \frac{1}{2}\{1 - a + 1 - 2a + 1 - a\} + a^2 \text{ [from Eqs. (i), (ii), (iii) and (iv)]}$$

$$= \frac{3}{2} - 2a + a^2 = (a-1)^2 + \frac{1}{2} > \frac{1}{2} \quad [\because a \ne 1]$$

Example 11. If A, B and C are three events, such that $P(A) = 0.3$, $P(B) = 0.4$, $P(C) = 0.8$, $P(AB) = 0.08$, $P(AC) = 0.28$, $P(ABC) = 0.09$. If $P(A \cup B \cup C) \ge 0.75$, then show that $P(BC)$ lies in the interval $0.23 \le x \le 0.48$.

Sol. Let $P(BC) = x$

Since, $P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(AB) - P(BC) - P(CA) + P(ABC)$

$\therefore \quad = 0.3 + 0.4 + 0.8 - 0.08 - x - 0.28 + 0.09 = 1.23 - x$

But given that, $P(A \cup B \cup C) \ge 0.75$ and $P(A \cup B \cup C) \le 1$

$\therefore \quad 0.75 \le 1.23 - x \le 1 \Rightarrow -0.75 \ge -1.23 + x \ge -1$

or $1.23 - 0.75 \ge x \ge 1.23 - 1$ or $0.23 \le x \le 0.48$

Conditional Probability

The probability of occurrence of an event E_1, given that E_2 has already occurred is called the conditional probability of occurrence of E_1 on the condition that E_2 has already occurred, it is denoted by $P\left(\frac{E_1}{E_2}\right)$.

Thus, $P\left(\frac{E_1}{E_2}\right) = \frac{P(E_1 \cap E_2)}{P(E_2)}, E_2 \ne \phi = \frac{\frac{n(E_1 \cap E_2)}{n(S)}}{\frac{n(E_2)}{n(S)}}$

$\Rightarrow \quad = \frac{n(E_1 \cap E_2)}{n(E_2)}$

Remark

1. If E_1 and E_2 are independent events, then $P\left(\frac{E_2}{E_1}\right) = P(E_2)$
2. If E_1 and E_2 are two events such that $E_2 \ne \phi$, then $P\left(\frac{E_1}{E_2}\right) + P\left(\frac{\bar{E}_1}{E_2}\right) = 1$
3. If $E_1, E_2, E_3, \ldots, E_4$ are independent events, then $P(E_1 \cup E_2 \cup E_3 \cup \ldots \cup E_n) = 1 - P(\bar{E}_1) \cdot P(\bar{E}_2) \cdot P(\bar{E}_3) \ldots P(\bar{E}_n)$
4. If E_1, E_2 and E_3 are three events such that $E_1 \ne \phi$, $E_1E_2 \ne \phi$, then $P(E_1 \cap E_2 \cap E_3) = P(E_1) \cdot P\left(\frac{E_2}{E_1}\right) \cdot P\left(\frac{E_3}{E_1E_2}\right)$

Generalised form

If $E_1, E_2, E_3, \ldots, E_n$ are n events such that $E_1 \ne \phi$, $E_1E_2 \ne \phi$, $E_1E_2E_3 \ne \phi$, ..., $E_1E_2E_3 \ldots E_{n-1} \ne \phi$, then $P(E_1 \cap E_2 \cap E_3 \cap \ldots \cap E_n)$

$$= P(E_1) \cdot P\left(\frac{E_2}{E_1}\right) \cdot P\left(\frac{E_3}{E_1E_2}\right) \cdot P\left(\frac{E_4}{E_1E_2E_3}\right) \ldots P\left(\frac{E_n}{E_1E_2E_3 \ldots E_{n-1}}\right)$$

Example 12. Two dice are thrown. Find the probability that the sum of the numbers coming up on them is 9, if it is known that the number 5 always occurs on the first dice.

Sol. Let S be the sample space

$\therefore \quad S = \{1, 2, 3, 4, 5, 6\} \times \{1, 2, 3, 4, 5, 6\}$

$\therefore \quad n(S) = 36$

and let $E_1 \equiv$ The event that the sum of the numbers coming up is 9.

and $E_2 \equiv$ The event of occurrence of 5 on the first dice.

$\therefore \quad E_1 \equiv \{(3, 6), (6, 3), (4, 5), (5, 4)\}$

$\therefore \quad n(E_1) = 4$

and $E_2 = \{(5,1),(5,2),(5,3),(5,4),(5,5),(5,6)\}$

$\therefore \quad n(E_2) = 6$

$E_1 \cap E_2 = \{(5,4)\}$

$\therefore \quad n(E_1 \cap E_2) = 1$

Now, $P(E_1 \cap E_2) = \dfrac{n(E_1 \cap E_2)}{n(S)} = \dfrac{1}{36}$

and $P(E_2) = \dfrac{n(E_2)}{n(S)} = \dfrac{6}{36} = \dfrac{1}{6}$

$\therefore$ Required probability,

$$P\left(\frac{E_1}{E_2}\right) = \frac{P(E_1 \cap E_2)}{P(E_2)} = \frac{\frac{1}{36}}{\frac{1}{6}} = \frac{1}{6}$$

Aliter $P\left(\dfrac{E_1}{E_2}\right) = \dfrac{n(E_1 \cap E_2)}{n(E_2)} = \dfrac{1}{6}$

Example 13. In a class, 30% students fail in English; 20% students fail in Hindi and 10% students fail in English and Hindi both. A student is chosen at random, then what is the probability that he will fail in English, if he has failed in Hindi?

Sol. Let S be the sample space.

If $n(S) = 100$, then

$E_1 \equiv$ The event that the student chosen fail in English

$\therefore n(E_1) = 30$

and $E_2 \equiv$ The event that the student chosen fail in Hindi

$\therefore \quad n(E_2) = 20$ and $n(E_1 \cap E_2) = 10$

$\therefore \quad P(E_2) = \dfrac{n(E_2)}{n(S)}$

$= \dfrac{20}{100} = \dfrac{1}{5}$

and $P(E_1 \cap E_2) = \dfrac{n(E_1 \cap E_2)}{n(S)} = \dfrac{10}{100} = \dfrac{1}{10}$

$\therefore$ Required probability, $P\left(\dfrac{E_1}{E_2}\right) = \dfrac{P(E_1 \cap E_2)}{P(E_2)} = \dfrac{\frac{1}{10}}{\frac{1}{5}} = \dfrac{1}{2}$

Aliter $P\left(\dfrac{E_1}{E_2}\right) = \dfrac{n(E_1 \cap E_2)}{n(E_2)}$

$= \dfrac{10}{20} = \dfrac{1}{2}$

Exercise for Session 2

1 If $P(A) = 0{\cdot}8$, $P(B) = 0{\cdot}5$, then $P(A \cap B)$ lies in the interval

(a) $[0{\cdot}2, 0{\cdot}5]$ (b) $[0{\cdot}2, 0{\cdot}3]$ (c) $[0{\cdot}3, 0{\cdot}5]$ (d) $[0{\cdot}1, 0{\cdot}5]$

2 If $P(A) = \dfrac{1}{4}$, $P(B) = \dfrac{1}{13}$ and $P(A \cap B) = \dfrac{1}{52}$, then the value of $P(\bar{A} \cap \bar{B})$, is

(a) $\dfrac{3}{13}$ (b) $\dfrac{5}{13}$ (c) $\dfrac{7}{13}$ (d) $\dfrac{9}{13}$

3 If A and B are independent events such that $P(\bar{A} \cap B) = \dfrac{2}{15}$ and $P(A \cap \bar{B}) = \dfrac{1}{6}$, then $P(B)$ is

(a) $\dfrac{1}{5}$ (b) $\dfrac{1}{6}$ (c) $\dfrac{4}{5}$ (d) $\dfrac{5}{6}$

4 If A and B are two events such that $P(A \cup B) = \dfrac{5}{6}$, $P(A) = \dfrac{1}{3}$, $P(B) = \dfrac{3}{4}$, then A and B are

(a) mutually exclusive (b) dependent (c) independent (d) None of these

5 If A, B and C are mutually exclusive and exhaustive events associated with a random experiment. If $P(B) = \dfrac{3}{2}P(A)$ and $P(C) = \dfrac{1}{2}P(B)$, then $P(A)$ is equal to

(a) $\dfrac{2}{13}$ (b) $\dfrac{4}{13}$ (c) $\dfrac{6}{13}$ (d) $\dfrac{8}{13}$

6 If A and B are two events, then $P(A) + P(B) = 2P(A \cap B)$ if and only if

(a) $P(A) + P(B) = 1$ (b) $P(A) = P(B)$ (c) $P(A) + P(B) > 1$ (d) None of these

7 If A and B are two events such that $P(A \cap B) = \dfrac{1}{4}$, $P(\bar{A} \cap \bar{B}) = \dfrac{1}{5}$ and $P(A) = P(B) = p$, then p is equal to

(a) $\dfrac{17}{40}$ (b) $\dfrac{19}{40}$ (c) $\dfrac{21}{40}$ (d) $\dfrac{23}{40}$

8 If A and B are two events such that $P(A \cup B) = \frac{3}{4}$, $P(A \cap B) = \frac{1}{4}$, $P(\bar{A}) = \frac{2}{3}$. Then $(\bar{A} \cap B)$ is equal to

(a) $\frac{5}{12}$ (b) $\frac{3}{8}$ (c) $\frac{5}{8}$ (d) $\frac{1}{4}$

9 If $P(B) = \frac{3}{4}$, $P(A \cap B \cap \bar{C}) = \frac{1}{3}$ and $P(\bar{A} \cap B \cap \bar{C}) = \frac{1}{3}$, then $P(B \cap C)$ is equal to

(a) $\frac{1}{12}$ (b) $\frac{1}{6}$ (c) $\frac{1}{15}$ (d) $\frac{1}{9}$

10 If A and B are two events such that $P(A) > 0$ and $P(B) \neq 1$, then $P\left(\frac{\bar{A}}{\bar{B}}\right)$ is equal to

(a) $1 - P\left(\frac{A}{B}\right)$ (b) $1 - P\left(\frac{A}{\bar{B}}\right)$ (c) $\frac{1 - P(A \cup B)}{P(B)}$ (d) $\frac{P(\bar{A})}{P(B)}$

11 If $P(A) = \frac{3}{8}$, $P(B) = \frac{5}{8}$ and $P(A \cup B) = \frac{3}{4}$, then $P\left(\frac{\bar{A}}{\bar{B}}\right)$ is equal to

(a) $\frac{1}{4}$ (b) $\frac{1}{3}$ (c) $\frac{2}{3}$ (d) $\frac{3}{4}$

12 If two events A and B are such that $P(\bar{A}) = 0 \cdot 3$, $P(B) = 0 \cdot 4$ and $P(A \cap \bar{B}) = 0 \cdot 5$, then $P\left(\frac{B}{A \cup \bar{B}}\right)$ is equal to

(a) $\frac{1}{4}$ (b) $\frac{1}{5}$ (c) $\frac{2}{5}$ (d) $\frac{3}{5}$

13 Two dice are thrown. The probability that the number appeared have a sum of 8. If it is known that the second die always exhibits 4, is

(a) $\frac{5}{6}$ (b) $\frac{1}{6}$ (c) $\frac{2}{3}$ (d) $\frac{1}{3}$

14 A is targetting to B, B and C are targetting to A. The probability of hitting the target by A, B and C are $\frac{2}{3}, \frac{1}{2}, \frac{1}{3}$ respectively. If A is hit, the probability that B hits the target and C does not, is

(a) $\frac{1}{3}$ (b) $\frac{1}{2}$ (c) $\frac{2}{3}$ (d) $\frac{3}{4}$

15 If A and B are two events such that $A \cap B \neq \phi$, $P\left(\frac{A}{B}\right) = P\left(\frac{B}{A}\right)$. Then,

(a) $A = B$ (b) $P(A) = P(B)$
(c) A and B are independent (d) All of these

Session 3

Total Probability Theorem, Baye's Theorem or Inverse Probability

Total Probability Theorem

Let $E_1, E_2, \ldots, E_n$ be n mutually exclusive and exhaustive events i.e., $E_i \cap E_j = \phi$ for $i \neq j$ and $\bigcup_{i=1}^{n} E_i = S$.

Suppose that, $P(E_i) > 0, \forall\ 1 \le i \le n$

Then for any event E

$$P(E) = \sum_{i=1}^{n} P(E_i) \cdot P\left(\frac{E}{E_i}\right)$$

Proof Since, $E_1, E_2, \ldots, E_n$ are disjoint

$\therefore E \cap E_1, E \cap E_2, \ldots, E \cap E_n$ are also disjoint.

Now, $$E = E \cap S = E \cap \left(\bigcup_{i=1}^{n} E_i\right) = \bigcup_{i=1}^{n} (E \cap E_i)$$

$\therefore$ $$P(E) = \sum_{i=1}^{n} P(E \cap E_i) = \sum_{i=1}^{n} P(E_i) \cdot P\left(\frac{E}{E_i}\right)$$

Example 14. The probability that certain electronic component fails, when first used is 0.10. If it does not fail immediately, then the probability that it lasts for one year is 0.99. What is the probability that a new component will last for one year?

Sol. Given probability of electronic component fails, when first used $= 0.10$

i.e., $P(\underline{F}) = 0.10$

$\therefore$ $P(F) = 1 - P(F) = 0.90$

and let $P(Y)$ = Probability of new component to last for one year

$\because$ $P(F) + P(\overline{F}) = 1$

Obviously, the two events are mutually exclusive and exhaustive

$\therefore$ $$P\left(\frac{Y}{F}\right) = 0 \text{ and } P\left(\frac{Y}{\overline{F}}\right) = 0.99$$

$\therefore$ $$P(Y) = P(F) \cdot P\left(\frac{Y}{F}\right) + P(\overline{F}).P\left(\frac{Y}{\overline{F}}\right)$$

$$= 0.10 \times 0 + 0.90 \times 0.99$$

$$= 0 + (0.9)(0.99) = 0.891$$

Example 15. Three groups A, B and C are contesting for positions on the Board of Directors of a company. The probabilities of their winning are 0.5, 0.3 and 0.2, respectively. If the group A wins, then the probability of introducing a new product is 0.7 and the corresponding probabilities for groups B and C are 0.6 and 0.5, respectively. Find the probability that the new product will be introduced.

Sol. Given, $P(A) = 0.5$, $P(B) = 0.3$ and $P(C) = 0.2$

$\therefore$ $P(A) + P(B) + P(C) = 1$

Then, events A, B, C are exhaustive.

If $P(E)$ = Probability of introducing a new product, then as given

$$P\left(\frac{E}{A}\right) = 0.7,\ P\left(\frac{E}{B}\right) = 0.6 \text{ and } P\left(\frac{E}{C}\right) = 0.5$$

$$P(E) = P(A) \cdot P\left(\frac{E}{A}\right) + P(B) \cdot P\left(\frac{E}{B}\right) + P(C) \cdot P\left(\frac{E}{C}\right)$$

$$= 0.5 \times 0.7 + 0.3 \times 0.6 + 0.2 \times 0.5$$

$$= 0.35 + 0.18 + 0.10 = 0.63$$

Example 16. An urn contains 2 white and 2 black balls. A ball is drawn at random. If it is white, it is not replace into urn, otherwise it is replaced along with another ball of the same colour. The process is repeated, find the probability that the third ball drawn is black.

Sol. For the first two draw, the balls taken out may be

Let E_1 = White and White; E_2 = White and Black

E_3 = Black and White; E_4 = Black and Black

$\therefore$ $$P(E_1) = P(W) \cdot P\left(\frac{W}{W}\right) = \frac{2}{4} \cdot \frac{1}{3} = \frac{1}{6}$$

$$P(E_2) = P(W) \cdot P\left(\frac{B}{W}\right) = \frac{2}{4} \cdot \frac{2}{3} = \frac{1}{3}$$

$$P(E_3) = P(B) \cdot P\left(\frac{W}{B}\right) = \frac{2}{4} \cdot \frac{2}{5} = \frac{1}{5}$$

and $$P(E_4) = P(B) \cdot P\left(\frac{B}{B}\right) = \frac{2}{4} \cdot \frac{3}{5} = \frac{3}{10}$$

$$\therefore\ P(E_1)+P(E_2)+P(E_3)+P(E_4)=\frac{1}{6}+\frac{1}{3}+\frac{1}{5}+\frac{3}{10}$$
$$=\frac{10+20+12+18}{60}=1$$

Then, events E_1, E_2, E_3 and E_4 are exhaustive. Obviously, these events are mutually exclusive, then

$$P\left(\frac{B}{E_1}\right)=\frac{2}{2}=1;\ P\left(\frac{B}{E_2}\right)=\frac{3}{4}$$

$$P\left(\frac{B}{E_3}\right)=\frac{3}{4}\text{ and }P\left(\frac{B}{E_4}\right)=\frac{4}{6}=\frac{2}{3}$$

$\therefore$ Required probability,

$$P(B)=P(E_1)\cdot P\left(\frac{B}{E_1}\right)+P(E_2)\cdot P\left(\frac{B}{E_2}\right)$$
$$+P(E_3)\cdot P\left(\frac{B}{E_3}\right)+P(E_4)\cdot P\left(\frac{B}{E_4}\right)$$
$$=\frac{1}{6}\times 1+\frac{1}{3}\times\frac{3}{4}+\frac{1}{5}\times\frac{3}{4}+\frac{3}{10}\times\frac{2}{3}$$
$$=\frac{1}{6}+\frac{1}{4}+\frac{3}{20}+\frac{1}{5}$$
$$=\frac{10+15+9+12}{60}=\frac{46}{60}=\frac{23}{30}$$

Baye's Theorem or Inverse Probability

If an event E can occur only with one of the n mutually exclusive and exhaustive events $E_1, E_2, E_3,..., E_n$ and the probabilities $P(E/E_1), P(E/E_2), ..., P(E/E_n)$ are known, then

$$P\left(\frac{E_k}{E}\right)=\frac{P(E_k)\cdot P\left(\frac{E}{E_k}\right)}{\sum_{k=1}^{n}P(E_k)\cdot P\left(\frac{E}{E_k}\right)}$$

Proof The event E occurs with one of the n mutually exclusive and exhaustive events $E_1, E_2, E_3,..., E_n$, then

$$E=EE_1+EE_2+EE_3+...+EE_n$$
$$\Rightarrow\quad P(E)=P(EE_1)+P(EE_2)+P(EE_3)+...+P(EE_n)$$
$$=\sum_{k=1}^{n}P(EE_k)=\sum_{k=1}^{n}P(E_k)\cdot P\left(\frac{E}{E_k}\right)$$

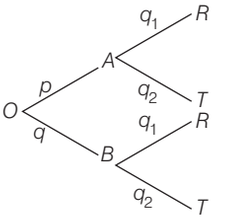
$$\therefore\ P\left(\frac{E_k}{E}\right)=\frac{P(E_k\ E)}{P(E)}=\frac{P(E_k)\cdot P\left(\frac{E}{E_k}\right)}{\sum_{k=1}^{n}P(E_k)\cdot P\left(\frac{E}{E_k}\right)}$$

Remark

The probabilities $P(E_k)$ and $P\left(\frac{E_k}{E}\right)$ are known as **priori** and **posteriori** probabilities, respectively.

Remarks We can visualise a tree structure here

$$P(A)=p,\ P(B)=q$$
$$P\left(\frac{R}{A}\right)=p_1,\ P\left(\frac{T}{A}\right)=q_1$$
$$P\left(\frac{R}{B}\right)=p_2,\ P\left(\frac{T}{B}\right)=q_2$$



If we are to find $P\left(\frac{A}{R}\right)$, we go

$$\therefore\quad P\left(\frac{A}{R}\right)=\frac{P(A)\cdot P\left(\frac{R}{A}\right)}{P(A)\cdot P\left(\frac{R}{A}\right)+P(B)\cdot P\left(\frac{R}{B}\right)}$$

Example 17. A bag A contains 2 white and 3 red balls and a bag B contains 4 white and 5 red balls. One ball is drawn at random from one of the bags and it is found to be red. Then, find the probability that it was drawn from the bag B.

Sol. Let $E_1 \equiv$ The event of ball being drawn from bag A.

$E_2 \equiv$ The event of ball being drawn from bag B.

and $E \equiv$ The event of ball being red.

Since, both the bag are equally likely to be selected, therefore

$$P(E_1)=P(E_2)=\frac{1}{2}\ \text{ and }\quad P\left(\frac{E}{E_1}\right)=\frac{3}{5}\text{ and }P\left(\frac{E}{E_2}\right)=\frac{5}{9}$$

$\therefore$ Required probability,

$$P\left(\frac{E_2}{E}\right)=\frac{P(E_2)\cdot P\left(\frac{E}{E_2}\right)}{P(E_1)\cdot P\left(\frac{E}{E_1}\right)+P(E_2)\cdot P\left(\frac{E}{E_2}\right)}$$
$$=\frac{\frac{1}{2}\times\frac{5}{9}}{\frac{1}{2}\times\frac{3}{5}+\frac{1}{2}\times\frac{5}{9}}=\frac{\frac{5}{9}}{\frac{3}{5}+\frac{5}{9}}=\frac{25}{52}$$

Example 18. A man is known to speak the truth 3 out of 4 times. He throws a die and reports that it is a six. Find the probability that it is actually a six.

Sol. Let E_1 be the event that the man reports that it is a six and E be the event that a six occurs.

Then, $P(E)=\frac{1}{6}$

$\therefore \quad P(\bar{E})=1-P(E)=1-\frac{1}{6}=\frac{5}{6}$

$\therefore \quad P\left(\frac{E_1}{E}\right)=P$ (man speaking the truth) $=\frac{3}{4}$

and $P\left(\frac{E_1}{\bar{E}}\right)=P$ (man not speaking the truth) $=1-\frac{3}{4}=\frac{1}{4}$

Clearly, $\left(\frac{E}{E_1}\right)$ is the event that it is actually a six, when it is known that the man reports a six.

$$P\left(\frac{E}{E_1}\right)=\frac{P(E)\cdot P\left(\frac{E_1}{E}\right)}{P(E)\cdot P\left(\frac{E_1}{E}\right)+P(\bar{E})\cdot P\left(\frac{E_1}{E}\right)}$$

$$=\frac{\frac{1}{6}\times\frac{3}{4}}{\frac{1}{6}\times\frac{3}{4}+\frac{5}{6}\times\frac{1}{4}}=\frac{3}{8}$$

Example 19. In a test, an examinee either guesses or copies or knows the answer to a multiple choice question with four choices. The probability that he makes a guess is $\frac{1}{3}$ and the probability that he copies the answer is $\frac{1}{6}$. The probability that his answer is correct given that he copied it is $\frac{1}{8}$. Find the probability that he knew the answer to the question given that he correctly answered it.

Sol. Lest E_1 be the event that the answer is guessed, E_2 be the event that the answer is copied, E_3 be the event that the examinee knows the answer and E be the event that the examinee answers correctly.

Given, $P(E_1)=\frac{1}{3}$, $P(E_2)=\frac{1}{6}$

Assume that events E_1, E_2 and E_3 are exhaustive

$\therefore \quad P(E_1)+P(E_2)+P(E_3)=1$

$\therefore \quad P(E_3)=1-P(E_1)-P(E_2)=1-\frac{1}{3}-\frac{1}{6}=\frac{1}{2}$

Now, $P\left(\frac{E}{E_1}\right)$

$\equiv$ Probability of getting correct answer by guessing

$=\frac{1}{4}$ [since 4 alternatives]

$P\left(\frac{E}{E_2}\right)\equiv$ Probability of answering correctly by copying $=\frac{1}{8}$

and $P\left(\frac{E}{E_3}\right)\equiv$ Probability of answering correctly by knowing = 1

Clearly, $\left(\frac{E_3}{E}\right)$ is the event he knew the answer to the question, given that he correctly answered it.

$$\therefore \quad P\left(\frac{E_3}{E}\right)=\frac{P(E_3)\cdot P\left(\frac{E}{E_3}\right)}{P(E_1)\cdot P\left(\frac{E}{E_1}\right)+P(E_2)\cdot P\left(\frac{E}{E_2}\right)+P(E_2)\cdot P\left(\frac{E}{E_3}\right)}$$

$$=\frac{\frac{1}{2}\times 1}{\frac{1}{3}\times\frac{1}{4}+\frac{1}{6}\times\frac{1}{8}+\frac{1}{2}\times 1}=\frac{24}{29}$$

Example 20. A and B are two independent witnesses (i.e., there is no collusion between them) in a case. The probability that A will speak the truth is x and the probability that B will speak the truth is y. A and B agree in a certain statements. Show that the probability that the statements is true, is $\frac{xy}{1-x-y+2xy}$.

Sol. Let E_1 be the event that both A and B speak the truth, E_2 be the event that both A and B tell a lie and E be the event that A and B agree in a certain statements.

And also, let C be the event that A speak the truth and D be the event that B speaks the truth.

$\therefore \quad E_1=C\cap D$

[$\because C$ and D are independent events]

and $E_2=\bar{C}\cap\bar{D}$

then, $P(E_1)=(C\cap D)=P(C)\cdot P(D)=xy$

and $P(E_2)=P(\bar{C}\cap\bar{D})=P(\bar{C})\,P(\bar{D})$

$=\{1-P(C)\}\{1-P(D)\}=(1-x)(1-y)$

$=1-x-y-xy$

Now, $P\left(\frac{E}{E_1}\right)\equiv$ Probability that A and B will agree, when both of them speak the truth $=1$

and $P\left(\frac{E}{E_2}\right)=$ Probability that A and B will agree, when both of them tell a lie = 1

Clearly, $\left(\frac{E_1}{E}\right)$ be the event that the statement is true

$$\therefore \quad P\left(\frac{E_1}{E}\right)=\frac{P(E_1)\cdot P\left(\frac{E}{E_1}\right)}{P(E_1)\cdot P\left(\frac{E}{E_1}\right)+P(E_2)\cdot P\left(\frac{E}{E_2}\right)}$$

$$=\frac{xy\cdot 1}{xy\cdot 1+(1-x-y+xy)\cdot 1}=\frac{xy}{1-x-y+2xy}$$

Exercise for Session 3

1. A bag A contains 3 white and 2 black balls and another bag B contains 2 white and 4 black balls. A bag and a ball out of it are picked at random. The probability that the ball is white, is

(a) $\frac{2}{7}$ (b) $\frac{7}{9}$ (c) $\frac{4}{15}$ (d) $\frac{7}{15}$

2. There are two bags, one of which contains 3 black and 4 white balls, while the other contains 4 black and 3 white balls. A die is cast. If the face 1 or 3 turns up a ball is taken out from the first bag and if any other face turns up, a ball is taken from the second bag. The probability of choosing a black ball, is

(a) $\frac{7}{15}$ (b) $\frac{8}{15}$ (c) $\frac{10}{21}$ (d) $\frac{11}{21}$

3. There are two groups of subjects, one of which consists of 5 Science subjects and 3 Engineering subjects and the other consists of 3 Science and 5 Engineering subjects. An unbiased die is cast. If number 3 or 5 turns up, a subject from group I is selected, otherwise a subject is selected from group II. The probability that an Engineering subject is selected ultimately, is

(a) $\frac{7}{13}$ (b) $\frac{9}{17}$ (c) $\frac{13}{24}$ (d) $\frac{11}{20}$

4. Urn A contains 6 red and 4 white balls and urn B contains 4 red and 6 white balls. One ball is drawn at random from urn A and placed in urn B. Then a ball is drawn from urn B and placed in urn A. Now, if one ball is drawn from urn A, the probability that it is red, is

(a) $\frac{6}{11}$ (b) $\frac{17}{50}$ (c) $\frac{16}{55}$ (d) $\frac{32}{55}$

5. A box contains N coins, of which m are fair and the rest are biased. The probability of getting head when a fair coin is tossed is $\frac{1}{2}$, while it $\frac{2}{3}$ when a biased coin is tossed. A coin is drawn from the box at random and is tossed twice. The first time it shows head and the second time it shows tail. The probability that the coin drawn is fair, is

(a) $\frac{5m}{m+8N}$ (b) $\frac{3m}{m+8N}$ (c) $\frac{7m}{m+8N}$ (d) $\frac{9m}{m+8N}$

6. A pack of playing cards was found to contain only 51 cards. If the first 13 cards which are examined are all red, then the probability that the missing card is black, is

(a) $\frac{1}{3}$ (b) $\frac{2}{3}$ (c) $\frac{15}{26}$ (d) $\frac{16}{39}$

7. A purse contains n coins of unknown values. A coin is drawn from it at random and is found to be a rupee. Then the chance that it is the only rupee coin in the purse, is

(a) $\frac{1}{n}$ (b) $\frac{2}{n+1}$ (c) $\frac{1}{n(n+1)}$ (d) $\frac{2}{n(n+1)}$

8. A card is lost from a pack of 52 playing cards. From the remainder of the pack, one card is drawn and is found to be a spade. The probability that the missing card is a spade, is

(a) $\frac{2}{17}$ (b) $\frac{3}{17}$ (c) $\frac{4}{17}$ (d) $\frac{5}{17}$

9. A person is known to speak the truth 4 times out of 5. He throws a die and reports that it is an ace. The probability that it is actually an ace, is

(a) $\frac{1}{3}$ (b) $\frac{2}{9}$ (c) $\frac{4}{9}$ (d) $\frac{5}{9}$

10. Each of the n urns contains 4 white and 6 black balls, the $(n+1)$ th urn contains 5 white and 5 black balls. Out of $(n+1)$ urns an urn is chosen at random and two balls are drawn from it without replacement. Both the balls are found to be black. If the probability that the $(n+1)$th urn was chosen to drawn the balls is $\frac{1}{16}$, the value of n, is

(a) 10 (b) 11 (c) 12 (d) 13

Session 4

Binomial Theorem on Probability, Poisson Distribution, Expectation, Multinomial Theorem, Uncountable Uniform Spaces (Geometrical Problems)

Binomial Theorem on Probability

Suppose, a binomial experiment has probability of success p and that of failure q (i.e., $p+q=1$). If E be an event and let $X=$ number of successes i.e., number of times event E occurs in n trials. Then, the probability of occurrence of event E exactly r times in n trials is denoted by $P(X=r)$ or $P(r)$ and is given by $P(X=r)$

or $P(r) = {}^nC_r\, p^r q^{n-r}$

$= (r+1)$ th terms in the expansion of $(q+p)^n$

where, $r=0, 1, 2, 3, \ldots, n$.

Remark

1. The probability of getting atleast k success is
$$P(r \geq k) = \sum_{r=k}^{n} {}^nC_r p^r q^{n-r}.$$
2. The probability of getting atmost k success is
$$P(0 \leq r \leq k) = \sum_{r=0}^{k} {}^nC_r p^r q^{n-r}.$$
3. The probability distribution of the random variable X is as given below

X	0	1	2	…	r	…	n
$P(X)$	q^n	${}^nC_1\, pq^{n-1}$	${}^nC_2\, p^2 q^{n-2}$	…	${}^nC_r\, p^r q^{n-r}$		p^n

4. The mean, the variance and the standard deviation of binomial distribution are np, npq, $\sqrt{npq}$.
5. **Mode of binomial distribution** Mode of Binomial distribution is the value of r when $P(X=r)$ is maximum.
$$(n+1)\,p - 1 \leq r \leq (n+1)p$$

Example 21. If on an average, out of 10 ships, one is drowned, then what is the probability that out of 5 ships, atleast 4 reach safely?

Sol. Let p be the probability that a ship reaches safely.

$\therefore \quad p = \dfrac{9}{10}$

$\therefore \quad q =$ Probability that a ship is drowned $= 1 - p = 1 - \dfrac{9}{10}$

$\therefore \qquad q = \dfrac{1}{10}$

Let X be the random variable, showing the number of ships reaching safely.

Then, P (atleast 4 reaching safely) $= P(X=4 \text{ or } X=5)$

$= P(X=4) + P(X=5)$

$$= {}^5C_4\left(\frac{9}{10}\right)^4\left(\frac{1}{10}\right)^{5-4} + {}^5C_5\left(\frac{9}{10}\right)^5\left(\frac{1}{10}\right)^{5-5}$$

$$= \frac{5\times 9^4}{10^5} + \frac{9^5}{10^5} = \frac{9^4\times 14}{10^5}$$

Example 22. Numbers are selected at random one at a time, from the numbers 00, 01, 02, ..., 99 with replacement. An event E occurs, if and only if the product of the two digits of a selected number is 18. If four numbers are selected, then find the probability that E occurs atleast 3 times.

Sol. Out of the numbers 00, 01, 02, ..., 99, those numbers the product of whose digits is 18 are 29, 36, 63, 92 i.e., only 4.

$$p = P(E) = \frac{4}{100} = \frac{1}{25},\ q = P(\bar{E}) = 1 - \frac{1}{25} = \frac{24}{25}$$

Let X be the random variable, showing the number of times E occurs in 4 selections.

Then, $P(E$ occurs atleast 3 times$) = P(X=3 \text{ or } X=4)$

$= P(X=3) + P(X=4) = {}^4C_3\, p^3 q^1 + {}^4C_4\, p^4 q^0$

$$= 4p^3 q + p^4 = 4\times\left(\frac{1}{25}\right)^3 \times \frac{24}{25} + \left(\frac{1}{25}\right)^4$$

$$= \frac{97}{390625}$$

Example 23. A man takes a step forward with probability 0.4 and backward with probability 0.6. Then, find the probability that at the end of eleven steps he is one step away from the starting point.

Sol. Since, the man is one step away from starting point mean that either

(i) man has taken 6 steps forward and 5 steps backward.

(ii) man has taken 5 steps forward and 6 steps backward.

Taking, movement 1 step forward as success and 1 step backward as failure.

$\therefore \quad p$ = Probability of success = 0.4

and q = Probability of failure = 0.6

$\therefore$ Required probability = $P(X = 6 \text{ or } X = 5)$

$$= P(X = 6) + P(X = 5) = {}^{11}C_6\ p^6q^5 + {}^{11}C_5\ p^5q^6$$

$$= {}^{11}C_5(p^6q^5 + p^5q^6)$$

$$= \frac{11 \cdot 10 \cdot 9 \cdot 8 \cdot 7}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}\{(0 \cdot 4)^6(0 \cdot 6)^5 + (0 \cdot 4)^5(0 \cdot 6)^6\}$$

$$= \frac{11 \cdot 10 \cdot 9 \cdot 8 \cdot 7}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}(0 \cdot 24)^5 = 0 \cdot 37$$

Hence, the required probability is 0·37.

Example 24. Find the minimum number of tosses of a pair of dice, so that the probability of getting the sum of the digits on the dice equal to 7 on atleast one toss, is greater than 0.95. (Given, $\log_{10} 2 = 0 \cdot 3010$, $\log_{10} 3 = 0 \cdot 4771$)

Sol. The sample space,

$$S = \{1, 2, 3, 4, 5, 6\} \times \{1, 2, 3, 4, 5, 6\}$$

$\therefore \quad n(S) = 36$ and let E be the event getting the sum of digits on the dice equal to 7, then

$$E = \{(1, 6), (6, 1), (2, 5), (5, 2), (3, 4), (4, 3)\}$$

$\therefore \quad n(E) = 6$

p = Probability of getting the sum 7

$$p = \frac{6}{36} = \frac{1}{6} \quad \therefore \quad q = 1 - p = 1 - \frac{1}{6} = \frac{5}{6}$$

$\because$ Probability of not throwing the sum 7 in first m trials = q^m

$\therefore$ P (atleast one 7 in m throws) = $1 - q^m = 1 - \left(\frac{5}{6}\right)^m$

According to the question, $1 - \left(\frac{5}{6}\right)^m > 0 \cdot 95$

$$\Rightarrow \quad \left(\frac{5}{6}\right)^m < 1 - 0 \cdot 95 \ \Rightarrow \ \left(\frac{5}{6}\right)^m < 0.05$$

$$\Rightarrow \quad \left(\frac{5}{6}\right)^m < \frac{1}{20}$$

Taking logarithm,

$$\Rightarrow \quad m\{\log_{10} 5 - \log_{10} 6\} < \log_{10} 1 - \log_{10} 20$$

$$\Rightarrow m\{1 - \log_{10} 2 - \log_{10} 2 - \log_{10} 3\} < 0 - \log_{10} 2 - \log_{10} 10$$

$$\Rightarrow \quad m\{1 - 2\log_{10} 2 - \log_{10} 3\} < -\log_{10} 2 - 1$$

$$\Rightarrow \quad m\{1 - 0.6020 - 0.4771\} < -0.3010 - 1$$

$$\Rightarrow \quad -0.079\,m < -1.3010$$

$$\Rightarrow \quad m > \frac{1.3010}{0.079} = 16.44$$

$$\therefore \quad m > 16.44$$

Hence, the least number of trials is 17.

Example 25. Write probability distribution, when three coins are tossed.

Sol. Let X be a random variable denoting the number of heads occurred, then $P(X = 0)$ = Probability of occurrence of zero head

$$= P(TTT) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{8}$$

$P(X = 1)$ = Probability of occurrence of one head

$$= P(HTT) + P(THT) + P(TTH)$$

$$= \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{3}{8}$$

$P(X = 2)$ = Probability of occurrence of two heads

$$= P(HHT) + P(HTH) + P(THH)$$

$$= \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{3}{8}$$

$P(X = 3)$ = Probability of occurrence of three heads

$$= P(HHH) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{8}$$

Thus, the probability distribution when three coins are tossed is as given below

X	0	1	2	3
$P(X)$	$\frac{1}{8}$	$\frac{3}{8}$	$\frac{3}{8}$	$\frac{1}{8}$

another form,

$$X : \begin{pmatrix} 0 & 1 & 2 & 3 \\ \frac{1}{3} & \frac{3}{8} & \frac{3}{8} & \frac{1}{8} \end{pmatrix}$$

$$P(X) :$$

Example 26. The mean and variance of a binomial variable X are 2 and 1, respectively. Find the probability that X takes values greater than 1.

Sol. Given, mean, $np = 2$ ...(i)

and variance, $npq = 1$ ...(ii)

On dividing Eq. (ii) by Eq. (i), we get $q = \frac{1}{2}$

$$\therefore \quad p = 1 - q = \frac{1}{2}$$

From Eq. (i), $n \times \frac{1}{2} = 2 \ \therefore \ n = 4$

The binomial distribution is $\left(\frac{1}{2} + \frac{1}{2}\right)^4$

Now, $P(X > 1) = P(X = 2) + P(X = 3) + P(X = 4)$

$$= {}^4C_2\left(\frac{1}{2}\right)^2\left(\frac{1}{2}\right)^2 + {}^4C_4\left(\frac{1}{2}\right)^1\left(\frac{1}{2}\right)^3 + {}^4C_4\left(\frac{1}{2}\right)^4$$

$$= \frac{6 + 4 + 1}{16} = \frac{11}{16}$$

Aliter $P(X > 1) = 1 - \{P(X = 0) + P(X = 1)\}$

$$= 1 - \left\{{}^4C_0\left(\frac{1}{2}\right)^0\left(\frac{1}{2}\right)^4 + {}^4C_3\left(\frac{1}{2}\right)\left(\frac{1}{2}\right)^3\right\} = 1 - \left(\frac{1 + 4}{16}\right) = \frac{11}{16}$$

Poisson Distribution

It is the limiting case of binomial distribution under the following conditions :

(i) Number of trails are very large i.e. $n \to \infty$

(ii) $p \to 0$

(iii) $nq \to \lambda$, a finite quantity (λ is called parameter)

(a) Probability of r success for poisson distribution is given by $P(X = r) = \dfrac{e^{-\lambda}\lambda^r}{r!}, r = 0, 1, 2, \ldots$

(b) Recurrence formula for poisson distribution is given by $P(r+1) = \dfrac{\lambda}{(r+1)} P(r)$

Remark

1. For poisson distribution, mean = variance = $\lambda = np$
2. If X and Y are independent poisson variates with parameters λ_1 and λ_2, then $X + Y$ has poisson distribution with parameter $\lambda_1 + \lambda_2$.

Expectation

If p be the probability of success of a person in any venture and m be the sum of money which he will receive in case of success, the sum of money denoted by pm is called his expectation.

Example 27. A random variable X has Poisson's distribution with mean 3. Then find the value of $P(X > 2.5)$

Sol. $P(X > 2.5) = 1 - P(X = 0) - P(X = 1) - P(X = 2)$

$\because \quad P(X = k) = e^{-\lambda} \cdot \dfrac{\lambda^k}{k!}$

$\therefore \quad P(X > 2.5) = 1 - \dfrac{e^{-\lambda}}{0!} - \dfrac{e^{-\lambda} \cdot \lambda^1}{1!} - \dfrac{e^{-\lambda} \cdot \lambda^2}{2!}$

$= 1 - e^{-\lambda}\left(1 + \lambda + \dfrac{\lambda^2}{2}\right)$

$= 1 - e^{-3}\left(1 + 3 + \dfrac{9}{2}\right) \qquad (\because \ \lambda = np = 3)$

$= 1 - \dfrac{17}{2e^3}$

Example 28. *A and B throw with one die for a stake of ₹ 11 which is to be won by the player who first throw 6. If A has the first throw, then what are their respective expectations?*

Sol. Since, A can win the game at the 1st, 3rd, 5th,..., trials.

If p be the probability of success and q be the probability of fail, then

$$p = \frac{1}{6} \quad \text{and} \quad q = \frac{5}{6}$$

$P(A \text{ wins at the first trial}) = \dfrac{1}{6}$

$P(A \text{ wins at the 3rd trials}) = \dfrac{5}{6} \cdot \dfrac{5}{6} \cdot \dfrac{1}{6}$

$P(A \text{ wins at the 5th trials}) = \dfrac{5}{6} \cdot \dfrac{5}{6} \cdot \dfrac{5}{6} \cdot \dfrac{5}{6} \cdot \dfrac{1}{6}$ and so on.

Therefore, $P(A \text{ wins}) = \dfrac{1}{6} + \left(\dfrac{5}{6}\right)^2 \dfrac{1}{6} + \left(\dfrac{5}{6}\right)^4 \cdot \dfrac{1}{6} + \ldots \infty$

$$= \frac{\frac{1}{6}}{1 - \left(\frac{5}{6}\right)^2} = \frac{6}{11}$$

Similarly, $P(B \text{ wins}) = \dfrac{5}{6} \cdot \dfrac{1}{6} + \left(\dfrac{5}{6}\right)^3 \dfrac{1}{6} + \left(\dfrac{5}{6}\right)^5 \dfrac{1}{6} + \ldots \infty$

$$= \frac{\frac{5}{6} \cdot \frac{1}{6}}{1 - \left(\frac{5}{6}\right)^2} = \frac{5}{11}$$

Hence, expectations of A and B are ₹ $\dfrac{6}{11} \times 11$ and ₹ $\dfrac{5}{11} \times 11$, respectively. i.e. Expectations of A and B are ₹ 6 and ₹ 5, respectively.

Multinomial Theorem

If a dice has m faces marked 1, 2, 3,..., m and if such n dice are thrown, then the probability that the sum of the numbers of the upper faces is equal to r is given by the coefficient of x^r in $\dfrac{(x + x^2 + \ldots + x^m)^n}{m^n}$.

Example 29. A person throws two dice, one the common cube and the other a regular tetrahedron, the number on the lowest face being taken in the case of the tetrahedron, then find the probability that the sum of the numbers appearing on the dice is 6.

Sol. Let S be the sample space, then

$$S = \{1, 2, 3, 4\} \times \{1, 2, 3, 4, 5, 6\}$$

$\therefore \quad n(S) = 24$

If E be the event that the sum of the numbers on dice is 6.

Then, $n(E)$ = Coefficient of x^6 in

$(x^1 + x^2 + x^3 + x^4) \times (x^1 + x^2 + x^3 + x^4 + x^5 + x^6)$

$= 1 + 1 + 1 + 1 = 4$

$\therefore$ Required probability, $P(E) = \dfrac{n(E)}{n(S)} = \dfrac{4}{24} = \dfrac{1}{6}$

Example 30. Five ordinary dice are rolled at random and the sum of the numbers shown on them is 16. What is the probability that the numbers shown on each is any one from 2, 3, 4 or 5?

Sol. If the integers x_1, x_2, x_3, x_4 and x_5 are shown on the dice, then $x_1 + x_2 + x_3 + x_4 + x_5 = 16$

where, $1 \le x_i \le 6 \qquad (i = 1, 2, 3, 4, 5)$

The number of total solutions of this equation.

$= \text{Coefficient of } x^{16} \text{ in } (x^1 + x^2 + x^3 + x^4 + x^5 + x^6)^5$

$= \text{Coefficient of } x^{16} \text{ in } x^5 (1 + x + x^2 + x^3 + x^4 + x^5)^5$

$= \text{Coefficient of } x^{11} \text{ in } (1 + x + x^2 + x^3 + x^4 + x^5)^5$

$= \text{Coefficient of } x^{11} \text{ in } \left\{\left(\frac{1 - x^6}{1 - x}\right)^5\right\}$

$= \text{Coefficient of } x^{11} \text{ in } (1 - x^6)^5 (1 - x)^{-5}$

$= \text{Coefficient of } x^{11} \text{ in}$

$(1 - 5x^6 + \ldots)(1 + {}^5C_1 x + {}^6C_2 x^2 + \ldots$

$+ {}^9C_{C_5} x^5 + \ldots + {}^{15}C_{11} x^{11} + \ldots)$

$= {}^{15}C_{11} - 5 \cdot {}^9C_5$

$= {}^{15}C_4 - 5 \cdot {}^9C_4 = \frac{15 \cdot 14 \cdot 13 \cdot 12}{1 \cdot 2 \cdot 3 \cdot 4} - 5 \cdot \frac{9 \cdot 8 \cdot 7 \cdot 6}{1 \cdot 2 \cdot 3 \cdot 4} = 735$

If S be the sample space

$\therefore \qquad n(S) = 735$

Let E be the occurrence event, then

$n(E) =$ The number of integral solutions of

$x_1 + x_2 + x_3 + x_4 + x_5 = 16,$

where $2 \le x_i \le 5 \qquad (i = 1, 2, 3, 4, 5)$

$= \text{Coefficient of } x^{16} \text{ in } (x^2 + x^3 + x^4 + x^5)^5$

$= \text{Coefficient of } x^{16} \text{ in } x^{10}(1 + x + x^2 + x^3)^5$

$= \text{Coefficient of } x^6 \text{ in } (1 + x + x^2 + x^3)^5$

$= \text{Coefficient of } x^6 \text{ in } \left\{\left(\frac{1 - x^4}{1 - x}\right)^5\right\}$

$= \text{Coefficient of } x^6 \text{ in } (1 - x^4)^5 (1 - x)^{-5}$

$= \text{Coefficient of } x^6 \text{ in}$

$(1 - 5x^4 + \ldots)(1 + {}^5C_1 x + {}^6C_2 x^2 + \ldots + {}^{10}C_6 x^6 + \ldots)$

$= {}^{10}C_6 - 5 \cdot {}^6C_2 = {}^{10}C_4 - 5 \cdot {}^6C_2$

$= \frac{10 \cdot 9 \cdot 8 \cdot 7}{1 \cdot 2 \cdot 3 \cdot 4} - 5 \cdot \frac{6 \cdot 5}{1 \cdot 2} = 210 - 75 = 135$

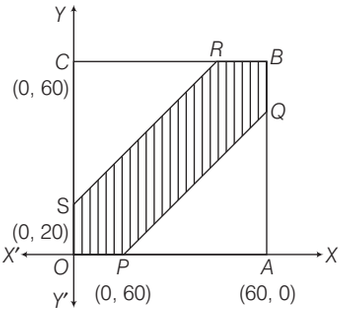
$\therefore$ The required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{135}{735} = \frac{9}{49}$

Uncountable Uniform Spaces

(Geometrical Problems)

Example 31. Two persons A and B agree to meet at a place between 11 to 12 noon. The first one to arrive waits for 20 min and then leave. If the time of their arrival be independent and at random, then what is the probability that A and B meet?

Sol. Let A and B arrive at the place of their meeting x minutes and y minutes after 11 noon.



The given condition $\Rightarrow$ their meeting is possible only if

$|x - y| \le 20 \qquad \ldots(i)$

$OABC$ is a square, where $A \equiv (60, 0)$ and $C \equiv (0, 60)$

Considering the equality part of Eq. (i)

i.e., $\qquad |x - y| = 20$

$\therefore$ The area representing the favourable cases

$=$ Area $OPQBRSO$

$=$ Area of square $OABC -$ Area of $\Delta PAQ -$ Area of ΔSRC

$= (60)(60) - \frac{1}{2}(40)(40) - \frac{1}{2}(40)(40)$

$= 3600 - 1600 = 2000$ sq units

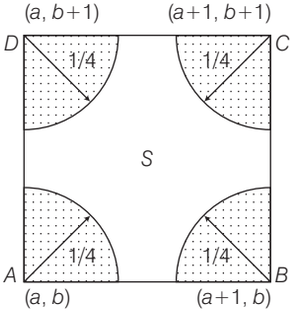
Total way $=$ Area of square $OABC = (60)(60) = 3600$ sq units

Required probability $= \frac{2000}{3600} = \frac{5}{9}$

Example 32. Consider the cartesian plane R^2 and let X denote the subset of points for which both coordinates are integers. A coin of diameter $\frac{1}{2}$ is tossed randomly onto the plane. Find the probability p that the coin covers a point of X.

Sol. Let S denote the set of points inside a square with corners

$(a, b), (a, b + 1), (a + 1, b), (a + 1, b + 1) \in X$



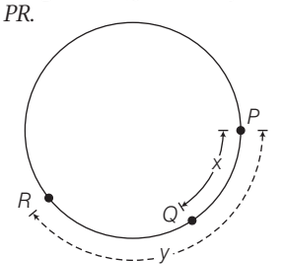
Let P denotes the set of points in S with distance less than $\frac{1}{4}$ from any corner point. (observe that the area of P is equal to the area inside a circle of

radius $\frac{1}{4}$). Thus a coin, whose centre falls in S, will cover a point of X if and only if its centre falls in a point of P.

Hence, $p = \frac{\text{area of } P}{\text{area of } S} = \frac{\pi\left(\frac{1}{4}\right)^2}{1} = \frac{\pi}{15} \approx 0.2$

Example 33. Three points P, Q and R are selected at random from the circumference of a circle. Find the probability p that the points lie on a semi-circle.

Sol. Let the length of the circumference is $2s$. Let x denote the clockwise arc length of PQ and let y denote the clockwise arc length of PR.



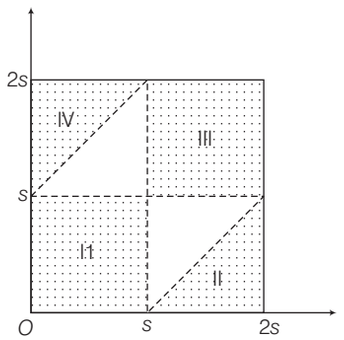
Thus, $0 < x < 2s$ and $0 < y < 2s$

Let A denotes the subset of S for which any of the following conditions holds:

(i) $x, y < s$ (ii) $x < s$ and $y - x > s$

(iii) $x, y > s$ (iv) $y < s$ and $x - y > s$

Then, A consists of those points for which P, Q and R lie on a semi-circle. Thus,



$$p = \frac{\text{area of } A}{\text{area of } S} = \frac{3s^2}{4s^2} = \frac{3}{4}$$

Example 34. A wire of length l is cut into three pieces. Find the probability that the three pieces form a triangle.

Sol. Let the lengths of three parts of the wire be x, y and $l - (x + y)$. Then, $x > 0$, $y > 0$

and $l - (x + y) > 0$

i.e., $x + y < l$ or $y < l - x$

Since, in a triangle, the sum of any two sides is greater than third side, so

$$x + y > l - (x + y) \Rightarrow y > \frac{l}{2} - x$$

and $$x + l - (x + y) > y \Rightarrow y < \frac{l}{2}$$

and $$y + l - (x + y) > x \Rightarrow x < \frac{l}{2}$$

$$\Rightarrow \quad \frac{l}{2} - x < y < \frac{l}{2} \text{ and } 0 < x < \frac{l}{2}$$

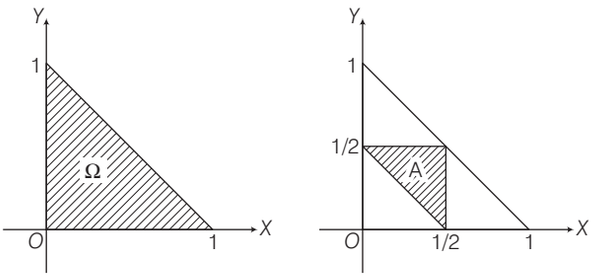
So, required probability $= \dfrac{\int_0^{l/2}\int_{l/2-x}^{l/2} dy\,dx}{\int_0^{l}\int_0^{l-x} dy\,dx}$

$$= \frac{\int_0^{l/2}\left\{\frac{l}{2} - \left(\frac{l}{2} - x\right)\right\}dx}{\int_0^{l}(l-x)dx} = \frac{\int_0^{l/2} x\,dx}{\int_0^{l}(l-x)\,dx} = \frac{l^2/8}{l^2/2} = \frac{1}{4}$$

Aliter

The elementary event w is characterised by two parameters x and y [since $z = l - (x + y)$]. We depict the event by a point on x, y plane. The conditions $x > 0$, $y > 0$, $x + y < l$ are imposed on the quantities x and y, the sample space is the interior of a right angled triangle with unit legs

i.e. $S_\Omega = \frac{1}{2}$.



The condition A requiring that a triangle could be formed from the segments $x, y, l - (x + y)$ reduces to the following two conditions: (1) The sum of any two sides is larger than the third side, (2) The difference between any two sides is smaller than the third side. This condition is associated with the triangular domain A with area.

$$S_A = \left(\frac{1}{2}\right)\left(\frac{1}{4}\right) = \frac{1}{8} \;\therefore\; P(A) = \frac{S_A}{S_\Omega} = \frac{\left(\frac{1}{8}\right)}{\left(\frac{1}{2}\right)} = \frac{1}{4}$$

Exercise for Session 4

1 A coin is tossed three times. The probability of getting exactly 2 heads is

(a) $\frac{1}{4}$ (b) $\frac{1}{8}$ (c) $\frac{3}{8}$ (d) $\frac{5}{8}$

2 A coin is tossed 4 times. The probability that atleast one head turns up is

(a) $\frac{1}{16}$ (b) $\frac{1}{8}$ (c) $\frac{7}{8}$ (d) $\frac{15}{16}$

3 The following is the probability distribution of a random variable X.

X	1	2	3	4	5
$P(X)$	0.1	0.2	k	0.3	$2k$

The value of k is

(a) $\frac{4}{15}$ (b) $\frac{1}{15}$ (c) $\frac{1}{5}$ (d) $\frac{2}{15}$

4 A random variable X has the distribution

X	2	3	4
$P(X = x)$	0.3	0.4	0.3

Then, variance of the distribution, is

(a) 0·6 (b) 0·7 (c) 0·77 (d) 1·55

5. In a box containing 100 bulbs, 10 bulbs are defective. Probability that out of a sample of 5 bulbs, none is defective, is

(a) 10^{-5} (b) 2^{-5} (c) $(0 \cdot 9)^5$ (d) $0 \cdot 9$

6. A pair of dice is rolled together till a sum of either 5 or 7 is obtained. The probability that 5 comes before 7, is

(a) $\frac{2}{5}$ (b) $\frac{2}{7}$ (c) $\frac{3}{7}$ (d) None of these

7. If X follows the binomial distribution with parameters $n = 6$ and p and $9P(X = 4) = P(X = 2)$, then p is

(a) $\frac{1}{4}$ (b) $\frac{1}{3}$ (c) $\frac{1}{2}$ (d) $\frac{2}{3}$

8. If probability of a defective bolt is 0.1, then mean and standard deviation of distribution of bolts in a total of 400, are

(a) 30, 3 (b) 40, 5 (c) 30, 4 (d) 40, 6

9. The mean and variance of a binomial distribution are $\frac{5}{4}$ and $\frac{15}{16}$ respectively, then value of p, is

(a) $\frac{1}{2}$ (b) $\frac{15}{16}$ (c) $\frac{1}{4}$ (d) $\frac{3}{4}$

10. The mean and variance of a binomial distribution are 6 and 4, then n is

(a) 9 (b) 12 (c) 18 (d) 10

11. A die is thrown 100 times. Getting an even number is considered a success. Variance of number of successes, is

(a) 10 (b) 20 (c) 25 (d) 50

12. 10% of tools produced by a certain manufacturing process turn out to be defective. Assuming binomial distribution, the probability of 2 defective in sample of 10 tools chosen at random, is

(a) 0.368 (b) 0.194 (c) 0.271 (d) None of these

13. If X follows a binomial distribution with parameters $n = 100$ and $p = \frac{1}{3}$, then $P(X = r)$ is maximum, when r equals

(a) 16 (b) 32 (c) 33 (d) None of these

14. The expected value of the number of points, obtained in a single throw of die, is

(a) $\frac{3}{2}$ (b) $\frac{5}{2}$ (c) $\frac{7}{2}$ (d) $\frac{9}{2}$

15. Two points P and Q are taken at random on a line segment OA of length a. The probability that $PQ > b$, where $0 < b < a$, is

(a) $\frac{b}{a}$ (b) $\frac{b^2}{a^2}$ (c) $\left(\frac{a-b}{a}\right)^2$ (d) $\left(\frac{a-2b}{a-b}\right)^2$

Shortcuts and Important Results to Remember

1 If n letters corresponding to n envelopes are placed in the envelopes at random, then

(i) probability that all letters are in right envelopes $= \frac{1}{n!}$.

(ii) probability that all letters are not in right envelopes $= 1 - \frac{1}{n!}$.

(iii) probability that no letter is in right envelopes $= \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \ldots + (-1)^n \frac{1}{n!}$.

(iv) probability that exactly r letters are in right envelopes $= \frac{1}{r!}\left[\frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \ldots + (-1)^{n-r} \frac{1}{(n-r)!}\right]$.

2 When two dice are thrown, the probability of getting a total r (sum of numbers on upper faces), is

(i) $\frac{(r-1)}{36}$, if $2 \le r \le 7$ (ii) $\frac{(13-r)}{36}$, if $8 \le r \le 12$

3 When three dice are thrown, the probability of getting a total r (sum of numbers on upper faces), is

(i) $\frac{{}^{r-1}C_2}{216}$, if $3 \le r \le 8$ (ii) $\frac{25}{216}$, if $r = 9$

(iii) $\frac{27}{216}$, if $r = 10, 11$ (iv) $\frac{25}{216}$, if $r = 12$

(v) $\frac{{}^{(20-r)}C_2}{216}$, if $13 \le r \le 18$

4 If A and B are two finite sets (Let $n(A) = n$ and $n(B) = m$) and if a mapping is selected at random from the set of all mappings from A to B, the probability that the mapping is

(i) a one-one function is $\frac{{}^mP_n}{m^n}$.

(ii) a one-one onto function is $\frac{n!}{m^n}$.

(iii) a many one function is $1 - \frac{{}^mP_n}{m^n}$.

5 If r squares are selected from a chess board of size 8×8, then the probability that they lie on a diagonal line, is $\frac{4({}^7C_r + {}^6C_r + {}^5C_r + \ldots + {}^rC_r) + 2({}^8C_r)}{{}^{64}C_r}$ for $1 \le r \le 7$.

6 If n objects are distributed among n persons, then the probability that atleast one of them will not get anything, is $\frac{n^n - n!}{n^n}$.

7 Points about coin, dice and playing cards:

(a) **Coin** If 'one' coin is tossed n times 'n' coins are tossed once, then number of simple events (or simple points) in the space of the experiment is 2^n. All these events are equally likely.

(b) **Dice** If 'one' die is thrown 'n' times or 'n' dice are thrown once, then number of simple events (or simple points) in the space of the experiment is 6^n (here dice is cubical). All events are equally likely.

(c) **Playing Cards** A pack of playing cards has 52 cards. There are four suits Spade (♠ black face), Heart (♥ red face), Diamond (♦ red face) and Club (♣ black face) each having 13 cards. In 13 cards of each suit, there are 3 face (or court) cards namely King, Queen and Jack (or knave), so there are in all 12 face cards 4 King, 4 Queen and 4 Jacks (or knaves). 4 of each suit namely Ace (or Ekka), King, Queen and Jack (or knave).

(i) **Game of bridge** It is played by 4 players, each player is given 13 cards.

(ii) **Game of whist** It is played by two pairs of persons.

(iii) If two cards (one after the other) can be drawn out of a well-shuffled pack of 52 cards, then number of ways; (×) With replacement is $52 \times 52 = (52)^2 = 2704$ (β) Without replacement is $52 \times 51 = 2652$.

(iv) Two cards (simultaneously) can be drawn out of a well-shuffled pack of 52 cards, then number of ways is ${}^{52}C_2 = \frac{52 \times 51}{2} = 1326$.

8 Out of $(2n + 1)$ tickets consecutively numbered, three are drawn at random, then the probability that the numbers on them are in AP, is $\frac{3n}{4n^2 - 1}$.

9 Out of $3n$ consecutive integers, three are selected at random, then the probability that their sum is divided by 3, is $\frac{(3n^2 - 3n + 2)}{(3n-1)(3n-2)}$.

10 Two numbers a and b are chosen at random from the set $\{1, 2, 3, \ldots, 5n\}$, the probability that $a^4 - b^4$ is divisible by 5, is $\frac{17n - 5}{5(5n-1)}$.

11 Two numbers a and b are chosen at random from the set $\{1, 2, 3, \ldots, 3n\}$ the probability that $a^2 - b^2$ is divisible by 3, is $\frac{(5n-3)}{3(3n-1)}$.

12 Two numbers a and b are chosen at random from the set $\{1, 2, 3, \ldots, 3n\}$, the probability that $a^3 + b^3$ is divisible by 3, is $\frac{1}{3}$.

13 There are n stations between two cities A and B. A train is to stop at three of these n stations. The probability that no two of these three stations are consecutive, is $\frac{(n-3)(n-4)}{n(n-1)}$.

JEE Type Solved Examples :
Single Option Correct Type Questions

■ This section contains **10 multiple choice examples.** Each example has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

● ***Ex. 1*** *The probability that in a year of* 22nd *century chosen at random, there will be* 53 *Sundays, is*

(a) $\frac{3}{28}$ (b) $\frac{2}{28}$ (c) $\frac{7}{28}$ (d) $\frac{5}{28}$

Sol. (d) In the 22nd century, there are 25 leap years viz. 2100, 2104, 2108,..., 2196 and 75 non-leap years.

Consider the following events:

E_1 = Selecting a leap year from 22nd century

E_2 = Selecting a non-leap year from 22nd century

E = There are 53 Sundays in a year of 22nd century

We have,

$$P(E_1) = \frac{25}{100},\ P(E_2) = \frac{75}{100},\ P\left(\frac{E}{E_1}\right) = \frac{2}{7} \text{ and } P\left(\frac{E}{E_2}\right) = \frac{1}{7}$$

Required probability $= P(E) = P((E \cap E_1) \cup (E \cap E_2))$

$$= P(E \cap E_1) + P(E \cap E_2)$$

$$= P(E_1).P\left(\frac{E}{E_1}\right) + P(E_2).P\left(\frac{E}{E_2}\right)$$

$$= \frac{25}{100} \times \frac{2}{7} + \frac{75}{100} \times \frac{1}{7} = \frac{5}{28}$$

● ***Ex. 2*** *In a convex hexagon two diagonals are drawn at random. The probability that the diagonals intersect at an interior point of the hexagon, is*

(a) $\frac{5}{12}$ (b) $\frac{7}{12}$ (c) $\frac{2}{5}$ (d) $\frac{3}{5}$

Sol. (a) We have,

Number of diagonals of a hexagon $= {}^6C_2 - 6 = 9$

$\therefore$ $n(s)$ = Total number of selections of two diagonals

$= {}^9C_2 = 36$

and $n(E)$ = The number of selections of two diagonals which intersect at an interior point

= The number of selections of four vertices $= {}^6C_4 = 15$

Hence, required probability $= \frac{n(E)}{n(S)} = \frac{15}{36} = \frac{5}{12}$

● ***Ex. 3*** *If three integers are chosen at random from the set of first* 20 *natural numbers, the chance that their product is a multiple of* 3*, is*

(a) $\frac{1}{57}$ (b) $\frac{13}{19}$

(c) $\frac{2}{19}$ (d) $\frac{194}{285}$

Sol. (d) $n(S)$ = Total number of ways of selecting 3 integers from 20 natural numbers $= {}^{20}C_3 = 1140$.

Their product is multiple of 3 means atleast one number is divisible by 3. The number which are divisible by 3 are 3, 6, 9, 12, 15 and 16.

$\therefore$ $n(E)$ = The number of ways of selecting atleast one of them multiple of 3

$$= {}^6C_1 \times {}^{14}C_2 + {}^6C_2 \times {}^{14}C_1 \times {}^6C_3 = 776$$

$\therefore$ Required probability $= \frac{n(E)}{n(S)}$

$$= \frac{776}{1140} = \frac{194}{285}$$

● ***Ex. 4*** *If three numbers are selected from the set of the first 20 natural numbers, the probability that they are in GP, is*

(a) $\frac{1}{285}$ (b) $\frac{4}{285}$

(c) $\frac{11}{1140}$ (d) $\frac{1}{71}$

Sol. (c) $n(S)$ = Total number of ways of selecting 3 numbers from first 20 natural numbers $= {}^{20}C_3 = 1140$

Three numbers are in GP, the favourable cases are 1, 2, 4; 1, 3, 9; 1, 4, 16; 2, 4, 8; 2, 6, 18; 3, 6, 12; 4, 8, 16; 5, 10, 20; 4, 6, 9; 8, 12, 18; 9, 12, 16

$\therefore$ $n(E)$ = The number of favourable cases = 11

$\therefore$ Required probability $= \frac{n(E)}{n(S)} = \frac{11}{1140}$

● ***Ex. 5*** *Two numbers b and c are chosen at random with replacement from the numbers* 1, 2, 3, 4, 5, 6, 7, 8 *and* 9*. The probability that* $x^2 + bx + c > 0$ *for all* $x \in R$*, is*

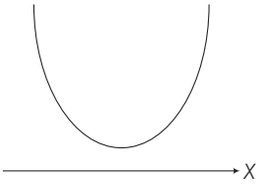
(a) $\frac{17}{123}$ (b) $\frac{32}{81}$

(c) $\frac{82}{125}$ (d) $\frac{45}{143}$

Sol. (b) Here, $x^2 + bx + c > 0, \forall\ x \in R$

$\therefore$ $D < 0$

$\Rightarrow$ $b^2 < 4c$



Value of b	Possible values of c		
1	$1 < 4c$	$\Rightarrow c > \frac{1}{4} \Rightarrow$	{1, 2, 3, 4, 5, 6, 7, 8, 9}
2	$4 < 4c$	$\Rightarrow c > 1 \Rightarrow$	{2, 3, 4, 5, 6, 7, 8, 9}
3	$9 < 4c$	$\Rightarrow c > \frac{9}{4} \Rightarrow$	{3, 4, 5, 6, 7, 8, 9}
4	$16 < 4c$	$\Rightarrow c > 4 \Rightarrow$	{5, 6, 7, 8, 9}
5	$25 < 4c$	$\Rightarrow c > 6.25 \Rightarrow$	{7, 8, 9}
6	$36 < 4c$	$\Rightarrow c > 9 \Rightarrow$	Impossible
7	Impossible		
8	Impossible		
9	Impossible		

$n(E)$ = Number of favourable cases = 9 + 8 + 7 + 5 + 3 = 32

$n(S)$ = Total ways = $9 \times 9 = 81$

$\therefore$ Required probability = $\frac{n(E)}{n(S)} = \frac{32}{81}$

● **Ex. 6** *Three dice are thrown. The probability of getting a sum which is a perfect square, is*

(a) $\frac{2}{5}$ (b) $\frac{9}{20}$

(c) $\frac{1}{4}$ (d) None of these

Sol. (d) $n(S)$ = Total number of ways = $6 \times 6 \times 6 = 216$

The sum of the numbers on three dice varies from 3 to 18 and among these 4, 9 and 16 are perfect squares.

$\therefore n(E)$ = Number of favourable ways

= Coefficient of x^4 in $(x + x^2 + \ldots + x^6)^3$ + Coefficient of x^9 in $(x + x^2 + \ldots + x^6)^3$ + Coefficient of x^{16} in $(x + x^2 + \ldots + x^6)^3$

= Coefficient of x in $(1 + x + \ldots + x^5)^3$ + Coefficient of x^6 in $(1 + x + x^2 + \ldots + x^5)^3$ + Coefficient of x^{13} in $(1 + x + x^2 + \ldots + x^5)^3$

= Coefficient of x in $(1 - x^6)^3(1 - x)^{-3}$ + Coefficient of x^6 in $(1 - x^6)^3(1 - x)^{-3}$ + Coefficient of x^{13} in $(1 - x^6)^3(1 - x)^{-3}$

= Coefficient of x in $(1)(1 + {}^3C_1 x + \ldots)$ + Coefficient of x^6 in $(1 - 3x^6)(1 + {}^3C_1 x + \ldots)$ + Coefficient of x^{13} in $(1 - 3x^6 + 3x^{12} + \ldots); (1 + {}^3C_1 x + \ldots)$

$= {}^3C_1 + ({}^8C_6 - 3) + ({}^{15}C_{13} - 3 \times {}^9C_7 + 9)$

$= {}^3C_1 + ({}^8C_2 - 3) + ({}^{15}C_2 - 3 \times {}^9C_2 + 9)$

$= 3 + 25 + 6$

$= 34$

$\therefore$ Required probability = $\frac{n(E)}{n(S)} = \frac{34}{216} = \frac{17}{108}$

● **Ex. 7** *A quadratic equation is chosen from the set of all quadratic equations which are unchanged by squaring their roots. The chance that the chosen equation has equal roots, is*

(a) $\frac{1}{2}$ (b) $\frac{1}{3}$

(c) $\frac{1}{4}$ (d) None of these

Sol. (a) Let α and β be the roots of the quadratic equation.

According to question,

$\alpha + \beta = \alpha^2 + \beta^2$ and $\alpha\beta = \alpha^2\beta^2 \Rightarrow \alpha\beta(\alpha\beta - 1) = 0$

$\Rightarrow \alpha\beta = 1$ or $\alpha\beta = 0$

$\Rightarrow \alpha = 1, \beta = 1; \alpha = \omega, \beta = \omega^2$ [cube roots and unity]

$\alpha = 1, \beta = 0; \alpha = 0, \beta = 0$

$\therefore n(S)$ = Number of quadratic equations which are unchanged by squaring their roots = 4

and $n(E)$ = Number of quadratic equations have equal roots = 2

$\therefore$ Required probability = $\frac{n(E)}{n(S)} = \frac{2}{4} = \frac{1}{2}$

● **Ex. 8** *Three-digit numbers are formed using the digits* 0, 1, 2, 3, 4, 5 *without repetition of digits. If a number is chosen at random, then the probability that the digits either increase or decrease, is*

(a) $\frac{1}{10}$ (b) $\frac{2}{11}$ (c) $\frac{3}{10}$ (d) $\frac{4}{11}$

Sol. (c) $n(S)$ = Total number of three digit numbers

$= {}^6P_3 - {}^5P_2 = 120 - 20 = 100$

$n(E)$ = Number of numbers with digits either increase or decrease

= Number of numbers with increasing digits + Number of numbers with decreasing digits

$= {}^5C_3 + {}^6C_3 = 10 + 20 = 30$

$\therefore$ Required probability = $\frac{n(E)}{n(S)} = \frac{30}{100} = \frac{3}{10}$

● **Ex. 9** *If X follows a binomial distribution with parameters* $n = 8$ *and* $p = \frac{1}{2}$, *then* $p(|x - 4| \le 2)$ *is equal to*

(a) $\frac{121}{128}$ (b) $\frac{119}{128}$ (c) $\frac{117}{128}$ (d) $\frac{115}{128}$

Sol. (b) Here, $p = \frac{1}{2}, n = 8$

$\therefore \quad q = 1 - p = 1 - \frac{1}{2} = \frac{1}{2}$

$\therefore$ The binomial distribution is $\left(\frac{1}{2} + \frac{1}{2}\right)^8$

Also, $|x - 4| \le 2$

$\Rightarrow \quad -2 \le x - 4 \le 2 \Rightarrow 2 \le x \le 6$

$$\therefore\ p(|x-4|\le 2) = p(x=2)+p(x=3)+p(x=4)+p(x=5)+p(x=6)$$

$$= {}^8C_2\left(\frac{1}{2}\right)^2\left(\frac{1}{2}\right)^6 + {}^8C_3\left(\frac{1}{2}\right)^3\left(\frac{1}{2}\right)^5 + {}^8C_4\left(\frac{1}{2}\right)^4\left(\frac{1}{2}\right)^4 + {}^8C_5\left(\frac{1}{2}\right)^5\left(\frac{1}{2}\right)^3 + {}^8C_6\left(\frac{1}{2}\right)^6\left(\frac{1}{2}\right)^2$$

$$= \frac{{}^8C_2 + {}^8C_3 + {}^8C_4 + {}^8C_5 + {}^8C_6}{2^8}$$

$$= \frac{238}{256} = \frac{119}{128}$$

● ***Ex. 10*** *A doctor is called to see a sick child. The doctor knows (prior to the visit) that* 90% *of the sick children in that neighbourhood are sick with the flue, denoted by F, while* 10% *are sick with the measles, denoted by M. A well-known symptom of measles is a rash, denoted by R. The probability of having a rash for a child sick with the measles is* 0.95. *However, occasionally children with the flue also develop a rash with conditional probability* 0.08. *Upon examination the child, the doctor finds a rash, then the probability that the child has the measles, is*

(a) $\frac{89}{167}$ (b) $\frac{91}{167}$ (c) $\frac{93}{167}$ (d) $\frac{95}{167}$

Sol. (d) $\because P(F) = 0\cdot90,\ P(M) = 0\cdot10,$

$$P\left(\frac{R}{F}\right) = 0\cdot08,\ P\left(\frac{R}{M}\right) = 0\cdot95$$

$$\therefore\ P\left(\frac{M}{R}\right) = \frac{P(M)\cdot P\left(\frac{R}{M}\right)}{P(M)\cdot P\left(\frac{R}{M}\right) + P(F)\cdot P\left(\frac{R}{F}\right)}$$

$$= \frac{0\cdot10\times 0\cdot95}{0\cdot10\times 0\cdot95 + 0\cdot90\times 0\cdot08} = \frac{0\cdot095}{0\cdot167} = \frac{95}{167}$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **5 multiple choice examples.** Each example has four choices (a), (b), (c) and (d) out of **which more than one** may be correct.

● ***Ex. 11*** *Let p_n denote the probability of getting n heads, when a fair coin is tossed m times. If p_4, p_5, p_6 are in AP, then values of m can be*

(a) 5 (b) 7 (c) 10 (d) 14

Sol. (b, d) $\because\ p_4 = {}^mC_4\left(\frac{1}{2}\right)^4\left(\frac{1}{2}\right)^{m-4} = {}^mC_4\left(\frac{1}{2}\right)^m$

$$p_5 = {}^mC_5\left(\frac{1}{2}\right)^5\left(\frac{1}{2}\right)^{m-5} = {}^mC_5\left(\frac{1}{2}\right)^m$$

and $$p_6 = {}^mC_6\left(\frac{1}{2}\right)^6\left(\frac{1}{2}\right)^{m-6} = {}^mC_6\left(\frac{1}{2}\right)^m$$

According to the question, p_4, p_5, p_6 are in AP

$$\therefore\quad 2p_5 = p_4 + p_6$$

$$\Rightarrow\quad 2\times {}^mC_5\left(\frac{1}{2}\right)^m = {}^mC_4\left(\frac{1}{2}\right)^m + {}^mC_6\left(\frac{1}{2}\right)^m$$

or $$2\times {}^mC_5 = {}^mC_4 + {}^mC_6$$

or $$2 = \frac{{}^mC_4}{{}^mC_5} + \frac{{}^mC_6}{{}^mC_5} \Rightarrow 2 = \frac{5}{m-5+1} + \frac{m-6+1}{6}$$

$$\Rightarrow\quad 2 = \frac{5}{m-4} + \frac{m-5}{6} \Rightarrow (m^2-2)\,m + 98 = 0$$

$$\Rightarrow\quad (m-14)(m-7) = 0$$

$$\Rightarrow\quad m = 7 \text{ or } 14$$

● ***Ex. 12*** *A random variable X follows binomial distribution with mean a and variance b. Then,*

(a) $a > b > 0$ (b) $\frac{a}{b} > 1$

(c) $\frac{a^2}{a-b}$ is an integer (d) $\frac{a^2}{a+b}$ is an integer

Sol. (a, b, c) Suppose, $X \sim B(n, p)$ i.e. $(q+p)^n$

Here, $np = a$ and $npq = b$

$$\therefore\quad q = \frac{b}{a}, \text{ then } p = 1-q = 1-\frac{b}{a}$$

Now, $0 < q < 1 \Rightarrow 0 < \frac{b}{a} < 1 \Rightarrow a > b > 0$ [alternate (a)]

and $\frac{a}{b} > 1$ [alternate (b)]

Also, $\frac{a^2}{a-b} = \frac{(np)^2}{np-npq} = \frac{np}{1-q} = \frac{np}{p} = n =$ Integer [alternate (c)]

● ***Ex. 13*** *If $A_1, A_2, ..., A_n$ are n independent events, such that $P(A_i) = \frac{1}{i+1}$, $i = 1, 2, .., n$, then the probability that none of $A_1, A_2, A_3, ..., A_n$ occur, is*

(a) $\frac{n}{n+1}$ (b) $\frac{1}{n+1}$

(c) less than $\frac{1}{n}$ (d) greater than $\frac{1}{n+2}$

Sol. (b, c, d) $\because A_1, A_2, A_3, \ldots, A_n$ are n independent, then

Required probability $= P(A_1' \cap A_2' \cap A_3' \cap \ldots \cap A_n')$

$= P(A_1').P(A_2').P(A_3') \ldots P(A_n')$

$= (1 - P(A_1))(1 - P(A_2))(1 - P(A_3)) \ldots (1 - P(A_n))$

$= \left(1 - \frac{1}{2}\right)\left(1 - \frac{1}{3}\right)\left(1 - \frac{1}{4}\right) \ldots \left(1 - \frac{1}{n+1}\right)$

$= \frac{1}{2} \times \frac{2}{3} \times \frac{3}{4} \times \ldots \times \frac{n}{n+1} = \frac{1}{n+1}$

$\because n + 2 > n + 1 > n; \ \therefore \ \frac{1}{n+2} < \frac{1}{n+1} < \frac{1}{n}$

● ***Ex. 14*** *A and B are two events, such that* $P(A \cup B) \geq \frac{3}{4}$ *and* $\frac{1}{8} \leq P(A \cap B) \leq \frac{3}{8}$, *then*

(a) $P(A) + P(B) \leq \frac{11}{8}$ (b) $P(A) \cdot P(B) \leq \frac{3}{8}$

(c) $P(A) + P(B) \geq \frac{7}{8}$ (d) None of these

Sol. (a, c) $\because \ \frac{3}{4} \leq P(A \cup B) \leq 1$

$\Rightarrow \quad \frac{3}{4} \leq P(A) + P(B) - P(A \cap B) \leq 1$

As the minimum value of $P(A \cap B) = \frac{1}{8}$, we get

$P(A) + P(B) - \frac{1}{8} \geq \frac{3}{4} \Rightarrow P(A) + P(B) \geq \frac{7}{8}$ [alternate (c)]

As the maximum value of $P(A \cap B) = \frac{3}{8}$, we get

$P(A) + P(B) - \frac{3}{8} \leq 1 \Rightarrow P(A) + P(B) \leq \frac{11}{8}$ [alternate (a)]

● ***Ex. 15*** *A, B, C and D cut a pack of* 52 *cards successively in the order given. If the person who cuts a spade first receives* ₹ 350, *then the expectations of*

(a) B is ₹ 96 (b) D is ₹ 54

(c) $(A + C)$ is ₹ 200 (d) $(B - D)$ is ₹ 56

Sol. (a, b, c) Let E be the event of any one cutting a spade in one cut and let S be the sample space, then

$n(E) = {}^{13}C_1 = 13$ and $n(S) = {}^{52}C_1 = 52$

$\therefore \quad p = P(E) = \frac{n(E)}{n(S)} = \frac{1}{4}$ and $q = p(\bar{E}) = 1 - p = \frac{3}{4}$

The probability of A winning (when A starts the game)

$$= p + q^4 p + q^8 p + \ldots \infty = \frac{p}{1 - q^4} = \frac{\frac{1}{4}}{1 - \left(\frac{3}{4}\right)^4} = \frac{64}{175}$$

$\therefore \quad E(A) = ₹\,350 \times \frac{64}{175} = ₹\,128$

$E(B) = ₹128 \times q = ₹128 \times \frac{3}{4} = ₹\,96$

$E(C) = ₹96 \times q = ₹96 \times \frac{3}{4} = ₹\,72$

and $E(D) = ₹72 \times q = ₹72 \times \frac{3}{4} = ₹\,54$

$\therefore \ E(A + C) = ₹\,200$ and $E(B - D) = ₹\,42$.

JEE Type Solved Examples : Passage Based Questions

■ This section contains **3 solved passages** based upon each of the passage **3 multiple choice** examples have to be answered. Each of these examples has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I

(Ex. Nos. 16 to 18)

Each coefficient in the equation $ax^2 + bx + c = 0$ *is determined by throwing an ordinary die.*

16. *The probability that roots of quadratic are real and distinct, is*

(a) $\frac{5}{216}$ (b) $\frac{19}{108}$ (c) $\frac{173}{216}$ (d) $\frac{17}{108}$

Sol. (b) For roots of $ax^2 + bx + c = 0$ to be real and distinct,

$$b^2 - 4ac > 0$$

Value of b	Possible values of a and c
1, 2	No values of a and c
3	(1, 1), (1, 2), (2, 1)
4	(1, 1), (1, 2), (2, 1), (1, 3), (3, 1)
5	(1, 1), (1, 2), (2, 1), (1, 3), (3, 1), (2, 2), (1, 4), (4, 1), (1, 5), (5, 1), (2, 3), (3, 2), (1, 6), (6, 1)
6	(1, 1), (1, 2), (2, 1), (1, 3), (3, 1), (2, 2), (1, 4), (4, 1), (1, 5), (5, 1), (2, 3), (3, 2), (1, 6), (6, 1), (2, 4), (4, 2)

If E be the event of favourable cases, then $n(E) = 38$

Total ways, $n(S) = 6 \times 6 \times 6 = 216$

Hence, the required probability, $p_1 = \frac{n(E)}{n(S)} = \frac{38}{216} = \frac{19}{108}$

17. *The probability that roots of quadratic are equal, is*

(a) $\frac{5}{216}$ (b) $\frac{7}{216}$ (c) $\frac{11}{216}$ (d) $\frac{17}{216}$

Sol. (a) For roots of $ax^2 + bx + c = 0$ to be equal $b^2 = 4ac$

i.e. b^2 must be even.

Value of b	Possible values of a and c
2	(1, 1)
4	(2, 2), (1, 4), (4, 1)
6	(3, 3)

If E be the event of favourable cases, then $n(E) = 5$

Total ways, $n(S) = 6 \times 6 \times 6 = 216$

Hence, the required probability, $p_2 = \dfrac{n(E)}{n(S)} = \dfrac{5}{216}$

18. *The probability that roots of quadratic are imaginary, is*

(a) $\dfrac{103}{216}$ (b) $\dfrac{133}{216}$ (c) $\dfrac{157}{216}$ (d) $\dfrac{173}{216}$

Sol. (d) Let p_3 = Probability that roots of $ax^2 + bx + c = 0$ are imaginary

$= 1 -$ (Probability that roots of $ax^2 + bx + c = 0$ are real)

$= 1 - (p_1 + p_2)$ [from above]

$= 1 - \dfrac{43}{216} = \dfrac{173}{216}$

Passage II

(Ex. Nos. 19 to 21)

A box contains n coins. Let $P(E_i)$ be the probability that exactly i out of n coins are biased. If $P(E_i)$ is directly proportional to $i(i+1); 1 \le i \le n$.

19. *Proportionality constant k is equal to*

(a) $\dfrac{3}{n(n^2+1)}$ (b) $\dfrac{1}{(n^2+1)(n+2)}$

(c) $\dfrac{3}{n(n+1)(n+2)}$ (d) $\dfrac{1}{(n+1)(n+2)(n+3)}$

Sol. (c) $\because P(E_i) \propto i(i+1)$

$\Rightarrow P(E_i) = k\,i(i+1)$, where k is proportionality constant.

We have, $P(E_1) + P(E_2) + P(E_3) + \ldots + P(E_n) = 1$

($\because E_1, E_2, \ldots, E_n$ are mutually exclusive and exhaustive events)

$$\Rightarrow \sum_{i=1}^{n} P(E_i) = 1$$

$$\Rightarrow k \sum_{i=1}^{n} (i^2 + i) = 1$$

$$\Rightarrow k\,[\Sigma n^2 + \Sigma n] = 1$$

$$\Rightarrow k\left[\frac{n(n+1)(2n+1)}{6} + \frac{n(n+1)}{2}\right] = 1$$

$$\therefore \quad k = \frac{3}{n(n+1)(n+2)} \quad \ldots(i)$$

20. *If P be the probability that a coin selected at random is biased, then $\lim_{x \to \infty} P$ is*

(a) $\dfrac{1}{4}$ (b) $\dfrac{3}{4}$ (c) $\dfrac{3}{5}$ (d) $\dfrac{7}{8}$

Sol. (b) $\because P = P(E) = \sum_{i=1}^{n} \cdot P(E_i)\, P\left(\dfrac{E}{E_i}\right)$ ...(ii)

$$= \sum_{i=1}^{n} k\, i(i+1) . \frac{i}{n}$$

$$= \frac{k}{n} \sum_{i=1}^{n} (i^3 + i^2) = \frac{k}{n} [\Sigma n^3 + \Sigma n^2]$$

$$= \frac{k}{n}\left[\left(\frac{n(n+1)^2}{2}\right) + \frac{n(n+1)(2n+1)}{6}\right]$$

$$= \frac{k\,(n+1)\,(n+2)\,(3n+1)}{12}$$

$$= \frac{3}{n(n+1)(n+2)} \cdot \frac{(n+1)\,(n+2)\,(3n+1)}{12}$$ [from Eq. (i)]

$$= \frac{3n+1}{4n} = \frac{3}{4} + \frac{1}{4n}$$

$$\therefore \lim_{n \to \infty} P = \lim_{n \to \infty}\left[\frac{3}{4} + \frac{1}{3n}\right] = \frac{3}{4} + 0 = \frac{3}{4}$$

21. *If a coin is selected at random is found to be biased, the probability that it is the only biased coin the box, is*

(a) $\dfrac{1}{(n+1)(n+2)(n+3)(n+4)}$ (b) $\dfrac{12}{n(n+1)(n+2)(3n+1)}$

(c) $\dfrac{24}{n(n+1)(n+2)(2n+1)}$ (d) $\dfrac{24}{n(n+1)(n+2)(3n+1)}$

Sol. (d) $P\left(\dfrac{E_1}{E}\right) = \dfrac{P(E_1) \cdot P\left(\dfrac{E}{E_1}\right)}{\sum_{i=1}^{n} P(E_i) \cdot P\left(\dfrac{E}{E_i}\right)} = \dfrac{2k \times \dfrac{1}{n}}{P(E)}$ [from Eq. (ii)]

$$= \frac{\dfrac{2k}{n}}{\left(\dfrac{3n+1}{4n}\right)} = \frac{8k}{(3n+1)}$$

$$= \frac{24}{n\,(n+1)\,(n+2)\,(3n+1)}$$ [from Eq. (i)]

Passage III

(Ex. Nos. 22 to 24)

Let S be the set of the first 21 natural numbers, then the probability of

22. *Choosing $\{x, y\} \subseteq S$, such that $x^3 + y^3$ is divisible by 3, is*

(a) $\dfrac{1}{6}$ (b) $\dfrac{1}{5}$ (c) $\dfrac{1}{4}$ (d) $\dfrac{1}{3}$

Sol. (d) $\because S = \{1, 2, 3, 4, 5, \ldots, 21\}$

Total number of ways choosing x and y is

$${}^{21}C_2 = \frac{21 \cdot 20}{1 \cdot 2} = 210$$

Now, arrange the given numbers as below:

1	4	7	10	13	16	19
2	5	8	11	14	17	20
3	6	9	12	15	18	21

We see that, $x^3 + y^3 = (x + y)(x^2 - xy + y^2)$ will be divisible by 3 in the following cases:

One of two numbers belongs to the first row and one of the two numbers belongs to the second row or both numbers occurs in third row.

$\therefore$ Number of favourable cases $= ({}^7C_1)({}^7C_1) + {}^7C_2 = 70$

$\therefore$ Required probability $= \frac{70}{210} = \frac{1}{3}$

23. *Choosing $\{x, y, z\} \subseteq S$, such that x, y, z are in AP, is*

(a) $\frac{5}{133}$ (b) $\frac{10}{133}$ (c) $\frac{3}{133}$ (d) $\frac{2}{133}$

Sol. (b) Given, x, y, z are in AP

$\therefore \quad 2y = x + z$

It is clear that sum of x and z is even.

$\therefore$ x and z both are even or odd out of set S.

i.e., 11 numbers (1, 3, 5,..., 21) are odd and 10 numbers (2, 4, 6,..., 20) are even.

$\therefore$ Number of favourable cases

$$= {}^{21}C_2 + {}^{10}C_2 = \frac{11 \cdot 10}{1 \cdot 2} + \frac{10 \cdot 9}{1 \cdot 2} = 100$$

and total number of ways choosing x, y and z is

$${}^{21}C_3 = \frac{21 \cdot 20 \cdot 19}{1 \cdot 2 \cdot 3} = 1330$$

$\therefore$ Required probability $= \frac{100}{1330} = \frac{10}{133}$

24. *Choosing $\{x, y, z\} \subseteq S$, such that x, y, z are not consecutive, is*

(a) $\frac{17}{70}$ (b) $\frac{34}{70}$ (c) $\frac{51}{70}$ (d) $\frac{34}{35}$

Sol. (c) Given, x, $y$and z are not consecutive.

$\therefore$ Number of favourable ways $= {}^{21-3+1}C_3$

$$= {}^{19}C_3 = \frac{19 \cdot 18 \cdot 17}{1 \cdot 2 \cdot 3} = 969$$

and total number of ways $= {}^{21}C_3 = \frac{21 \cdot 20 \cdot 19}{1 \cdot 2 \cdot 3} = 1330$

$\therefore$ Required probability $= \frac{969}{1330} = \frac{51}{70}$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **2 examples.** The answer to each example is a **single digit integer** ranging from **0** to **9** (both inclusive).

● **Ex. 25** *The altitude through A of ΔABC meets BC at D and the circumscribed circle at E. If $D \equiv (2, 3)$, $E \equiv (5, 5)$, the ordinate of the orthocentre being a natural number. If the probability that the orthocentre lies on the lines $y = 1;\ y = 2;\ y = 3 \ldots\ldots y = 10$ is $\frac{m}{n}$, where m and n are relative primes, the value of $m + n$ is*

Sol. (8) Let the orthocentre be $O(x, y)$.

It is clear from the OE is perpendicular bisector of line BC.

$\therefore \quad OD = DE$

$\Rightarrow \sqrt{(x-2)^2 + (y-3)^2} = \sqrt{(5-2)^2 + (5-3)^2}$

$\Rightarrow \quad (x-2)^2 + (y-3)^2 = (5-2)^2 + (5-3)^2$

$\Rightarrow \quad x^2 + y^2 - 4x - 6y = 0 \Rightarrow x = 2 \pm \sqrt{13 - (y-3)^2}$

$\Rightarrow y$ can take the values as 1, 2, 3, 4, 5, 6

$\therefore \quad$ Required probability $= \frac{6}{10} = \frac{3}{5} = \frac{m}{n}$ [given]

$\Rightarrow \quad m = 3$ and $n = 5$

$\therefore \quad m + n = 8$

● **Ex. 26** *The digits 1, 2, 3, 4, 5, 6, 7, 8 and 9 are written in random order to form a nine digit number. Let p be the probability that this number is divisible by 36, the value of $9p$ is*

Sol. (2) $\because$ $1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9 = 45$, a number consisting all these digits will be divisible by 9. Thus, the number will be divisible by 36, if and only if it is divisible by 4. The number formed by its last two digits must be divisible by 4. The possible values of the last pair to the following:

12, 16, 24, 28, 32, 36, 48, 52, 56, 64, 68, 72, 76, 84, 92, 96.

i.e., There are 16 ways of choosing last two digits.

The remaining digits can be arranged in ${}^7P_7 = 7!$ ways.

Therefore, number of favourable ways $= 16 \times 7!$

and number of total ways $= 9!$

$\therefore$ Required probability, $p = \frac{16 \times 7!}{9!} = \frac{16}{9 \times 8} = \frac{2}{9}$

$\Rightarrow \quad 9p = 2$

JEE Type Solved Examples : Matching Type Questions

■ This section contains **2 examples.** Examples 27 and 28 have four statements (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II.** Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II.**

● ***Ex. 27*** *If n positive integers taken at random are multiplied together.*

	Column I		Column II
(A)	The probability that the last digit is 1, 3, 7 or 9 is $P(n)$, then 100 $P(2)$ is divisible by	(p)	3
(B)	The probability that the last digit is 2, 4, 6 or 8 is $Q(n)$, then 100 $Q(2)$ is divisible by	(q)	4
(C)	The probability that the last digit is 5 is $R(n)$, then 100 $R(2)$ is divisible by	(r)	6
(D)	The probability that the last digit is zero is $S(n)$, then 100 $S(2)$ is divisible by	(s)	9

Sol. A → (q); B → (p, q, r); C → (p, s); D → (p, s)

Let n positive integers be $x_1, x_2, x_3, \ldots, x_n$

Let $a = x_1 . x_2 . x_3 \ldots x_n$

Since, the last digit in each of the numbers $x_1, x_2, \ldots, x_n$ can be any one of the digits

0, 1, 2,..., 9 (total 10)

$\therefore \quad n(S) = 10^n$

Let E_1, E_2, E_3 and E_4 are the events given in A, B, C and D, respectively.

(A) $n(E_1) = 4^n \Rightarrow P(E_1) = \left(\frac{4}{10}\right)^n = P(n)$ [given]

$\therefore \quad 100\, P(2) = 16$

(B) $n(E_2) = n$ (last digit is 1 or 2 or 3 or 4 or 6 or 7 or 8 or 9) $- n(E_1) = 8^n - 4^n$

$\Rightarrow \quad P(E_2) = \frac{8^n - 4^n}{10^n} = Q(n)$ [given]

$\therefore \quad 100\, Q(2) = 64 - 16 = 48$

(C) $n(E_3) = n$ (last digit is 1 or 3 or 5 or 7 or 9) $- n(E_1)$

$= 5^n - 4^n$

$\Rightarrow \quad P(E_3) = \frac{5^n - 4^n}{10^n} = R(n)$ [given]

$\therefore \; 100\, R(2) = 25 - 16 = 9$

(D) $n(E_4) = n(S) - n$ (last digit is 1 or 2 or 3 or 4 or 6 or 7 or 8 or 9) $- n(E_3) = 10^n - 8^n - (5^n - 4^n)$

$\therefore \quad P(E_4) = \frac{10^n - 8^n - 5^n + 4^n}{10^n} = S(n)$ [given]

$\therefore \quad 100\, S(2) = 27$

● ***Ex. 28*** *If A and B are two independent events, such that* $P(A) = \frac{1}{3}$ *and* $P(B) = \frac{1}{4}$.

	Column I		Column II
(A)	If $P\left(\frac{A}{B}\right) = \lambda_1$, then $12\lambda_1$ is	(p)	a prime number
(B)	If $P\left(\frac{A}{A \cup B}\right) = \lambda_2$, then $9\lambda_2$ is	(q)	a composite number
(C)	If $P[(A \cap \bar{B}) \cup (\bar{A} \cap B)] = \lambda_3$, then $12\lambda_3$ is	(r)	a natural number
(D)	If $P(\bar{A} \cup B) = \lambda_4$, then $12\lambda_4$ is	(s)	a perfect number

Sol. A → (q, r); B (q, r, s); C → (p, r); D → (q, r)

$\because$ A and B are independent events.

$\therefore \quad P(A \cap B) = P(A) \cdot P(B) = \frac{1}{12},$

$P(A \cap \bar{B}) = P(A) \cdot P(\bar{B}) = \frac{1}{3} \times \left(1 - \frac{1}{4}\right) = \frac{1}{4},$

$P(\bar{A} \cap B) = P(\bar{A}) \cdot P(B) = \left(1 - \frac{1}{3}\right) \cdot \frac{1}{4} = \frac{1}{6}$

(A) $P\left(\frac{A}{B}\right) = \frac{P(A \cap B)}{P(B)} = \frac{\frac{1}{12}}{\frac{1}{4}} = \frac{1}{3} = \lambda_1$ [given]

$\therefore \quad 12\lambda_1 = 4$ [natural number and composite number]

(B) $P\left(\frac{A}{A \cup B}\right) = \frac{P(A \cap (A \cup B))}{P(A \cup B)}$

$= \frac{P(A)}{P(A \cup B)} = \frac{P(A)}{P(A) + P(B)} - P(A \cap B)$

$= \frac{\frac{1}{3}}{\frac{1}{3} + \frac{1}{4} - \frac{1}{12}} = \frac{2}{3} = \lambda_2$ [given]

$\therefore \quad 9\lambda_2 = 6$

[natural number, composite number and perfect number]

(C) $P(A \cap \bar{B}) \cup (\bar{A} \cap B)) = P(A \cap \bar{B}) + P(\bar{A} \cap B)$

$= \frac{1}{4} + \frac{1}{6} = \frac{5}{12} = \lambda_3$ [given]

$\therefore \quad 12\lambda_3 = 5$ [prime number and natural number]

(D) $P(\bar{A} \cup B) = P(\bar{A}) + P(B) - P(\bar{A} \cap B)$

$= \left(1 - \frac{1}{3}\right) + \frac{1}{4} - \frac{1}{6} = \frac{3}{4} = \lambda_4$ [given]

$\therefore \quad 12\lambda_4 = 9$ [natural number and composite number]

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** Example numbers 29 and 30 are Assertion-Reason type examples. Each of these examples contains two statements:
Statement-1 (Assertion) and **Statement-2** (Reason)
Each of these examples also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

● ***Ex. 29.*** *A man P speaks truth with probability p and another man Q speaks truth with probability* $2p$.

Statement-1 *If P and Q contradict each other with probability* $\frac{1}{2}$*, then there are two values of p.*

Statement-2 *A quadratic equation with real coefficients has two real roots.*

Sol. (c) Let E_1 be the event that P speaks the truth, then $P(E_1) = p$ and let E_2 be the event that Q speaks the truth, then $P(E_2) = 2p$.

Statement-1 If P and Q contradict each other with probability $\frac{1}{2}$, then $P(E_1)\cdot P(E_2') + P(E_1')\cdot P(E_2) = \frac{1}{2}$

$\Rightarrow p\cdot(1-2p) + (1-p)\cdot 2p = \frac{1}{2} \Rightarrow 8p^2 - 6p + 1 = 0$

$\Rightarrow (2p-1)(4p-1) = 0 \Rightarrow p = \frac{1}{2}$ and $p = \frac{1}{4}$

$\therefore$ Statement-1 is true.

Statement-2 Let quadratic equation $ax^2 + bx + c = 0$, where $a, b, c \in R$

If $b^2 - 4ac < 0$

then, roots are imaginary.

$\therefore$ Statement-2 is false.

● ***Ex. 30*** *A fair die thrown twice. Let* (a, b) *denote the outcome in which the first throw shows a and the second shows b. Let A and B be the following two events:*

$A = \{(a, b) | \ a \text{ is even}\}$, $B = \{(a, b) | \ b \text{ is even}\}$

Statement-1 If $C = \{(a, b) | \ a + b \text{ is odd}\}$, then $P(A \cap B \cap C) = \frac{1}{8}$.

Statement-2 If $D = \{(a, b) | \ a + b \text{ is even}\}$, then $P[(A \cap B \cap D) | (A \cup B)] = \frac{1}{3}$

Sol. (c) If a and b are both even, then $a + b$ is even, therefore $P(A \cap B \cap C) = 0$

$\therefore$ Statement-1 is false.

Also, $P(A) = \frac{1}{2}$, $P(B) = \frac{1}{2}$, $P(A \cap B) = \frac{1}{2} \times \frac{1}{2} = \frac{1}{4}$

$\therefore P(A \cup B) = P(A) + P(B) - P(A \cap B)$
$= \frac{1}{2} + \frac{1}{2} - \frac{1}{4} = \frac{3}{4}$

$\therefore P[(A \cap B \cap D) | (A \cup B)] = \frac{P((A \cap B \cap D) \cap (A \cup B))}{P(A \cup B)}$

$= \frac{P(A \cap B)}{P(A \cup B)} = \frac{\frac{1}{4}}{\frac{3}{4}} = \frac{1}{3}$ $[\because A \cap B \subseteq D]$

$\therefore$ Statement-2 is true.

Subjective Type Examples

■ In this section, there are **24 subjective** solved examples.

● ***Ex. 31*** *Three critics review a book. Odds in favour of the book are* $5:2$, $4:3$ *and* $3:4$ *respectively for the three critics. Find the probability that majority are in favour of the book.*

Sol. Let the critics be E_1, E_2 and E_3. Let $P(E_1)$, $P(E_2)$ and $P(E_3)$ denotes the probabilities of the critics E_1, E_2 and E_3 to be in favour of the book. Since, the odds in favour of the book for the critics E_1, E_2 and E_3 are $5:2$, $4:3$ and $3:4$, respectively.

$\therefore \quad P(E_1) = \frac{5}{5+2} = \frac{5}{7}$, $P(E_2) = \frac{4}{4+3} = \frac{4}{7}$

and $\quad P(E_3) = \frac{3}{3+4} = \frac{3}{7}$

Clearly, the event of majority being in favour = the event of atleast two critics being in favour

$\therefore$ The required probability

$= P(E_1E_2\bar{E}_3) + P(\bar{E}_1E_2E_3) + P(E_1\bar{E}_2E_3) + P(E_1E_2E_3)$

$= P(E_1)\cdot P(E_2)\cdot P(\bar{E}_3) + P(\bar{E}_1)\cdot P(E_2)\cdot P(E_3)$

$+ P(E_1)\cdot P(\bar{E}_2)\cdot P(E_3) + P(E_1)\cdot P(E_2)\cdot P(E_3)$

$[\because E_1, E_2$ and E_3 are independent$]$

$$= \frac{5}{7}\cdot\frac{4}{7}\cdot\left(1-\frac{3}{7}\right)+\left(1-\frac{5}{7}\right)\cdot\frac{4}{7}\cdot\frac{3}{7}+\frac{5}{7}\cdot\left(1-\frac{4}{7}\right)\cdot\frac{3}{7}+\frac{5}{7}\cdot\frac{4}{7}\cdot\frac{3}{7}$$

$$= \frac{1}{7^3}[80+24+45+60] = \frac{209}{343}$$

● ***Ex. 32*** *A has 3 shares is a lottery containing 3 prizes and 9 blanks; B has 2 shares in a lottery containing 2 prizes and 6 blanks. Compare their chances of success.*

Sol. Let E_1 and E_2 be the events of success of A and B, respectively. Therefore, E'_1 and E'_2 are the events of unsuccess of A and B, respectively.

Since, A has 3 shares in a lottery containing 3 prizes and 9 blanks, therefore A will draw 3 tickets out of 12 tickets (3 prizes + 9 blanks). Then, A will get success if he draws atleast one prize out of 3 draws. Similarly, B will get success if he draws atleast one prize out of 2 draws.

$$\therefore \quad P(E'_1) = \frac{{}^9C_3}{{}^{12}C_3} = \frac{\frac{9\cdot8\cdot7}{1\cdot2\cdot3}}{\frac{12\cdot11\cdot10}{1\cdot2\cdot3}} = \frac{21}{55}$$

$$\therefore \quad P(E_1) = 1 - P(E'_1) = 1 - \frac{21}{55} = \frac{34}{55}$$

$$\text{Again,} \quad P(E'_2) = \frac{{}^6C_2}{{}^8C_2} = \frac{\frac{6\cdot5}{1\cdot2}}{\frac{8\cdot7}{1\cdot2}} = \frac{15}{28}$$

$$\therefore \quad P(E_2) = 1 - P(E'_2) = 1 - \frac{15}{28} = \frac{13}{28}$$

$$\text{Hence,} \quad \frac{P(E_1)}{P(E_2)} = \frac{\frac{34}{55}}{\frac{13}{28}} = \frac{952}{715}$$

$$\therefore \quad P(E_1) : P(E_2) = 952 : 715$$

● ***Ex. 33*** *A bag contains a white and b black balls. Two players A and B alternately draw a ball from the bag, replacing the ball each time after the draw till one of them draws a white ball and wins the game. If A begins the game and the probability of A winning the game is three times that of B, show that $a : b = 2 : 1$.*

Sol. Let E_1 denote the event of drawing a white ball at any draw and E_2 that for a black ball and let E be the event for A winning the game

$$\therefore P(E_1) = \frac{a}{a+b} \text{ and } P(E_2) = \frac{b}{a+b}$$

$$\therefore P(E) = P(E_1 \text{ or } E_2E_2E_1 \text{ or } E_2E_2E_2E_2E_1 \text{ or } \ldots)$$

$$= P(E_1) + P(E_2E_2E_1) + P(E_2E_2E_2E_2E_1) + \ldots$$

$$= P(E_1) + P(E_2)\,P(E_2)\,P(E_1) + P(E_2)\,P(E_2)\,P(E_2)\,P(E_2)\,P(E_1) + \ldots$$

[$\because E_1$ and E_2 are independent]

$$= \frac{P(E_1)}{1-\{P(E_2)\}^2} \qquad \text{[sum of infinite GP]}$$

$$= \frac{\frac{a}{a+b}}{1-\left(\frac{b}{a+b}\right)^2} = \frac{a(a+b)}{a^2+2ab} \quad \therefore \; P(E) = \frac{a+b}{a+2b}$$

Then, $P(E')$ is the probability for B winning the game

$$\therefore \quad P(E') = 1 - P(E) = 1 - \frac{a+b}{a+2b} = \frac{b}{a+2b}$$

According to the problem, $P(E) = 3P(E')$

$$\Rightarrow \qquad \frac{a+b}{a+2b} = \frac{3b}{a+2b} \quad \Rightarrow \alpha + \beta = 3\beta \Rightarrow \alpha = 2\beta$$

$$\therefore \qquad \frac{a}{b} = \frac{2}{1} \qquad \Rightarrow \alpha : \beta = 2 : 1$$

● ***Ex. 34*** *Five persons entered the lift cabin on the ground floor of an 8 floors house. Suppose that each of them, independently and with equal probability can leave the cabin at any floor beginning with the first. Find out the probability of all five persons leaving at different floors.*

Sol. Let S be the sample space and E be the event that the five persons get down at different floors.

Total number of floors excluding the ground floor = 7

Since, each of the 5 persons can get down at any one of the 7 floors in 7 ways.

$\therefore$ $n(S)$ = Total number of ways in which the 5 persons can get down = 7^5

and $n(E)$ = number of ways in which the 5 persons can get down at 5 different floors out of 7 floors = ${}^7P_5$

$\therefore$ Required probability, $P(E) = \dfrac{n(E)}{n(S)} = \dfrac{{}^7P_5}{7^5}$

● ***Ex. 35*** *Let X be a set containing n elements. Two subsets A and B of X are chosen at random. Find the probability that $A \cup B = X$.*

Sol. Let $X = \{x_1, x_2, \ldots, x_n\}$

For each $x_i \in X$ $(1 \le i \le n)$, we have the following four choices

(i) $x_i \in A$ and $x_i \in B$ (ii) $x_i \in A$ and $x_i \notin B$

(iii) $x_i \notin A$ and $x_i \in B$ (iv) $x_i \notin A$ and $x_i \notin B$

Let S be the sample space and E be the event favourable for the occurrence of $A \cup B = X$.

$$\therefore \qquad n(S) = 4^n$$

$$\text{and} \qquad n(E) = 3^n \qquad [\because \text{case (iv)} \notin X]$$

Hence, the required probability,

$$P(E) = \frac{n(E)}{n(S)} \Rightarrow = \frac{3^n}{4^n} = \left(\frac{3}{4}\right)^n$$

● **Ex. 36** *Two persons each makes a single throw with a pair of dice. Find the probability that the throws are unequal.*

Sol. Let E be the event that the throws of the two persons are unequal. Then, E' be the event that the throws of the two persons are equal.

$\therefore$ The total number of cases for E' is $(36)^2$

i.e., $n(S) = (36)^2$ [$\because S$ be the sample space]

We now proceed to find out the number of favourable cases for E'. Suppose

$$(x + x^2 + x^3 + \ldots + x^6)^2 = a_2 x^2 + a_3 x^3 + \ldots + a_{12} x^{12}$$

The number of favourable ways of $E' = a_2^2 + a_3^2 + \ldots + a_{12}^2$

$\therefore$ $n(E')$ = coefficient of constant term in

$$(a_2 x^2 + a_3 x^3 + \ldots + a_{12} x^{12}) \times \left(\frac{a_2}{x^2} + \frac{a_3}{x^3} + \ldots + \frac{a_{12}}{x^{12}}\right)$$

$$= \text{coefficient of constant term in } \frac{(1 - x^6)^2}{(1 - x)^2} \times \frac{\left(1 - \frac{1}{x^6}\right)^2}{\left(1 - \frac{1}{x}\right)^2}$$

$$= \text{coefficient of } x^{10} \text{ in } (1 - x^6)^4 (1 - x)^{-4}$$

$$= \text{coefficient of } x^{10} \text{ in } (1 - 4x^6 + \ldots)(1 + {}^4C_1 x + {}^5C_2 x^2 + \ldots + {}^{13}C_{10} x^{10} + \ldots)$$

$$= {}^{13}C_{10} - 4 \cdot {}^7C_4$$

$$= {}^{13}C_3 - 4 \cdot {}^7C_3 = \frac{13 \cdot 12 \cdot 11}{1 \cdot 2 \cdot 3} - 4 \cdot \frac{7 \cdot 6 \cdot 5}{1 \cdot 2 \cdot 3} = 146$$

$\therefore$ $P(E') = \dfrac{n(E')}{n(S)} = \dfrac{146}{(36)^2} = \dfrac{73}{648}$

Hence, required probability,

$$P(E) = 1 - P(E') = 1 - \frac{73}{648} = \frac{575}{648}$$

● **Ex. 37** *If X and Y are independent binomial variates $B(5, 1/2)$ and $B(7, 1/2)$, find the value of $P(X + Y = 3)$.*

Sol. We have,

$$P(X + Y = 3) = P(X = 0, Y = 3) + P(X = 1, Y = 2) + P(X = 2, Y = 1) + P(X = 3, Y = 0)$$

$$= P(X = 0)\, P(Y = 3) + P(X = 1)\, P(Y = 2) + P(X = 2)\, P(Y = 1) + P(X = 3)\, P(Y = 0)$$

[$\because X$ and Y are independent]

$$= {}^5C_0 \left(\frac{1}{2}\right)^5 \cdot {}^7C_3 \left(\frac{1}{2}\right)^7 + {}^5C_1 \left(\frac{1}{2}\right)^5 {}^7C_2 \left(\frac{1}{2}\right)^7 + {}^5C_2 \left(\frac{1}{2}\right)^5 {}^7C_1 \left(\frac{1}{2}\right)^7 + {}^5C_3 \left(\frac{1}{2}\right)^5 {}^7C_0 \left(\frac{1}{2}\right)^7$$

$$= \left(\frac{1}{2}\right)^{12} [(1)(35) + (5)(21) + (10)(7) + (10)(1)]$$

$$= \frac{220}{2^{12}} = \frac{55}{1024}$$

● **Ex. 38** *If $a \in [-20, 0]$, find the probability that the graph of the function $y = 16x^2 + 8(a + 5)\, x - 7a - 5$ is strictly above the X-axis.*

Sol. Since, the graph $y = 16x^2 + 8(a + 5)\, x - 7a - 5$ is strictly above the X-axis, therefore $y > 0$ for all x

$\Rightarrow$ $16x^2 + 8(a + 5)\, x - 7a - 5 > 0, \forall x$

$\therefore$ Discriminant < 0

$\Rightarrow$ $64(a + 5)^2 - 4 \cdot 16(-7a - 5) < 0$

$\Rightarrow a^2 + 17a + 30 < 0 \Rightarrow (a + 15)(a + 2) < 0$

$\Rightarrow$ $-15 < a < -2$

$\therefore$ Required probability $= \dfrac{\int_{-15}^{-2} dx}{\int_{-20}^{0} dx} = \dfrac{13}{20}$

● **Ex. 39** *3 distinct integers are selected at random from* 1, 2, 3,..., 20. *Find out the probability that the sum is divisible by* 5.

Sol. The number of wayds choosing 3 distinct integers from 1, 2, 3, ..., 20 is

$${}^{20}C_3 = \frac{20 \cdot 19 \cdot 18}{1 \cdot 2 \cdot 3} = 20 \times 57 = 1140$$

Now, arrange the given numbers as below:

1	6	11	16
2	7	12	17
3	8	13	18
4	9	14	19
5	10	15	20

We see that the sum of three digits divisible by 5 in the following cases :

Two number from 1st row and one number from 3rd row or one number from 2nd row and two numbers from 4th row or three numbers from 5th row or one number from each (1st row, 4th row, 5th row) or one number from each (2nd row, 3rd row, 5th row).

Then, the number of favourable ways

$$= {}^4C_2 \times {}^4C_1 + {}^4C_1 \times {}^4C_2 + {}^4C_3 + {}^4C_1 \times {}^4C_1 \times {}^4C_1 + {}^4C_1 \times {}^4C_1 \times {}^4C_1$$

$$= 24 + 24 + 4 + 64 + 64 = 180$$

Hence, the required probability $= \dfrac{180}{1140} = \dfrac{3}{19}$

Note

If divisible by 4, then take four rows and if divisible by 3, then take three rows, etc.

● ***Ex. 40*** *5 girls and 10 boys sit at random in a row having 15 chairs numbered as 1 to 15. Find the probability that end seats are occupied by the girls and between any two girls odd number of boys sit.*

Sol. There are four gaps in between the girls where the boys can sit. Let the number of boys in these gaps be $2a+1$, $2b+1$, $2c+1$, $2d+1$, then

$$2a+1+2b+1+2c+1+2d+1=10$$

or $$a+b+c+d=3$$

The number of solutions of above equation

$$= \text{coefficient of } x^3 \text{ in } (1-x)^{-4} = {}^6C_3 = 20$$

Thus, boys and girls can sit in $20\times 10!\times 5!$ ways. Total ways $= 15!$

Hence, the required probability $= \dfrac{20\times 10!\times 5!}{15!}$

● ***Ex. 41*** *A four digit number (numbered from 0000 to 9999) is said to be lucky if sum of its first two digits is equal to the sum of its last two digits. If a four-digit number is picked up at random, find the probability that it is lucky number.*

Sol. The total number of ways of choosing a four digit number is $10^4 = 10000$. Let a_k denote the number of distinct non-negative integral solutions of the equation $x+y=k$ $(0\le k\le 18)$

$\therefore$ The number of favourable cases $= a_0^2 + a_1^2 + \ldots + a_{18}^2$

Suppose, $(1+x+x^2+\ldots+x^9)^2$

$$= a_0 + a_1x + a_2x^2 + \ldots + a_{18}x^{18}$$

Thus, $a_0^2 + a_1^2 + \ldots + a_{18}^2$ = coefficient of constant term in

$$(a_0 + a_1x + \ldots + a_{18}x^{18}) \times \left(a_0 + \frac{a_1}{x} + \ldots + \frac{a_{18}}{x^{18}}\right)$$

= coefficient of constant term in

$$(1+x+x^2+\ldots+x^9)^2 \times \left(1+\frac{1}{x}+\frac{1}{x^2}+\ldots+\frac{1}{x^9}\right)^2$$

= coefficient of x^{18} in $(1+x+x^2+\ldots+x^9)^4$

= coefficient of x^{18} in $(1-x^{10})^4\,(1-x)^{-4}$

= coefficient of x^{18} in $(1-4x^{10})\,(1+{}^4C_1x+{}^5C_2x^2+\ldots)$

$= {}^{21}C_{18} - 4\cdot{}^{11}C_8 = 1330 - 660 = 670$

Hence, the required probability $= \dfrac{670}{10000} = 0.067$

● ***Ex. 42***

(i) If four squares are chosen at random on a chess board, find the probability that they lie on a diagonal line.

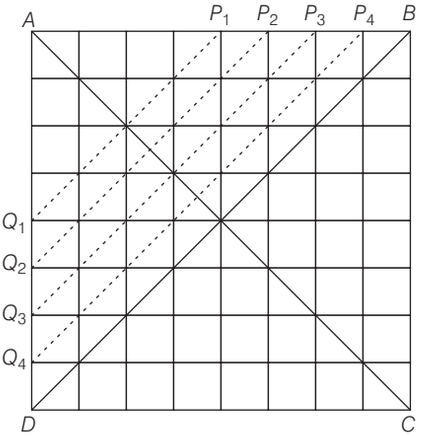
(ii) If two squares are chosen at random on a chess board, what is the probability that they have exactly one corner in common?

(iii) If nine squares are chosen at random on a chess board, what is the probability that they form a square of size 3×3?

Sol. (i) Total number of ways $= {}^{64}C_4$

The chess board can be divided into two parts by a diagonal line BD. Now, if we begin to select four squares from the diagonal P_1Q_1, P_2Q_2, …, BD, then we can find number of squares selected

$$= 2({}^4C_4 + {}^5C_4 + {}^6C_4 + {}^7C_4) = 112$$



Similarly, number of squares for the diagonals chosen parallel to $AC = 112$

$\therefore$ Total favourable ways $= 364$

$\therefore$ Required probability $= \dfrac{364}{{}^{64}C_4}$.

(ii) Total ways $= 64\times 63$

Now, if first square is in one of the four corners, then the second square can be chosen in just one way $= (4)(1) = 4$

If the first square is one of the 24 non-corner squares along the sides of the chess board, the second square can be chosen in two ways $= (24)(2) = 48$.

Now, if the first square is any of the 36 remaining squares, the second square can be chosen in four ways

$$= (36)(4) = 144$$

$\therefore$ Favourable ways $= 4 + 48 + 144 = 196$

$\therefore$ Required probability $= \dfrac{196}{64\times 63} = \dfrac{7}{144}$.

(iii) Total ways $= {}^{64}C_9$

A chess board has 9 horizontal and 9 vertical lines. We see that a square of size 3×3 can be formed by choosing four consecutive horizontal and vertical lines.

Hence, favourable ways $= ({}^6C_1)({}^6C_1) = 36$

$\therefore$ Required probability $= \dfrac{36}{{}^{64}C_9}$.

● ***Ex. 43*** *Out of $(2n+1)$ tickets consecutively numbered, three are drawn at random. Find the chance that the numbers on them are in AP.*

Sol. Let us consider first $(2n+1)$ natural numbers as $(2n+1)$ consecutive numbers.

Let S be the sample space and E be the event of favourable cases.

$$\therefore \quad n(S) = {}^{2n+1}C_3$$

$$= \frac{(2n+1)\,2n(2n-1)}{1\cdot 2\cdot 3} = \frac{n(4n^2-1)}{3}$$

Let the three numbers drawn be a, b, c where $a < b < c$.

Common difference d	Triplets (a, b, c)	Number of Triplets
1	$(1, 2, 3), (2, 3, 4), \ldots, (2n-1, 2n, 2n+1)$	$2n-1$
2	$(1, 3, 5), (2, 4, 6), \ldots, (2n-3, 2n-1, 2n+1)$	$2n-3$
3	$(1, 4, 7), (2, 5, 8), \ldots, (2n-5, 2n-2, 2n+1)$	$2n-5$
...	.....	...
...	.....	...
...	.....	...
$n-1$	$(1, n, 2n-1), (2, n+1, 2n), (3, n+2, 2n+1)$	3
n	$(1, n+1, 2n+1)$	1

$$\therefore \quad n(E) = 1 + 3 + \ldots + (2n-5) + (2n-3) + (2n-1)$$

$$= \frac{n}{2}\{1 + 2n - 1\} = n^2$$

$$\therefore \text{ Required probability, } P(E) = \frac{n(E)}{n(S)}$$

$$= \frac{n^2}{\frac{n(4n^2-1)}{3}} = \frac{3n}{4n^2-1}$$

Aliter Let S be the sample space and E be the event of favourable cases.

$$\therefore \quad n(S) = {}^{2n+1}C_3 = \frac{(2n+1)\,2n(2n-1)}{1\cdot 2\cdot 3} = \frac{n(4n^2-1)}{3}$$

Let the three numbers a, b, c are drawn where $a < b < c$ and given a, b, c are in AP.

$$\therefore \quad b = \frac{a+c}{2} \text{ or } 2b = a + c \qquad \ldots(i)$$

It is clear from Eq. (i), a and c are both odd or both even.

Out of $(2n+1)$ tickets consecutively numbers either $(n+1)$ of them will be odd and n of them will be even (if the numbers begin with an odd number) or $(n+1)$ of them will be even and n of them will be odd (if the number begin with an even number).

$$\therefore \quad n(E) = {}^{n+1}C_2 + {}^{n}C_2$$

$$= \frac{(n+1)\,n}{2} + \frac{n(n-1)}{2} = n^2$$

$\therefore$ Required probability,

$$P(E) = \frac{n(E)}{n(S)} = \frac{n^2}{\frac{n(4n^2-1)}{3}} = \frac{3n}{4n^2-1}$$

● ***Ex. 44*** *Out of $3n$ consecutive integers, three are selected at random. Find the chance that their sum is divisible by 3.*

Sol. Let $3n$ consecutive integers (start with the integer m) are

$$m, m+1, m+2, \ldots, m+3n-1$$

Now, we write these $3n$ numbers in 3 rows as follows :

$$m, m+3, m+6, \ldots, m+3n-3$$

$$m+1, m+4, m+7, \ldots, m+3n-2$$

$$m+2, m+5, m+8, \ldots, m+3n-1$$

The total number of ways of choosing 3 integers out of $3n$ is

$${}^{3n}C_3 = \frac{3n(3n-1)(3n-2)}{1\cdot 2\cdot 3}$$

$$= \frac{n(3n-1)(3n-2)}{2}$$

The sum of the three numbers shall be divisible by 3 if and only if either all the three numbers are from the same row or all the three numbers are from different rows.

Therefore, the number of favourable ways are

$$3({}^{n}C_3) + ({}^{n}C_1)({}^{n}C_1)({}^{n}C_1)$$

$$= \frac{3n(n-1)(n-2)}{1\cdot 2\cdot 3} + n^3 = \frac{3n^3 - 3n^2 + 2n}{2}$$

$\therefore$ The required probability

$$= \frac{\text{Favourable ways}}{\text{Total ways}}$$

$$= \frac{\frac{3n^3 - 3n^2 + 2n}{2}}{\frac{n(3n-1)(3n-2)}{2}}$$

$$= \frac{3n^2 - 3n + 2}{(3n-1)(3n-2)}$$

● ***Ex. 45*** *If $6n$ tickets numbered 0, 1, 2, ..., $6n-1$ are placed in a bag and three are drawn out, show that the chance that the sum of the numbers on them is equal to $6n$ is $\dfrac{3n}{(6n-1)(6n-2)}$.*

Sol. Total number of ways to selecting 3 tickets from $6n$ tickets

$$= {}^{6n}C_3 = n(6n-1)(6n-2) \quad \text{...(i)}$$

For the sum of these tickets of be $6n$, we have the following pattern :

Lowest number	Numbers	Ways
0	$(0, 1, 6n-1), (0, 2, 6n-2) \ldots (0, 3n-1, 3n+1)$	$(3n-1)$
1	$(1, 2, 6n-3), (1, 3, 6n-4) \ldots (1, 3n-1, 3n)$	$(3n-2)$
2	$(2, 3, 6n-5), (2, 4, 6n-6) \ldots (2, 3n-2, 3n)$	$(3n-4)$
3	$(3, 4, 6n-7), (3, 5, 6n-8) \ldots (3, 3n-2, 3n-1)$	$(3n-5)$
4		
5		
:		
$(2n-2)$	$(2n-2, 2n-1, 2n+3), (2n-2, 2n, 2n+2)$	2
$(2n-1)$	$(2n-1, 2n, 2n+1)$	1

Lowest number cannot be greater than $(2n-1)$ as their sum will become $> 6n$.

$\therefore$ Favourable ways $= 1 + 2 + \ldots + (3n-5) + (3n-4) + (3n-2) + (3n-1)$

Adding Ist with last, 2nd with last one, respectively

$$= [1 + 3n - 1] + [2 + 3n - 2] + \ldots \text{upto } n \text{ terms}$$

$$= 3n + 3n + \ldots n \text{ terms}$$

$$= 3n(n) = 3n^2$$

Hence, probability $= \dfrac{3n^2}{n(6n-1)(6n-2)}$

$$= \frac{3n}{(6n-1)(6n-2)}$$

Probability Exercise 1 :
Single Option Correct Type Questions

- This section contains **30 multiple choice questions.** Each question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct

1. There are two vans each having numbered seats, 3 in the front and 4 at the back. There are 3 girls and 9 boys to be seated in the vans. The probability of 3 girls sitting together in a back row on adjacent seats, is

(a) $\frac{1}{13}$ (b) $\frac{1}{39}$ (c) $\frac{1}{65}$ (d) $\frac{1}{91}$

2. The probability that a year chosen at random has 53 Sundays, is

(a) $\frac{1}{7}$ (b) $\frac{2}{7}$ (c) $\frac{3}{28}$ (d) $\frac{5}{28}$

3. The probability that a leap year selected at random contains either 53 Sundays or 53 Mondays, is

(a) $\frac{1}{7}$ (b) $\frac{2}{7}$ (c) $\frac{3}{7}$ (d) $\frac{4}{7}$

4. A positive integer N is selected so as to be $100 < N < 200$. Then, the probability that it is divisible by 4 or 7, is

(a) $\frac{7}{33}$ (b) $\frac{17}{33}$ (c) $\frac{32}{99}$ (d) $\frac{34}{99}$

5. Two numbers a and b are selected at random from $1, 2, 3, \ldots, 100$ and are multiplied. Then, the probability that the product ab is divisible by 3, is

(a) $\frac{67}{150}$ (b) $\frac{83}{150}$ (c) $\frac{67}{75}$ (d) $\frac{8}{75}$

6. Three different numbers are selected at random from the set $A = \{1, 2, 3, \ldots, 10\}$. The probability that the product of two of the numbers is equal to third, is

(a) $\frac{3}{4}$ (b) $\frac{1}{40}$ (c) $\frac{1}{8}$ (d) $\frac{39}{40}$

7. The numbers $1, 2, 3, \ldots, n$ are arranged in a random order. Then, the probability that the digits $1, 2, 3, \ldots, k (k < n)$ appears as neighbours in that order, is

(a) $\frac{1}{n!}$ (b) $\frac{k!}{n!}$ (c) $\frac{(n-k)!}{n!}$ (d) $\frac{(n-k+1)!}{n!}$

8. The numbers $1, 2, 3, \ldots, n$ are arranged in a random order. Then, the probability that the digits $1, 2, 3, \ldots, k (k < n)$ appears as neighbours, is

(a) $\frac{(n-k)!}{n!}$ (b) $\frac{(n-k+1)}{{}^{n}C_{k}}$

(c) $\frac{(n-k)}{{}^{n}C_{k}}$ (d) $\frac{k!}{n!}$

9. Four identical dice are rolled once. The probability that atleast three different numbers appear on them, is

(a) $\frac{13}{42}$ (b) $\frac{17}{42}$ (c) $\frac{23}{42}$ (d) $\frac{25}{42}$

10. Three of the six vertices of a regular hexagon are chosen at random. The probability that the triangle formed by these vertices is equilateral, is

(a) $\frac{1}{2}$ (b) $\frac{1}{3}$ (c) $\frac{1}{10}$ (d) $\frac{1}{20}$

11. Two small squares on a chess board are chosen at random. Then, the probability that they have a common side, is

(a) $\frac{1}{3}$ (b) $\frac{1}{9}$ (c) $\frac{1}{18}$ (d) $\frac{5}{18}$

12. A letter is known to have come from CHENNAI, JAIPUR, NAINITAL, DUBAI and MUMBAI. On the post mark only two consecutive letters AI are legible. Then the probability that it come from MUMBAI, is

(a) $\frac{42}{319}$ (b) $\frac{84}{403}$ (c) $\frac{39}{331}$ (d) $\frac{42}{331}$

13. Let a die is loaded in such a way that prime number faces are twice as likely to occur as a non-prime number faces. Then, the probability that an odd number will be show up when the die is tossed, is

(a) $\frac{1}{3}$ (b) $\frac{2}{3}$ (c) $\frac{4}{9}$ (d) $\frac{5}{9}$

14. One ticket is selected at random from 100 tickets numbered $00, 01, 02, \ldots, 99$.
Suppose, X and Y are the sum and product of the digit found on the ticket $P(X = 7 / Y = 0)$ is given by

(a) $\frac{2}{3}$ (b) $\frac{2}{19}$ (c) $\frac{1}{50}$ (d) None of these

15. All the spades are taken out from a pack of cards. From these cards, cards are drawn one by one without replacement till the ace of spades comes. The probability that the ace comes in the 4th draw, is

(a) $\frac{1}{13}$ (b) $\frac{12}{13}$

(c) $\frac{4}{13}$ (d) None of these

16. A number is selected at random from the first twenty-five natural numbers. If it is a composite number, then it is divided by 5. But if it is not a composite number, then it is divided by 2. The probability that there will be no remainder in the division, is

(a) $\frac{11}{30}$ (b) 0.4

(c) 0.2 (d) None of these

17. If a bag contains 50 tickets, numbered 1, 2, 3, …, 50 of which five are drawn at random and arranged in ascending order of magnitude $(x_1 < x_2 < x_3 < x_4 < x_5)$. The probability that $x_3 = 30$, is

(a) $\frac{{}^{20}C_2 \times {}^{29}C_2}{{}^{50}C_5}$ (b) $\frac{{}^{20}C_2}{{}^{50}C_5}$

(c) $\frac{{}^{29}C_2}{{}^{50}C_5}$ (d) None of these

18. India play two matches each with West Indies and Australia. In any match the probabilities of India getting points 0, 1 and 2 are 0.45, 0.05 and 0.50, respectively. Assuming that the outcomes are independent, then the probability of India getting atleast 7 points, is

(a) 0.8750 (b) 0.0875 (c) 0.0625 (d) 0.0250

19. Three six faced dice are tossed together, then the probability that exactly two of the three numbers are equal, is

(a) $\frac{165}{216}$ (b) $\frac{177}{216}$ (c) $\frac{51}{216}$ (d) $\frac{90}{216}$

20. Three six-faced fair dice are thrown together. The probability that the sum of the numbers appearing on the dice is $k (3 \le k \le 8)$, is

(a) $\frac{(k-1)(k-2)}{432}$ (b) $\frac{k(k-1)}{432}$

(c) $\frac{k^2}{432}$ (d) None of these

21. A book contains 1000 pages. A page is chosen at random. The probability that the sum of the digits of the marked number on the page is equal to 9, is

(a) $\frac{23}{500}$ (b) $\frac{11}{200}$

(c) $\frac{7}{100}$ (d) None of these

22. A bag contains four tickets numbered 00, 01, 10 and 11. Four tickets are chosen at random with replacement, then the probability that sum of the numbers on the tickets is 23, is

(a) $\frac{3}{32}$ (b) $\frac{1}{64}$ (c) $\frac{5}{256}$ (d) $\frac{7}{256}$

23. Fifteen coupons are numbered 1 to 15. Seven coupons are selected at random, one at a time with replacement. Then, the probability that the largest number appearing on a selected coupon be 9, is

(a) $\left(\frac{1}{15}\right)^7$ (b) $\left(\frac{8}{15}\right)^7$

(c) $\left(\frac{3}{5}\right)^7$ (d) None of these

24. A box contains tickets numbered 1 to 20. 3 tickets are drawn from the box with replacement. The probability that the largest number on the tickets is 7, is

(a) $\frac{7}{20}$ (b) $1 - \left(\frac{7}{20}\right)^3$

(c) $\frac{2}{19}$ (d) None of these

25. An unbiased die with faces marked 1, 2, 3, 4, 5 and 6 is rolled four times. Out of four face values obtained, then the probability that the minimum face value is not less than 2 and the maximum face value is not greater than 5, is

(a) $\frac{16}{81}$ (b) $\frac{1}{81}$ (c) $\frac{80}{81}$ (d) $\frac{65}{81}$

26. A bag contains four tickets marked with numbers 112, 121, 211 and 222. One ticket is drawn at random from the bag. Let $E_i (i = 1, 2, 3)$ denote the event that ith digit on the ticket is 2. Then, which of the following is not true?

(a) E_1 and E_2 are independent
(b) E_2 and E_3 are independent
(c) E_3 and E_1 are independent
(d) E_1, E_2 and E_3 are not independent

27. Two non-negative integers are chosen at random. The probability that the sum of the square is divisible by 10, is

(a) $\frac{17}{100}$ (b) $\frac{9}{50}$ (c) $\frac{7}{50}$ (d) $\frac{9}{16}$

28. Two positive real numbers x and y satisfying $x \le 1$ and $y \le 1$ are chosen at random. The probability that $x + y \le 1$, given that $x^2 + y^2 \le 1/4$, is

(a) $\frac{8-\pi}{16-\pi}$ (b) $\frac{4-\pi}{16-\pi}$

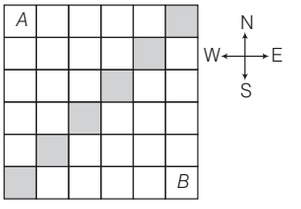
(c) $\frac{4-\pi}{8-\pi}$ (d) None of these

29. If the sides of a triangle are decided by the throw of a single dice thrice, the probability that triangle is of maximum area given that it is an isosceles triangle, is

(a) $\frac{1}{7}$ (b) $\frac{1}{27}$

(c) $\frac{1}{14}$ (d) None of these

30. A and B are persons standing in corner square as shown in the figure. They start to move on same time with equal speed, if A can move only in East or South direction and B can move only in North or West direction. If in each step they reach in next square and their choice of direction are equality. If it is given that A and B meet in shaded region, then the probability that they have met in the top most shaded square, is



(a) $\frac{1}{6}$ (b) $\frac{{}^5C_2}{{}^{10}C_3}$ (c) $\frac{1}{{}^{10}C_5}$ (d) $\frac{1}{2^5 \times 6}$

Probability Exercise 2 :
More than One Correct Option Type Questions

- This section contains **15 multiple choice questions**. Each question has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

31. For two given events A and B, $P(A \cap B)$ is
(a) not less than $P(A) + P(B) - 1$
(b) not greater than $P(A) + P(B)$
(c) equal to $P(A) + P(B) - P(A \cup B)$
(d) equal to $P(A) + P(B) + P(A \cup B)$

32. If E and F are independent events such that $0 < P(E) < 1$ and $0 < P(F) < 1$, then
(a) E and F are mutually exclusive
(b) E and $\overline{F}$ (complement of the event F) are independent
(c) $\overline{E}$ and $\overline{F}$ are independent
(d) $P(E / F) + P(\overline{E} / F) = 1$

33. For any two events A and B in a sample space:
(a) $P\left(\frac{A}{B}\right) \geq \frac{P(A) + P(B) - 1}{P(B)}$, $P(B) \neq 0$, is always true
(b) $P(A \cap \overline{B}) = P(A) - P(A \cap B)$, does not hold
(c) $P(A \cup B) = 1 - P(\overline{A})\, P(\overline{B})$, if A and B are independent
(d) $P(A \cup B) = 1 - P(\overline{A})\, P(\overline{B})$, if A and B are disjoint

34. Let E and F be two independent events. Then, the probability that both E and F happens is $\frac{1}{12}$ and the probability that neither E nor F happens is $\frac{1}{2}$. Then,
(a) $P(E) = 1/3$, $P(F) = 1/4$ (b) $P(E) = 1/2$, $P(F) = 1/6$
(c) $P(E) = 1/6$, $P(F) = 1/2$ (d) $P(E) = 1/4$, $P(F) = 1/3$

35. If $\overline{E}$ and $\overline{F}$ are the complementary events of events E and F, respectively and if $0 < P(F) < 1$, then
(a) $P(\overline{E} / F) + P(\overline{E} / F) = 1$ (b) $P(E / F) + P(E / \overline{F}) = 1$
(c) $P(\overline{E} / F) + P(E / \overline{F}) = 1$ (d) $P(E / \overline{F}) + P(\overline{E} / \overline{F}) = 1$

36. Let $0 < P(A) < 1$, $0 < P(B) < 1$ and $P(A \cup B) = P(A) + P(B) - P(A)\, P(B)$. Then,
(a) $P(B - A) = P(B) - P(A)$ (b) $P(A' \cup B') = P(A') + P(B')$
(c) $P((A \cup B)') = P(A')\, P(B')$ (d) $P(A / B) = P(A)$

37. If A and B are two events, then the probability that exactly one of them occurs is given by
(a) $P(A) + P(B) - 2P(A \cap B)$
(b) $P(A \cap B') + P(A' \cap B)$
(c) $P(A \cup B) - P(A \cap B)$
(d) $P(A') + P(B') - 2P(A' \cap B')$

38. If A and B are two independent events such that $P(A) = 1/2$ and $P(B) = 1/5$. Then,
(a) $P(A \cup B) = 3/5$ (b) $P(A / B) = 1/2$
(c) $P(A / A \cup B) = 5/6$ (d) $P(A \cap B) / (A' \cup B') = 0$

39. A student appears for tests I, II and III. The student is successful if he passes either in tests I and II or tests I and III. The probabilities of the student passing in tests I, II and III are p, q and $1/2$, respectively. If the probability that the student is successful is $1/2$, then
(a) $p = 1$, $q = 0$ (b) $p = 2/3$, $q = 1/2$
(c) $p = 3/5$, $q = 2/3$ (d) infinitely values of p and q

40. Let X be a set containing n elements. If two subsets A and B of X are picked at random, then the probability that A and B have same number of elements, is
(a) $\frac{{}^{2n}C_n}{2^{2n}}$ (b) $\frac{1}{{}^{2n}C_n}$ (c) $\frac{1 \cdot 3 \cdot 5 \ldots (2n-1)}{2^n \cdot (n!)}$ (d) $\frac{3^n}{4^n}$

41. Suppose m boys and m girls take their seats randomly around a circle. The probability of their sitting is $({}^{2m-1}C_m)^{-1}$, when
(a) no two boys sit together (b) no two girls sit together
(c) boys and girls sit alternatively
(d) all the boys sit together

42. The probabilities that a student passes in Mathematics, Physics and Chemistry are m, p and c, respectively. In these subjects, the student has a 75% chance of passing in atleast one, a 50% chance of passing in atleast two and a 40% chance of passing in exactly two. Which of the following relations are true?
(a) $p + m + c = 19/20$ (b) $p + m + c = 27/20$
(c) $pmc = 1/10$ (d) $pmc = 1/4$

43. $(n \geq 5)$ persons are sitting in a row. Three of these are selected at random, the probability that no two of the selected persons are sit together, is
(a) $\frac{{}^{n-3}P_2}{{}^{n}P_2}$ (b) $\frac{{}^{n-3}C_2}{{}^{n}C_2}$ (c) $\frac{(n-3)(n-4)}{n(n-1)}$ (d) $\frac{{}^{n-3}C_2}{{}^{n}P_2}$

44. Given that $x \in [0, 1]$ and $y \in [0, 1]$. Let A be the event of (x, y) satisfying $y^2 \leq x$ and B be the event of (x, y) satisfying $x^2 \leq y$, then not true, is
(a) $P(A \cap B) = \frac{1}{3}$
(b) A and B are exhaustive
(c) A and B are mutually exclusive
(d) A and B are independent

45. If the probability of chosing an integer 'k' out of $2n$ integers $1, 2, 3, \ldots, 2n$ is inversely proportional to $k^4 (1 \leq k \leq n)$. If α is the probability that chosen number is odd and β is the probability that chosen number is even, then
(a) $\alpha > \frac{1}{2}$ (b) $\alpha > \frac{2}{3}$ (c) $\beta < \frac{1}{2}$ (d) $\beta < \frac{2}{3}$

Probability Exercise 3 : Passage Based Questions

- This section contains **9 passages**. Based upon each of the passage **3 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I

(Q. Nos. 46 to 48)

If p and q are chosen randomly from the set $\{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$ with replacement.

46. The probability that roots of $x^2 + px + q = 0$ are real and distinct, is

(a) 0.38 (b) 0.03 (c) 0.59 (d) 0.89

47. The probability that roots of $x^2 + px + q = 0$ are equal, is

(a) 0.58 (b) 0.55 (c) 0.38 (d) 0.03

48. The probability that roots of $x^2 + px + q = 0$ are imaginary, is

(a) 0.62 (b) 0.38 (c) 0.59 (d) 0.89

Passage II

(Q. Nos. 49 to 51)

A chess game between two grandmasters X and Y is won by whoever first wins a total of two games. X 's chances of winning, drawing or loosing any particular game are a, b and c, respectively. The games are independent and $a + b + c = 1$.

49. The probability that X wins the match after $(n+1)$ th game $(n \geq 1)$, is

(a) $na^2 b^{n-1}$ (b) $na^2 b^{n-2}(b + (n-1)c)$

(c) $na^2 bc^{n-1}$ (d) $na\, b^{n-1}(b + nc)$

50. The probability that Y wins the match after the 4th game, is

(a) $abc(2a + 3b)$ (b) $bc^2(a + 3b)$

(c) $2ac^2(b + c)$ (d) $3bc^2(2a + b)$

51. The probability that X wins the match, is

(a) $\frac{a^2(a+2c)}{(a+c)^3}$ (b) $\frac{a^3}{(a+c)^3}$ (c) $\frac{a^2(a+3c)}{(a+c)^3}$ (d) $\frac{c^3}{(a+c)^3}$

Passage III

(Q. Nos. 52 to 54)

There are n students in a class. Let $P(E_\lambda)$ be the probability that exactly λ out of n pass the examination. If $P(E_\lambda)$ is directly proportional to $\lambda^2 (0 \leq \lambda \leq n)$.

52. Proportionality constant k is equal to

(a) $\frac{1}{\Sigma n}$ (b) $\frac{1}{\Sigma n^2}$ (c) $\frac{1}{\Sigma n^3}$ (d) $\frac{1}{\Sigma n^4}$

53. If $P(A)$ be the probability that a student selected at random has passed the examination, then $\lim_{x \to \infty} P(A)$, is

(a) 0.25 (b) 0.50

(c) 0.75 (d) 0.35

54. If a selected student has been found to pass the examination, then the probability that he is the only student to have passed the examination, is

(a) $\frac{1}{\Sigma n}$ (b) $\frac{1}{\Sigma n^2}$

(c) $\frac{1}{\Sigma n^3}$ (d) $\frac{1}{\Sigma n^4}$

Passage IV

(Q. Nos. 55 to 57)

A cube having all of its sides painted is cut to be two horizontal, two vertical and other two planes, so as to form 27 cubes all having the same dimensions of these cubes, a cube is selected at random.

55. If P_1 be the probability that the cube selected having atleast one of its sides painted, then the value of $27P_1$, is

(a) 14 (b) 18 (c) 22 (d) 26

56. If P_2 be the probability that the cube selected has two sides painted, then the value of $27P_2$, is

(a) 3 (b) 8 (c) 12 (d) 17

57. If P_3 be the probability that the cube selected has none of its sides painted, then the value of $27P_3$, is

(a) 1 (b) 2

(c) 3 (d) 5

Passage V

(Q. Nos. 58 to 60)

A JEE aspirant estimates that she will be successful with an 80% chance, if she studies 10 h per day with a 60% chance, if she studies 7 h per day and with a 40% chance if she studies 4 h per day. She further believes that she will study 10 h, 7 h and 4 h per day with probabilities 0.1, 0.2, and 0.7, respectively.

58. The probability that she will be successful, is

(a) 0.28 (b) 0.38 (c) 0.48 (d) 0.58

59. Given that she is successful, the chances that she studied for 4 h, is

(a) $\frac{1}{12}$ (b) $\frac{5}{12}$

(c) $\frac{7}{12}$ (d) $\frac{11}{12}$

60. Given that she does not achieve success, the chance that she studied for 4 h, is

(a) $\frac{15}{26}$ (b) $\frac{17}{26}$ (c) $\frac{19}{26}$ (d) $\frac{21}{26}$

Passage VI

(Q. Nos. 61 to 63)

Suppose E_1, E_2 and E_3 be three mutually exclusive events such that $P(E_i) = p_i$ for $i = 1, 2, 3$.

61. If p_1, p_2 and p_3 are the roots of $27x^3 - 27x^2 + ax - 1 = 0$, the value of a is

(a) 3 (b) 6 (c) 9 (d) 12

62. P (none of E_1, E_2 , E_3) equals

(a) 0
(b) $p_1 + p_2 + p_3$
(c) $(1 - p_1)(1 - p_2)(1 - p_3)$
(d) None of the above

63. $P(E_1 \cap \bar{E}_2) + P(E_2 \cap \bar{E}_3) + P(E_3 \cap \bar{E}_1)$ equals

(a) $p_1(1 - p_2) + p_2(1 - p_3) + p_3(1 - p_1)$
(b) $p_1p_2 + p_2p_3 + p_3p_1$
(c) $p_1 + p_2 + p_3$
(d) None of the above

Passage VII

(Q. Nos. 64 to 66)

Let $A = \{1, 2, 3\}$ and $B = \{-2, -1, 0, 1, 2, 3\}$.

64. The probability of increasing functions from A to B, is

(a) $\frac{1}{27}$ (b) $\frac{1}{18}$ (c) $\frac{5}{54}$ (d) $\frac{7}{54}$

65. The probability of non-decreasing functions from A to B, is

(a) $\frac{5}{27}$ (b) $\frac{7}{27}$
(c) $\frac{1}{3}$ (d) $\frac{11}{27}$

66. The probability of onto functions from B to B, such that $f(i) \neq i$, $i = -2, -1, 0, 1, 2, 3$, is

(a) $\frac{53}{144}$ (b) $\frac{35}{144}$ (c) $\frac{29}{72}$ (d) $\frac{25}{72}$

Passage VIII

(Q. Nos. 67 to 69)

A random variable X takes values $0, 1, 2, 3, \ldots$ with probability proportional to $(x+1)\left(\frac{1}{5}\right)^x$.

67. $P(X = 0)$ equals

(a) $\frac{2}{25}$ (b) $\frac{4}{25}$ (c) $\frac{9}{25}$ (d) $\frac{16}{25}$

68. $P(X \geq 2)$ equals

(a) $\frac{11}{25}$ (b) $\frac{13}{25}$ (c) $\frac{11}{125}$ (d) $\frac{13}{125}$

69. The expectation of X i.e., $E(X)$ is equal to

(a) $\frac{1}{4}$ (b) 2 (c) $\frac{1}{2}$ (d) 4

Passage IX

(Q. Nos. 70 to 72)

Let $n = 10\lambda + r$, where $\lambda, r \in N$, $0 \leq r \leq 9$. A number a is chosen at random from the set $\{1, 2, 3, \ldots, n\}$ and let p_n denote the probability that $(a^2 - 1)$ is divisible by 10.

70. If $r = 0$, then np_n equals

(a) 2λ (b) $(\lambda + 1)$
(c) $(2\lambda + 1)$ (d) λ

71. If $r = 9$, then np_n equals

(a) 2λ (b) $2(\lambda + 1)$
(c) $(2\lambda + 1)$ (d) λ

72. If $1 \leq r \leq 8$, then np_n equals

(a) $(2\lambda - 1)$ (b) 2λ
(c) $(2\lambda + 1)$ (d) λ

Probability Exercise 4 : Single Integer Answer Type Questions

- This section contains **10 questions**. The answer to each question is a **single digit integer**, ranging from **0 to 9** (both inclusive).

73. A bag contains $(n + 1)$ coins. It is known that one of these coins shows heads on both sides, whereas the other coins are fair. One coin is selected at random and tossed. If the probability that the toss result in heads is $\frac{7}{12}$, then the value of n is

74. A determinant of the second order is made with the elements 0 and 1. If $\frac{m}{n}$ be the probability that the determinant made is non-negative, where m and n are relative primes, then the value of $n - m$ is

75. Three students appear in an examination of Mathematics. The probabilities of their success are $\frac{1}{3}, \frac{1}{4}$ and $\frac{1}{5}$, respectively. If the probability of success of atleast two is $\frac{\lambda}{12}$, then the value of λ is

76. A die is rolled three times, if p be the probability of getting a large number than the previous number, then the value of $54p$ is

77. In a multiple choice question, there are five alternative answers of which one or more than one are correct. A candidate will get marks on the question, if he ticks all the correct answers. If he decides to tick answers at random, then the least number of choices should he be allowed, so that the probability of his getting marks on the question exceeds $\frac{1}{8}$ is

78. There are n different objects $1, 2, 3, \ldots, n$ distributed at random in n places marked $1, 2, 3, \ldots, n$. If p be the probability that atleast three of the objects occupy places corresponding to their number, then the value of $6p$ is

79. A sum of money is rounded off to the nearest rupee, if $\left(\frac{m}{n}\right)^2$ be the probability that the round off error is atleast ten paise, where m and n are positive relative primes, then the value of $(n - m)$ is

80. A special die is so constructed that the probabilities of throwing 1, 2, 3, 4, 5 and 6 are $(1-k)/6, (1+2k)/6, (1-k)/6, (1+k)/6, (1-2k)/6$ and $(1+k)/6$, respectively. If two such dice are thrown and the probability of getting a sum equal to lies between $\frac{1}{9}$ and $\frac{2}{9}$, then the integral value of k is

81. Seven digits from the numbers 1, 2, 3, 4, 5, 6, 7, 8 and 9 are written in random order. If the probability that this seven-digit number divisible by 9 is p, then the value of $18p$ is

82. 8 players $P_1, P_2, P_3, \ldots, P_8$ play a knock out tournament. It is known that all the players are of equal strength. The tournament is held in three rounds where the players are paired at random in each round. If it is given that P_1 wins in the third round. If p be the probability that P_2 loses in the second round, then the value of $7p$ is

Probability Exercise 5 : Matching Type Questions

- This section contains **6 questions**. Questions 83 to 88 have four statements (A, B C and D) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

83.

	Column I		**Column II**
(A)	If $P(\overline{A}) = 0.3$, $P(B) = 0.4$ and $P(A\overline{B}) = 0.5$ and $P[B/(A \cup \overline{B})] = \lambda_1$, then $\frac{1}{\lambda_1}$ is	(p)	A prime number
(B)	The coefficient of a quadratic equation $ax^2 + bx + c = 10 (a \neq b \neq c)$ are chosen from first three prime numbers, then the probability that roots of the equation are real is λ_2, then $\frac{1}{\lambda_2}$ is	(q)	A composite number
(C)	A fair coin is tossed repeatedly. If tail appears on first four tosses, then the probability of head appearing on the fifth toss is λ_3, then $\frac{1}{\lambda_3}$ is	(r)	A natural number
(D)	Three persons A, B and C are to speak at a function along with 6 other persons. If the persons speak in random order, then the probability that A speaks before B and B speaks before C is λ_4, then $\frac{1}{\lambda_4}$ is	(s)	A perfect number

84. A and B are two events, such that $P(A) = \frac{3}{5}$ and $P(B) = \frac{2}{3}$

Column I		Column II	
(A)	$P(A \cap B) \in$	(p)	$\left[\frac{2}{3}, 1\right]$
(B)	$P(A \cup B) \in$	(q)	$\left[\frac{4}{9}, 1\right]$
(C)	$P(A / B) \in$	(r)	$\left[\frac{2}{5}, \frac{9}{10}\right]$
(D)	$P(B / A) \in$	(s)	$\left[\frac{4}{15}, \frac{3}{5}\right]$

85. Three players A, B and C alternatively throw a die in that order, the first player to throw a 6 being deemed the winner. A's die is fair whereas B and C throw dice with probabilities p_1 and p_2 respectively, of throwing a 6.

Column I		Column II	
(A)	If $p_1 = \frac{1}{5}$, $p_2 = \frac{1}{4}$ and probability that A wins the game is $\frac{1}{\lambda_1}$, then λ_1 is divisor of	(p)	6
(B)	If $p_1 = \frac{1}{5}$, $p_2 = \frac{1}{4}$ and probability that C wins the game is $\frac{1}{\lambda_2}$, then λ_2 is divisor of	(q)	8
(C)	If $P(A \text{ wins}) = P(B \text{ wins})$ and $\frac{1}{p_1} = \lambda_3$, then λ_3 is divisor of	(r)	12
(D)	If game is equiprobable to all the three players and $\frac{1}{p_1} = \lambda_4$, then λ_4 is divisor of	(s)	15

86. Two numbers a and b are chosen at random from the set $\{1, 2, 3, 4, \ldots, 9\}$ with replacement. The probability that the equation $x^2 + \sqrt{2}(a - b)x + b = 0$ has

Column I		Column II	
(A)	Real and distinct roots is p_1, then the value of $[9p_1]$, where $[\cdot]$ denotes the greatest integer function, is	(p)	2
(B)	Imaginary roots is p_2, then the value of $[9p_2]$, where $[\cdot]$ denotes the greatest integer function, is	(q)	3
(C)	Equal roots is p_3, then the value of $[81p_3]$, where $[\cdot]$ denotes the greatest integer function, is	(r)	4
(D)	Real roots is p_4, then the value of $[9p_4]$, where $[\cdot]$ denotes the greatest integer function, is	(s)	5

87. Three numbers are chosen at random without replacement from the set $\{|x| 1 \le x \le 10, x \in N\}$

Column I		Column II	
(A)	Let p_1 be the probability that the minimum of the chosen numbers is 3 and maximum is 7, then the value of $\frac{2}{5p_1}$, is	(p)	10
(B)	Let p_2 be the probability that the minimum of the chosen numbers is 4 or their maximum is 8, then the value of $80p_2$, is	(q)	14
(C)	Let p_3 be the probability that their minimum is 3, given that their maximum is 7, then the value of $\frac{2}{p_3}$, is	(r)	16
(D)	Let p_4 be the probability that their minimum is 4, given that their maximum is 8, then the value of $\frac{2}{p_4}$, is	(s)	22

88.

Column I		Column II	
(A)	If the integers m and n are chosen at random between 1 and 100, then the probability that a number of the form $7^m + 7^n$ is divisible by 5, is	(p)	$\frac{1}{7}$
(B)	A second order determinant is written down at random using the numbers 1, −1 as elements. The probability that the value of the determinant is non-zero, is	(q)	$\frac{1}{5}$
(C)	The probability of a number n showing in a throw of a die marked 1 to 6 is proportional to n. Then, the probability of the number 3 showing in a throw, is	(r)	$\frac{2}{5}$
(D)	A pair of dice is rolled together till a sum of either 5 or 7 is obtained. Then, the probability that 5 comes before 7, is	(s)	$\frac{1}{2}$

Probability Exercise 6 :
Statement I and II Type Questions

■ **Directions** (Q. Nos. 89 to 100) are Assertion-Reason type questions. Each of these questions contains two statements:
Statement-1 (Assertion) and
Statement-2 (Reason) Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(c) Statement1 is true, Statement-2 is false

(d) Statement-1 is false, Statement-2 is true

89. **Statement-1** If 10 coins are thrown simultaneously, then the probability of appearing exactly four heads is equal to probability of appearing exactly six heads.

Statement-2 ${}^{n}C_{r} = {}^{n}C_{s} \Rightarrow$ either $r = s$ or $r + s = n$ and $P(H) = P(T)$ in a single trial.

90. **Statement-1** If A is any event and $P(B) = 1$, then A and B are independent.

Statement-2 $P(A \cap B) = P(A) \cdot P(B)$, if A and B are independent.

91. **Statement-1** If A and B be the events in a sample space, such that $P(A) = 0.3$ and $P(B) = 0.2$, then $P(A \cap \overline{B})$ cannot be found.
Statement-2 $P(A \cap \overline{B}) = P(A) - P(A \cap B)$

92. **Statement-1** Let A and B be two events, such that $P(A \cup B) = P(A \cap B)$, then

$$P(A \cap B') = P(A' \cap B) = 0$$

Statement-2 Let A and B be two events, such that $P(A \cup B) = P(A \cap B)$, then $P(A) + P(B) = 1$

93. A fair die is rolled once.
Statement-1 The probability of getting a composite number is $\frac{1}{3}$, is

Statement-2 There are three possibilities for the obtained number.

(i) The number is prime number.

(ii) The number is a composite number and

(iii) The number is 1.

Hence, probabilities of getting a prime number is $\frac{1}{3}$.

94. From a well shuffled pack of 52 playing cards, a card is drawn at random. Two events A and B are defined as
A : Red card is drawn
B : Card drawn is either a Diamond or Heart
Statement-1 $P(A + B) = P(AB)$
Statement-2 $A \subseteq B$ and $B \subseteq A$

95. **Statement-1** The probability that A and B can solve a problem is $\frac{1}{2}$ and $\frac{1}{3}$ respectively, then the probability that problem will be solved is $\frac{5}{6}$.

Statement-2 Above mentioned events are independent events.

96. **Statement-1** Out of 21 tickets with numbers 1 to 21, 3 tickets are drawn at random, the chance that the numbers on them are in AP is $\frac{10}{133}$.

Statement-2 Out of $(2n + 1)$ tickets consecutively numbered three are drawn at random, the chance that the numbers on them are in AP is $(4n - 10)/(4n^2 - 1)$.

97. **Statement-1** If A and B are two events, such that $0 < P(A)$, $P(B) < 1$, then $P\left(\frac{A}{\overline{B}}\right) + P\left(\frac{\overline{A}}{\overline{B}}\right) = \frac{3}{2}$

Statement-2 If A and B are two events, such that $0 < P(A)$, $P(B) < 1$, then
$P(A / B) = \frac{P(A \cap B)}{P(B)}$ and $P(\overline{B}) = P(A \cap \overline{B}) + P(\overline{A} \cap \overline{B})$

98. In a T-20 tournament, there are five teams. Each team plays one match against every other team.

Each team has 50% chance of winning any game it plays. No match ends in a tie.

Statement-1 The probability that there is an undefeated team in the tournament is $\frac{5}{16}$.

Statement-2 The probability that there is a winless team in the tournament is $\frac{3}{16}$.

99. **Statement-1** If p is chosen at random in the closed interval $[0, 5]$, then the probability that the equation $x^2 + px + \frac{1}{4}(p + 2) = 0$ has real is $\frac{3}{5}$.

Statement-2 If discriminant ≥ 0, then roots of the quadratic equation are always real.

100. Let a sample space S contains n elements. Two events A and B are defined on S and $B \neq \phi$.

Statement-1 The conditional probability of the event A given B, is the ratio of the number of elements in AB divided by the number of elements in B.

Statement-2 The conditional probability model given B, is equally likely model on B.

Probability Exercise 7 : Subjective Type Questions

- In this section, there are **24 subjective** questions.

101. A five digit number is formed by the digits 1, 2, 3, 4 and 5 without repetition. Find the probability that the number formed is divisible by 4.

102. A dice is rolled three times, then find the probability of getting a large number than the previous number.

103. A car is parked among N cars standing in a row but not at either end. On his return, the owner finds that exactly r of the N places are still occupied. What is the probability that both the places neighbouring his car are empty?

104. Two teams A and B play a tournament. The first one to win $(n+1)$ games win the series. The probability that A wins a game is p and that B wins a game is q (no ties). Find the probability that A wins the series.

Hence or otherwise prove that $\sum_{r=0}^{n} {}^{n+1}C_r \cdot \frac{1}{2^{n+r}} = 1$.

105. An artillery target may be either at point I with probability $\frac{8}{9}$ or at point II with probability $\frac{1}{9}$. We have 21 shells each of which can be fired either at point I or II. Each shell may hit the target independently of the other shell with probability $\frac{1}{2}$.

How many shells must be fired at point I to hit the target with maximum probability?

106. There are 6 red and 8 green balls in a bag. 5 balls are drawn at random and placed in a red box. The remaining balls are placed in a green box. What is the probability that the number of red balls in the green box plus the number of green balls in the red box is not a prime number?

107. An urn contains 'a' green and 'b' pink balls $k\ (< a, b)$ balls are drawn and laid a side, their colour being ignored. Then, one more ball is drawn. Find the probability that it is green.

108. A fair coin is tossed 12 times. Find the probability that two heads do not occur consecutively.

109. Given that $x + y = 2a$, where a is constant and that all values of x between 0 and $2a$ are equally likely, then show that the chance that $xy > \frac{3}{4}a^2$, is $\frac{1}{2}$.

110. A chess game between Kamsky and Anand is won by whoever first wins a out of 2 games. Kamsky's chance of winning, drawing or loosing a particular game are 2. The games are independent and $p + q + r = 1$. Prove that the probability that Kamsky wins the match is $\frac{p^2(p+3r)}{(p+r)^3}$.

111. Of three independent events, the chance that only the first occurs is a, the other that only the second occurs is b and the chance of only third occurs is c. Show that the cases of three events are respectively $a/(a+x)$, $b/(b+x)$, $c/(c+x)$, where x is a root of the equation $(a+x)(b+x)(c+x) = x^2$.

112. A is a set containing n elements. A subset P of A is chosen at random and the set A is reconstructed by replacing the elements of P. Another subset Q of A is now chosen at random. Find the probability that $P \cup Q$ contains exactly r elements, with $1 \leq r \leq n$.

113. An electric component manufactured by 'RASU electronics' is tested for its defectiveness by a sophisticated testing device. Let A denote the even ''the device is defective'' and B the event ''the testing device reveals the component to be defective.'' Suppose, $P(A) = \alpha$ and $P(B/A) = P(B'/A') = 1 - \alpha$, where $0 < \alpha < 1$. Show that the probability that the component is not defective, given that the testing device reveals it to be defective is independent of α.

114. A bag contains n white and n red balls. Pairs of balls are drawn without replacement until the bag is empty. Show that the probability that each pair consists of one white and one red ball is $2^n / ({}^{2n}C_n)$.

115. If m things are distributed among 'a' men and 'b' women, then show that the probability that the number of things received by men is odd, is $\frac{1}{2}\frac{\{(b+a)^m - (b-a)^m\}}{(b+a)^m}$.

Probability Exercise 8 :
Questions Asked in Previous 13 Year's Exam

■ This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to year **2017**.

116. A person goes to office either by car, scooter, bus or train. The probability of which being $\frac{1}{7}, \frac{3}{7}, \frac{2}{7}$ and $\frac{1}{7}$, respectively. Probability that he reaches office late, if he takes car, scooter, bus or train is $\frac{2}{9}, \frac{1}{9}, \frac{4}{9}$ and $\frac{1}{9}$, respectively. Given that he reached office in time, then what is the probability that he travelled by a car.
[IIT-JEE 2005, 2M]

117. A six faced fair die is thrown until 1 comes. Then, the probability that 1 comes in even number of trials, is
[IIT-JEE 2005, 3M]
(a) $\frac{5}{11}$ (b) $\frac{5}{6}$ (c) $\frac{6}{11}$ (d) $\frac{1}{6}$

118. Let A and B be two events such that $P(\overline{A \cup B}) = \frac{1}{6}$, $P(A \cap B) = \frac{1}{4}$ and $P(\overline{A}) = \frac{1}{4}$, where $\overline{A}$ stands for complement of event A. Then, events A and B are
[IIT-JEE 2005, 3M]
(a) independent but not equally likely
(b) mutually exclusive and independent
(c) equally likely and mutually exclusive
(d) equally likely but not independent

119. Three houses are available in a locality. Three persons apply for the houses. Each applies for one house without consulting others. The probability that all the three apply for the same house, is **[AIEEE 2005, 3M]**
(a) $\frac{8}{9}$ (b) $\frac{7}{9}$ (c) $\frac{2}{9}$ (d) $\frac{1}{9}$

120. A random variable X has Poisson's distribution with mean 2. Then, $P(X > 1.5)$ is equal to **[AIEEE 2005, 3M]**
(a) $1 - \frac{3}{e^2}$ (b) $\frac{3}{e^2}$ (c) $\frac{2}{e^2}$ (d) 0

121. There are n urns each containing $(n + 1)$ balls such that the ith urn contains i white balls and $(n + 1 - i)$ red balls. Let u_i be the event of selecting ith urn, $i = 1, 2, 3, \ldots, n$ and w denotes the event of getting a white ball.
[IIT-JEE 2006, 5+5+5M]

(i) If $P(u_1) \propto i$, where $i = 1, 2, 3, \ldots, n$, then $\lim_{n \to \infty} P(w)$, is
(a) 1 (b) $\frac{2}{3}$ (c) $\frac{3}{4}$ (d) $\frac{1}{4}$

(ii) If $P(u_i) = c$, where c is a constant, then $P\left(\frac{u_n}{w}\right)$, is
(a) $\frac{2}{n+1}$ (b) $\frac{1}{n+1}$ (c) $\frac{n}{n+1}$ (d) $\frac{1}{2}$

(iii) If n is even and E denotes the event of choosing even numbered urn $\left(P(u_i) = \frac{1}{n}\right)$, then the value of $P\left(\frac{w}{E}\right)$, is
(a) $\frac{n+2}{2n+1}$ (b) $\frac{n+2}{2(n+1)}$ (c) $\frac{n}{n+1}$ (d) $\frac{1}{n+1}$

122. At a telephone enquiry system, the number of phone calls regarding relevant enquiry follow Poisson's distribution with an average of 5 phone calls during 10 min time interval. The probability that there is atmost one phone call during a 10 min time period, is **[AIEEE 2006, 4, 5M]**
(a) $\frac{6}{5^e}$ (b) $\frac{5}{6}$ (c) $\frac{6}{55}$ (d) $\frac{6}{e^5}$

123. One Indian and four American men and their wives are to be seated randomly around a circular table. Then, the conditional probability that the Indian man is seated adjacent to his wife given that each American man is seated adjacent to his wife, is **[IIT-JEE 2007, 3M]**
(a) $\frac{1}{2}$ (b) $\frac{1}{3}$ (c) $\frac{2}{5}$ (d) $\frac{1}{5}$

124. Let $H_1, H_2, \ldots, H_n$ be mutually exclusive events with $P(H_i) > 0, i = 1, 2, \ldots, n$. Let E be any other event with $0 < P(E) < 1$.

Statement-1 $P(H_i / E) > P(E / H_i)\, P(H_i)$, for $i = 1, 2, \ldots, n$.

Statement-2 $\sum_{i=1}^{n} P(H_i) = 1$
[IIT-JEE 2007, 3M]
(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

125. Let E^c denote the complement of an event E. Let E, F and G be pairwise independent events with $P(G) > 0$ and $P(E \cap F \cap G) = 0$, then $P(E^c \cap F^c / G)$, is **[IIT-JEE 2007, 3M]**
(a) $P(E^c) + P(F^c)$ (b) $P(E^c) - P(F^c)$
(c) $P(E^c) - P(F)$ (d) $P(E) - P(F^c)$

126. A pair of fair dice is thrown independently three times. Then, the probability of getting a score of exactly 9 twice, is **[AIEEE 2007, 3M]**
(a) $\frac{1}{729}$ (b) $\frac{8}{9}$ (c) $\frac{8}{729}$ (d) $\frac{8}{243}$

127. Two aeroplanes I and II bomb a target in successions. The probabilities of I and II scoring a hit correctly are 0.3 and 0.2, respectively. The second plane will bomb only if the first misses the target. The probability that the target is hit by the second plane, is **[AIEEE 2007, 3M]**
(a) 0.06 (b) 0.14 (c) 0.2 (d) 0.7

128. An experiment has 10 equally likely outcomes. Let A and B be two non-empty events of the experiment. If A consists of 4 outcomes, then the number of outcomes that B must have, so that A and B are independent, is **[IIT-JEE 2008, 3M]**

(a) 2, 4 or 8 (b) 3, 6 or 9 (c) 4 or 8 (d) 5 or 10

129. Consider the system of equations $ax + by = 0$ and $cx + dy = 0$, where $a, b, c, d \in \{0, 1\}$.

Statement-1 The probability that the system of equations has a unique solution is 3/8 and **[IIT-JEE 2008, 3M]**

Statement-2 The probability that the system of equations has a solution is 1.

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1.

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1.

(c) Statement-1 is true, Statement-2 is false.

(d) Statement-1 is false, Statement-2 is true.

130. A die is thrown. Let A be the event that the number obtained is greater than 3. Let B be the event that the number obtained is less than 5. Then $P(A \cup B)$ is **[AIEEE 2008, 3M]**

(a) 0 (b) 1 (c) $\frac{2}{5}$ (d) $\frac{3}{5}$

131. It is given that the events A and B are such that $P(A) = \frac{1}{4}$, $P\left(\frac{A}{B}\right) = \frac{1}{2}$ and $P\left(\frac{B}{A}\right) = \frac{2}{3}$. Then $P(B)$ is **[AIEEE 2008, 3M]**

(a) $\frac{1}{3}$ (b) $\frac{2}{3}$ (c) $\frac{1}{2}$ (d) $\frac{1}{6}$

■ **Passage for Question Nos. 132 to 134**

A fair die is tossed repeatedly until a six is obtained. Let X denote the number of tosses required.

132. The probability that $X = 3$ is

(a) $\frac{25}{216}$ (b) $\frac{25}{36}$ (c) $\frac{5}{36}$ (d) $\frac{125}{216}$

133. The probability that $X \geq 3$ is

(a) $\frac{125}{216}$ (b) $\frac{25}{36}$ (c) $\frac{5}{36}$ (d) $\frac{25}{216}$

134. The conditional probability that $X \geq 6$ given $X > 3$, is

(a) $\frac{125}{216}$ (b) $\frac{25}{216}$ (c) $\frac{5}{36}$ (d) $\frac{25}{36}$ **[IIT-JEE 2009, 4+4+4M]**

135. In a binomial distribution $B\left(n, p = \frac{1}{4}\right)$, if the probability of atleast one success is greater than or equal to $\frac{9}{10}$, then n is greater than **[AIEEE 2009, 4M]**

(a) $\frac{4}{\log_{10} 4 - \log_{10} 3}$ (b) $\frac{1}{\log_{10} 4 - \log_{10} 3}$

(c) $\frac{1}{\log_{10} 4 + \log_{10} 3}$ (d) $\frac{9}{\log_{10} 4 - \log_{10} 3}$

136. One ticket is selected at random from 50 tickets numbered 00, 01, 02, ..., 49. Then, the probability that the sum of the digits on the selected ticket is 8, given that the product of these digits is zero, is **[AIEEE 2009, 4M]**

(a) $\frac{1}{50}$ (b) $\frac{1}{14}$

(c) $\frac{1}{7}$ (d) $\frac{5}{14}$

137. Let ω be a complex cube root of unity with $\omega \neq 1$. A fair die is thrown three times. If r_1, r_2 and r_3 are the numbers obtained on the die, then the probability that $\omega^{r_1} + \omega^{r_2} + \omega^{r_3} = 0$, is **[IIT-JEE 2010, 3M]**

(a) $\frac{1}{18}$ (b) $\frac{1}{9}$ (c) $\frac{2}{9}$ (d) $\frac{1}{36}$

138. A signal which can be green or red with probability $\frac{4}{5}$ and $\frac{1}{5}$ respectively, is received by station A and then transmitted to station B. The probability of each station receiving the signal correctly is $\frac{3}{4}$. If the signal received at station B is green, then the probability that the original signal was green, is **[IIT-JEE 2010, 5M]**

(a) $\frac{3}{5}$ (b) $\frac{6}{7}$ (c) $\frac{20}{23}$ (d) $\frac{9}{20}$

139. Four numbers are chosen at random (without replacement) from the set $\{1, 2, 3, \ldots, 20\}$.

Statement-1 The probability that the chosen numbers, when arranged in some order will form an AP is $\frac{1}{85}$.

Statement-2 If the four chosen number form an AP, then the set of all possible values of common difference is $\{\pm 1, \pm 2, \pm 3, \pm 4, \pm 5\}$. **[AIEEE 2010, 8M]**

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is false

(c) Statement-1 is false, Statement-2 is true

(d) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

140. An urn contains nine balls of which three are red, four are blue and two are green. Three balls are drawn at random without replacement from the urn. The probability that the three balls have different colour, is **[AIEEE 2010, 4M]**

(a) $\frac{2}{7}$ (b) $\frac{1}{21}$ (c) $\frac{2}{23}$ (d) $\frac{1}{3}$

■ **Passage for Question Nos. 141 and 142**

Let U_1 and U_2 be two urns such that U_1 contains 3 white balls and 2 red balls and U_2 contains only 1 white ball. A fair coin is tossed. If head appears, then 1 ball is drawn at random from U_1 and put into U_2. However, if tail appears, then 2 balls are drawn at random from U_1 and put into U_2. Now, 1 ball is drawn at random from U_2.

141. The probability of the drawn ball from U_2 being white, is

(a) $\frac{13}{30}$ (b) $\frac{23}{30}$ (c) $\frac{19}{30}$ (d) $\frac{11}{30}$

142. Given that the drawn ball from U_2 is white, then the probability that head appeared on the coin, is **[IIT-JEE 2011, 3+3M]**

(a) $\frac{17}{23}$ (b) $\frac{11}{23}$ (c) $\frac{15}{23}$ (d) $\frac{12}{23}$

143. Let E and F be two independent events. The probability that exactly one of them occurs is $\frac{11}{25}$ and the probability of none of them occurring is $\frac{2}{25}$. If $P(T)$ denotes the probability of occurrence of the event T, then **[IIT-JEE 2011, 4M]**

(a) $P(E)=\frac{4}{5}, P(F)=\frac{3}{5}$ (b) $P(E)=\frac{1}{5}, P(F)=\frac{2}{5}$

(c) $P(E)=\frac{2}{5}, P(F)=\frac{1}{5}$ (d) $P(E)=\frac{3}{5}, P(F)=\frac{4}{5}$

144. Consider 5 independent Bernoulli's trials each with probability of success P. If the probability of atleast one failure is greater than or equal to $\frac{31}{32}$, then P lies in the interval **[AIEEE 2011, 4M]**

(a) $\left(\frac{3}{4}, \frac{11}{12}\right]$ (b) $\left[0, \frac{1}{2}\right]$ (c) $\left(\frac{11}{12}, 1\right]$ (d) $\left(\frac{1}{2}, \frac{3}{4}\right]$

145. If C and D are two events, such that $C \subset D$ and $P(D) \neq 0$, then the correct statement among the following, is **[AIEEE 2011, 4M]**

(a) $P\left(\frac{C}{D}\right) \geq P(C)$ (b) $P\left(\frac{C}{D}\right) < P(C)$

(c) $P\left(\frac{C}{D}\right) = \frac{P(D)}{P(C)}$ (d) $P\left(\frac{C}{D}\right) = P(C)$

146. Let A, B and C are pairwise independent events with $P(C) > 0$ and $P(A \cap B \cap C) = 0$. Then, $P\left(\frac{(A^c \cap B^c)}{C}\right)$ is

(a) $P(A^c) - P(B)$ (b) $P(A) - P(B^c)$

(c) $P(A^c) + P(B^c)$ (d) $P(A^c) - P(B^c)$

147. A ship is fitted with three engines E_1, E_2 and E_3. The engines function independently of each other with respective probabilities $\frac{1}{2}, \frac{1}{4}$ and $\frac{1}{4}$, respectively. For the ship to be operational atleast two of its engines must function. Let X denote the event that the ship is operational and let X_1, X_2 and X_3 denote respectively the events that the engines E_1, E_2 and E_3 are functioning. Which of the following is (are) true? **[IIT-JEE 2012, 4M]**

(a) $P[X_1^c / X] = \frac{3}{16}$

(b) P [exactly two engines of the ship are functioning $/X] = \frac{7}{8}$

(c) $P[X / X_2] = \frac{5}{16}$

(d) $P[X / X_1] = \frac{7}{16}$

148. Four fair dice D_1, D_2, D_3 and D_4 each having six faces numbered 1, 2, 3, 4, 5 and 6 are rolled simultaneously. The probability that D_4 shows a number appearing on one of D_1, D_2 and D_3, is **[IIT-JEE 2012, 3M]**

(a) $\frac{91}{216}$ (b) $\frac{108}{216}$ (c) $\frac{25}{216}$ (d) $\frac{127}{216}$

149. Let X and Y be two events, such that $P(X / Y) = \frac{1}{2}$, $P(Y / X) = \frac{1}{3}$ and $P(X \cap Y) = \frac{1}{6}$. Which of the following is (are) correct? **[IIT-JEE 2012, 4M]**

(a) $P(X \cup Y) = \frac{2}{3}$ (b) X and Y are independent

(c) X and Y are not independent

(d) $P(X^c \cap Y) = \frac{1}{3}$

150. Three numbers are chosen at random without replacement from {1, 2, 3, …, 8}. The probability that their minimum is 3, given that their maximum is 6, is **[AIEEE 2012, 4M]**

(a) $\frac{1}{4}$ (b) $\frac{2}{5}$ (c) $\frac{3}{8}$ (d) $\frac{1}{5}$

151. A multiple choice examination has 5 questions. Each question has three alternative answers of which exactly one is correct. The probability that a student will get 4 or more correct answers just by guessing, is **[JEE Main 2013, 4M]**

(a) $\frac{13}{3^5}$ (b) $\frac{11}{3^5}$ (c) $\frac{10}{3^5}$ (d) $\frac{17}{3^5}$

152. Four persons independently solve a certain problem correctly with probabilities $\frac{1}{2}, \frac{3}{4}, \frac{1}{4}$ and $\frac{1}{8}$. Then, the probability that the problem is solved correctly by atleast one of them, is **[JEE Advanced 2013, 2M]**

(a) $\frac{235}{256}$ (b) $\frac{21}{256}$ (c) $\frac{3}{256}$ (d) $\frac{253}{256}$

153. Of the three independent events E_1, E_2 and E_3, the probability that only E_1 occurs α, only E_2 occurs is β and only E_3 occurs is γ. Let the probability p that none of events E_1, E_2 or E_3 occurs satisfy the equation $(\alpha - 2\beta)p = \alpha\beta$ and $(\beta - 3\gamma)p = 2\beta\gamma$. All the given probabilities are assumed to lie in the interval $(0, 1)$.

Then, $\dfrac{\text{Probability of occurrence of } E_1}{\text{Probability of occurrence of } E_3}$ is

[JEE Advanced 2013, 4M]

■ **Passage for Question Nos. 154 and 155**

A box B_1 contains 1 white ball, 3 red balls and 2 black balls. Another box B_2 contains 2 white balls, 3 red balls and 4 black balls. A third box B_3 contains 3 white balls, 4 red balls and 5 black balls.

154. If 2 balls are drawn (without replacement) from a randomly selected box and one of the balls is white and the other ball is red, then the probability that these 2 balls are drawn from box B_2 , is

(a) $\dfrac{116}{181}$ (b) $\dfrac{126}{181}$ (c) $\dfrac{65}{181}$ (d) $\dfrac{55}{181}$

155. If 1 ball is drawn from each of the boxes B_1, B_2 and B_3, then the probability that all 3 drawn balls are of the same colour, is **[JEE Advanced 2013, 3+3M]**

(a) $\dfrac{82}{648}$ (b) $\dfrac{90}{648}$ (c) $\dfrac{558}{648}$ (d) $\dfrac{566}{648}$

156. Let A and B be two events, such that $P(\overline{A \cup B}) = \dfrac{1}{6}$, $P(A \cap B) = \dfrac{1}{4}$ and $P(\overline{A}) = \dfrac{1}{4}$, where $\overline{A}$ stands for the complement of the event A. Then, the events A and B are

(a) independent but not equally likely **[JEE Main 2014, 4M]**
(b) independent and equally likely
(c) mutually exclusive and independent
(d) equally likely but not independent

157. Three boys and two girls stand in a queue. The probability that the number of boys ahead of every girl is atleast one more than the number of girls ahead of her, is **[JEE Advanced 2014, 3M]**

(a) $\dfrac{1}{2}$ (b) $\dfrac{1}{3}$ (c) $\dfrac{2}{3}$ (d) $\dfrac{3}{4}$

■ **Passage for Question Nos. 158 and 159**

Box 1 contains three cards bearing numbers 1, 2, 3, box 2 contains five cards bearing numbers 1, 2, 3, 4, 5 and box 3 contains seven cards bearing numbers 1, 2, 3, 4, 5, 6, 7. A card is drawn from each of the boxes. Let x_i be the number on the card drawn from the ith box, $i = 1, 2, 3$.

158. The probability that $x_1 + x_2 + x_3$ is odd, is

(a) $\dfrac{29}{105}$ (b) $\dfrac{53}{105}$ (c) $\dfrac{57}{105}$ (d) $\dfrac{1}{2}$

159. The probability that x_1, x_2 and x_3 are in arithmetic progression, is **[JEE Advanced 2014, 3+3M]**

(a) $\dfrac{9}{105}$ (b) $\dfrac{10}{105}$ (c) $\dfrac{11}{105}$ (d) $\dfrac{7}{105}$

160. If 12 identical balls are to be placed in 3 identical boxes, then the probability that one of the boxes contains exactly 3 balls, is **[JEE Main 2015, 4M]**

(a) $220\left(\dfrac{1}{3}\right)^{12}$ (b) $22\left(\dfrac{1}{3}\right)^{11}$ (c) $\dfrac{55}{3}\left(\dfrac{2}{3}\right)^{11}$ (d) $55\left(\dfrac{2}{3}\right)^{10}$

161. The minimum number of times a fair coin needs to be tossed, so that the probability of getting atleast two heads is atleast 0.96, is **[JEE Advanced 2015, 4M]**

■ **Passage for Question Nos. 162 and 163**

Let n_1 and n_2 be the number of red and black balls respectively, in box I. Let n_3 and n_4 be the number of red and black balls respectively, in box II.

162. One of the two boxes, box I and box II, was selected at random and a ball was drawn randomly out of this box. The ball was found to be red. If the probability that this red ball was drawn from box II is $1/3$, then the correct option(s) with the possible values of n_1, n_2, n_3 and n_4 is (are)

(a) $n_1 = 3, n_2 = 3, n_3 = 5, n_4 = 15$ (b) $n_1 = 3, n_2 = 6, n_3 = 10, n_4 = 50$
(c) $n_1 = 8, n_2 = 6, n_3 = 5, n_4 = 20$ (d) $n_1 = 6, n_2 = 12, n_3 = 5, n_4 = 20$

163. A ball is drawn at random from box I and transferred to box II. If the probability of drawing a red ball from box I, after this transfer is $\dfrac{1}{3}$, then correct option(s) with possible values of n_1 and n_2 is (are) **[JEE Advanced 2015, 4+4M]**

(a) $n_1 = 4$ and $n_2 = 6$ (b) $n_1 = 2$ and $n_2 = 3$
(c) $n_1 = 10$ and $n_2 = 20$ (d) $n_1 = 3$ and $n_2 = 6$

164. Let two fair six-faced dice A and B be thrown simultaneously. If E_1 is the event that die A shows up four, E_2 is the event that die B shows up two and E_3 is the event that the sum of numbers on both dice is odd, then which of the following statements is NOT true? **[JEE Main 2016, 4M]**

(a) E_2 and E_3 are independent (b) E_1 and E_3 are independent
(c) E_1, E_2 and E_3 are independent (d) E_1 and E_2 are independent

165. A computer producing factory has only two plants T_1 and T_2. Plant T_1 produces 20% and plant T_2 produces 80% of the total computers produced 7% of computers produced in the factory turn out to be defective. It is known that P (computer terms out to be defective given that it is produced in plant T_1) = $10P$ (computer terms out to be defective given that it is produced in plant T_2), when $P(E)$ denotes the probability of an event E. A computer produced in the factory is randomly selected and it does not turn out to be defective. Then, the probability that it is produced in plant T_2 is

[JEE Advanced 2016, 3M]

(a) $\dfrac{36}{73}$ (b) $\dfrac{47}{79}$ (c) $\dfrac{78}{93}$ (d) $\dfrac{75}{83}$

■ **Passage for Question Nos. 166 and 167**

Football teams T_1 and T_2 have to play two games against each other. It is assumed that the outcomes of the two games are independent. The probabilities of T_1 winning, drawing and losing a game against T_2 are $\frac{1}{2}, \frac{1}{6}$ and $\frac{1}{3}$ respectively. Each team gets 3 points for a win, 1 point for a draw and 0 point for a loss in a game. Let X and Y denote the total points scored by teams T_1 and T_2 respectively, after two games. **[JEE Advanced 2016, 3+3M]**

(a) $\frac{1}{4}$ (b) $\frac{5}{12}$ (c) $\frac{1}{2}$ (d) $\frac{7}{12}$

167. $P(X = Y)$ is

(a) $\frac{11}{36}$ (b) $\frac{1}{3}$ (c) $\frac{13}{36}$ (d) $\frac{1}{2}$

168. A box contains 15 green and 10 yellow balls. If 10 balls are randomly drawn, one-by-one with replacement, then the variance of the number of green balls drawn is **[JEE Main 2017, 4M]**

(a) $\frac{6}{25}$ (b) $\frac{12}{5}$ (c) 6 (d) 4

169. If two different numbers are taken from the set $\{0, 1, 2, 3, \ldots, 10\}$, then the probability that their sum as well as absolute difference are both multiple of 4, is **[JEE Main 2017, 4M]**

(a) $\frac{7}{55}$ (b) $\frac{6}{55}$ (c) $\frac{12}{55}$ (d) $\frac{14}{45}$

170. For three events A, B and C.

P(Exactly one of A or B or C occurs)

= P(Exactly one of B or C occurs)

= P(Exactly one of C or A occurs) = $\frac{1}{4}$

and P (All the three events occur simultaneously) = $\frac{1}{16}$,

Then the probability that atleast one of the events occurs, is **[JEE Main 2017, 4M]**

(a) $\frac{3}{16}$ (b) $\frac{7}{32}$

(c) $\frac{7}{16}$ (d) $\frac{7}{64}$

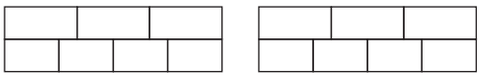
Solutions

1.



$n(S)$ = Number of total ways = ${}^{14}P_{12} = \frac{14!}{2!} = 7 \times 13!$

The girls can be seated together in the back seats leaving a corner seat in $4 \times 3! = 24$ ways and the boys can be seated in the remaining 11 seats in

${}^{11}P_9 = \frac{11!}{2!} = \frac{1}{2} \times 11!$ ways

$\therefore$ $n(E)$ = Number of favourable ways $= 24 \times \frac{1}{2} \times 11! = 12!$

The required probability $= \frac{n(E)}{n(S)} = \frac{12!}{7 \times 13!} = \frac{1}{91}$

2. **For non-leap year**

The probability of 53 Sundays $= \frac{1}{7}$

For leap year

The probability of 53 Sundays $= \frac{2}{7}$

$\therefore$ Required probability $= \frac{3}{4} \times \frac{1}{7} + \frac{1}{4} \times \frac{2}{7} = \frac{5}{28}$

3. Let us consider two events:

A : The leap year contains 53 Sundays.

B : The leap year contains 53 Mondays. We have,

$P(A) = \frac{2}{7}$, $P(B) = \frac{2}{7}$ and $P(A \cap B) = \frac{1}{7}$

$\therefore$ Required probability $= P(A \cup B)$

$= P(A) + P(B) - P(A \cap B)$

$= \frac{2}{7} + \frac{2}{7} - \frac{1}{7} = \frac{3}{7}$

4. Let us consider two events:

A : Numbers divisible by 4.

B : Numbers divisible by 7.

We have, $A = \{104, 108, \ldots, 196\}$

$\Rightarrow$ $n(A) = 24$

$B = \{105, 112, \ldots, 196\}$

$n(B) = 14$ and $A \cap B = \{112, 140, 168, 196\}$

$\Rightarrow$ $n(A \cap B) = 4$

$n(E)$ = Number of favourable ways $n(A \cup B)$

$= n(A) + n(B) - n(A \cap B) = 34$

$n(S)$ = Total number of ways $= 99$

$\therefore$ Required probability $= \frac{n(E)}{n(S)} = \frac{34}{99}$

5. $n(S)$ = Total number of ways = ${}^{100}C_2 = 50 \times 99$

The product is divisible by 3, if atleast one of the two numbers is divisible by 3.

Let $n(E)$ = Number of ways, if atleast one of the two numbers is divisible by 3.

and $n(\bar{E})$ = Number of ways, if none of the two numbers chosen is divisible by 3.

$= {}^{67}C_2 = \frac{67 \times 66}{1 \times 2} = 67 \times 33$

$\therefore$ Required probability $= \frac{n(E)}{n(S)} = \frac{n(S) - n(\bar{E})}{n(S)}$

$= 1 - \frac{67 \times 33}{50 \times 99} = \frac{83}{150}$

6. $n(S)$ = Total number of ways = ${}^{10}C_3 = \frac{10 \cdot 9 \cdot 8}{1 \cdot 2 \cdot 3} = 120$

The product of two numbers is equal to third number, the favourable cases are 2, 3, 6; 2, 4, 8; 2, 5, 10

$\therefore$ $n(E)$ = The number of favourable cases = 3

$\therefore$ Required probability $= \frac{n(E)}{n(S)} = \frac{3}{120} = \frac{1}{40}$

7. $n(S)$ = Total number of ways = ${}^{n}P_n = n!$

Considering digits 1, 2, 3, 4, …, k as one digit, we have $(n - k + 1)$ digits which can be arranged $= (n - k + 1)!$

$\therefore$ $n(E)$ = Number of favourable ways $= (n - k + 1)!$

Hence, required probability $= \frac{n(E)}{n(S)} = \frac{(n - k + 1)!}{n!}$

8. $n(S)$ = Total number of ways = ${}^{n}P_n = n!$

The number of ways in which the digits 1, 2, 3, 4, …, k $(k < n)$ occur together $= k!(n - k + 1)!$

Hence, required probability $= \frac{n(E)}{n(S)} = \frac{k!(n - k + 1)!}{n!} = \frac{(n - k + 1)}{{}^{n}C_k}$

9. Let a, b, c and d are four different numbers out of {1, 2, 3, 4, 5, 6}.

$\Rightarrow$ (a, a, a, a) can appear in ${}^{6}C_1 = 6$ ways

$\Rightarrow$ (a, a, a, b) can appear in $2 \times {}^{6}C_2 = 30$ ways

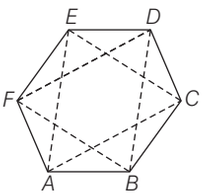
$\Rightarrow$ (a, a, b, b) can appear in ${}^{6}C_2 = 15$ ways

$\Rightarrow$ (a, a, b, c) can appear in $3 \times {}^{6}C_3 = 60$ ways

$\Rightarrow$ (a, b, c, d) can appear in ${}^{6}C_4 = 15$ ways

$\therefore$ Required probability $= \frac{60 + 15}{6 + 30 + 15 + 60 + 15} = \frac{75}{126} = \frac{25}{42}$

10. Let $ABCDEF$ be the regular hexagon.



Number of total triangles $= {}^{6}C_3 = 20$ ways

For the favourable event, the vertices should be either A, C, E or B, D, F

$\therefore$ The required probability $= \dfrac{\text{Favourable ways}}{\text{Total ways}} = \dfrac{2}{20} = \dfrac{1}{10}$

11. Total number of ways to choose two squares

$$= {}^{64}C_2 = \frac{64 \cdot 63}{2} = 32 \cdot 63$$

For favourable ways we must chosen two consecutive small squares for any row or any columns.

$\therefore$ Number of favourable ways $= 7 \cdot 8 + 8 \cdot 7 = 2 \cdot 8 \cdot 7$

$\therefore$ Required probability $= \dfrac{2 \cdot 8 \cdot 7}{32 \cdot 63} = \dfrac{1}{18}$

12. In the word MUMBAI, there are 5 adjacent pairs of letters of which only one gives AI.

$$\therefore \text{ Required probability} = \frac{\frac{1}{5}}{\frac{1}{6}+\frac{1}{5}+\frac{1}{7}+\frac{1}{4}+\frac{1}{5}} = \frac{84}{403}$$

13. Numbers on die are 1, 2, 3, 4, 5, 6.

Prime numbers are 2, 3, 5 and non-prime numbers are 1, 4, 6.

Now, let weight assigned to non-prime numbers is λ, then weight assigned to prime number is 2λ.

$\therefore \lambda + 2\lambda + 2\lambda + \lambda + 2\lambda + \lambda = 1$

$$\Rightarrow \qquad \lambda = \frac{1}{9}$$

$\therefore$ Probability that an odd number will be show up when the die is tossed 1 or 3 or 5.

$$\lambda + 2\lambda + 2\lambda = 5\lambda = \frac{5}{9}$$

14. We have,

$$(X = 7) = \{07, 16, 25, 34, 43, 52, 61, 70\}$$

and $\quad (Y = 0) = \{00, 01, 02, \ldots, 10, 20, 30, \ldots, 90\}$

Thus, $\quad (X = 7) \cap (Y = 0) = \{07, 70\}$

$$\therefore \qquad P\left(\frac{X=7}{Y=0}\right) = \frac{P\{(X=7) \cap (Y=0)\}}{P(Y=0)} = \frac{2}{19}$$

15. The probability of not drawing the ace in the first draw, in the second draw and in the third draw are (here all spades i.e., 13 cards) $\dfrac{12}{13}, \dfrac{11}{12}, \dfrac{10}{11}$, respectively.

Probability of drawing ace of spades in the 4th draw

$$= \frac{1}{10} \text{ (only one ace and remaining cards = 10)}$$

$\therefore$ Required probability $= \dfrac{12}{13} \times \dfrac{11}{12} \times \dfrac{10}{11} \times \dfrac{1}{10} = \dfrac{1}{13}$

16. $n(S) =$ Total number of ways $= {}^{25}C_1 = 25$

Set of composite numbers $= \{4, 6, 8, 9, 10, 12, 14, 15, 16, 18, 20, 21, 22, 24, 25\}$ and set of non-composite numbers $= \{1, 2, 3, 5, 7, 11, 13, 17, 19, 23\}$

Now, set of composite numbers of the form $5k\,(k \in N)$ $= \{10, 15, 20, 25\}$

and set of non-composite numbers of the form $2k\,(k \in N) = \{2\}$

$$\therefore \text{ Required prabability} = \frac{{}^4C_1 + {}^1C_1}{{}^{25}C_1} = \frac{5}{25} = 0.2$$

17. $n(S) =$ Total number of ways $= {}^{50}C_5$

Now, x_3 is fixed to be 30 and x_1, x_2 (two numbers) are to be chosen from first 29 numbers and x_4, x_5 (two numbers) from last 20 numbers are to be chosen.

$\therefore \quad n(E) =$ Number of favourable ways $= {}^{29}C_2 \times {}^{20}C_2$

Hence, required probability $= \dfrac{n(E)}{n(S)} = \dfrac{{}^{29}C_2 \times {}^{20}C_2}{{}^{50}C_5}$

18. The points are 2, 2, 2, 2 or 2, 2, 2, 1

$\therefore$ Required probability

$$= (0.5)^4 + {}^4C_1 \times (0.5)^3 \times (0.05)^1 = 0.0875$$

19. $n(S) =$ Total number of ways $= 6^3 = 216$

$n(E) =$ Number of favourable ways $= 2 \times {}^6C_2 \times \dfrac{3!}{2!} = 90$

$\therefore$ Required probability $= \dfrac{n(E)}{n(S)} = \dfrac{90}{216}$

20. $n(S) =$ Total number of ways $= 6 \times 6 \times 6 = 216$

$n(E) =$ Number of favourable cases

$= $ Coefficient of x^k in $(x + x^2 + x^3 + x^4 + x^5 + x^6)^3$

$= $ Coefficient of x^{k-3} in $(1 + x + x^2 + x^3 + x^4 + x^5)^3$

$= $ Coefficient of x^{k-3} in $(1 - x^6)^3 (1 - x)^{-3}$

$= $ Coefficient of x^{k-3} in $(1 - x)^{-3}$ $\qquad [\because\ 0 \le k - 3 \le 5]$

$= $ Coefficient of x^{k-3} in $(1 + {}^3C_1 x + \ldots)$

$= {}^{k-1}C_{k-3} = {}^{k-1}C_2 = \dfrac{(k-1)(k-2)}{2}$

$\therefore$ Required probability $= \dfrac{n(E)}{n(S)} = \dfrac{(k-1)(k-2)}{432}$

21. $n(S) =$ Total number of ways $= 1000$

The favourable cases that the sum of the digits of the marked number on the page is equal to 9 are one digit number or two digits numbers or three digits numbers, if three digit number is abc. Then, $a + b + c = 9;\ 0 \le a, b, c \le 9$

$\therefore \qquad n(E) =$ Number of favourable ways

$=$ Number of solutions of the equation

$= {}^{9+3-1}C_{3-1} = {}^{11}C_2 = 55$

$\therefore$ Required probability $= \dfrac{n(E)}{n(S)} = \dfrac{55}{1000} = \dfrac{11}{200}$

22. $n(S) =$ The total number of ways of choosing the tickets

$= 4 \times 4 \times 4 \times 4 = 256$

$n(E) =$ The number of ways in which the sum can be 23

$= $ Coefficient of x^{23} in $(1 + x + x^{10} + x^{11})^4$

$= $ Coefficient of x^{23} in $(1 + x^4) + (1 + x^{10})^4$

$= $ Coefficient of x^{23} in $(1 + 4x + 6x^2 + 4x^3 + x^4) \times (1 + 4x^{10} + 6x^{20})$

$= 4 \times 6 = 24$

The probability of required event $= \dfrac{n(E)}{n(S)} = \dfrac{24}{256} = \dfrac{3}{32}$

23. Total coupons $= 15$

$1 \le$ selected coupon number ≤ 9 i.e., 1, 2, 3, 4, 5, 6, 7, 8, 9

$\therefore$ Probability of one selected coupon $= \frac{9}{15} = \frac{3}{5}$

Hence, the required probability

$$= \left(\frac{3}{5}\right) \times \left(\frac{3}{5}\right) \times \ldots \times 7 \text{ times} = \left(\frac{3}{5}\right)^7$$

24. Let X denote the largest number on the 3 tickets drawn.

We have, $P(X \leq 7) = \left(\frac{7}{20}\right)^3$ and $P(X \leq 6) = \left(\frac{6}{20}\right)^3$

Thus, $P(X = 7) = P(X \leq 7) - P(X \leq 6) = \left(\frac{7}{20}\right)^3 - \left(\frac{6}{20}\right)^3$

25. Total number = 6 (i.e., 1, 2, 3, 4, 5, 6)

Favourable number = 2, 3, 4, 5 = 4

Probability of favourable number in one draw $= \frac{4}{6} = \frac{2}{3}$

$\therefore$ Required probability $= \left(\frac{2}{3}\right)^4 = \frac{16}{81}$

26. We have, $P(E_i) = \frac{2}{4} = \frac{1}{2}$ for $i = 1, 2, 3$

Also, for $i \neq j$, $P(E_i \cap E_j) = \frac{1}{4} = P(E_i)\, P(E_j)$

Therefore, E_i and E_j are independent for $i \neq j$.

Also, $P(E_1 \cap E_2 \cap E_3) = \frac{1}{4} \neq P(E_1) P(E_2) P(E_3)$

$\therefore$ E_1, E_2 and E_3 are not independent.

27. Let x and y are two non-negative integers are chosen such that $x^2 + y^2$ is divisible by 10.

By the division algorithm, there exist integers x_1, y_1, a_1 and b_1 such that $x = 10x_1 + a_1$ and $y = 10y_1 + b_1$ with $0 \leq a, b_1 \leq 9$.

Thus, we can write

$x^2 + y^2 = 100(x_1^2 + y_1^2) + 20(a_1x_1 + b_1y_1) + (a_1^2 + b_1^2)$

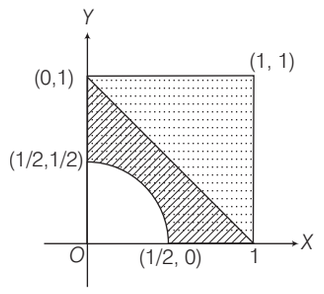
We see that $x^2 + y^2$ will be divisible by 10 if and only if $a_1^2 + b_1^2$ is divisible by 10. Now, there are 10 choices each for a_1 and b_1, so that there are $10 \times 10 = 100$ ways of choosing them. The pairs (a_1, b_1) for which $a_1^2 + b_1^2$ is divisible by 10 are follows:

(0, 0), (1, 3), (1, 7), (2, 4), (2, 6), (3, 1), (3, 9), (4, 2), (4, 8), (5, 5), (6, 2), (6, 8), (7, 1), (7, 9), (8, 4), (8, 6), (9, 3), (9, 7)

Therefore, 18 distinct ways.

$\therefore$ Required probability $= \frac{18}{100} = \frac{9}{50}$

28. Required probability $= \frac{\text{Area of strips region}}{\text{Area of dotted region}}$



$$= \frac{\frac{1}{2} \times 1 \times 1 - \frac{1}{4} \times \pi \left(\frac{1}{2}\right)^2}{1 \times 1 - \frac{1}{4} \times \pi \left(\frac{1}{2}\right)^2} = \frac{8 - \pi}{16 - \pi}$$

29. When the two equal sides are 1 each, then third side could be only 1.

When the two equal sides are 2 each, then third side can take values 1, 2, 3.

When two equal sides are 3 each, then third side can take values 1, 2, 3, 4, 5. When the two equal sides are 4 each, then third side can take values 1, 2, 3, 4, 5, 6 same in the case when two equal sides are 5 and 6.

$\therefore$ Total number of triangles = 1 + 3 + 5 + 6 + 6 + 6 = 27

Required probability $= \frac{1}{27}$

30. Required probability

$$= \frac{\left(\frac{1}{2}\right)^5 \times \left(\frac{1}{2}\right)^5}{\left(\sum_{r=0}^{5} {}^5C_r \left(\frac{1}{2}\right)^r \left(\frac{1}{2}\right)^{5-r}\right)^2} = \frac{1}{\left(\sum_{r=0}^{5} {}^5C_r\right)^2} = \frac{1}{{}^{10}C_5}$$

31. $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

$P(A \cap B) = P(A) + P(B) - P(A \cup B)$

$\therefore 0 \leq P(A \cup B) \leq 1 - 1 \leq -P(A \cup B) \leq 0$

$P(A) + P(B) - 1 \leq P(A) + P(B) - P(A \cup B) \leq P(A) + P(B)$

32. E and F are independent events. Then,

$$P(E \cap F) = P(E) \cdot P(F) \qquad \ldots(i)$$

Option (a) is obviously not true. So, check for options (b), (c) and (d)

$$\begin{aligned} P(E \cap \bar{F}) &= P(E) - P(E \cap F) \\ &= P(E) - P(E) \cdot P(F) \qquad \text{[from Eq. (i)]} \\ &= P(E)[1 - P(F)] \\ &= P(E) \cdot P(\bar{F}) \end{aligned}$$

$\therefore$ E and $\bar{F}$ are independent events.

Now, $P(\bar{E} \cap \bar{F}) = P(\overline{E \cup F})$

$$\begin{aligned} &= 1 - P(E \cup F) \\ &= 1 - [P(E) + P(F) - P(E \cap F)] \\ &= [1 - P(E)] - P(F) + P(E) \cdot P(F) \\ &= P(\bar{E}) - P(F)[1 - P(E)] \\ &= P(\bar{E})\,[1 - P(F)] \\ &= P(\bar{E}) \cdot P(\bar{F}) \end{aligned}$$

$\therefore$ $\bar{E}$ and $\bar{F}$ are independent events.

Again, $P\left(\frac{E}{F}\right) + P\left(\frac{\bar{E}}{F}\right) = \frac{P(E \cap F)}{P(F)} + \frac{P(\bar{E} \cap F)}{P(F)}$

$$\begin{aligned} &= \frac{P(E) \cdot P(F)}{P(F)} + \frac{P(\bar{E}) \cdot P(F)}{P(F)} \\ &= P(E) + P(\bar{E}) = 1 \end{aligned}$$

33. We know that, $P(A \cap B) \geq P(A) + P(B) - 1$ ...(i)

$$P\left(\frac{A}{B}\right) = \frac{P(A \cap B)}{P(B)} \qquad [P(B) \neq 0]$$

$$\Rightarrow \quad P\left(\frac{A}{B}\right) \geq \frac{P(A)+P(B)-1}{P(B)} \qquad \text{[from Eq. (i)]}$$

Option (a) is true.

$$P(A \cap \overline{B}) = P(A) - P(A \cap B)$$

Option (b) is not true.

$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

If A and B are independent events, then $P(A \cap B) = P(A) \cdot P(B)$.

Then, $P(A \cup B) = P(A) + P(B) - P(A) \cdot P(B)$

$$= P(A) + P(B)\,[1 - P(A)] + 1 - 1$$

$$= 1 + P(B)\,P(\overline{A}) - P(\overline{A}) \qquad [\because P(\overline{A}) = 1 - P(A)]$$

$$= 1 + P(\overline{A})[P(B) - 1] = 1 - P(\overline{A}) \cdot P(\overline{B})$$

Option (c) is true.

If A and B are disjoint, then $P(A \cap B) = 0$.

Then, $P(A \cup B) = 1 - P(\overline{A})\,P(\overline{B})$ does not hold.

34. E and F are two independent events

$$P(E \cap F) = P(E) \cdot P(F) \qquad \ldots(i)$$

$$P(E \cap F) = \frac{1}{12} \qquad \ldots(ii)$$

$$P(\overline{E} \cap \overline{F}) = \frac{1}{2}$$

$$\Rightarrow \quad 1 - P(E \cup F) = \frac{1}{2}$$

$$\Rightarrow \quad P(E) + P(F) - P(E \cap F) = \frac{1}{2}$$

$$\Rightarrow \quad P(E) + P(F) - \frac{1}{12} = \frac{1}{2}$$

$$\Rightarrow \quad P(E) + P(F) = \frac{1}{2} + \frac{1}{12}$$

$$\Rightarrow \quad P(E) + P(F) = \frac{7}{12} \qquad \ldots(iii)$$

From Eqs. (i) and (ii), we get,

$$P(E) \cdot P(F) = \frac{1}{12}$$

$$P(E) = \frac{1}{12P(F)}$$

Put this value in Eq. (iii) we get

$$P(F) + \frac{1}{12P(F)} = \frac{7}{12}$$

Let $P(F) = x$

Then, $x + \frac{1}{12x} = \frac{7}{12}$

$$\Rightarrow \quad \frac{12x^2 + 1}{12x} = \frac{7}{12} \Rightarrow 12x^2 - 7x + 1 = 0$$

$$12x^2 - 4x - 3x + 1 = 0$$

$$\Rightarrow \quad 4x(3x-1) - 1(3x-1) = 0$$

$$(3x-1)(4x-1) = 0 \Rightarrow x = \frac{1}{3} \text{ or } \frac{1}{4}$$

$$\therefore \quad P(E) = \frac{1}{4}, P(F) = \frac{1}{3}$$

or $P(E) = \frac{1}{3}, P(F) = \frac{1}{4}$

35. $P\left(\frac{E}{F}\right) + P\left(\frac{\overline{E}}{F}\right) = \frac{P(E \cap F)}{P(F)} + \frac{P(\overline{E} \cap F)}{P(F)}$

$$= \frac{P(E \cap F) + P(\overline{E} \cap F)}{P(F)} = \frac{P(E \cap F) + P(F) - P(E \cap F)}{P(F)}$$

$$= \frac{P(F)}{P(F)} = 1$$

and $P\left(\frac{E}{F}\right) + P\left(\frac{\overline{E}}{F}\right) = \frac{P(E \cap \overline{F})}{P(\overline{F})} + \frac{P(\overline{E} \cap \overline{F})}{P(\overline{F})}$

$$= \frac{[P(E) - P(E \cap F)] + [1 - P(E \cup F)]}{P(\overline{F})}$$

$$= \frac{[P(E \cup F) - P(F)] + [1 - P(E \cup F)]}{P(\overline{F})}$$

$$= \frac{1 - P(F)}{P(\overline{F})} = \frac{P(\overline{F})}{P(\overline{F})} = 1$$

36. $P(B - A) = P(B \cap \overline{A}) = P(B) - P(A \cap B)$

Option (a) is not correct.

$P(A' \cup B') = 1 - P(A \cap B) = 1 - P(A) \cdot P(B)$ [by given condition]

$P(A') + P(B') = 1 - P(A) + 1 - P(B) = 2 - [P(A) + P(B)]$

Option (b) is not correct $P[(A \cup B)'] = 1 - P(A \cup B)$

$$= 1 - [P(A) + P(B) - P(A) \cdot P(B)]$$ [by given condition]

$$= 1 - P(A) - P(B)\,[1 - P(A)]$$

$$= P(\overline{A}) - P(B) \cdot P(\overline{A}) = P(\overline{A}) \cdot P(\overline{B})$$

Option (c) is correct.

$$P\left(\frac{A}{B}\right) = \frac{P(A \cap B)}{P(B)} = \frac{P(A) \cdot P(B)}{P(B)} = P(A)$$

37. Required probability $= P(A - B) + P(B - A)$

$$= P(A \cap \overline{B}) + P(B \cap \overline{A})$$

$$= P(A) - P(A \cap B) + P(B) - P(A \cap B)$$

$$= P(A) + P(B) - 2P(A \cap B)$$

So, options (a) and (b) are true.

$P(A - B) + P(B - A) = P(A \cup B) - P(A \cap B)$ [by venn diagram]

So, option (c) is also true.

$P(A') + P(B') - 2P(A' \cap B') = 1 - P(A) + 1 - P(B) - 2 + 2P(A \cup B)$

$$= 2P(A \cup B) - P(A) - P(B)$$

$$= 2P(A) + 2P(B) - 2P(A \cap B) - P(A) - P(B)$$

$$= P(A) + P(B) - 2P(A \cap B)$$

$\therefore$ Option (d) is also true.

38. A and B are independent events, then $P(A \cap B) = P(A) \cdot P(B)$

$$P(A) = \frac{1}{2} \text{ and } P(B) = \frac{1}{5}$$

$$P(A \cap B) = \frac{1}{10}$$

$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

$$= \frac{1}{2} + \frac{1}{5} - \frac{1}{10} = \frac{5 + 2 - 1}{10} = \frac{6}{10} = \frac{3}{5}$$

$$P\left(\frac{A}{B}\right) = P(A) = \frac{1}{2}$$

$$P\left(\frac{A}{A \cup B}\right) = \frac{P[A \cap (A \cup B)]}{P(A \cup B)} = \frac{P(A)}{P(A \cup B)} = \frac{\frac{1}{2}}{\frac{3}{5}} = \frac{5}{6}$$

$$P\left(\frac{A \cap B}{A' \cup B'}\right) = P\left(\frac{A \cap B}{(A \cap B)'}\right)$$

$$= \frac{P[(A \cap B) \cap (A \cap B)']}{P(A \cap B)'} = 0$$

39. Let A, B and C be the event that the student is successful in tests I, II and III, respectively.

P (the student is successful)

$= P(A \cap B \cap C') + P(A \cap B' \cap C) + P(A \cap B \cap C)$

$= P(A) \cdot P(B) \cdot P(C') + P(A) \cdot P(B') \cdot P(C) + P(A) \cdot P(B) \cdot P(C)$

$\therefore$ A, B and C are independent events.

$$= pq\left(1 - \frac{1}{2}\right) + p(1-q)\left(\frac{1}{2}\right) + pq\,\frac{1}{2}$$

$$= \frac{1}{2}[pq + p(1-q) + pq] = \frac{1}{2}p(1+q)$$

$$\therefore \qquad \frac{1}{2} = \frac{1}{2}p(1+q) \implies p(1+q) = 1$$

which is satisfied for all pairs of values in (a), (b) and (c). Also, it is satisfied for infinitely many values as p and q. For instance, when $p = \frac{n}{n+1}$ and $q = \frac{1}{n}$, where n is any positive integer.

40. Total number of subset of set contain n elements $= 2^n$

Number of ways choosing A and $B = 2^n \cdot 2^n = 2^{2n}$.

The number of subset of x which contains exactly r elements

$= {}^nC_r$

$\therefore$ The number of ways of choosing A and B, so that they have the same number of elements

$$= ({}^nC_0)^2 + ({}^nC_1)^2 + \ldots + ({}^nC_n)^2 = {}^{2n}C_n$$

$$= \frac{1 \cdot 2 \cdot 3 \ldots (2n-1)(2n)}{n!\,n!} = \frac{2^n(1 \cdot 3 \cdot 5 \ldots (2n-1))}{n!}$$

41. The number of ways in which m boys and m girls can take their seats around a circle is $(2m-1)!$

(a) We make the girls sit first around the circle. This can be done in $(m-1)!$ ways, after this boys can take their seats in $(m!)$ ways.

$\therefore$ Favourable number of ways $= m!(m-1)!$

Required probability $= \dfrac{m!(m-1)!}{(2m-1)!} = \dfrac{1}{{}^{2m-1}C_m}$

(b) Similarly as (a)

(c) Similarly as (a)

(d) Required probability $= \dfrac{m!m!}{(2m-1)!} \neq \dfrac{1}{{}^{2m-1}C_m}$

42. According to the question,

$$(m + p + c) - mp - mc - pc + mpc = \frac{3}{4} \qquad \ldots(i)$$

$$mp(1-c) + mc(1-p) + pc(1-m) = \frac{2}{5}$$

or $$mp + mc + pc - 3mpc = \frac{2}{5} \qquad \ldots(ii)$$

Also, $$mp + pc + mc - 2mpc = \frac{1}{2} \qquad \ldots(iii)$$

From Eqs. (ii) and (iii), we get

$$mpc = \frac{1}{2} - \frac{2}{5} = \frac{1}{10}$$

$$\therefore \qquad mp + mc + pc = \frac{2}{5} + \frac{3}{10} = \frac{7}{10}$$

$$m + p + c = \frac{3}{4} + \frac{7}{10} - \frac{1}{10} = \frac{27}{20}$$

43. Favourable number of cases $= {}^{n-3}P_2$

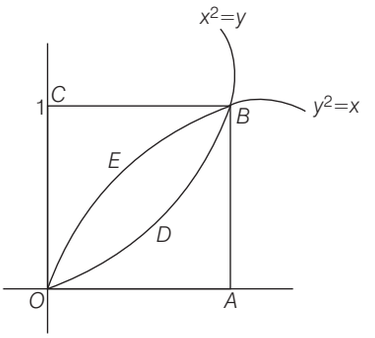
Total number of cases $= {}^nP_2$

$$\therefore \text{ Required probability} = \frac{{}^{n-3}P_2}{{}^nP_2} = \frac{{}^{n-3}C_2 \times 2!}{{}^nC_2 \times 2!} = \frac{{}^{n-3}C_2}{{}^nC_2}$$

$$= \frac{\frac{(n-3)(n-4)}{2 \times 1}}{\frac{n(n-1)}{2 \times 1}} = \frac{(n-3)(n-4)}{n(n-1)}$$

44. A = The event of (x, y) belonging to the area $OEBAO$

B = The event of (x, y) belonging to the area $ODBCO$



$$\therefore \qquad P(A) = \frac{\text{area of } OEBAO}{\text{area of } OABCO} = \frac{\int_0^1 \sqrt{x}\,dx}{1 \times 1} = \frac{2}{3}$$

and $$P(B) = \frac{\text{area of } ODBCO}{\text{area of } OABCO} = \frac{\int_0^1 \sqrt{y}\,dy}{1 \times 1} = \frac{2}{3}$$

and $$P(A \cap B) = \frac{\text{area of } ODBEO}{\text{area of } OABCO} = \frac{\int_0^1 \sqrt{x}\,dx - \int_0^1 x^2 dx}{1 \times 1} = \frac{1}{3}$$

$\therefore$ $P(A) + P(B) = \frac{2}{3} + \frac{2}{3} \neq 1$.

So, A and B are not exhaustive,

$$P(A) \cdot P(B) = \frac{2}{3} \cdot \frac{2}{3} \neq \frac{1}{3}.$$

So, A and B are not independent

and $P(A \cup B) = 1$, $P(A) + P(B) \neq P(A \cup B)$.

So, A and B are not mutually exclusive.

45. Let $P(k) \propto \frac{1}{k^4} \Rightarrow P(k) = \frac{\lambda}{k^4}$

where λ is proportionality constant

Then $\sum_{k=1}^{2n} \frac{\lambda}{k^4} = 1 \Rightarrow \lambda \sum_{k=1}^{2n} \frac{1}{k^4} = 1$

$\therefore \quad \alpha = \sum_{k=1}^{n} P(2k-1) = \lambda \sum_{k=1}^{n} \frac{1}{(2k-1)^4}$

and $\quad \beta = \sum_{k=1}^{n} P(2k) = \lambda \sum_{k=1}^{n} \frac{1}{(2k)^4} < \lambda \sum_{k=1}^{n} \frac{1}{(2k-1)^4}$

$\Rightarrow \quad \beta < \alpha$ and $\alpha + \beta = 1$

Then, $1 - \alpha < \alpha$ and $\beta < 1 - \beta$

$\therefore \quad \alpha > \frac{1}{2}$ and $\beta < \frac{1}{2}$

46. Roots of $x^2 + px + q = 0$ are real and distinct, if $p^2 > 4q$.

Value of p	Possible values of q
1	No value
2	No value
3	1, 2
4	1, 2, 3
5	1, 2, 3, 4, 5, 6
6	1, 2, 3,..., 8
7	1, 2, 3,..., 10
8	1, 2, 3,..., 10
9	1, 2, 3,..., 10
10	1, 2, 3,..., 10

$\therefore$ Number of favourable ways
$= 2 + 3 + 6 + 8 + 10 + 10 + 10 + 10 = 59$
and total ways $= 10 \times 10 = 100$

Hence, the required probability $= \frac{59}{100} = 0.59$

47. Roots of $x^2 + px + q = 0$ are equal, if $p^2 = 4q$
i.e., p^2 must be even.

Value of p	Possible values of q
2	1
4	4
6	9
8	No value
10	No value

$\therefore$ Number of favourable ways $= 1 + 1 + 1 = 3$
and total ways $= 10 \times 10 = 100$

Hence, the required probability $= \frac{3}{100} = 0.03$

48. Roots of $x^2 + px + q = 0$ are imaginary, if $p^2 < 4q$

Hence, the required probability $= 1 -$(Probability that roots of $x^2 + px + q = 0$ are real) $= 1 - (0.59 - 0.03) = 1 - 0.62$

$= 0.38$

49. X can win after the $(n+1)$ th game in the following two mutually exclusive ways.

(i) X wins exactly one of the first n games draws $(n-1)$ games and wins the $(n+1)$ th game.

$\therefore$ Probability, $P_1 = ({}^nP_1\, a\, b^{n-1})a = na^2b^{n-1}$

(ii) X losses exactly one of the first n games, wins exactly one of the first n games and draws $(n-2)$ games and wins the $(n+1)$ th game.

$\therefore$ Probability, $P_2 = ({}^nP_2(ac)b^{n-2})a = n(n-1)a^2b^{n-2}c$

Hence, the probability that X wins two match after $(n+1)$ th game.

$$P_n = P_1 + P_2 = na^2b^{n-2}[b + (n-1)c]$$

50. Put $n = 3$ in solution of question 4 and interchange a and c, then required probability $= 3c^2 \cdot b^1(b + 2a) = 3bc^2(2a + b)$

51. The probability that X wins the match

$$= \sum_{n=1}^{\infty} Pn = \sum_{n=1}^{\infty} na^2b^{n-1} + \sum_{n=1}^{\infty} n(n-1)a^2b^{n-2}c$$

$$= \frac{a^2}{b}\sum_{n=1}^{\infty} nb^n + \frac{a^2c}{b^2}\sum_{n=1}^{\infty} n(n-1)b^n$$

$$= \frac{a^2}{b}\cdot\frac{b}{(1-b)^2} + \frac{a^2c}{b^2}\cdot\frac{2b^2}{(1-b)^3}$$

[sum of infinite AGS]

$$= \frac{a^2(1-b+2c)}{(1-b)^3} = \frac{a^2(a+3c)}{(a+c)^3} \quad \left[\because a+b+c=1 \;\because 1-b=a+c\right]$$

52. $\because P(E_\lambda) \propto \lambda^2$

$\Rightarrow P(E_\lambda) = k\lambda^2$, where k is proportionality constant.

$\because E_0, E_1, E_2, \ldots, E_n$ are mutually exclusive and exhaustive events.
We have, $P(E_0) + P(E_1) + P(E_2) + \ldots + P(E_n) = 1$

$$0 + k(1)^1 + k(2)^2 + \ldots + k(n)^2 = 1$$

$$\Rightarrow \quad k(\sum n^2) = 1$$

$$\therefore \quad k = \frac{1}{\sum n^2} \qquad \ldots(i)$$

53. $P(A) = \sum_{\lambda=0}^{n} P(E_\lambda)\cdot P\left(\frac{A}{E_\lambda}\right)$

$$= \sum_{\lambda=0}^{n}\left(k\lambda^2 \times \frac{\lambda}{n}\right) = \frac{k}{n}\sum_{\lambda=1}^{n}\lambda^3 = \frac{k}{n}\sum_{\lambda=0}^{n}\lambda^3$$

$$= \frac{k}{n}\sum n^3 = \frac{1}{n}\times\frac{1}{\sum n^2}\times\sum n^3 \qquad \text{[from Eq. (i)]}$$

$$= \frac{\left(\frac{n(n+1)}{2}\right)^2}{\frac{n\cdot n(n+1)(2n+1)}{6}} = \frac{3}{2}\cdot\left(\frac{n+1}{2n+1}\right) = \frac{3}{4}\cdot\frac{\left(1+\frac{1}{n}\right)}{\left(1+\frac{1}{2n}\right)}$$

$$\therefore \lim_{n\to\infty} P(A) = \frac{3}{4}\lim_{n\to\infty}\left(\frac{1+\frac{1}{n}}{1+\frac{1}{2n}}\right) = \frac{3}{4}\cdot\left(\frac{1+0}{1+0}\right) = \frac{3}{4} = 0.75$$

54. $$P\left(\frac{E_1}{A}\right) = \frac{P(E_1)\cdot P\left(\frac{A}{E_1}\right)}{\sum_{\lambda=0}^{n} P(E_\lambda)\cdot P\left(\frac{A}{E_\lambda}\right)} = \frac{P(E_1)\cdot P\left(\frac{A}{E_1}\right)}{P(A)}$$

$$= \frac{\frac{6}{n(n+1)(2n+1)}\times\frac{1}{n}}{\frac{3n(n+1)}{2(2n+1)}} = \frac{4}{[n(n+1)]^2} = \frac{1}{\sum n^3}$$

55. The number of cubes having atleast one side painted is

$9 + 9 + 3 + 3 + 1 + 1 = 26$ and total cubes $= 27$

$\therefore$ Required probability, $P_1 = \frac{26}{27} \Rightarrow 27P_1 = 26$

56. The number of cubes having two sides painted is

$4 + 4 + 1 + 1 + 1 + 1 = 12$ and total cubes $= 27$

$\therefore$ Required probability, $P_2 = \frac{12}{27} \Rightarrow 27P_2 = 12$

57. Required probability, $P_3 = 1 - p_1 = 1 - \frac{26}{27} = \frac{1}{27} \Rightarrow 27P_3 = 1$

58. A : She gets a success

E_1 : She studies 10 h

$\therefore \quad P(E_1) = 0.1$

E_2 : She studies 7 h

$\therefore \quad P(E_2) = 0.2$

and E_3: She studies 4h

$\therefore \quad P(E_3) = 0.7$

and $P\left(\frac{A}{E_1}\right) = 0.80$, $P\left(\frac{A}{E_2}\right) = 0.60$ and $P\left(\frac{A}{E_3}\right) = 0.40$

$$\therefore \quad P(A) = P(E_1)\cdot P\left(\frac{A}{E_1}\right) + P(E_2)\cdot P\left(\frac{A}{E_2}\right) + P(E_3)\cdot P\left(\frac{A}{E_3}\right)$$

$$= 0.1\times 0.80 + 0.2\times 0.60 + 0.7\times 0.40 = 0.48$$

59. $$P\left(\frac{E_3}{A}\right) = \frac{P(E_3\cap A)}{P(A)} = \frac{P(E_3)\cdot P\left(\frac{A}{E_3}\right)}{P(A)} = \frac{0.7\times 0.40}{0.48} = \frac{7}{12}$$

60. $$P\left(\frac{E_3}{A}\right) = \frac{P(E_3\cap \bar{A})}{P(\bar{A})} = \frac{P(E_3) - P(E_3\cap A)}{1 - P(A)}$$

$$= \frac{0.7 - 0.28}{1 - 0.48} = \frac{0.42}{0.52} = \frac{21}{26}$$

61. $\because p_1$, p_2 and p_3 are mutually exclusive events.

$$\therefore \quad p_1 + p_2 + p_3 = 1$$

Also, p_1, p_2 and p_3 are the roots of

$$27x^3 - 27x^2 + ax - 1 = 0$$

$$\therefore \quad p_1 + p_2 + p_3 = 1 \qquad \ldots(i)$$

$$p_1p_2 + p_2p_3 + p_3p_1 = \frac{a}{27} \qquad \ldots(ii)$$

and $$p_1p_2p_3 = \frac{1}{27}$$

Now, AM of $p_1, p_2, p_3 = \frac{p_1 + p_2 + p_3}{3} = \frac{1}{3}$

and GM of $p_1, p_2, p_3 = (p_1p_2p_3)^{1/3} = \left(\frac{1}{27}\right)^{1/3} = \frac{1}{3}$

Here, AM = GM

$$\therefore \quad p_1 = p_2 = p_3 = \frac{1}{3}$$

From Eq. (ii), we get

$$\frac{1}{3}\cdot\frac{1}{3} + \frac{1}{3}\cdot\frac{1}{3} + \frac{1}{3}\cdot\frac{1}{3} = \frac{a}{27} \Rightarrow a = 9$$

62. P (none of E_1, E_2, E_3) $= 1 - P(E_1 \cup E_2 \cup E_3)$

$$= 1 - [P(E_1) + P(E_2) + P(E_3)]$$

$$= 1 - (p_1 + p_2 + p_3) = 0$$

[$\because E_1$, E_2 and E_3 are mutually exclusive]

63. $P(E_1 \cup \bar{E}_2) + P(E_2 \cap \bar{E}_3) + P(E_3 \cap \bar{E}_1)$

$= P(E_1) - P(E_1 \cap E_2) + P(E_2) - P(E_2 \cap E_3)$

$\quad + P(E_3) - P(E_3 \cap E_1)$

$= P(E_1) - 0 + P(E_2) - 0 + P(E_3) - 0$

$= p_1 + p_2 + p_3$ [$\because E_1$, E_2 and E_3 are mutually exclusive]

64. The number of increasing functions $= {}^6C_3 = 20$

and the number of total functions $= 6^3 = 216$

$\therefore$ Required probability $= \frac{20}{216} = \frac{5}{54}$

65. The number of non-decreasing functions $= {}^{6+3-1}C_3 = {}^8C_3 = 56$

the number of total functions $= 6^3 = 216$

$\therefore$ Required probability $= \frac{56}{216} = \frac{7}{27}$

66. The number of onto functions such that $f(i) \neq i$ is

$$6!\left(1 - \frac{1}{1!} + \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \frac{1}{5!} + \frac{1}{6!}\right) = 265$$

and number of total functions $= 6! = 720$

$\therefore$ Required probability $= \frac{265}{720} = \frac{53}{144}$

67. $\because P(X = x) \propto (x+1)\left(\frac{1}{5}\right)^x$

$$P(X = x) = k(x+1)\left(\frac{1}{5}\right)^x$$

We have, $k\left[1 + 2\left(\frac{1}{5}\right) + 3\left(\frac{1}{5}\right)^2 + \ldots\right] = 1$

$$\Rightarrow \quad k\left[\frac{1}{\left(1-\frac{1}{5}\right)^2}\right] = 1 \Rightarrow k = \frac{16}{25}$$

Now, $P(X = 0) = k(1)\left(\frac{1}{5}\right)^0 = k = \frac{16}{25}$

68. $P(X \geq 2) = 1 - [P(X = 0) + P(X = 1)]$

$$= 1 - k\left[1 + \frac{2}{5}\right] = 1 - \frac{7k}{5} = 1 - \frac{7}{5} \times \frac{16}{25} = \frac{13}{125}$$

69. $E(X) = \sum_{x=0}^{\infty} x\, P(X = x) = k \sum_{x=0}^{\infty} x(x+1)\left(\frac{1}{5}\right)^x$

$$= k\left[(1)(2)\left(\frac{1}{5}\right)^1 + (2)(3)\left(\frac{1}{5}\right)^2 + (3)(4)\left(\frac{1}{5}\right)^3 + \ldots + \infty\right]$$

$$E(X) = k\left[\frac{2}{5} + \frac{6}{25} + \frac{12}{125} + \ldots + \infty\right] \quad \ldots(i)$$

and $\frac{1}{5}E(X) = k\left[\frac{2}{25} + \frac{6}{125} + \frac{12}{625} + \ldots + \infty\right]$ ...(ii)

On subtracting Eq. (ii) from Eq. (i), we get

$$\frac{4}{5}E(X) = k\left[\frac{2}{5} + \frac{4}{25} + \frac{6}{125} + \ldots + \infty\right] \quad \ldots(iii)$$

On multiplying both sides by $\frac{1}{5}$ in Eq. (i), we get

$$\frac{4}{25}E(X) = k\left[\frac{2}{25} + \frac{4}{125} + \frac{6}{625} + \ldots + \infty\right] \quad \ldots(iv)$$

On subtracting Eq. (iv) from Eq. (iii), we get

$$\frac{16}{25}E(X) = k\left[\frac{2}{5} + \frac{2}{25} + \frac{2}{125} + \ldots + \infty\right]$$

$$= k\left[\frac{\frac{2}{5}}{1 - \frac{1}{5}}\right] = \frac{k}{2} = \frac{16}{25} \times \frac{1}{2} \qquad \left[\because k = \frac{16}{25}\right]$$

$\therefore \quad E(x) = \frac{1}{2}$

70. $\because (a^2 - 1)$ is divisible by 10, if and only if last digit of a is 1 or 9.

If $r = 0$, then there are 2λ ways to choose a.

$\therefore \quad p_n = \frac{2\lambda}{n} \Rightarrow n p_n = 2\lambda$

71. If $r = 9$, then there are $2(\lambda + 1)$ ways to choose a.

$\therefore \quad p_n = \frac{2(\lambda + 1)}{n}$

$\Rightarrow \quad n p_n = 2(\lambda + 1)$

72. If $1 \leq r \leq 8$, then there are $2(\lambda + 1)$ ways to choose a.

$\therefore \quad p_n = \frac{2(\lambda + 1)}{n}$

$\Rightarrow \quad x p_n = 2(\lambda + 1)$

73. $\frac{7}{12} = \frac{1}{(n+1)} \cdot 1 + \frac{n}{(n+1)} \cdot \frac{1}{2}$

$\Rightarrow \frac{7}{6} = \frac{(n+2)}{(n+1)} \Rightarrow n = 5$

74. Let S be the sample space, then

$n(S)$ = Total number of determinants that can be made with 0 and 1 $= 2 \times 2 \times 2 \times 2 = 16$

$\because \begin{vmatrix} a & b \\ c & d \end{vmatrix}$, each element can be replaced by two types

i.e., 0 and 1

and let E be the event that the determinant made is non-negative.

Also, E' be the event that the determinant is negative.

$\therefore \quad E' = \left\{\begin{vmatrix} 1 & 1 \\ 1 & 0 \end{vmatrix}, \begin{vmatrix} 0 & 1 \\ 1 & 1 \end{vmatrix}, \begin{vmatrix} 0 & 1 \\ 1 & 0 \end{vmatrix}\right\}$

$\therefore \quad P(E') = 3$

then $P(E') = \frac{n(E')}{n(S)} = \frac{3}{16}$

Hence, the required probability,

$$P(E) = 1 - P(E')$$

$$= 1 - \frac{3}{16} = \frac{13}{16} = \frac{m}{n} \qquad \text{[given]}$$

$\Rightarrow \quad m = 13$ and $n = 16$, then $n - m = 3$

75. Let E_1, E_2 and E_3 be the events that first, second and third student get success. Then,

$$P(E_1) = \frac{1}{3},\ P(E_2) = \frac{1}{4} \text{ and } P(E_3) = \frac{1}{5}$$

Given, probability of success of atleast two $= \frac{\lambda}{12}$

$\Rightarrow \quad P(E_1 \cap E_2 \cap \bar{E}_3) + P(\bar{E}_1 \cap E_2 \cap E_3)$

$$+ P(E_1 \cap \bar{E}_2 \cap E_3) + P(E_1 \cap E_2 \cap E_3) = \frac{\lambda}{12}$$

$\Rightarrow \quad P(E_1) \cdot P(E_2) \cdot P(\bar{E}_3) + P(\bar{E}_1) \cdot P(E_2) \cdot P(E_3)$

$$+ P(E_1) \cdot P(\bar{E}_2) \cdot P(E_3) + P(E_1) \cdot P(E_2) \cdot P(E_3) = \frac{\lambda}{12}$$

$\Rightarrow \quad \frac{1}{3} \cdot \frac{1}{4} \cdot \frac{4}{5} + \frac{2}{3} \cdot \frac{1}{4} \cdot \frac{1}{5} + \frac{1}{3} \cdot \frac{3}{4} \cdot \frac{1}{5} + \frac{1}{3} \cdot \frac{1}{4} \cdot \frac{1}{5} = \frac{\lambda}{12}$

$\Rightarrow \quad \frac{10}{60} = \frac{\lambda}{12}$

$\therefore \quad \lambda = 2$

76. Let S be the sample space and E be the event of getting a large number than the previous number.

$\therefore \quad n(S) = 6 \times 6 \times 6 = 216$

Now, we count the number of favourable ways. Obviously, the second number has to be greater than 1. If the second number is $i (i > 1)$, then the number of favourable ways $= (i - 1) \times (6 - i)$

$\therefore \quad n(E)$ = Total number of favourable ways

$$= \sum_{i=1}^{6} (i - 1) \times (6 - i)$$

$$= 0 + 1 \times 4 + 2 \times 3 + 3 \times 2 + 4 \times 1 + 5 \times 0$$

$$= 4 + 6 + 6 + 4 = 20$$

Therefore, the required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{20}{216}$

$$= \frac{5}{54} = p \qquad \text{[given]}$$

$\therefore \quad 54p = 5$

77. The number of ways to answer a question $= 2^5 - 1 = 31$.

i.e., In 31 ways only one correct.

Let number of choices $= n$

Now, according to the question $\frac{n}{31} > \frac{1}{8}$

$\Rightarrow \quad n > \frac{31}{8} \Rightarrow n > 3.8$

$\therefore$ Least value of $n = 4$

78. Let E_i denote the event that the ith object goes to the ith place, we have

$$P(E_i \cap E_j \cap E_k) = \frac{(n-3)!}{n!} \text{ for } i < j < k$$

Since, we can choose 3 places out of n is ${}^nC_3$ ways, the probability of the required event is

$$p = {}^nC_3 \cdot \frac{(n-3)!}{n!} = \frac{n!}{3!(n-3)!} \cdot \frac{(n-3)!}{n!} = \frac{1}{6}$$

$\therefore \quad 6p = 1$

79. The sample space is

$S = \{-0.50, -0.49, -0.48, \ldots, -0.01, 0.00, 0.01, \ldots, 0.49\}$

Let E be the event that the round off error is atleast 10 paise, then E' is the event that the round off error is atmost a paise.

$\therefore \quad E' = \{-0.09, -0.08, \ldots, -0.01, 0.00, 0.01, \ldots, 0.09\}$

$\therefore \quad n(E') = 19$ and $n(S) = 100$

$\therefore \; P(E') = \frac{n(E')}{n(S)} = \frac{19}{100}$

$\therefore$ Required probability, $P(E) = 1 - P(E') = 1 - \frac{19}{100}$

$$= \frac{81}{100} = \left(\frac{m}{n}\right)^2$$

$\therefore \quad m = 9$ and $n = 10$

$\Rightarrow \quad n - m = 1$

80. Let E_1, E_2, E_3, E_4, E_5 and E_6 be the events of occurrence of 1, 2, 3, 4, 5 and 6 on the dice respectively and let E be the event of getting a sum of numbers equal to 9.

$\therefore \quad P(E_1) = \frac{1-k}{6}; P(E_2) = \frac{1+2k}{6}; P(E_3) = \frac{1-k}{6};$

$P(E_4) = \frac{1+k}{6}; P(E_5) = \frac{1-2k}{6}; P(E_6) = \frac{1+k}{6}$

and $\frac{1}{9} \le P(E) \le \frac{2}{9}$

Then, $E \equiv \{(3, 6), (6, 3), (4, 5), (5, 4)\}$

Hence, $P(E) = P(E_3E_6) + P(E_6E_3) + P(E_4E_5) + P(E_5E_4)$

$= P(E_3)P(E_6) + P(E_6)P(E_3) + P(E_4)P(E_5) + P(E_5)P(E_4)$

$= 2P(E_3)P(E_6) + 2P(E_4)P(E_5)$

[since E_1, E_2, E_3, E_4, E_5 and E_6 are independent]

$$= 2\left(\frac{1-k}{6}\right)\left(\frac{1+k}{6}\right) + 2\left(\frac{1+k}{6}\right)\left(\frac{1-2k}{6}\right)$$

$$= \frac{1}{18}[2 - k - 3k^2]$$

Since, $\frac{1}{9} \le P(E) \le \frac{2}{9}$

$\Rightarrow \quad \frac{1}{9} \le \frac{1}{18}[2 - k - 3k^2] \le \frac{2}{9}$

$\Rightarrow \quad 2 \le 2 - k - 3k^2 \le 4$

$\Rightarrow \quad 2 \le 2 - k - 3k^2$ and $2 - k - 3k^2 \le 4$

$\Rightarrow \quad 3k\left(k + \frac{1}{3}\right) \le 0$ and $3k^2 + k + 2 \ge 0$

$\Rightarrow \quad -\frac{1}{3} \le k \le 0$ and $k \in R$

$\therefore \quad -\frac{1}{3} \le k \le 0$

Hence, integral value of k is 0.

81. Let $a_1, a_2, a_3, a_4, a_5, a_6$ and a_7 be the seven digits and the remaining two be a_8 and a_9.

Let $a_1 + a_2 + a_3 + a_4 + a_5 + a_6 + a_7 = 9k, k \in I$ ...(i)

Also, $a_1 + a_2 + a_3 + a_4 + \ldots + a_9 = 1 + 2 + 3 + 4 + \ldots + 9$

$$= \frac{9 \times 10}{2} = 45 \quad \ldots(ii)$$

On subtracting Eq. (i) from Eq. (ii), we get

$a_8 + a_9 = 45 - 9k$ ...(iii)

Since, $a_1 + a_2 + a_3 + a_4 + \ldots + a_9$ and $a_1 + a_2 + \ldots + a_7$ are divisible by 9, if and only if $a_8 + a_9$ is divisible by 9. Let S be the sample space and E be the event that the sum of the digits a_8 and a_9 is divisible by 9.

$\because \quad a_8 + a_9 = 45 - 9k$

Maximum value of $a_8 + a_9 = 17$ and minimum value of

$a_8 + a_9 = 3$

$\therefore \quad 3 \le 45 - 9k \le 17$

$\Rightarrow \quad -42 \le -9k \le -28 \;\Rightarrow\; \frac{42}{9} \le k \ge \frac{28}{9}$

or $\frac{28}{9} \le k \ge \frac{42}{9}$

Hence, $k = 4$ [$\because k$ is positive integer]

$\therefore$ From Eq. (iii), we get

$a_8 + a_9 = 45 - 9 \times 4$

$\therefore \quad a_8 + a_9 = 9$

Now, possible pair of (a_8, a_9) can be$\{(1, 8), (2, 7), (3, 6), (4, 5)\}$

$\therefore \quad E = \{(1, 8), (2, 7), (3, 6), (4, 5)\}$

$n(E) = 4$ and $n(S) = {}^9C_2 = 36$

$\therefore$ Required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{4}{36} = \frac{1}{9} = p$ [given]

$\therefore \quad 18p = 2$

82. Let A be the event of P_1 winning in third round and B be the event of P_2 winning in first round but loosing in second round.

We have, $P(A) = \frac{1}{{}^8C_1} = \frac{1}{8}$

$P(B \cap A)$ = Probability of both P_1 and P_2 winning in first round $\times$ Probability of P_1 winning and P_2 loosing in second round $\times$ Probability of P_1 winning in third round

$$= \frac{{}^{8-2}C_{4-2}}{{}^8C_4} \times \frac{{}^{4-2}C_{2-1}}{{}^4C_2} \times \frac{{}^{2-1}C_{1-1}}{{}^2C_1}$$

$$= \frac{{}^6C_2}{{}^8C_4} \times \frac{{}^2C_1}{{}^4C_2} \times \frac{{}^1C_0}{{}^2C_1} = \frac{1}{28}$$

Hence, $P\left(\frac{B}{A}\right)=\frac{P(B\cap A)}{P(A)}=\frac{\frac{1}{28}}{\frac{1}{8}}=\frac{2}{7}=p$ [given]

$\therefore \quad 7p=2$

83. (A) $\rightarrow$(q,r); (B) $\rightarrow$ (p,r); (C) $\rightarrow$ (p,r); (D) $\rightarrow$ (q,r,s)

(A) $P(\overline{A})=0.3\Rightarrow P(A)=1-P(\overline{A})=0.7,\ P(B)=0.4,$

$\Rightarrow \quad 0.5=0.7-P(AB)$

$\therefore \quad P(AB)=0.2$

$$\Rightarrow P\left[\frac{B}{(A\cup\overline{B})}\right]=\frac{P[B\cap(A\cup\overline{B})]}{P(A\cup\overline{B})}=\frac{P(A\cap B)}{P(A)+P(\overline{B})-P(A\overline{B})}$$

$$=\frac{0.2}{0.7+0.6-0.5}=\frac{1}{4}=\lambda_1 \quad \text{[given]}$$

$\therefore \quad \frac{1}{\lambda_1}=4$ [composite number and natural number]

(B) First three prime numbers are 2, 3 and 5.

For roots to be real $D\geq 0$

Thus, real roots are obtained by $b=5, a=2, c=3$

and $b=5, a=3, c=2$

i.e., two ways.

Total ways of choosing $a, b, c=3\times 2\times 1=6$

$\therefore$ Required probability $=\frac{2}{6}=\frac{1}{3}=\lambda_2$ [given]

$\therefore \quad \frac{1}{\lambda_2}=3$

[prime number and natural number]

(C) Here, tossing of the coin is an independent event. Thus, the result of 5th trial is independent of outcome of previous trials.

$\therefore \quad \lambda_3=\frac{1}{2} \Rightarrow \frac{1}{\lambda_3}=2$

[prime number and natural number]

(D) Clearly, $n(S)={}^9P_9=9!$

Now, 3 positions out of 9 positions can be chosen in ${}^9C_3$ ways and at these positions A, B and C can speak in required order, further remaining 6 persons can speak in 6! ways.

$\therefore$ Required probability $=\frac{{}^9C_3\times 6!}{9!}$

$$=\frac{9!\times 6!}{3!\times 6!\times 9!}=\frac{1}{6}=\lambda_4 \quad \text{[given]}$$

$\therefore \quad \frac{1}{\lambda_4}=6$

[a composite number, a natural number and a perfect number]

84. (A) $\rightarrow$ (s); (B) $\rightarrow$ (p); (C) $\rightarrow$ (r); (D) $\rightarrow$ (q)

(A) $\frac{3}{5}\geq P(A\cap B)\geq P(A)+P(B)-1=\frac{3}{5}+\frac{2}{3}-1=\frac{4}{15}$

$\therefore \quad \frac{3}{5}\geq P(A\cap B)\geq\frac{4}{15}$

$\Rightarrow \quad P(A\cap B)\in\left[\frac{4}{15},\frac{3}{5}\right]$

(B) $\because P(A\cup B)=P(A)+P(B)-P(A\cap B)$

$$=\frac{3}{5}+\frac{2}{3}-P(A\cap B)=\frac{19}{15}-P(A\cap B)$$

$\Rightarrow \quad \frac{2}{3}\leq P(A\cup B)\leq 1 \quad \left[\because P(A\cap B)\in\left[\frac{4}{15},\frac{3}{5}\right]\right]$

$\therefore \quad P(A\cup B)\in\left[\frac{2}{3},1\right]$

(C) $P\left(\frac{A}{B}\right)=\frac{P(A\cap B)}{P(B)}=\frac{3}{2}P(A\cap B)$

$\Rightarrow \quad \frac{2}{5}\leq P\left(\frac{A}{B}\right)\leq\frac{9}{10}\left[\because P(A\cap B)\in\left[\frac{4}{15},\frac{3}{5}\right]\right]$

$\therefore \quad P\left(\frac{A}{B}\right)\in\left[\frac{2}{5},\frac{9}{10}\right]$

(D) $P\left(\frac{B}{A}\right)=\frac{P(B\cap A)}{P(A)}=\frac{5}{3}P(A\cap B)$

$\Rightarrow \quad \frac{4}{9}\leq P\left(\frac{B}{A}\right)\leq 1 \quad \left[\because P(A\cap B)\in\left[\frac{4}{15},\frac{3}{5}\right]\right]$

$\therefore \quad P\left(\frac{B}{A}\right)\in\left[\frac{4}{9},1\right]$

85. (A) $\rightarrow$ (p,r,s) ; (B) $\rightarrow$ (p,r,s); (C) $\rightarrow$ (s); (D) $\rightarrow$ (q,r)

Let $q_1=1-p_1$ and $q_2=1-p_2$

(A) $\because A$ can win the game at the 1st, 4th, 7th,... trials.

$$\therefore P(A \text{ wins})=\frac{1}{6}+\frac{5}{6}(q_1)(q_2)\left(\frac{1}{6}\right)+\left(\frac{5}{6}\right)^2(q_1)^2(q_2)^2\left(\frac{1}{6}\right)+\ldots$$

$$=\frac{\frac{1}{6}}{1-\frac{5}{6}q_1q_2}=\frac{1}{6-5q_1q_2}=\frac{1}{6-5\left(\frac{4}{5}\right)\left(\frac{3}{4}\right)}=\frac{1}{\lambda_1} \text{ [given]}$$

$\therefore \quad \lambda_1=3$

(B) $P(C \text{ wins})=\frac{5}{6}.q_1.p_2+\left(\frac{5}{6}\right)^2.q_1^2.q_2p_2+\ldots$

$$=\frac{\frac{5}{6}q_1.p_2}{1-\frac{5}{6}q_1q_2}=\frac{5q_1p_2}{6-5q_1q_2}=\frac{5\times\frac{4}{5}\times\frac{1}{4}}{6-5\times\frac{4}{5}\times\frac{3}{4}}=\frac{1}{3}$$

$$=\frac{1}{\lambda_2} \quad \text{[given]}$$

$\therefore \quad \lambda_2=3$

(C) $\because$ $P(A \text{ wins})=P(B \text{ wins})$

$$\Rightarrow \quad \frac{1}{6-5q_1q_2}=\frac{5p_1}{6-5q_1q_2}$$

$\therefore \quad p_1=\frac{1}{5}=\frac{1}{\lambda_3}$ [given]

$\therefore \quad \lambda_3=5$

(D) $P(A \text{ wins}) = P(B \text{ wins}) = P(C \text{ wins})$

$$\Rightarrow \quad \frac{1}{6-5q_1q_2} = \frac{5p_1}{6-5q_1q_2} = \frac{5q_1p_2}{6-5\,q_1q_2}$$

$$\Rightarrow \quad 1 = 5p_1 = 5q_1p_2$$

$$\Rightarrow \quad p_1 = \frac{1}{5}, \frac{1}{p_2} = 5q_1 = 5\left(1-\frac{1}{5}\right) = 4 = \lambda_4 \qquad \text{[given]}$$

$$\therefore \quad \lambda_4 = 4$$

86. (A) → (q); (B) → (r); (C) → (p); (D) → (s)

(A) $\because a, b \in \{1, 2, 3, \ldots, 9\}$

For real and distinct roots $D > 0$

i.e., $2(a-b)^2 > 4b \Rightarrow (a-b)^2 > 2b$

The possible pairs are

b	a	Total pairs of a and b
1	3, 4, 5, ..., 9	7
2	5, 6, ..., 9	5
3	6, 7, 8, 9	4
4	1, 7, 8, 9	4
5	1, 9	2
6	1, 2	2
7	1, 2, 3	3
8	1, 2, 3	3
9	1, 2, 3, 4	4
		34

$n(S) = 9 \times 9 = 81$ and $n(E) = 34$

$$\therefore \quad p_1 = \frac{34}{81} \Rightarrow 9p_1 = \frac{34}{9}$$

$$\therefore \quad [9p_1] = \left[\frac{34}{9}\right] = 3$$

(B) For imaginary roots,

$$p_2 = 1 - p_4 = 1 - \frac{5}{9} = \frac{4}{9}$$

$$\therefore \quad [9p_2] = 4$$

(C) For equal roots, there are only 2 possible pairs are

$$b = 2, a = 4 \text{ and } b = 8, a = 4$$

$$\therefore \quad n(S) = 81, n(E) = 2$$

$$\therefore \quad p_3 = \frac{2}{81}$$

$$\Rightarrow \quad [81p_3] = 2$$

(D) For real roots,

$$p_4 = 1 - (p_1 + p_3) = 1 - \left(\frac{34}{81} + \frac{2}{81}\right)$$

$$= 1 - \frac{36}{81} = 1 - \frac{4}{9} = \frac{5}{9}$$

$$\therefore \quad [9p_4] = 5$$

87. (A) → (r); B → (s); (C) → (p); D → (q)

(A) $n(S) = {}^{10}C_3 = 120$ and $n(E) = {}^3C_1 = 3$, because on selection 3 and 7, we have to select one from 4, 5 and 6.

$$\therefore \quad P(E) = \frac{n(E)}{n(S)} = \frac{3}{120} = \frac{1}{40} = p_1 \qquad \text{[given]}$$

$$\Rightarrow \quad \frac{2}{5p_1} = 16$$

(B) The probability of 4 being the minimum number

$= \frac{{}^6C_2}{{}^{10}C_3} = \frac{1}{8}$ [because after selecting 4 any two can be selected from 5, 6, 7, 8, 9, 10]

and the probability of being the maximum number

$= \frac{{}^7C_2}{{}^{10}C_3} = \frac{7}{40}$ [because after selecting 8 any two can be selected from 1, 2, 3, 4, 5, 6, 7]

and the probability of 4 being the minimum number and 8 being the maximum number

$= \frac{{}^3C_1}{{}^{10}C_3} = \frac{1}{40}$ [because on selecting 4, 8 and we have to select one from 5, 6, 7]

$\therefore$ Required probability

$$= P(A \cup B) = P(A) + P(B) - P(A \cap B)$$

$$= \frac{1}{8} + \frac{7}{40} - \frac{1}{40} = \frac{11}{40} = p_2 \qquad \text{[given]}$$

$$\therefore \quad 80p_2 = 22$$

(C) Let A = {maximum of three numbers is 7}

$\therefore \quad A = \{1, 2, 3, 4, 5, 6, 7\}$

and B = {minimum of three numbers is 3}

$\therefore \quad B = \{3, 4, 5, 6, 7, 8, 9, 10\}$

and $A \cap B = \{3, 4, 5, 6, 7\}$

$$\therefore \quad P\left(\frac{B}{A}\right) = \frac{P(B \cap A)}{P(A)} = \frac{{}^3C_1}{{}^6C_2} = \frac{1}{5} = p_3 \qquad \text{[given]}$$

$$\therefore \quad \frac{2}{p_3} = 10$$

(D) Let A = { maximum of three numbers is 8 }

$\therefore \quad A = \{1, 2, 3, 4, 5, 6, 7, 8\}$

and B = { minimum of three numbers is 4 }

$\therefore \quad B = \{4, 5, 6, 7, 8, 9, 10\}$ and $A \cap B = \{4, 5, 6, 7, 8\}$

$$\therefore \quad P\left(\frac{B}{A}\right) = \frac{P(B \cap A)}{P(A)} = \frac{{}^3C_1}{{}^7C_2} = \frac{1}{7} = p_4 \qquad \text{[given]}$$

$$\therefore \quad \frac{2}{p_4} = 14$$

88. (A) → (q); (B) → (s); C → (p); (D) → (r)

(A) We know that 7^λ, $\lambda \in N$ has 1, 3, 7, 9 at the unit's place for $\lambda = 4k, 4k-1, 4k-2, 4k-3$ respectively, when $k = 1, 2, 3, \ldots$

Clearly, $7^m + 7^n$ will be divisible by 5, if 7^m has 3 or 7 in the unit's place and 7^n has 7 or 3 in the unit's place or 7^m has 1 or 9 in the unit's place and 7^n has 9 or 1 in the unit's place.

$\therefore$ For any choice of m, n the digit in the unit's place of $7^m + 7^n$ is 2, 4, 6, 8, 0

It is divisible by 5 only when this digit is 0.

$\therefore$ Required probability $= \frac{1}{5}$

(B) $n(S) = 2 \times 2 \times 2 \times 2 = 16$

[because each of the four places in determinant can be filled in 2 ways]

The zero determinants are

$$\begin{vmatrix} 1 & 1 \\ 1 & 1 \end{vmatrix}, \begin{vmatrix} -1 & -1 \\ -1 & -1 \end{vmatrix}, \begin{vmatrix} 1 & 1 \\ -1 & -1 \end{vmatrix}, \begin{vmatrix} -1 & -1 \\ 1 & 1 \end{vmatrix}, \begin{vmatrix} 1 & -1 \\ -1 & 1 \end{vmatrix}, \begin{vmatrix} 1 & -1 \\ 1 & -1 \end{vmatrix}, \begin{vmatrix} -1 & 1 \\ -1 & 1 \end{vmatrix}, \begin{vmatrix} -1 & 1 \\ 1 & -1 \end{vmatrix}$$

Number of zero determinants = 8, number of non-zero determinants

$= 16 - 8 = 8 = n(E)$ [say]

$\therefore$ Required probability $= \frac{n(E)}{n(S)} = \frac{8}{16} = \frac{1}{2}$

(C) $\because P(E_n) \propto n$

$\Rightarrow P(E_n) = kn$, where k is proportionality constant.

Clearly,

$P(E_1) + P(E_2) + P(E_3) + P(E_4) + P(E_5) + P(E_6) = 1$

$\Rightarrow \quad k(1 + 2 + 3 + 4 + 5 + 6) = 1 \Rightarrow k = \frac{1}{21}$

$\therefore$ Required probability $= P(E_3) = 3k = 3 \times \frac{1}{21} = \frac{1}{7}$

(D) 5 can be thrown in 4 ways and 7 can be thrown in 6 ways in a single throw of two dice.

Number of ways of throwing neither 5 nor 7

$= 36 - (4 + 6) = 26$

Probability of throwing a sum of 5 in a throw $= \frac{4}{36} = \frac{1}{9}$

and probability of throwing neither 5 nor 7 $= \frac{26}{36} = \frac{13}{18}$

$\therefore$ Required probability

$$= \frac{1}{9} + \frac{13}{18}\left(\frac{1}{9}\right) + \left(\frac{13}{18}\right)^2\left(\frac{1}{9}\right) + \ldots = \frac{\frac{1}{9}}{1 - \frac{13}{18}} = \frac{2}{5}$$

89. $\text{In}\left(\frac{1}{2} + \frac{1}{2}\right)^{10}$

Probability of appearing exactly four heads

$$= {}^{10}C_4\left(\frac{1}{2}\right)^4\left(\frac{1}{2}\right)^6 = {}^{10}C_{10-4}\left(\frac{1}{2}\right)^6\left(\frac{1}{2}\right)^4$$

$$= {}^{10}C_6\left(\frac{1}{2}\right)^6\left(\frac{1}{2}\right)^4$$

= Probability of appearing exactly six heads. Both statements are true,

Statement-2 is a correct explanation for Statement-1.

90. If A and B are independent, then

$P(A \cap B) = P(A) \cdot P(B) = P(A)$ [$\because P(B) = 1$] ...(i)

and $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

$= P(A) + P(B) - P(A)$ [from Eq. (i)]

$= P(B) = 1$ which is true.

Hence, both statements are true and Statement-2 is a correct explanation for Statement-1.

91. $\because \quad P(A \cap \overline{B}) = P(A) - P(A \cap B)$

$\Rightarrow \quad P(A \cap \overline{B}) = 0.3 - P(A \cap B)$

$\therefore P(A \cap \overline{B})$ cannot be found. Hence, both statements are true and Statement-2 is a correct explanation for Statement-1.

92. $\because P(A \cup B) = P(A \cap B)$

$\Rightarrow P(A) + P(B) - P(A \cap B) = P(A \cap B)$

$\Rightarrow (P(A) - P(A \cap B)) + (P(B) - P(A \cap B)) = 0$

$\Rightarrow \quad P(A \cap B') + P(A' \cap B) = 0$ ...(i)

$\because \quad A \cap B \subseteq A$ and $A \cap B \subseteq B$

$\Rightarrow \quad P(A \cap B) \le P(A)$ and $P(A \cap B) \le P(B)$

$\Rightarrow P(A) - P(A \cap B) \ge 0$ and $P(B) - P(A \cap B) \ge 0$

$\Rightarrow \quad P(A \cap B') \ge 0$ ...(ii)

and $P(A' \cap B) \ge 0$ ...(iii)

From Eqs. (i), (ii) and (iii), we get

$P(A \cap B') = 0$ and $P(A' \cap B) = 0$

or $P(A \cap B') = P(A' \cap B) = 0$

$\Rightarrow$ Statement-1 is true and Statement-2 is false.

93. **Statement-1** There are six equally likely possibilities of which only 2 are favourable (4 and 6)

$\therefore$ Probability that the obtained number is composite $= \frac{2}{6} = \frac{1}{3}$

$\therefore$ Statement-1 is true.

Statement-2 As the given 3 possibilities are not equally likely.

$\therefore$ Statement-2 is false.

94. Total cards = 52 = 26 Red + 26 Black

13 Diamond 13 Heart

Given A : Red card is drawn

B : Card drawn is either a diamond or heart

It is clear that $A \subseteq B$ and $B \subseteq A$

$\therefore$ Statement-2 is true.

and $P(A + B) = P(A \cup B) = P(A \cup A) = P(A)$ [$\because A \subseteq B$ and $B \subseteq A$]

and $P(AB) = P(A \cap B) = P(A \cap A) = P(A)$ [$\because A \subseteq B$ and $B \subseteq A$]

$\therefore \quad P(A + B) = P(AB)$

Statement-1 is true.

Hence, both statements are true and Statement-2 is a correct explanation for Statement-1.

95. Required probability = 1 − Problem will not be solved

$= 1 - P(\overline{A} \cap \overline{B}) = 1 - P(\overline{A})P(\overline{B}) = 1 - (1 - P(A))(1 - P(B))$

$= 1 - \left(1 - \frac{1}{2}\right)\left(1 - \frac{1}{3}\right) = 1 - \frac{1}{2} \times \frac{2}{3} = 1 - \frac{1}{3} = \frac{2}{3}$

$\therefore$ Statement-1 is false and Statement-2 is true.

96. Total ways $= {}^{2n+1}C_3 = \dfrac{(2n+1).2n.(2n-1)}{1\cdot 2\cdot 3} = \dfrac{n(4n^2-1)}{3}$

Let the three numbers a, b, c are drawn, where $a < b < c$ and given a, b and c are in AP.

$\therefore \quad 2b = a + c$...(i)

It is clear from Eq. (i) that a and c both are odd or both are even.

$\therefore$ Favourable ways $= {}^{n+1}C_2 + {}^{n}C_2$

$$= \frac{(n+1)n}{1\cdot 2} + \frac{n(n-1)}{1\cdot 2} = n^2$$

$\therefore$ Required probability $= \dfrac{n^2}{\dfrac{n(4n^2-1)}{3}} = \dfrac{3n}{(4n^2-1)}$

$\Rightarrow$ Statement-2 is false.

In Statement-1, $2n + 1 = 21$

$\Rightarrow \quad n = 10$

$\because$ Required probability $= \dfrac{3\times 10}{4(10)^2 - 1} = \dfrac{30}{399} = \dfrac{10}{133}$

$\therefore$ Statement-1 is true.

97. In Statement-2 $P\left(\dfrac{A}{B}\right) = \dfrac{P(A\cap B)}{P(B)}$ [by definition]

$P(\overline{B}) = P((A\cup\overline{A})\cap\overline{B}) = P((A\cap\overline{B})\cup(\overline{A}\cap\overline{B}))$

$= P(A\cap\overline{B}) + P(\overline{A}\cap\overline{B})$ ...(i)

$\therefore$ Statement-2 is true.

In Statement-1

$$P\left(\frac{A}{\overline{B}}\right) + P\left(\frac{\overline{A}}{\overline{B}}\right) = \frac{P(A\cap\overline{B})}{P(\overline{B})} + \frac{P(\overline{A}\cap\overline{B})}{P(\overline{B})}$$

$$= \frac{P(A\cap\overline{B}) + P(\overline{A}\cap\overline{B})}{P(\overline{B})} = \frac{P(\overline{B})}{P(\overline{B})} = 1 \quad \text{[From Eq. (i)]}$$

$\therefore$ Statement-1 is false.

98. The total number of matches played in the tournament

$= {}^5C_2 = 10$

The probability that a particular team (say A) wins all its 4 matches $= \left(\dfrac{1}{2}\right)^4 = \dfrac{1}{16}$

$\therefore$ Probability that team is undefeated in the tournament

$$= {}^5C_1\left(\frac{1}{2}\right)^4 = \frac{5}{16}$$

$\Rightarrow$ Statement-1 is true.

Similarly, the probability that there is an winless team $= \dfrac{5}{16}$

$\Rightarrow$ Statement-2 is false.

99. For real roots, $D \geq 0$

$\Rightarrow \quad p^2 - 4\cdot 1\cdot\dfrac{1}{4}(p+2) \geq 0$

$\Rightarrow \quad p^2 - p - 2 \geq 0$

$\Rightarrow \quad (p-2)(p+1) \geq 0$

$\Rightarrow \quad p \leq -1$ or $p \geq 2$

But $p \in [0, 5]$.

So, $E = [2, 5]$

$n(E)$ = length of the interval $[2, 5] = 3$

and $n(S)$ = length of the interval $[0, 5] = 5$

$\therefore$ Required probability $= \dfrac{n(E)}{n(S)} = \dfrac{3}{5}$

Hence, both statements are true and Statement-2 is a correct explanation for Statement-1

100. $P\left(\dfrac{A}{B}\right) = \dfrac{P(A\cap B)}{P(B)} = \dfrac{\dfrac{n(A\cap B)}{n(S)}}{\dfrac{n(B)}{n(S)}} = \dfrac{n(A\cap B)}{n(B)} = \dfrac{n(AB)}{n(B)}$

Hence, both statements are true and Statement-2 is a correct explanation for Statement-1.

101. Let S be the sample space, then

$n(S)$ = Total number of numbers of five digits formed with the digits 1, 2, 3, 4 and 5 without repetition $= {}^5P_5 = 5! = 120$

We know that, a number is divisible by 4 if the last two digits of the number is divisible by 4.

Then, for divisible by 4, last two digits 12 or 24 or 32 or 52.

Let E be the event that the number formed is divisible by 4.

$\therefore \quad n(E) = 3! \times 4 = 24$

$\therefore$ Required probability, $P(E) = \dfrac{n(E)}{n(S)} = \dfrac{24}{120} = \dfrac{1}{5}$

102. Let S be the sample space and E be the event of getting a large number than the previous number.

$\therefore \quad n(S) = 6\times 6\times 6 = 216$

Now, we count the number of favourable ways. Obviously, the second number has to be greater than 1. If the second number is $i (i > 1)$, then the number of favourable ways $= (i-1)\times(6-i)$

$\therefore$ $n(E)$ = Total number of favourable ways

$$= \sum_{i=1}^{6}(i-1)\times(6-i)$$

$$= 0 + 1\times 4 + 2\times 3 + 3\times 2 + 4\times 1 + 5\times 0$$

$$= 4 + 6 + 6 + 4 = 20$$

Therefore, the required probability,

$$P(E) = \frac{n(E)}{n(S)} = \frac{20}{216} = \frac{5}{54}$$

103. Finding r cars in N places, there are $(r-1)$ cars other than his own in $(N-1)$ places.

$\therefore$ Total number of ways $= {}^{N-1}C_{r-1} = \dfrac{(n-1)!}{(r-1)!\,(N-r)!}$

Now, the $(r-1)$ cars must be parked in $N-3$ places (because neighbouring slots are empty).

$\therefore$ Number of favourable ways $= {}^{N-3}C_{r-1}$

$$= \frac{(N-3)!}{(r-1)!\,(N-r-2)!}$$

$\therefore$ Required probability $= \dfrac{\text{Favourable ways}}{\text{Total ways}}$

$$= \frac{(N-3)!}{(r-1)!\,(N-r-2)!}\times\frac{(r-1)!\,(N-r)!}{(N-1)!}$$

$$= \frac{(N-r)\,(N-r-1)}{(N-1)\,(N-2)}$$

104. A wins the series in $(n + r + 1)$ games (say). He wins the $(n + r + 1)$ th game and
n out of the first $(n + r)$ games.

$$\therefore \qquad P(A) = \sum_{r=0}^{n} ({}^{n+r}C_n)\, q^r p^{n+1} \qquad [\text{where } p + q = 1]$$

Similarly, $\quad P(B) = \sum_{r=0}^{n} ({}^{n+r}C_n)\, q^{n+1} p^r$

Now, $P(A) + P(B) = 1$

$$\therefore \qquad \sum_{r=0}^{n} [q^r p^{n+1} + q^{n+1} p^r]\, {}^{n+r}C_n = 1$$

Now, put $p = q = \frac{1}{2}$

$$\therefore \qquad \sum_{r=0}^{n} {}^{n+r}C_n \left[\frac{1}{2^{n+r+1}} + \frac{1}{2^{n+r+1}}\right] = 1$$

$$\Rightarrow \qquad \sum_{r=0}^{n} ({}^{n+r}C_n)\, \frac{1}{2^{n+r}} = 1$$

105. Let A denotes the event that the target is hit when x shells are fired at point I.
Let $E_1 (E_2)$ denote the event.
We have, $P(E_1) = \frac{8}{9}$, $P(E_2) = \frac{1}{9}$

$$\Rightarrow \qquad P\left(\frac{A}{E_1}\right) = 1 - \left(\frac{1}{2}\right)^x \text{ and } P\left(\frac{A}{E_2}\right) = 1 - \left(\frac{1}{2}\right)^{21-x}$$

$$\text{Now,} \quad P(A) = \frac{8}{9}\left[1 - \left(\frac{1}{2}\right)^x\right] + \frac{1}{9}\left[1 - \left(\frac{1}{2}\right)^{21-x}\right]$$

$$\Rightarrow \qquad \frac{dP(A)}{dx} = \frac{8}{9}\left[\left(\frac{1}{2}\right)^x \log 2\right] + \frac{1}{9}\left[-\left(\frac{1}{2}\right)^{21-x} \log 2\right]$$

Now, we must have $\frac{dP(A)}{dx} = 0 \Rightarrow \quad x = 12$, also $\frac{d^2P(A)}{dx^2} < 0$

Hence, $P(A)$ is maximum where $x = 12$.

106. The composition of the balls in the red box and in the green box; and the sum suggested in the problem may be one of the following:

Red box		**Green box**		**Sum of Green in Red and Red in Green**
Red	**Green**	**Green**	**Red**	
0	5	3	6	11
1	4	4	5	9
2	3	5	4	7
3	2	6	3	5
4	1	7	2	3
5	0	8	1	1

Of these the 2nd and the last correspond to the sum being NOT a prime number. Hence, the required probability

$$= \frac{{}^6C_1 \times {}^8C_4 \times {}^6C_5 \times {}^8C_0}{{}^{14}C_5} = \frac{420 + 6}{2002} = \frac{213}{1001}$$

107. Let E_i denote the event that out of the first k balls drawn, i balls are green. Let A denote the event that $(k + 1)$th ball drawn is also green. We have, now $P(E_i) = \frac{{}^aC_1 \times {}^bC_{k-i}}{{}^{a+b}C_k}$

Here, $0 \le i \le k$ and $P\left(\frac{A}{E_i}\right) = \frac{a - i}{a + b - k}$

$$\text{Now,} \qquad P(A) = \sum_{j=0}^{k} \frac{{}^aC_j \times {}^bC_{k-j}}{{}^{a+b}C_k} \times \frac{a - j}{a + b - k}$$

Also, $(1 + x)^{a-1} (1 + x)^b$

$$= [{}^{a-1}C_0 + {}^{a-1}C_1 x + \ldots + {}^{a-1}C_{a-1} x^{a-1}] \times [{}^bC_0 + {}^bC_1 x + \ldots + {}^bC_b x^b]$$

$$\Rightarrow \sum_{j=0}^{n} ({}^{a-1}C_j)\, ({}^bC_{k-j}) = \text{coefficient of } x^k$$

$$\text{Hence,} \qquad P(A) = \frac{a}{a + b}$$

108. Total number of outcomes $= 2 \times 2 \times 2 \ldots 12$ times $= 4096$

Let a_n denote the number of outcomes in which two consecutive heads do not occur when the fair coin is tossed n times.

$$\Rightarrow \qquad a_1 = 2,\ a_2 = 3$$

For $n \ge 3$, if the last outcome is T, then we cannot have two consecutive heads in the first $(n - 1)$ tosses. This can happen in a_{n-1} ways. If the last outcome is H, we must have T the $(n - 1)$th toss and we cannot have two consecutive heads in the first $(n - 2)$ tosses. This can happen in a_{n-2} ways.

$$\Rightarrow \qquad a_n = a_{n-1} + a_{n-2} \text{ for } n \ge 3$$

$$\Rightarrow \qquad a_{10} = 144,\ a_{11} = 233$$

$$\Rightarrow \qquad a_{12} = 377$$

Hence, the required probability is $\frac{377}{4096}$.

109. Let PQ be a diameter of a circle with centre O and radius a. Take a point A at random in PQ.
Let, $AP = x$, $AQ = y$, then $x + y = 2a$ and all values of x between 0 and $2a$ are equally likely.
Draw the ordinate AB, then $AB^2 = AP, AQ = xy$
If P', Q' are the mid-points of OP, OQ, the ordinates at these points are equal to $a\sqrt{\frac{3}{4}}$.
Hence, $AB > a\sqrt{\frac{3}{4}}$ if and only if, A lies in $P'Q'$.
Hence, the chance that $xy > \frac{3}{4}a^2$ is $\frac{A'B'}{AB}$ i.e., $\frac{1}{2}$.

110. (i) Kamsky wins one of the first n games and draws the remaining $[(n - 1)$ or
(ii) Kamsky wins exactly one of the first n games and draws the remaining$]$ $n - 2$. We have,

$$P(i) = {}^nP_1 pq^{n-1}$$

and $\qquad P(ii) = {}^nP_2\, pq^{n-2} r$

$\Rightarrow$ The probability that Kamsky wins this match is

$$\sum_{n=1}^{\infty} p^2 [nq^{n-1} + n(n-1)\, rq^{n-2}]$$

$$= p^2 \sum_{n=1}^{\infty} nq^{n-1} + p^2 r \sum_{n=1}^{\infty} n(n-1)\, q^{n-2}$$

Differentiating both sides w.r.t. q, we get

$$\sum_{n=1}^{\infty} nq^{n-1} = \frac{1}{(1-q)^2} \text{ and } \sum_{n=1}^{\infty} n(n-1)\, q^{n-2} = \frac{2}{(1-q)^3}$$

Thus, the probability that Kamsky wins the match is

$$\frac{p^2}{(1-q)^2} + \frac{2p^2 r}{(1-q)^3} = \frac{p^2(p+3r)}{(p+r)^3}$$

because $p + q + r = 1$.

111. Let A, B and C be three independent events having probabilities p, q and r, respectively.

Then, according to the question, we have

P (only the first occurs) $= P(A \cap \overline{B} \cap \overline{C})$

[$\because A, B, C$ are independent]

$$= P(A) \cdot P(\overline{B}) \cdot P(\overline{C})$$

$$= p(1-q)(1-r) = a \quad \text{...(i)}$$

P (only the second occurs) $= P(\overline{A} \cap B \cap \overline{C})$

$$= P(\overline{A}) \cdot P(B) \cdot P(\overline{C})$$

$$= (1-p)\, q(1-r) = b \quad \text{...(ii)}$$

and P (only the third occurs) $= P(\overline{A} \cap \overline{B} \cap C)$

$$= P(\overline{A}) \cdot P(\overline{B}) \cdot P(C)$$

$$= (1-p)(1-q)\, r = c \quad \text{...(iii)}$$

Multiplying Eqs. (i), (ii) and (iii), then

$$pqr\, \{(1-p)(1-q)(1-r)\}^2 = abc$$

or $$\frac{abc}{pqr} = [(1-p)(1-q)(1-r)]^2 = x^2 \quad \text{[say] ...(iv)}$$

$$(1-p)(1-q)(1-r) = x \quad \text{...(v)}$$

Dividing Eq. (i) by Eq. (v), then

$$\frac{p}{1-p} = \frac{a}{x} \text{ or } px = a - ap$$

$\therefore$ $$p = \frac{a}{(a+x)}$$

Similarly, $q = \dfrac{b}{b+x}$ and $r = \dfrac{c}{c+x}$

Replacing the values of p, q and r in Eq. (iv), then

$$\left\{\left(1 - \frac{a}{a+x}\right)\left(1 - \frac{b}{b+x}\right)\left(1 - \frac{c}{c+x}\right)\right\}^2 = x^2$$

$\Rightarrow$ $$\frac{(x^3)^2}{(a+x)^2(b+x)^2(c+x)^2} = x^2$$

$\Rightarrow$ $$\frac{x^3}{(a+x)(b+x)(c+x)} = x$$

or $$(a+x)(b+x)(c+x) = x^2$$

Hence, x is a root of the equation $(a+x)(b+x)(c+x) = x^2$

112. Let $A = \{a_1, a_2, \ldots, a_n\}$

For each $a_i \in A$ $(1 \le i \le n)$, we have the following choices.

(i) $a_i \in P$ and $a_i \in Q$ (ii) $a_i \in P$ and $a_i \notin Q$

(iii) $a_i \notin P$ and $a_i \in Q$ (iv) $a_i \notin P$ and $a_i \notin Q$

Therefore, for one element a_i of A, total number of cases is 4.

Let S be the sample space

$\therefore$ $$n(S) = 4^n$$

and number of cases in which $a_i \in P \cup Q$ is 3, since case $4 \notin P \cup Q$ and let E be the event of favourable cases, then

$n(E)$ = number of ways in which exactly r elements of A will belong to $P \cup Q$

$$= {}^nC_r (3)^r\, 1^{n-r} = {}^nC_r 3^r$$

$\therefore$ Required probability, $P(E) = \dfrac{n(E)}{n(S)} = \dfrac{{}^nC_r 3^r}{4^n}$

113. Given that $P(A) = \alpha$, $P(B/A) = P(B'/A') = 1 - \alpha$

Thus, $P(A') = 1 - P(A) = 1 - \alpha$

and $P(B/A') = 1 - P(B'/A') = 1 - (1-\alpha) = \alpha$ ...(i)

$\therefore$ $$P(A'/B) = \frac{P(A' \cap B)}{P(B)}$$

$$= \frac{P(B) - P(A \cap B)}{P(B)} = \frac{P(B) - P(A) \cdot P(B/A)}{P(B)}$$

$$\left[\because P\left(\frac{B}{A}\right) = \frac{P(A \cap B)}{P(A)}\right]$$

$$= \frac{P(B) - \alpha(1-\alpha)}{P(B)} \quad \text{...(ii)}$$

But $$P(B) = P(A) \cdot P(B/A) + P(A') \cdot P(B/A')$$

$$= \alpha(1-\alpha) + (1-\alpha) \cdot \alpha \quad \text{[from Eq. (i)]}$$

$$= 2\alpha(1-\alpha) \quad \text{...(3)}$$

Putting the value of $P(B)$ from Eq. (iii) in Eq. (ii), then

$$P\left(\frac{A'}{B}\right) = \frac{2\alpha(1-\alpha) - \alpha(1-\alpha)}{2\alpha(1-\alpha)} = \frac{\alpha(1-\alpha)}{2\alpha(1-\alpha)} = \frac{1}{2}$$

which is independent of α.

114. Let S be the sample space and E be the event that each of the n pairs of balls drawn consists of one white and one red ball.

$\therefore$ $$n(S) = ({}^{2n}C_2)({}^{2n-2}C_2)({}^{2n-4}C_2) \ldots ({}^4C_2)({}^2C_2)$$

$$= \left\{\frac{(2n)(2n-1)}{1 \cdot 2}\right\}\left\{\frac{(2n-2)(2n-3)}{1 \cdot 2}\right\}\left\{\frac{(2n-4)(2n-5)}{1 \cdot 2}\right\} \ldots \left\{\frac{4 \cdot 3}{1 \cdot 2}\right\}\left\{\frac{2 \cdot 1}{1 \cdot 2}\right\}$$

$$= \frac{1 \cdot 2 \cdot 3 \cdot 4 \ldots (2n-1)\, 2n}{2^n} = \frac{2n!}{2^n}$$

and $$n(E) = ({}^nC_1 \cdot {}^nC_1)({}^{n-1}C_1 \cdot {}^{n-1}C_1)({}^{n-2}C_1 \cdot {}^{n-2}C_1) \ldots ({}^2C_1 \cdot {}^2C_1)({}^1C_1 \cdot {}^1C_1)$$

$$= n^2 \cdot (n-1)^2 \cdot (n-2)^2 \ldots 2^2 \cdot 1^2 = [1 \cdot 2 \cdot 3 \ldots (n-1)\, n]^2 = (n!)^2$$

$\therefore$ Required probability,

$$P(E) = \frac{n(E)}{n(S)} = \frac{(n!)^2}{(2n)!/2^n} = \frac{2^n}{\dfrac{2n!}{(n!)^2}} = \frac{2^n}{{}^{2n}C_n}$$

115. Let p be the probability that any one thing is received by a men and q be the probability that any one thing is received by a women.

$\therefore$ $$p = \frac{a}{a+b} \text{ and } q = \frac{b}{a+b}$$

Clearly, $p + q = 1$ i.e., $q = 1 - p$

Out of m things, if r are received by a men, then the rest $(m-r)$ will be received by women.

The probability for this to happen is given by

$$P(r) = {}^{m}C_r p^r q^{m-r} \quad [r = 0, 1, ..., m]$$

The probability P that odd number of things are received by men is given by

$$P = P(1) + P(3) + P(5) + \ldots$$
$$= {}^{m}C_1 pq^{m-1} + {}^{m}C_3 p^3 q^{m-3} + {}^{m}C_5 p^5 q^{m-5} + \ldots \quad ...(i)$$

We know that,

$$(q+p)^m = q^m + {}^{m}C_1 q^{m-1} p + {}^{m}C_2 q^{m-2} p^2 + \ldots + p^m \quad ...(ii)$$

and $(q-p)^m = q^m - {}^{m}C_1 q^{m-1} p + {}^{m}C_2 q^{m-2} p^2 - \ldots + (-1)^m p^m$ ...(iii)

Subtracting Eq.(iii) from Eq. (ii), then

$(q+p)^m - (q-p)^m = 2\{{}^{m}C_1 q^{m-1} p + {}^{m}C_3 q^{m-3} p^3 + \ldots\}$

$= 2P$ [from Eq. (i)]

$$\therefore \quad P = \frac{1}{2}\{(q+p)^m - (q-p)^m\}$$

$$= \frac{1}{2}\left\{1 - \left(\frac{b-a}{b+a}\right)^m\right\} = \frac{1}{2}\left\{\frac{(b+a)^m - (b-a)^m}{(b+a)^m}\right\}$$

116. $\because P(C) = \frac{1}{7}, P(S) = \frac{3}{7}, P(B) = \frac{2}{7}, P(T) = \frac{1}{7}$

Let E be the event that person reaches late

$$\therefore \; P\left(\frac{E}{C}\right) = \frac{2}{9}, P\left(\frac{E}{S}\right) = \frac{1}{9}, P\left(\frac{E}{B}\right) = \frac{4}{9}, P\left(\frac{E}{T}\right) = \frac{1}{9}$$

To find $P\left(\frac{C}{E}\right)$ [$\because$ reaches in time = not late]

Using Baye's Theorem

$$P\left(\frac{C}{E}\right) = \frac{P(C).P\left(\frac{\overline{E}}{C}\right)}{P(C).P\left(\frac{\overline{E}}{C}\right) + P(S).P\left(\frac{\overline{E}}{S}\right) + P(B).P\left(\frac{\overline{E}}{B}\right) + P(T).P\left(\frac{\overline{E}}{T}\right)}$$

$$= \frac{\frac{1}{7}\times\left(1-\frac{2}{9}\right)}{\frac{1}{7}\times\left(1-\frac{2}{9}\right) + \frac{3}{7}\times\left(1-\frac{1}{9}\right) + \frac{2}{7}\times\left(1-\frac{4}{9}\right) + \frac{1}{7}\times\left(1-\frac{1}{9}\right)}$$

$$= \frac{7}{7+3\times8+2\times5+8} = \frac{7}{49} = \frac{1}{7}$$

117. Probability of getting 1 is $\frac{1}{6}$ and probability of not getting 1 is $\frac{5}{6}$.

Then, getting 1 in even number of chances = getting 1 in 2nd chance or in 4th chance or in 6th chance and so on.

$\therefore$ Required probability

$$= \frac{5}{6}\times\frac{1}{6} + \left(\frac{5}{6}\right)^3 \times\frac{1}{6} + \left(\frac{5}{6}\right)^6 \times\frac{1}{6} + \ldots\infty$$

$$= \frac{\frac{5}{36}}{1-\frac{25}{36}} = \frac{5}{11}$$

118. $P(\overline{A \cup B}) = \frac{1}{6}$; $P(A \cap B) = \frac{1}{4}$,

$$P(\overline{A}) = \frac{1}{4} \Rightarrow P(A) = \frac{3}{4},$$

$$P(\overline{A \cup B}) = 1 - P(A \cup B)$$

$$= 1 - P(A) - P(B) + P(A \cap B)$$

$$\Rightarrow \quad \frac{1}{6} = \frac{1}{4} - P(B) + \frac{1}{4}$$

$$\Rightarrow \quad P(B) = \frac{1}{3}$$

Since, $P(A \cap B) = P(A)\cdot P(B)$ and $P(A) \neq P(B)$

$\therefore$ A and B are independent but not equally likely.

119. For a particular house being selected, probability $= \frac{1}{3}$

Probability (all the persons apply for the same house)

$$= \left(\frac{1}{3}\times\frac{1}{3}\times\frac{1}{3}\right)3 = \frac{1}{9}$$

120. $P(X > 1.5) = 1 - P(X = 0) - P(X = 1)$

$$P(X = k) = e^{-\lambda}\frac{\lambda^k}{k!}$$

$$\therefore \quad P(x > 1.5) = 1 - \frac{1}{e^2} - \frac{2}{e^2} = 1 - \frac{3}{e^2} \qquad [\because \lambda = np = 2]$$

121. (i) $P(u_i) = ki, \Sigma P(u_i) = 1 \Rightarrow k = \frac{2}{n(n+1)}$

$$\lim_{n\to\infty} P(w) = \lim_{n\to\infty}\sum_{i=1}^{\infty}\frac{2i^2}{n(n+1)^2}$$

$$= \lim_{n\to\infty}\frac{2n(n+1)(2n+1)}{n(n+1)^2 6} = \frac{2}{3}$$

(ii) $$P\left(\frac{u_n}{w}\right) = \frac{P(u_n \cap w)}{P(w)} = \frac{P(u_n)\cdot P\left(\frac{w}{u_n}\right)}{\sum_{i=1}^{n} P(u_n)\cdot P\left(\frac{w}{u_i}\right)}$$

$$\frac{c\frac{n}{n+1}}{c\sum_{i=1}^{n}\frac{i}{(n+1)}} = \frac{n.2}{n(n+1)} = \frac{2}{n+1}$$

(iii) $E = u_2 \cup u_4 \cup u_6 \cup \ldots \cup u_n$

$$P(E) = P(u_2) + P(u_4) + \ldots + P(u_n)$$

$$= \frac{1}{n} + \frac{1}{n} + \ldots + \frac{1}{n} = \frac{1}{n}\frac{n}{2} = \frac{1}{2}$$

$$P\left(\frac{w}{E}\right) = \frac{P(w \cap E)}{P(E)}$$

$$= \frac{P(w \cap u_2) + P(w \cap u_4) + \ldots + P(w \cap u_n)}{\frac{1}{2}}$$

$$= 2\left[\frac{1}{n}.\frac{2}{n+1} + \frac{1}{n}.\frac{4}{n+1} + \ldots + \frac{1}{n}.\frac{n}{n+1}\right]$$

$$= \frac{2}{n}.\frac{\frac{n}{4}(2+n)}{n+1} = \frac{n+2}{2(n+1)}$$

122. $P(X=r)=\dfrac{e^{-m}m^r}{r!}$

$=P(X\le 1)=P(X=0)+P(X=1)$

$=e^{-5}+5\times e^{-5}=\dfrac{6}{e^5}$ $[\because m=\text{mean}=5]$

123. Let E be the event when each American man is seated adjacent to his wife and A be the event when Indian man is seated adjacent to his wife.

Now, $n(A\cap E)=(4!)\times(2!)^5$ and $n(E)=(5!)\times(2!)^4$

$\Rightarrow \quad P\left(\dfrac{A}{E}\right)=\dfrac{P(A\cap E)}{P(E)}=\dfrac{n(A\cap E)}{n(E)}=\dfrac{(4!)\times(2!)^5}{(5!)\times(2!)^4}=\dfrac{2}{5}$

124. **Statement-1** If $P(H_i\cap E)=0$ for some i, then

$$P\left(\frac{H_i}{E}\right)=P\left(\frac{E}{H_i}\right)=0$$

If $P(H_i\cap E)\ne 0,\ \forall\ i=1,2,3,\ldots,n$, then

$P\left(\dfrac{H_i}{E}\right)=\dfrac{P(H_i\cap E)}{P(E)}=\dfrac{P(H_i\cap E)}{P(H_i)}\times\dfrac{P(H_i)}{P(E)}$

$=P\left(\dfrac{E}{H_i}\right)\times\dfrac{P(H_i)}{P(E)}>P\left(\dfrac{E}{H_i}\right).P(H_i)$ [as $0<P(E)<1$]

Hence, Statement-1 may not always be true.

Statement -2 Clearly, $H_1\cup H_2\cup\ldots\cup H_n=S$ (Sample space)

$\Rightarrow\ P(H_1)+P(H_2)+\ldots+P(H_n)=1$

125. $P\left(\dfrac{E^c\cap F^c}{G}\right)=\dfrac{P(E^c\cap F^c\cap G)}{P(G)}$

$=\dfrac{P(G)-P(E\cap G)-P(F\cap G)}{P(G)}$

$=\dfrac{P(G)-P(E)\cdot P(G)-P(F)\cdot P(G)}{P(G)}$

$=1-P(E)-P(F)=P(E^c)-P(F)$

126. Probability of getting sum of nine in a single thrown $=\dfrac{1}{9}$

$\therefore$ Probability of getting sum nine exactly two times out of three draws $={}^3C_2\left(\dfrac{1}{9}\right)^2\left(\dfrac{8}{9}\right)=\dfrac{8}{243}$

127. $P(I)=0.3,\ P(II)=0.2$

$\therefore$ Required probability

$=P(\bar{I})P(II)=(1-P(I))P(II)=(1-0.3)\times 0.2=0.7\times 0.2=0.14$

128. Since, $P(A)=\dfrac{2}{5}$

For independent events,

$$P(A\cap B)=P(A)P(B)\ \Rightarrow\ P(A\cap B)\le\frac{2}{5}$$

$\Rightarrow \quad P(A\cap B)=\dfrac{1}{10},\dfrac{2}{10},\dfrac{3}{10},\dfrac{4}{10}$

[maximum 4 outcomes may be in $A\cap B$]

(i) Now, $P(A\cap B)=\dfrac{1}{10}$

$\Rightarrow \quad P(A)\cdot P(B)=\dfrac{1}{10}$

$\Rightarrow \quad P(B)=\dfrac{1}{10}\times\dfrac{5}{2}=\dfrac{1}{4}$, not possible

(ii) Now, $P(A\cap B)=\dfrac{2}{10}\ \Rightarrow\ \dfrac{2}{5}\times P(B)=\dfrac{2}{10}$

$\Rightarrow \quad P(B)=\dfrac{5}{10}$, outcomes of $B=5$

(iii) Now, $P(A\cap B)=\dfrac{3}{10}$

$\Rightarrow \quad P(A)P(B)=\dfrac{3}{10}\ \Rightarrow\ \dfrac{2}{5}\times P(B)=\dfrac{3}{10}$

$P(B)=\dfrac{3}{4}$, not possible

(iv) Now, $P(A\cap B)=\dfrac{4}{10}\ \Rightarrow\ P(A)\cdot P(B)=\dfrac{4}{10}$

$\Rightarrow \quad P(B)=1$, outcomes of $B=10$.

129. For unique solution $\begin{vmatrix}a & b\\ c & d\end{vmatrix}\ne 0$,

where $a, b, c, d\in\{0,1\}$. Total cases = 16

Favourable cases = 6 (Either $ad=1, bc=0$ or $ad=0, bc=1$)

Probability that system of equations has unique solution is $\dfrac{6}{16}=\dfrac{3}{8}$ and system of equations has either unique solution or infinite solutions, so that probability for system to have a solution is 1.

130. $A=\{4,5,6\},\ B=\{1,2,3,4\}$

$\therefore \quad A\cup B=\{1,2,3,4,5,6\}$

$\Rightarrow \quad n(A\cup B)=6$ and total ways $=6$

$\therefore \quad P(A\cup B)=\dfrac{6}{6}=1$

131. $\because \quad P\left(\dfrac{A}{B}\right)=\dfrac{1}{2}\ \Rightarrow\ \dfrac{P(A\cap B)}{P(B)}=\dfrac{1}{2}$ ...(i)

and $P\left(\dfrac{B}{A}\right)=\dfrac{2}{3}\ \Rightarrow\ \dfrac{P(A\cap B)}{P(A)}=\dfrac{2}{3}$ ...(ii)

On dividing Eq. (i) by Eq. (ii), we get

$$\frac{P(A)}{P(B)}=\frac{3}{4}\ \Rightarrow\ P(B)=\frac{4}{3}P(A)$$

$=\dfrac{4}{3}\times\dfrac{1}{4}=\dfrac{1}{3}\quad\left[\because P(A)=\dfrac{1}{4}\right]$

132. $P(X=3)=\left(\dfrac{5}{6}\right)\left(\dfrac{5}{6}\right)\dfrac{1}{6}=\dfrac{25}{216}$

133. $P(X\ge 3)=1-P(X\le 2)=1-\left\{\dfrac{1}{6}+\dfrac{5}{6}\times\dfrac{1}{6}\right\}=1-\dfrac{11}{36}=\dfrac{25}{36}$

134. $P(X\ge 6)=\dfrac{5^5}{6^6}+\dfrac{5^6}{6^7}+\ldots\infty=\dfrac{\frac{5^5}{6^6}}{1-\frac{5}{6}}=\left(\dfrac{5}{6}\right)^5$

and $P(X>3)=\dfrac{5^3}{6^4}+\dfrac{5^4}{6^5}+\dfrac{5^5}{6^6}+\ldots\infty=\dfrac{\frac{5^3}{6^4}}{1-\frac{5}{6}}=\left(\dfrac{5}{6}\right)^3$

Hence, the conditional probability $=\dfrac{\left(\frac{5}{6}\right)^5}{\left(\frac{5}{6}\right)^3}=\dfrac{25}{36}$

135. $1-q^n \geq \frac{9}{10} \Rightarrow q^n \leq \frac{1}{10} \Rightarrow \left(\frac{3}{4}\right)^n \leq \frac{1}{10}$

$\Rightarrow n(\log_{10}3 - \log_{10}4) \leq 0-1 \Rightarrow n \geq \frac{1}{(\log_{10}4 - \log_{10}3)}$

136. $S = \{00, 01, 02,..., 49\}$

Let A be the event that sum of the digits on the selected ticket is 8, then$A = \{08, 17, 26, 26, 35, 44\}$

and let B be the event that the product of the digits is zero, then

$B = \{00, 01, 02, ..., 09, 10, 20, 30, 40\}$

$\therefore \quad A \cap B = \{08\}$

$\therefore$ Required probability $= P\left(\frac{A}{B}\right) = \frac{P(A \cap B)}{P(B)} = \frac{\frac{1}{50}}{\frac{14}{50}} = \frac{1}{14}$

137. Required probability $= \frac{2 \times 2 \times 2(3!)}{6^3} = \frac{2}{9}$

138. Let E_1 denote original signal is green, E_2 denote original signal is red and E denote signal received at station B is green.

$$\therefore \quad P\left(\frac{E_1}{E}\right) = \frac{P(E_1)\cdot P\left(\frac{E}{E_1}\right)}{P(E_1)\cdot P\left(\frac{E}{E_1}\right) + P(E_2)\cdot P\left(\frac{E}{E_2}\right)}$$

$$= \frac{\frac{4}{5}\left[\left(\frac{3}{4}\right)^2 + \left(\frac{1}{4}\right)^2\right]}{\frac{4}{5}\left[\left(\frac{3}{4}\right)^2 + \left(\frac{1}{4}\right)^2\right] + \frac{1}{5}\left[\frac{3}{4}\times\frac{1}{4} + \frac{1}{4}\times\frac{3}{4}\right]} = \frac{40}{46} = \frac{20}{23}$$

139. Total ways $= {}^{20}C_4 = \frac{20 \,.\, 19 \,.\, 18 \,.\, 17}{1 \,.\, 2 \,.\, 3 \,.\, 4} = 4845$

Statement-1

Common difference (d)	Number of cases
1	17
2	14
3	11
4	8
5	5
6	2

$\therefore$ Number of favourable cases $= 17 + 14 + 11 + 8 + 5 + 2$

$= 57$

$\therefore$ Required probability $= \frac{57}{4845} = \frac{1}{85}$

Statement-1 is true and Statement-2 is false.

140. Total ways, ${}^9C_3 = \frac{9 \cdot 8 \cdot 7}{1 \cdot 2 \cdot 3} = 84$

Favourable ways $= {}^3C_1 \times {}^4C_1 \times {}^2C_1 = 24$

$\therefore$ Required probability $= \frac{24}{84} = \frac{2}{7}$

141. $H \rightarrow 1$ ball from U_1 to U_2

$T \rightarrow 2$ balls from U_1 to U_2

E : 1 ball drawn from U_2

$$\therefore \; P(W \text{ from } U_2) = \frac{1}{2}\times\left(\frac{3}{5}\times 1\right) + \frac{1}{2}\times\left(\frac{2}{5}\times\frac{1}{2}\right)$$

$$+\frac{1}{2}\times\left(\frac{{}^3C_2}{{}^5C_2}\times\frac{1}{3}\right) + \frac{1}{2}\times\left(\frac{{}^3C_1 \,.\, {}^2C_1}{{}^5C_2}\times\frac{2}{3}\right) = \frac{23}{30}$$

142. $$P\left(\frac{H}{W}\right) = \frac{P(H)\times P\left(\frac{W}{H}\right)}{P(H)\times P\left(\frac{W}{H}\right) + P(T)\times P\left(\frac{W}{T}\right)} = \frac{\frac{1}{2}\left(\frac{3}{2}\times 1 + \frac{2}{5}\times\frac{1}{2}\right)}{\frac{23}{30}}$$

$$= \frac{12}{23}$$

143. Let $P(E) = e$ and $P(F) = f$

$$\Rightarrow \quad P(E \cup F) - P(E \cap F) = \frac{11}{25}$$

$$\Rightarrow \quad P(E) + P(F) - 2P(E \cap F) = \frac{11}{25}$$

$$\Rightarrow \quad e + f - 2ef = \frac{11}{25} \qquad \text{...(i)}$$

$$P(\overline{E} \cap \overline{F}) = \frac{2}{25} \Rightarrow P(\overline{E}).\, P(\overline{F}) = \frac{2}{25} \Rightarrow (1-e)(1-f) = \frac{2}{25}$$

$$\Rightarrow \quad e + f - ef = \frac{23}{25} \qquad \text{...(ii)}$$

From Eqs. (i) and (ii), we get $ef = \frac{12}{25}$ and $e + f = \frac{7}{5}$

On solving, we get $e = \frac{4}{5}$, $f = \frac{3}{5}$ or $e = \frac{3}{5}$, $f = \frac{4}{5}$

144. Given probability of atleast one failure $\geq \frac{31}{32}$

$$\Rightarrow \quad 1 - P(X = 0) \geq \frac{31}{32}$$

$$\Rightarrow \; 1 - {}^5C_0 \cdot Q^0 \cdot P^5 \geq \frac{31}{32} \qquad [\because (P+Q)^5]$$

$$\Rightarrow \quad P^5 \leq \frac{1}{32}$$

$$\therefore \quad P \leq \frac{1}{2} \text{ and } P \geq 0 \;\Rightarrow\; P \in \left[0, \frac{1}{2}\right]$$

145. We have, $C \subset D \Rightarrow C \cap D = C$

$$\Rightarrow P\left(\frac{C}{D}\right) = \frac{P(C \cap D)}{P(D)} = \frac{P(C)}{P(D)} \geq P(C) \qquad [\because\, 0 < P(D) \leq 1]$$

146. $$P\left(\frac{A^c \cap B^c}{C}\right) = \frac{P(A^c \cap B^c \cap C)}{P(C)}$$

$$= \frac{P(C) - P(A \cap C) - P(B \cap C) + P(A \cap B \cap C)}{P(C)}$$

$$= \frac{P(C) - P(A)\cdot P(C) - P(B)\cdot P(C) + 0}{P(C)}$$

[$\because$ A, B, C are pairwise independent]

$$= 1 - P(A) - P(B) = P(A^c) - P(B)$$

147. $P(X) = P(X_1 \cap X_2 \cap X_3) + P(\overline{X}_1 \cap X_2 \cap X_3)$
$+ P(X_1 \cap \overline{X}_2 \cap X_3) + P(X_1 \cap X_2 \cap \overline{X}_3)$
$= \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{4} + \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{4} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{1}{4} + \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{3}{4} = \frac{1}{4}$

(a) $P\left(\frac{\overline{X}_1}{X}\right) = \frac{\frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{4}}{\frac{1}{4}} = \frac{1}{8}$

(b) P (exactly two engines of the ship are functioning / X)
$= \frac{\frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{4} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{1}{4} + \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{3}{4}}{1/4} = \frac{7}{8}$

(c) $P\left(\frac{X}{X_2}\right)$ = Probability that X occurs given that engine E_2 has started $\frac{P(X_1 \cap X_2 \cap X_3) + P(\overline{X}_1 \cap X_2 \cap X_3)}{P(X_1 \cap X_2 \cap X_3) + P(\overline{X}_1 \cap X_2 \cap X_3)}$
$+ P(X_1 \cap X_2 \cap \overline{X}_3)$
$+P(X_1 \cap X_2 \cap \overline{X}_3) + P(\overline{X}_1 \cap X_2 \cap \overline{X}_3) = \frac{5}{8}$

(d) $P\left(\frac{X}{X_1}\right)$ = Probability that X occurs given that engine E_1 has started $\frac{P(X_1 \cap X_2 \cap X_3)}{P(X_1 \cap X_2 \cap X_3) + P(X_1 \cap \overline{X}_2 \cap X_3)}$
$+ P(X_1 \cap \overline{X}_2 \cap X_3) + P(X_1 \cap X_2 \cap \overline{X}_3)$
$+P(X_1 \cap X_2 \cap \overline{X}_3) + P(X_1 \cap \overline{X}_2 \cap \overline{X}_3) = \frac{7}{16}$

148. ***Case* I** When D_1, D_2, D_3 all show different number and one of the number is shown by D_4, $P(E_1) = \frac{{}^6C_3 \times 3!}{216} \times \frac{3}{6} = \frac{60}{216}$

***Case* II** When D_1, D_2, D_3 all show same number and that number is shown byD_4, $P(E_2) = 6 \times \left(\frac{1}{6}\right)^4 = \frac{1}{216}$

***Case* III** When two numbers shown by D_1, D_2, D_3 are same and one is different and one of the number is shown by D_4,

$$P(E_3) = \frac{{}^6C_1 \times {}^5C_1}{216} \times \frac{3!}{2!} \times \frac{2}{6} = \frac{30}{216}$$

$\therefore$ Required probability $= P(E_1) + P(E_2) + P(E_3) = \frac{91}{216}$

149. $P\left(\frac{X}{Y}\right) = \frac{P(X \cap Y)}{P(Y)} = \frac{1}{2} \Rightarrow P(Y) = \frac{1}{3}$

$P\left(\frac{Y}{X}\right) = \frac{P(X \cap Y)}{P(X)} = \frac{1}{3} \Rightarrow P(X) = \frac{1}{2}$

(a) $P(X \cup Y) = P(X) + P(Y) - P(X \cap Y) = \frac{2}{3}$

(b) $\because P(X \cap Y) = P(X) \cdot P(Y)$, they are independent. Also, X^c and Y will be independent

Now, $P(X^c \cap Y) = \frac{1}{2} \times \frac{1}{3} = \frac{1}{6} \neq \frac{1}{3}$.

150. $\because S = \{1, 2, 3, \ldots, 8\}$

Let A : Maximum of three numbers is 6

$\therefore A = \{1, 2, 3, 4, 5, 6\}$

and B : Maximum of three numbers is 3

$\therefore B = \{3, 4, 5, 6, 7, 8\}$ and $A \cap B = \{3, 4, 5, 6\}$

$$\Rightarrow P\left(\frac{B}{A}\right) = \frac{P(A \cap B)}{P(A)} = \frac{\frac{n(A \cap B)}{n(S)}}{\frac{n(B)}{n(S)}} = \frac{n(A \cap B)}{n(B)} = \frac{{}^2C_1}{{}^5C_2} = \frac{1}{5}$$

151. Here, $p = \frac{1}{3}$ and $q = 1 - \frac{1}{3} = \frac{2}{3}$

$\therefore$ Required probability $= P(X = 4) + P(X = 5)$ $\left[\because \left(\frac{2}{3} + 1\right)^5\right]$

$$= {}^5C_4 \left(\frac{1}{3}\right)^4 \left(\frac{2}{3}\right) + {}^5C_5 \left(\frac{1}{3}\right)^5 = \frac{11}{3^5}$$

152. Probability of solving the problem correctly by atleast one of them $= 1 - \left(\left(1 - \frac{1}{2}\right)\left(1 - \frac{3}{4}\right)\left(1 - \frac{1}{4}\right)\left(1 - \frac{1}{8}\right)\right) = \frac{235}{256}$

153. Let x, y and z be the probability of occurrence of E_1, E_2 and E_3, respectively.

Then, $\alpha = x(1-y)(1-z) = \frac{px}{(1-x)}$ $[\because p = (1-x)(1-y)(1-z)]$

Similarly, $\beta = \frac{py}{(1-y)}$ and $\gamma = \frac{pz}{(1-z)}$

Now, $(\alpha - 2\beta)\, p = \alpha\beta$

$$\Rightarrow \frac{p}{\beta} - \frac{2p}{\alpha} = 1$$

$$\Rightarrow \frac{(1-y)}{y} - \frac{2(1-x)}{x} = 1$$

$$\Rightarrow x = 2y \quad \ldots(i)$$

and $(\beta - 3\gamma)\, p = 2\beta$

$$\Rightarrow \frac{p}{\gamma} - \frac{3p}{\beta} = 2$$

$$\Rightarrow \frac{(1-z)}{z} - \frac{3(1-y)}{y} = 2$$

$$\Rightarrow y = 3z \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get $x = 6z$ $\therefore$ $\frac{x}{z} = 6$

154. Let E = Event that one ball is white and the other ball is red.

Then, $P\left(\frac{B_2}{E}\right) = \frac{\frac{{}^2C_1 \times {}^3C_1}{{}^9C_2}}{\frac{{}^1C_1 \times {}^3C_1}{{}^6C_2} + \frac{{}^2C_1 \times {}^3C_1}{{}^9C_2} + \frac{{}^3C_1 \times {}^4C_1}{{}^{12}C_2}} = \frac{55}{181}$

155. Required probability $= \prod_{i=1}^{3} P(W_i) + \prod_{i=1}^{3} P(R_i) + \prod_{i=1}^{3} P(B_i)$

$$= \frac{1}{6} \times \frac{2}{9} \times \frac{3}{12} + \frac{3}{6} \times \frac{3}{9} \times \frac{4}{12} + \frac{2}{6} \times \frac{4}{9} \times \frac{5}{12}$$

$$= \frac{82}{648}$$

156. $\because P(A \cup B) = 1 - P(\overline{A \cup B}) = 1 - \frac{1}{6} = \frac{5}{6}$

$$P(A) = 1 - P(\overline{A}) = 1 - \frac{1}{4} = \frac{3}{4}$$

and $P(B) = P(A \cup B) - P(A) + P(A \cap B)$

$$= \frac{5}{6} - \frac{3}{4} + \frac{1}{4} = \frac{1}{3}$$

$\Rightarrow A$ and B are not equally likely.

Also, $P(A \cap B) = \frac{1}{4} = \frac{3}{4} \times \frac{1}{3} = P(A)\,.\,P(B)$

$\therefore$ A and B are independent.

Hence, A and B are independent but not equally likely.

157. $n(S) = 5! = 120$ and possible favourable cases are

$(B, G, G, B, B), (G, G, B, B, B), (G, B, G, B, B),$

$(G, B, B, G, B), (B, G, B, G, B)$

$\therefore$ Number of favourable cases $= n(E) = 5 \times 12 = 60$

$\therefore$ Required probability,

$$P(E) = \frac{n(E)}{n(S)} = \frac{60}{120} = \frac{1}{2}$$

158. $n(S) = 3 \times 5 \times 7 = 105$; $x_1 + x_2 + x_3 =$ odd

***Case* I** All three odd $= 2 \times 3 \times 4 = 24$

***Case* II** Two even and one odd

$= 1 \times 2 \times 4 + 1 \times 3 \times 3 + 2 \times 2 \times 3 = 29 \therefore n(E) = 24 + 29 = 53$

Required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{53}{105}$

159. x_1, x_2, x_3 are in AP.

AP with common difference $= 1$, $(1, 2, 3)$ $(2, 3, 4)$ $(3, 4, 5)$

AP with common difference $= 2$, $(1, 3, 5)$, $(2, 4, 6)$, $(3, 5, 7)$

AP with common difference $= 3$, $(1, 4, 7)$

AP with common difference $= 0$, $(1, 1, 1)$, $(2, 2, 2)$ $(3, 3, 3)$

$\therefore$ $n(E) = 10$

$\therefore$ Required probability, $P(E) = \frac{n(E)}{n(S)} = \frac{10}{105}$

160. We have mentioned that boxes are different and one particular box has 3 balls.

Then number of ways $= \frac{{}^{12}C_3 \times 2^9}{3^{12}} = \frac{55}{3}\left(\frac{2}{3}\right)^{11}$

161. Using Binomial distribution

$$P(X \geq 2) = 1 - P(X = 0) - P(X = 1)$$

$$= 1 - \left(\frac{1}{2}\right)^n - \left[{}^nC_1 \cdot \left(\frac{1}{2}\right) \cdot \left(\frac{1}{2}\right)^{n-1}\right]$$

$$= 1 - \frac{1}{2^n} - {}^nC_1 \cdot \frac{1}{2^n} = 1 - \left(\frac{1+n}{2^n}\right)$$

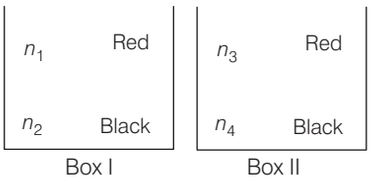
Given, $P(X \geq 2) \geq 0.96$

$$1 - \frac{(n+1)}{2^n} \geq \frac{24}{25}$$

$$\Rightarrow \quad \frac{(n+1)}{2^n} \leq \frac{1}{25}$$

$$\Rightarrow \quad n = 8$$

162.



Let A = Drawing red ball

$$\therefore \quad P(A) = P(B_1) \cdot P(A/B_1) + P(B_2) \cdot P(A/B_2)$$

$$= \frac{1}{2}\left(\frac{n_1}{n_1 + n_2}\right) + \frac{1}{2}\left(\frac{n_3}{n_3 + n_4}\right)$$

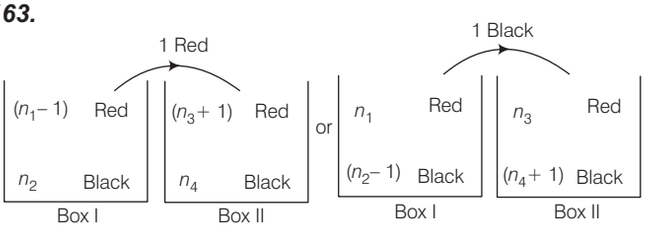
Given, $P(B_2/A) = \frac{1}{3} \Rightarrow \frac{P(B_2) \cdot P(B_2 \cap A)}{P(A)} = \frac{1}{3}$

$$\Rightarrow \quad \frac{\frac{1}{2}\left(\frac{n_3}{n_3 + n_4}\right)}{\frac{1}{2}\left(\frac{n_1}{n_1 + n_2}\right) + \frac{1}{2}\left(\frac{n_3}{n_3 + n_4}\right)} = \frac{1}{3}$$

$$\Rightarrow \quad \frac{n_3(n_1 + n_2)}{n_1(n_3 + n_4) + n_3(n_1 + n_2)} = \frac{1}{3}$$

Now, check options, then clearly options (a) and (b) satisfy.

163.



$\therefore$ P (drawing red ball from B_1) $= \frac{1}{3}$

$$\Rightarrow \quad \left(\frac{n_1 - 1}{n_1 + n_2 - 1}\right)\left(\frac{n_1}{n_1 + n_2}\right) + \left(\frac{n_2}{n_1 + n_2}\right)\left(\frac{n_1}{n_1 + n_2 - 1}\right) = \frac{1}{3}$$

$$\Rightarrow \quad \frac{n_1^2 + n_1 n_2 - n_1}{(n_1 + n_2)(n_1 + n_2 - 1)} = \frac{1}{3}$$

Clearly, options (c) and (d) satisfy.

164. $\because$ $P(E_1) = \frac{1}{6}, P(E_2) = \frac{1}{6},$

$$P(E_3) = \frac{2 + 4 + 6 + 4 + 2}{36} = \frac{1}{2}$$

Also, $P(E_1 \cap E_2) = \frac{1}{36},$

$$P(E_1 \cap E_3) = \frac{1}{12}, P(E_3 \cap E_1) = \frac{1}{12}$$

and $P(E_1 \cap E_2 \cap E_3) = 0 \neq P(E_1).P(E_2).P(E_3)$

Hence, E_1, E_2, E_3 are not independent

165. $P(T_1) = \frac{200}{100} = \frac{1}{5}, P(T_2) = \frac{80}{100} = \frac{4}{5},$

$P(D) = \frac{7}{100}$. Let $P\left(\frac{D}{T_2}\right) = x$, then

$$P\left(\frac{D}{T_1}\right) = 10 \cdot P\left(\frac{D}{T_2}\right) = 10x$$

$\because$ $P(D) = P(T_1) \times P\left(\frac{D}{T_1}\right) + P(T_2) \times P\left(\frac{D}{T_2}\right)$

$\Rightarrow$ $\frac{7}{100} = \frac{1}{5} \times 10x + \frac{4}{5} \times x$

$\therefore$ $x = \frac{1}{40}$

$\therefore$ $P\left(\frac{T_2}{\overline{D}}\right) = \frac{P(T_2) \times P\left(\frac{\overline{D}}{T_2}\right)}{P(T_1) \times P\left(\frac{\overline{D}}{T_1}\right) + P(T_2) \times P\left(\frac{\overline{D}}{T_2}\right)}$

$$= \frac{P(T_2) \times P\left(\frac{\overline{D}}{T_2}\right)}{P(\overline{D})}$$

$$= \frac{\frac{4}{5} \times \frac{39}{40}}{\frac{93}{100}}$$

$$= \frac{78}{93}$$

166. $P(x > y) = P(T_1$ wins 2 games or T_1 wins either of the matches and other is draw)

$$= \left(\frac{1}{2} \times \frac{1}{2}\right) + \left(\frac{1}{2} \times \frac{1}{6} + \frac{1}{6} \times \frac{1}{2}\right)$$

$$= \frac{1}{4} + \frac{1}{6} = \frac{5}{12}$$

167. $P(x = y) = P(T_1$ and T_2 win alternately)

$+ P$ (Both matches are draws)

$$= \left(\frac{1}{2} \times \frac{1}{3} + \frac{1}{3} \times \frac{1}{2}\right) + \left(\frac{1}{6} \times \frac{1}{6}\right)$$

$$= \frac{1}{3} + \frac{1}{36} = \frac{13}{36}$$

168. $P = \frac{15}{25} = \frac{3}{5}, Q = 1 - P = 1 - \frac{3}{5} = \frac{2}{5}$

and $n = 10$

$\therefore$ Variance $= nPQ = 10 \times \frac{3}{5} \times \frac{2}{5} = \frac{12}{5}$

169. **Cases**: (0, 4), (0, 8), (2, 6), (2, 10), (4, 8), (6, 10)

$\therefore$ Required probability $= \frac{6}{{}^1C_2} = \frac{6}{55}$

170. $\because$ $P(A) + P(B) - 2P(A \cap B) = \frac{1}{4}$ ...(i)

$P(B) + P(C) - 2P(B \cap C) = \frac{1}{4}$ ...(ii)

$P(C) + P(A) - 2P(C \cap A) = \frac{1}{4}$ ...(iii)

and $P(A \cap B \cap C) = \frac{1}{16}$ ...(iv)

Now, adding Eqs. (i), (ii) and (iii), then

$P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(C \cap A) = \frac{3}{8}$ ...(v)

On adding Eqs. (iv) and (v), we get

$$P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(C \cap A) + P(A \cap B \cap C) = \frac{3}{8} + \frac{1}{16}$$

or $P(A \cup B \cup C) = \frac{7}{16}$

Introduction

There are two basic processes of reasoning which are commonly used to draw mathematical or scientific conclusions. Reasoning or drawing conclusions can be classified in two categories:

(i) Inductive reasoning
(ii) Deductive reasoning

(i) **Inductive reasoning** This is the process of reasoning from particular to general.
The numbers 324, 576, 603, 732 are all divisible by 3. From these particular results, we can hope to have a general result that all numbers of 3-digits are divisible by 3. But this is not true, because 692 is not divisible by 3.
If at all this conjuctive were true, we would have to establish its validity either by verifying the conjuctive for all possible 3-digit numbers or by using some mathematical process. The process of reasoning a valid general result from particular results is called inductive reasoning.

(ii) **Deductive reasoning** This is the process of reasoning from general to particular.
The sum of first n natural numbers is $\frac{n(n+1)}{2}$. This is a general result. From this, we can deduce that the sum of first 100 natural numbers is $5050\left(=\frac{100(100+1)}{2}\right)$. This process of reasoning a valid particular result from general result is called deductive reasoning.
The principle of mathematical induction is a mathematical process which is used to establish the validity of a general result involving **natural numbers**.

Statement

A sentence or description which is either definitely true or definitely false is called a **statement**. *For example,*

1. Mumbai is the capital of Maharashtra is a true statement.
2. There are 30 days in February is a false statement.
3. Umang is a good boy is not a statement (as it is not a definite sentence. One day whose name is Umang may be a good boy while the other boy whose name is also Umang may not be a good boy. Also, the word 'good' is not well-defined).

Mathematical Statement

A statement involving mathematical relation or relations is called **mathematical statement**.

A statement concerning the natural number 'n' is generally denoted by $P(n)$.

For example, If $P(n)$ denotes the statement "$n(n+1)$ is divisible by 2",

then $P(3)$: "$3(3+1)=12$ is divisible by 2"

and $P(8)$: "$8(8+1)=72$ is divisible by 2", etc.

Here, $P(3)$ and $P(8)$ are both true.

First Principle of Mathematical Induction

To prove that $P(n)$ is true for all natural numbers $n \geq i$, we proceed as follows:

***Step* I** (*Verification Step*) : Verify $P(n)$ for $n = i$.

***Step* II** (*Assumption Step*) : Assume $P(n)$ is true for $n = k > i$.

***Step* III** (*Induction Step*) : Using results in Step I and Step II, prove that $P(k+1)$ is true.

Remark

If $P(n)$ is true for $n = 1$ (i.e., for $i =$).

Second Principle of Mathematical Induction

Sometimes the above procedure will not work. Then, we consider the alternative principle called the second principle of mathematical induction, which consists of the following steps:

***Step* I** (*Verification Step*) : Verify $P(n)$ for $n = i$.

***Step* II** (*Assumption Step*) : Assume $P(n)$ is true for $i < n \leq k$.

***Step* III** (*Induction Step*) : Prove $P(n)$ for $n = k+1$.

Remark

The second principle of mathematical induction is useful to prove recurrence relations which involve three successive terms,

For example, statements of the type

$$pT_{n+1} = qT_n + rT_{n-1}$$

Different Types of Problems of Mathematical Induction

Type I These problems are of the **Identity Type.** Examples of this type are as follows:

Example 1. Prove by mathematical induction that $1^3 + 2^3 + 3^3 + \ldots + n^3 = \left[\frac{n(n+1)}{2}\right]^2$ for every natural number n.

Sol. Let $P(n) : 1^3 + 2^3 + 3^3 + \ldots + n^3 = \left[\frac{n(n+1)}{2}\right]^2$ ...(i)

***Step* I** For $n = 1$, LHS of Eq. (i) $= 1^3 = 1$

and RHS of Eq. (i) $= \left[\frac{1(1+1)}{2}\right]^2 = 1^2 = 1$

$\therefore$ LHS = RHS

Therefore, $P(1)$ is true.

***Step* II** Assume $P(k)$ is true, then

$$P(k) : 1^3 + 2^3 + 3^3 + \ldots + k^3 = \left[\frac{k(k+1)}{2}\right]^2$$

***Step* III** For $n = k + 1$,

$$P(k+1) : 1^3 + 2^3 + 3^3 + \ldots + k^3 + (k+1)^3 = \left[\frac{(k+1)(k+2)}{2}\right]^2$$

$$\text{LHS} = 1^3 + 2^3 + 3^3 + \ldots + k^3 + (k+1)^3 = \left[\frac{k(k+1)}{2}\right]^2 + (k+1)^3$$

[by assumption step]

$$= \frac{(k+1)^2}{4}[k^2 + 4(k+1)] = \frac{(k+1)^2(k^2+4k+4)}{4} = \frac{(k+1)^2(k+2)^2}{4} = \left[\frac{(k+1)(k+2)}{2}\right]^2 = \text{RHS}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction, $P(n)$ is true for all $n \in N$.

Example 2. Prove by mathematical induction that $1\cdot2\cdot3 + 2\cdot3\cdot4 + \ldots + n(n+1)(n+2) = \frac{n(n+1)(n+2)(n+3)}{4}$ for every natural number.

Sol. Let $P(n) : 1\cdot2\cdot3 + 2\cdot3\cdot4 + \ldots + n(n+1)(n+2) = \frac{n(n+1)(n+2)(n+3)}{4}$ ...(i)

***Step* I** For $n = 1$, LHS of Eq. (i) $= 1\cdot2\cdot3 = 6$

and RHS of Eq. (i) $= \frac{1\cdot(1+1)(1+2)(1+3)}{4} = 6$

$\therefore$ LHS = RHS

Therefore, $P(1)$ is true.

***Step* II** Assume that $P(k)$ is true, then

$$P(k) : 1\cdot2\cdot3 + 2\cdot3\cdot4 + \ldots + k(k+1)(k+2) = \frac{k(k+1)(k+2)(k+3)}{4}$$

***Step* III** For $n = k + 1$

$$P(k+1) : 1\cdot2\cdot3 + 2\cdot3\cdot4 + \ldots + k(k+1)(k+2) + (k+1)(k+2)(k+3) = \frac{(k+1)(k+2)(k+3)(k+4)}{4}$$

$$\therefore \text{LHS} = 1\cdot2\cdot3 + 2\cdot3\cdot4 + \ldots + k(k+1)(k+2) + (k+1)(k+2)(k+3) = \frac{k(k+1)(k+2)(k+3)}{4} + (k+1)(k+2)(k+3)$$

[by assumption step]

$$= \frac{(k+1)(k+2)(k+3)}{4}(k+4) = \frac{(k+1)(k+2)(k+3)(k+4)}{4} = \text{RHS}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction $P(n)$ is true for all $n \in N$.

Example 3. Prove by mathematical induction that $\frac{1}{1\cdot2\cdot3} + \frac{1}{2\cdot3\cdot4} + \ldots + \frac{1}{n(n+1)(n+2)} = \frac{n(n+3)}{4(n+1)(n+2)}$, $\forall\, n \in N$.

Sol. Let $P(n) : \frac{1}{1\cdot2\cdot3} + \frac{1}{2\cdot3\cdot4} + \ldots + \frac{1}{n(n+1)(n+2)} = \frac{n(n+3)}{4(n+1)(n+2)}$ ...(i)

***Step* I** For $n = 1$,

LHS of Eq. (i) $= \frac{1}{1\cdot2\cdot3} = \frac{1}{6}$

and RHS of Eq. (i) $= \frac{1\cdot(1+3)}{4(1+1)(1+2)} = \frac{1}{6}$

Therefore, $P(1)$ is true.

***Step* II** Assume that $P(k)$ is true, then

$$P(k): \frac{1}{1\cdot 2\cdot 3}+\frac{1}{2\cdot 3\cdot 4}+\ldots+\frac{1}{k(k+1)(k+2)}$$
$$=\frac{k(k+3)}{4(k+1)(k+2)}$$

***Step* III** For $n=k+1$,

$$P(k+1): \frac{1}{1\cdot 2\cdot 3}+\frac{1}{2\cdot 3\cdot 4}+\ldots+\frac{1}{k(k+1)(k+2)}$$
$$+\frac{1}{(k+1)(k+2)(k+3)}=\frac{(k+1)(k+4)}{4(k+2)(k+3)}$$

$$\therefore \text{ LHS}=\frac{1}{1\cdot 2\cdot 3}+\frac{1}{2\cdot 3\cdot 4}+\ldots+\frac{1}{k(k+1)(k+2)}$$
$$+\frac{1}{(k+1)(k+2)(k+3)}$$
$$=\frac{k(k+3)}{4(k+1)(k+2)}+\frac{1}{(k+1)(k+2)(k+3)}$$
[by assumption step]
$$=\frac{k(k+3)^2+4}{4(k+1)(k+2)(k+3)}$$
$$=\frac{k^3+6k^2+9k+4}{4(k+1)(k+2)(k+3)}$$
$$=\frac{(k+1)^2(k+4)}{4(k+1)(k+2)(k+3)}$$
$$=\frac{(k+1)(k+4)}{4(k+2)(k+3)}=\text{RHS}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction $P(n)$ is true for all $n\in N$.

Example 4. *Prove by mathematical induction that* $\sum_{r=0}^{n} r\,{}^nC_r = n\cdot 2^{n-1}$, $\forall\, n\in N$.

Sol. Let $P(n): \sum_{r=0}^{n} r\,{}^nC_r = n\cdot 2^{n-1}$

***Step* I** For $n=1$,

$$\text{LHS of Eq. (i)}=\sum_{r=0}^{1} r\cdot {}^1C_r = 0+1\cdot {}^1C_1 = 1$$

and RHS of Eq. (i) $=1\cdot 2^{1-1}=2^0=1$

Therefore, $P(1)$ is true.

***Step* II** Assume that $P(k)$ is true, then $P(k)$: $\sum_{r=0}^{k} r\cdot {}^kC_r = k\cdot 2^{k-1}$

***Step* III** For $n=k+1$

$$P(k+1): \sum_{r=0}^{k+1} r\cdot {}^{k+1}C_r = (k+1)\cdot 2^k$$

$$\therefore \text{ LHS}=\sum_{r=0}^{k+1} r\cdot {}^{k+1}C_r = 0+\sum_{r=1}^{k+1} r\cdot {}^{k+1}C_r$$
$$=\sum_{r=1}^{k+1} r\cdot {}^{k+1}C_r = \sum_{r=1}^{k} r\cdot {}^{k+1}C_r + (k+1)^{k+1}C_{k+1}$$
$$=\sum_{r=1}^{k} r\,({}^kC_r + {}^kC_{r-1})+(k+1)$$
$$=\sum_{r=1}^{k} r\cdot {}^kC_r + \sum_{r=1}^{k} r\cdot {}^kC_{r-1}+(k+1)$$
$$=\sum_{r=0}^{k} r\cdot {}^kC_r + \sum_{r=0}^{k} r\cdot {}^kC_{r-1}+(k+1)$$
$$=\sum_{r=0}^{k} r\cdot {}^kC_r + \sum_{r=0}^{k+1} r\cdot {}^kC_{r-1}$$
$$=\sum_{r=0}^{k} r\cdot {}^kC_r + \sum_{r=0}^{k} (r+1)\cdot {}^kC_r$$
$$=\sum_{r=0}^{k} r\cdot {}^kC_r + \sum_{r=0}^{k} r\cdot {}^kC_r + \sum_{r=0}^{k} {}^kC_r$$
$$=P(k)+P(k)+2^k \qquad \text{[by assumption step]}$$
$$=k\cdot 2^{k-1}+k\cdot 2^{k-1}+2^k = 2\cdot k\cdot 2^{k-1}+2^k$$
$$=k\cdot 2^k+2^k=(k+1)\cdot 2^k=\text{RHS}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction $P(n)$ is true for all $n\in N$.

Type II These problems are of the **Divisibility Type**. Examples of this type are as follows:

Example 5. Use the principle of mathematical induction to show that $5^{2n+1}+3^{n+2}\cdot 2^{n-1}$ divisible by 19 for all natural numbers n.

Sol. Let $P(n)=5^{2n+1}+3^{n+2}\cdot 2^{n-1}$

***Step* I** For $n=1$, $P(1)=5^{2+1}+3^{1+2}\cdot 2^{1-1}$

$=125+27=152$, which is divisible by 19.

Therefore, the result is true for $n=1$.

***Step* II** Assume that the result is true for $n=k$, i.e.,

$P(k)=5^{2k+1}+3^{k+2}\cdot 2^{k-1}$ is divisible by 19.

$\Rightarrow$ $P(k)=19r$, where r is an integer.

***Step* III** For $n=k+1$,

$$P(k+1)=5^{2(k+1)+1}+3^{k+1+2}\cdot 2^{k+1-1}$$
$$=5^{2k+3}+3^{k+3}\cdot 2^k$$
$$=25\cdot 5^{2k+1}+3\cdot 3^{k+2}\cdot 2\cdot 2^{k-1}$$
$$=25\cdot 5^{2k+1}+6\cdot 3^{k+2}\cdot 2^{k-1}$$

Now, $5^{2k+1}+3^{k+2}\cdot 2^{k-1}\;\overline{)\;25\cdot 5^{2k+1}+6\cdot 3^{k+2}\cdot 2^{k-1}\;(25}$

$25\cdot 5^{2k+1}+25\cdot 3^{k+2}\cdot 2^{k-1}$

$- \qquad -$

$-19\cdot 3^{k+2}\cdot 2^{k-1}$

$\therefore \quad 25\cdot 5^{2k+1} + 6\cdot 3^{k+2}\cdot 2^{k-1}$

$= 25\cdot(5^{2k+1} + 3^{k-2}\cdot 2^{k-2}) - 19\cdot 3^{k+2}\cdot 2^{k-1}$

i.e., $P(k+1) = 25\,P(k) - 19\cdot 3^{k+2}\cdot 2^{k-1}$

But we know that $P(k)$ is divisible by 19. Also, $19\cdot 3^{k+2}\cdot 2^{k-1}$ is clearly divisible by 19.

Therefore, $P(k+1)$ is divisible by 19. This shows that the result is true for $n = k+1$.

Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

Example 6. Use the principle of mathematical induction to show that $a^n - b^n$ is divisible by $a-b$ for all natural numbers n.

Sol. Let $P(n) = a^n - b^n$

***Step* I** For $n = 1$,

$P(1) = a - b$, which is divisible by $a - b$.

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$,

i.e., $P(k) = a^k - b^k$ is divisible by $a - b$.

$\Rightarrow \quad P(k) = (a-b)\,r$, where r is an integer.

***Step* III** For $n = k+1$,

$\therefore \quad P(k+1) = a^{k+1} - b^{k+1}$

Now, $a^k - b^k \overline{)a^{k+1} - b^{k+1}}(a$

$\underline{-a^{k+1} \mp ab^k}$

$ab^k - b^{k+1} = b^k(a-b)$

$\therefore \quad a^{k+1} - b^{k+1} = a(a^k - b^k) + b^k(a-b)$

i.e., $P(k+1) = a\,P(k) + b^k\,(a-b)$

But we know that $P(k)$ is divisible by $a-b$. Also, $b^k\,(a-b)$ is clearly divisible by $a-b$.

Therefore, $P(k+1)$ is divisible by $a-b$.

This shows that the result is true for $n = k+1$.

Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

Type III These problems are of the **Inequality Type**. Examples of this type are as follows:

Example 7. ***Using mathematical induction, show that*** $\tan n\alpha > n\tan\alpha$***, where*** $0 < \alpha < \dfrac{\pi}{4(n-1)}, \forall\, n \in N$ ***and*** $n > 1$.

Sol. Let $P(n): \tan n\alpha > n\tan\alpha$

***Step* I** For $n = 2, \quad \tan 2\alpha > 2\tan\alpha$

$\Rightarrow \quad \dfrac{2\tan\alpha}{1-\tan^2\alpha} - 2\tan\alpha > 0$

$\Rightarrow \quad 2\tan\alpha\left(\dfrac{1-(1-\tan^2\alpha)}{1-\tan^2\alpha}\right) > 0$

$\Rightarrow \quad \tan^2\alpha\cdot\tan 2\alpha > 0 \quad \left[\because 0 < \alpha < \dfrac{\pi}{4} \text{ for } n = 2\right]$

$\Rightarrow \quad \tan 2\alpha > 0 \quad \left[\because 0 < 2\alpha < \dfrac{\pi}{2}\right]$

which is true ($\because$ in first quadrant, $\tan 2\alpha$ is positive)

Therefore, $P(2)$ is true.

***Step* II** Assume that $P(k)$ is true, then $P(k)$: $\tan k\alpha > k\tan\alpha$

***Step* III** For $n = k+1$, we shall prove that

$\tan(k+1)\alpha > (k+1)\tan\alpha$

$\because \quad \tan(k+1)\alpha = \dfrac{\tan k\alpha + \tan\alpha}{1-\tan k\alpha\tan\alpha}$ ...(i)

when $0 < \alpha < \dfrac{\pi}{4k}$ or $0 < k\alpha < \dfrac{\pi}{4}$

i.e. $0 < \tan k\alpha < 1$, also $0 < \tan\alpha < 1$

$\therefore \quad \tan k\alpha\tan\alpha < 1$

$1 - \tan k\alpha\tan\alpha > 0$ and $1 - \tan k\alpha\tan\alpha < 1$ ...(ii)

From Eqs. (i) and (ii), we get

$\tan(k+1)\alpha > \dfrac{\tan k\alpha + \tan\alpha}{1}$

$> \tan k\alpha + \tan\alpha > k\tan\alpha + \tan\alpha$ [by assumption step]

$\therefore \quad \tan(k+1)\alpha > (k+1)\tan\alpha$

Therefore, $P(k+1)$ is true. Hence by the principle of mathematical induction $P(n)$ is true for all $n \in N$.

Example 8. Show using mathematical induction that $n! < \left(\dfrac{n+1}{2}\right)^n$, where $n \in N$ and $n > 1$.

Sol. Let $P(n): n! < \left(\dfrac{n+1}{2}\right)^n$

***Step* I** For $n = 2, 2! < \left(\dfrac{2+1}{2}\right)^2 \Rightarrow 2 < \dfrac{9}{4}$

$\Rightarrow \quad 2 < 2\cdot 25$, which is true.

Therefore, $P(2)$ is true.

***Step* II** Assume that $P(k)$ is true, then

$P(k): k! < \left(\dfrac{k+1}{2}\right)^k$

***Step* III** For $n = k+1$, we shall prove that

$P(k+1): (k+1)! < \left(\dfrac{k+2}{2}\right)^{k+1}$

From assumption step $k! < \dfrac{(k+1)^k}{2^k}$

$$\Rightarrow \quad (k+1)k! < \frac{(k+1)^{k+1}}{2^k}$$

$$\Rightarrow \quad (k+1)! < \frac{(k+1)^{k+1}}{2^k} \quad \ldots(i)$$

Let us assume, $\frac{(k+1)^{k+1}}{2^k} < \left(\frac{k+2}{2}\right)^{k+1}$ ...(ii)

$$\Rightarrow \quad \left(\frac{k+2}{k+1}\right)^{k+1} > 2 \Rightarrow \left(1+\frac{1}{k+1}\right)^{k+1} > 2$$

$$\Rightarrow \quad 1+(k+1)\cdot\frac{1}{(k+1)} + {}^{k+1}C_2\left(\frac{1}{k+1}\right)^2 + \ldots > 2$$

$$\Rightarrow \quad 1+1+{}^{k+1}C_2\left(\frac{1}{k+1}\right)^2 + \ldots > 2$$

which is true, hence Eq. (ii) is true.

From Eqs. (i) and (ii), we get

$$(k+1)! < \frac{(k+1)^{k+1}}{2^k} < \left(\frac{k+2}{2}\right)^{k+1}$$

$$\Rightarrow \quad (k+1)! < \left(\frac{k+2}{2}\right)^{k+1}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction $P(n)$ is true for all $n \in N$.

Type IV These problems are of the **Second principle of induction**. Examples of this type are as follows:

Example 9. If $a+b=c+d$ and $a^2+b^2=c^2+d^2$, then show by mathematical induction

$$a^n+b^n=c^n+d^n$$

Sol. $P(n): a^n+b^n=c^n+d^n$

***Step* I** For $n=1$ and $n=2$,

$P(1): a+b=c+d$ and $P(2): a^2+b^2=c^2+d^2$

which are true (from given conditions).

Therefore, $P(1)$ and $P(2)$ are true.

***Step* II** Assume $P(k-1)$ and $P(k)$ to be true

$$\therefore \quad a^{k-1}+b^{k-1}=c^{k-1}+d^{k-1} \quad \ldots(i)$$

and $$a^k+b^k=c^k+d^k \quad \ldots(ii)$$

***Step* III** For $n=k+1$,

$P(k+1): a^{k+1}+b^{k+1}=c^{k+1}+d^{k+1}$

$$\therefore \quad \text{LHS} = a^{k+1}+b^{k+1}$$

$$= (a+b)(a^k+b^k) - ab^k - ba^k$$

$$= (a+b)(a^k+b^k) - ab(a^{k-1}+b^{k-1})$$

[given $a+b=c+d$ and $a^2+b^2=c^2+d^2$, then $ab=cd$]

$$= (c+d)(c^k+d^k) - cd(c^{k-1}+d^{k-1})$$

[from Eqs. (i) and (ii)]

$$= c^{k+1}+d^{k+1} = \text{RHS}$$

Therefore, $P(k+1)$ is true. Hence, by the principle of mathematical induction $P(n)$ is true for all $n \in N$.

Example 10. ***Let*** $I_m = \int_0^{\pi}\left(\frac{1-\cos mx}{1-\cos x}\right)dx$ ***use mathematical induction to prove that*** $I_m = m\pi$, $m = 0, 1, 2, \ldots$

Sol. $\because \quad I_m = \int_0^{\pi}\left(\frac{1-\cos mx}{1-\cos x}\right)dx$

***Step* I** For $m=1$, $I_1 = \int_0^{\pi}\left(\frac{1-\cos x}{1-\cos x}\right)dx$

$\therefore \quad I_1 = \pi$ and for $m=2$,

$$I_2 = \int_0^{\pi}\left(\frac{1-\cos 2x}{1-\cos x}\right)dx$$

$$= \int_0^{\pi}\frac{2\sin^2 x(1+\cos x)}{(1-\cos x)(1+\cos x)}dx$$

$$= \int_0^{\pi}\frac{2\sin^2 x(1+\cos x)}{\sin^2 x}dx = 2\int_0^{\pi}(1+\cos x)dx$$

$$= 2[x+\sin x]_0^{\pi} = 2[(\pi+0)-(0+0)] = 2\pi$$

which are true, therefore I_1 and I_2 are true.

***Step* II** Assume I_{k-1} and I_k to be true

$$\therefore \quad I_{k-1} = (k-1)\pi \quad \ldots(i)$$

and $$I_k = k\pi \quad \ldots(ii)$$

***Step* III** For $m=k+1$,

$$I_{k+1} = \int_0^{\pi}\frac{1-\cos(k+1)x}{1-\cos x}dx$$

$$\therefore \quad I_{k+1} - I_k = \int_0^{\pi}\frac{\cos kx - \cos(k+1)x}{1-\cos x}dx$$

$$= \int_0^{\pi}\frac{2\sin\left(\frac{2k+1}{2}\right)x\cdot\sin\left(\frac{x}{2}\right)}{2\sin^2\left(\frac{x}{2}\right)}dx$$

$$= \int_0^{\pi}\frac{\sin\left(\frac{2k+1}{2}\right)x}{\sin\left(\frac{x}{2}\right)}dx \quad \ldots(iii)$$

Similarly, $I_k - I_{k-1} = \int_0^{\pi}\frac{\sin\left(\frac{2k-1}{2}\right)x}{\sin\left(\frac{x}{2}\right)}dx \quad \ldots(iv)$

On subtracting Eq. (iv) from Eq. (iii), we get

$$I_{k+1} - 2I_k + I_{k-1} = \int_0^{\pi} \frac{\sin\left(\frac{2k+1}{2}\right)x - \sin\left(\frac{2k-1}{2}\right)x}{\sin\left(\frac{x}{2}\right)} dx$$

$$= \int_0^{\pi} \frac{2\cos(kx)\sin\left(\frac{x}{2}\right)}{\sin\left(\frac{x}{2}\right)} dx = 2\int_0^{\pi} \cos kx\, dx = 2\left[\frac{\sin kx}{k}\right]_0^{\pi} = 0$$

$$\Rightarrow \quad I_{k+1} = 2I_k - I_{k-1} = 2k\pi - (k-1)\pi \quad \text{[by assumption step]}$$

$$= k\pi + \pi = (k+1)\pi$$

This shows that the result is true for $m = k + 1$. Hence, by the principle of mathematical induction the result is true for all $m \in N$.

Type V These problems are of the **Recursion Type**. Examples of this type are as follows:

Example 11. ***Given*** $u_{n+1} = 3u_n - 2u_{n-1}$ ***and*** $u_0 = 2$, $u_1 = 3$. ***Prove that*** $u_n = 2^n + 1$, $\forall\, n \in N$.

Sol. $\because\ u_{n+1} = 3u_n - 2u_{n-1}$ ...(i)

***Step* I** Given, $u_1 = 3 = 2 + 1 = 2^1 + 1$ which is true for $n = 1$.

Putting $n = 1$ in Eq. (i), we get

$$u_{1+1} = 3u_1 - 2u_{1-1}$$

$$\Rightarrow \quad u_2 = 3u_1 - 2u_0 = 3\cdot 3 - 2\cdot 2 = 5 = 2^2 + 1$$

which is true for $n = 2$.

Therefore, the result is true for $n = 1$ and $n = 2$.

***Step* II** Assume it is true for $n = k$, then it is also true for $n = k - 1$.

Then, $u_k = 2^k + 1$ ...(ii)

and $u_{k-1} = 2^{k-1} + 1$ ...(iii)

***Step* III** Putting $n = k$ in Eq. (i), we get

$$u_{k+1} = 3u_k - 2u_{k-1}$$

$$= 3(2^k + 1) - 2(2^{k-1} + 1) \quad \text{[from Eqs. (ii) and (iii)]}$$

$$= 3\cdot 2^k + 3 - 2\cdot 2^{k-1} - 2 = 3\cdot 2^k + 3 - 2^k - 2$$

$$= (3-1)2^k + 1 = 2\cdot 2^k + 1 = 2^{k+1} + 1$$

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction the result is true for all $n \in N$.

Example 12. Let $u_1 = 1$, $u_2 = 2$, $u_3 = \frac{7}{2}$ and $u_{n+3} = 3u_{n+2} - \left(\frac{3}{2}\right)u_{n+1} - u_n$. Use the principle of mathematical induction to show that $u_n = \frac{1}{3}\left[2^n + \left(\frac{1+\sqrt{3}}{2}\right)^n + \left(\frac{1-\sqrt{3}}{2}\right)^n\right] \forall\, n \geq 1$.

Sol. $\because\ u_n = \frac{1}{3}\left[2^n + \left(\frac{1+\sqrt{3}}{2}\right)^n + \left(\frac{1-\sqrt{3}}{2}\right)^n\right]$ ...(i)

***Step* I** For $n = 1$, $u_1 = \frac{1}{3}\left[2^1 + \left(\frac{1+\sqrt{3}}{2}\right)^1 + \left(\frac{1-\sqrt{3}}{2}\right)^1\right]$

$$= \frac{1}{3}[2 + 1] = 1$$

which is true for $n = 1$ and for $n = 2$,

$$u_2 = \frac{1}{3}\left[2^2 + \left(\frac{1+\sqrt{3}}{2}\right)^2 + \left(\frac{1-\sqrt{3}}{2}\right)^2\right]$$

$$= \frac{1}{3}\left[4 + \left(\frac{4+2\sqrt{3}}{4}\right) + \left(\frac{4-2\sqrt{3}}{4}\right)\right] = \frac{1}{3}[6] = 2$$

which is true for $n = 2$.

Therefore, the result is true for $n = 1$ and $n = 2$.

***Step* II** Assume it is true for $n = k$, then it is also true for $n = k - 1$, $k - 2$

$$\therefore \quad u_k = \frac{1}{3}\left[2^k + \left(\frac{1+\sqrt{3}}{2}\right)^k + \left(\frac{1-\sqrt{3}}{2}\right)^k\right] \quad ...(ii)$$

$$u_{k-1} = \frac{1}{3}\left[2^{k-1} + \left(\frac{1+\sqrt{3}}{2}\right)^{k-1} + \left(\frac{1-\sqrt{3}}{2}\right)^{k-1}\right] \quad ...(iii)$$

$$u_{k-2} = \frac{1}{3}\left[2^{k-2} + \left(\frac{1+\sqrt{3}}{2}\right)^{k-2} + \left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\right] \quad ...(iv)$$

***Step* III** Given that, $u_{n+3} = 3u_{n+2} - \left(\frac{3}{2}\right)u_{n+1} - u_n$

Replace n by $k - 2$

Then, $u_{k+1} = 3u_k - \frac{3}{2}u_{k-1} - u_{k-2}$

$$= \frac{1}{3}\left[3\cdot 2^k + 3\left(\frac{1+\sqrt{3}}{2}\right)^k + 3\left(\frac{1-\sqrt{3}}{2}\right)^k\right]$$

$$+ \frac{1}{3}\left[-\frac{3}{2}\cdot 2^{k-1} - \frac{3}{2}\left(\frac{1+\sqrt{3}}{2}\right)^{k-1} - \frac{3}{2}\left(\frac{1-\sqrt{3}}{2}\right)^{k-1}\right]$$

$$+ \frac{1}{3}\left[-2^{k-2} - \left(\frac{1+\sqrt{3}}{2}\right)^{k-2} - \left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\right]$$

$$= \frac{1}{3}\left[3\cdot 2^k - 3\cdot 2^{k-2} - 2^{k-2} + \left(\frac{1+\sqrt{3}}{2}\right)^k\right.$$

$$- \frac{3}{2}\left(\frac{1+\sqrt{3}}{2}\right)^{k-1} - \left(\frac{1+\sqrt{3}}{2}\right)^{k-2} + 3\left(\frac{1-\sqrt{3}}{2}\right)^k$$

$$\left. - \frac{3}{2}\left(\frac{1-\sqrt{3}}{2}\right)^{k-1} - \left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\right]$$

$$= \frac{1}{3}\left[2^{k-2}(3\cdot 4-3-1)+\left(\frac{1+\sqrt{3}}{2}\right)^{k-2}\left[3\left(\frac{1+\sqrt{3}}{2}\right)^{2}-\frac{3}{2}\left(\frac{1+\sqrt{3}}{2}\right)-1\right]+\left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\left[3\left(\frac{1-\sqrt{3}}{2}\right)^{2}-\frac{3}{2}\left(\frac{1-\sqrt{3}}{2}\right)-1\right]\right]$$

$$= \frac{1}{3}\left[2^{k-2}\cdot 8+\left(\frac{1+\sqrt{3}}{2}\right)^{k-2}\left[\frac{3(1+\sqrt{3})^{2}-3(1+\sqrt{3})-4}{4}\right]+\left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\left[\frac{3(1-\sqrt{3})^{2}-3(1-\sqrt{3})-4}{4}\right]\right]$$

$$= \frac{1}{3}\left[2^{k+1}+\left(\frac{1+\sqrt{3}}{2}\right)^{k-2}\left[\frac{10+6\sqrt{3}}{8}\right]+\left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\left[\frac{10-6\sqrt{3}}{8}\right]\right]$$

$$= \frac{1}{3}\left[2^{k+1}+\left(\frac{1+\sqrt{3}}{2}\right)^{k-2}\left(\frac{1+\sqrt{3}}{2}\right)^{3}+\left(\frac{1-\sqrt{3}}{2}\right)^{k-2}\left(\frac{1-\sqrt{3}}{2}\right)^{3}\right]$$

$$= \frac{1}{3}\left[2^{k+1}+\left(\frac{1+\sqrt{3}}{2}\right)^{k+1}+\left(\frac{1-\sqrt{3}}{2}\right)^{k+1}\right]$$

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction the result is true for all $n \in N$.

Shortcuts and Important Results to Remember

1. Principle of mathematical induction is widely used in proving identities, theorems, divisibility of an expression by a number or by another expression, inequalities, etc.
2. Principle of mathematical induction can only help in verifying an established result. It cannot discover a new formula.
3. If $f(k)$ is divisible by a number p and it is to be proved that $f(k + 1)$ is divisible by p, sometimes it is easier to show that $f(k + 1) - f(k)$ is divisible by p.
4. $\underbrace{aaaaa\ldots a}_{m \text{ times}} = a\,(1 + 10 + 10^2 + 10^3 + \ldots + 10^{m-1})$
$= \dfrac{a\,(10^m - 1)}{9}$, $\forall\ 1 \le a \le 9$ and $a \in N$.

JEE Type Solved Examples :
Single Option Correct Type Questions

▪ This section contains **5 multiple choice examples**. Each example has four choices (a), (b), (c) and (d), out of which **ONLY ONE** is correct.

● ***Ex. 1*** *When P is a natural number, then* $P^{n+1} + (P+1)^{2n-1}$ *is divisible by*

(a) P (b) $P^2 + P$ (c) $P^2 + P + 1$ (d) $P^2 - 1$

Sol. (c) For $n = 1$, we get

$$P^{n+1} + (P+1)^{2n-1} = P^2 + (P+1)^1 = P^2 + P + 1,$$

which is divisible by $P^2 + P + 1$, so result is true for $n = 1$.

Let us assume that the given result is true for $n = m \in N$.

i.e., $P^{m+1} + (P+1)^{2m-1}$ is divisible by $P^2 + P + 1$.

i.e., $P^{m+1} + (P+1)^{2m-1} = k(P^2 + P + 1), \forall\ k \in N$ ...(i)

Now, $P^{(m+1)+1} + (P+1)^{2(m+1)-1}$

$= P^{m+2} + (P+1)^{2m+1}$

$= P^{m+2} + (P+1)^2 (P+1)^{2m-1}$

$= P^{m+2} + (P+1)^2 [k(P^2 + P + 1) - P^{m+1}]$

[by using Eq. (i)]

$= P^{m+2} + (P+1)^2 \cdot k(P^2 + P + 1) - (P+1)^2 (P)^{m+1}$

$= P^{m+1} [P - (P+1)^2] + (P+1)^2 \cdot k(P^2 + P + 1)$

$= P^{m+1} [P - P^2 - 2P - 1] + (P+1)^2 \cdot k(P^2 + P + 1)$

$= -P^{m+1} [P^2 + P + 1] + (P+1)^2 \cdot k(P^2 + P + 1)$

$= (P^2 + P + 1) [k \cdot (P+1)^2 - P^{m+1}]$

which is divisible by $P^2 + P + 1$, so the result is true for $n = m + 1$. Therefore, the given result is true for all $n \in N$ by induction.

● ***Ex. 2*** *Let* $P(n)$ *denote the statement that* $n^2 + n$ *is odd. It is seen that* $P(n) \Rightarrow P(n+1)$, $P(n)$ *is true for all*

(a) $n > 1$ (b) n

(c) $n > 2$ (d) None of these

Sol. (d) $P(n) = n^2 + n$. It is always odd (statement) but square of any odd number is always odd and also, sum of two odd numbers is always even. So, for no any 'n' for which this statement is true.

● ***Ex. 3*** *For a positive integer n,*

let $a(n) = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \ldots + \frac{1}{2^n - 1}$. *Then*

(a) $a(100) > 100$

(b) $a(100) < 200$

(c) $a(200) \le 100$

(d) $a(200) > 100$

Sol. (d) It can be proved with the help of mathematical induction that

$$\frac{n}{2} < a(n) \le n$$

$$\Rightarrow \quad \frac{200}{2} < a(200)$$

$$\Rightarrow \quad a(200) > 100$$

● ***Ex. 4*** *Let* $S(k) = 1 + 3 + 5 + \ldots + (2k-1) = 3 + k^2$. *Which of the following is true?*

(a) Principle of mathematical induction can be used to prove the formula

(b) $S(k) \Rightarrow S(k+1)$

(c) $S(k) \not\Rightarrow S(k+1)$

(d) $S(1)$ is correct

Sol. (c) We have, $S(k) = 1 + 3 + 5 + \ldots + (2k-1) = 3 + k^2$,

$S(1) \Rightarrow 1 = 4$, which is not true

and $S(2) \Rightarrow 4 = 7$, which is not true.

Hence, induction cannot be applied and $S(k) \ne S(k+1)$.

● ***Ex. 5*** $10^n + 3(4^{n+2}) + 5$ *is divisible by* ($n \in N$)

(a) 7 (b) 5

(c) 9 (d) 17

Sol. (c) $10^n + 3(4^{n+2}) + 5$

Taking $n = 2$,

$$10^2 + 3 \times 4^4 + 5 = 100 + 768 + 5 = 873$$

Therefore, this is divisible by 9.

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** Example numbers 6 and 7 are Assertion-Reason type Examples. Each of these Examples contains two statements :
Statement-1 (Assertion) and
Statement-2 (Reason)
Each of these examples also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below:

(a) Statement-1 is true, Statement-2 is true Statement-2 is correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true, Statement-2 is not the correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true

● ***Ex. 6*** **Statement-1** *For all natural number n,*

$$1+2+\ldots+n<(2n+1)^2$$

Statement-2 *For all natural numbers,* $(2n+3)^2<7(n+1)$

Sol. (*b*) Let $P(n):1+2+3+\ldots+n<(2n+1)^2$

***Step* I** For $n=1$,

$P(1):1<(2+1)^2 \Rightarrow 1<9$

which is true.

***Step* II** Assume $P(n)$ is true for $n=k$, then

$P(k):1+2+\ldots+k<(2k+1)^2$

***Step* III** For $n=k+1$, we shall prove that

$P(k+1):1+2+3+\ldots+k+(k+1)<(2k+3)^2$

From assumption step

$1+2+3+\ldots+k+(k+1)<(2k+1)^2+k+1$

$=4k^2+5k+2$

$=(2k+3)^2-7(k+1)<(2k+3)^2 \qquad [\because 7(k+1)>0]$

$\therefore$ $P(k+1)$ is true.

Here, both Statements are true but Statement-2 is not correct explanation of Statement-1.

● ***Ex. 7*** **Statement-1** *For all natural numbers n,*

$$7+77+777+\ldots\underbrace{777\ldots7}_{n \text{ digits}}=\frac{7}{81}(10^{n+1}-9n-10)$$

Statement-2 *For all natural numbers,*

$$\underbrace{777\ldots7}_{n \text{ digits}}=7+7\times10+7\times10^2+\ldots+7\times10^n$$

Sol. (*c*) $\because$ $\underbrace{777\ldots7}_{n \text{ digits}}=7\underbrace{(111\ldots1)}_{n \text{ digits}}$

$=7\,(1+10+10^2+\ldots+10^{n-1})$

$=7+7\times10+7\times10^2+\ldots+7\times10^{n-1}$

$\neq 7+7\times10+7\times10^2+\ldots+7\times10^n$

$\therefore$ Statement-2 is false.

Now, let $P(n):7+77+777+\ldots+\underbrace{777\ldots7}_{n \text{ digits}}=\frac{7}{81}$

$(10^{n+1}-9n-10)$

***Step* I** For $n=1$,

LHS $=7$ and RHS $=\frac{7}{81}(10^2-9-10)=7$

$\therefore$ LHS = RHS

which is true for $n=1$.

***Step* II** Assume $P(n)$ is true for $n=k$, then

$P(k):7+77+777+\ldots+\underbrace{777\ldots7}_{k \text{ digits}}$

$=\frac{7}{81}(10^{k+1}-9k-10)$

***Step* III** For $n=k+1$,

$P(k+1):7+77+777+\ldots+\underbrace{777\ldots7}_{k \text{ digits}}+\underbrace{777\ldots7}_{(k+1) \text{ digits}}$

$=\frac{7}{81}[10^{k+2}-9(k+1)-10]$

LHS $=7+77+777+\ldots+\underbrace{777\ldots7}_{k \text{ digits}}+\underbrace{777\ldots7}_{(k+1) \text{ digits}}$

$=\frac{7}{81}(10^{k+1}-9k-10)+7(1+10+10^2+\ldots+10^k)$

[from assumption step]

$=\frac{7}{81}(10^{k+1}-9k-10)+\frac{7(10^{k+1}-1)}{10-1}$

$=\frac{7}{81}(10^{k+1}-9k-10+9\cdot10^{k+1}-9)$

$=\frac{7}{81}[10^{k+1}(1+9)-9(k+1)-10]$

$=\frac{7}{81}[10^{k+2}-9(k+1)-10]$

= RHS

Therefore, $P(k+1)$ is true. Hence, by mathematical induction $P(n)$ is true for all natural numbers.

Hence, Statement-1 is true and Statement-2 is false.

Subjective Type Examples

■ In this section, there are **8 subjective** solved examples.

● ***Ex. 8*** *Prove by induction that the integer next greater than* $(3+\sqrt{5})^n$ *is divisible by* 2^n *for all* $n \in N$.

Sol. Let $\alpha = 3+\sqrt{5}$ and $\beta = 3-\sqrt{5}$

$\therefore \quad 0 < \beta^n < 1, \forall\, n \in N$

$\Rightarrow \quad \alpha+\beta = 6, \alpha\beta = 4$ ...(i)

Then, α and β are the roots of

$$x^2 - 6x + 4 = 0$$

$$\Rightarrow \quad \left.\begin{aligned}\alpha^2 &= 6\alpha - 4\\ \beta^2 &= 6\beta - 4\end{aligned}\right] \quad \text{...(ii)}$$

$\therefore \quad \alpha^2+\beta^2 = 6(\alpha+\beta) - 8 = 28$ ...(iii)

$\therefore \quad \alpha^n+\beta^n = (3+\sqrt{5})^n + (3-\sqrt{5})^n$

$= 2[3^n + {}^nC_2 3^{n-2}\cdot 5 + {}^nC_4 3^{n-4}\cdot 5^2 + \ldots]$

= Even integer.

As, $0 < \beta^n < 1$, $\alpha^n+\beta^n$ is the even integer next greater than α^n.

***Step* I** For $n = 1$,

$\alpha+\beta = 6$ [from Eq. (i)]

divisible by 2^1

and for $n = 2, \alpha^2+\beta^2 = 28$ [from Eq. (iii)]

divisible by 2^2

which is true for $n = 1, 2$.

***Step* II** Assume it is true for $n = k$.

i.e., $\alpha^k+\beta^k$ is divisible by 2^k.

***Step* III** For $n = k+1$,

the integer next greater than α^{k+1} is $\alpha^{k+1}+\beta^{k+1}$

$= \alpha^2\cdot\alpha^{k-1} + \beta^2\cdot\beta^{k-1}$

$= (6\alpha-4)\cdot\alpha^{k-1} + (6\beta-4)\cdot\beta^{k-1}$ [from Eq. (ii)]

$= 6(\alpha^k+\beta^k) - 4(\alpha^{k-1}+\beta^{k-1})$

= 3 (divisible by 2^{k+1}) − (divisible by 2^{k+1})

= Divisible by 2^{k+1}

This shows that the result is true for $n = k+1$. Hence, the integer next greater than α^{k+1} is divisible by 2^{k+1}.

● ***Ex. 9*** *Using mathematical induction, show that*

$$\left(1-\frac{1}{2^2}\right)\left(1-\frac{1}{3^2}\right)\left(1-\frac{1}{4^2}\right)\ldots\left(1-\frac{1}{(n+1)^2}\right) = \frac{n+2}{2(n+1)}, \forall\, n \in N.$$

Sol. Let $P(n): \left(1-\frac{1}{2^2}\right)\left(1-\frac{1}{3^2}\right)\left(1-\frac{1}{4^2}\right)\ldots\left(1-\frac{1}{(n+1)^2}\right)$

$$= \frac{n+2}{2(n+1)} \quad \text{...(i)}$$

***Step* I** For $n = 1$,

LHS of Eq. (i) $= 1-\frac{1}{2^2} = \frac{3}{4}$ and RHS of Eq. (i)

$$= \frac{3}{2\cdot 2} = \frac{3}{4}.$$

Therefore, $P(1)$ is true.

***Step* II** Assume it is true for $n = k$, then

$$P(k): \left(1-\frac{1}{2^2}\right)\left(1-\frac{1}{3^2}\right)\left(1-\frac{1}{4^2}\right)\ldots\left(1-\frac{1}{(k+1)^2}\right) = \frac{k+2}{2(k+1)}$$

***Step* III** For $n = k+1$,

$$P(k+1): \left(1-\frac{1}{2^2}\right)\left(1-\frac{1}{3^2}\right)\left(1-\frac{1}{4^2}\right)\ldots\left(1-\frac{1}{(k+1)^2}\right)\left(1-\frac{1}{(k+2)^2}\right) = \frac{k+3}{2(k+2)}$$

$$\therefore \quad \text{LHS} = \left(1-\frac{1}{2^2}\right)\left(1-\frac{1}{3^2}\right)\left(1-\frac{1}{4^2}\right)\ldots\left(1-\frac{1}{(k+1)^2}\right)\left(1-\frac{1}{(k+2)^2}\right)$$

$$= \frac{k+2}{2(k+1)}\left(1-\frac{1}{(k+2)^2}\right) \quad \text{[by assumption step]}$$

$$= \frac{(k+2)}{2(k+1)}\cdot\frac{[(k+2)^2-1)]}{(k+2)^2} = \frac{k^2+4k+3}{2(k+1)(k+2)}$$

$$= \frac{(k+1)(k+3)}{2(k+1)(k+2)} = \frac{(k+3)}{2(k+2)} = \text{RHS}$$

This shows that the result is true for $n = k+1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

● ***Ex. 10*** *Using the principle of mathematical induction to show that*

$$\tan^{-1}\left(\frac{x}{1+1\cdot 2\cdot x^2}\right) + \tan^{-1}\left(\frac{x}{1+2\cdot 3\cdot x^2}\right) + \ldots + \tan^{-1}\left(\frac{x}{1+n(n+1)\,x^2}\right) = \tan^{-1}(n+1)\,x - \tan^{-1}x, \forall\, x \in N.$$

Sol. Let $P(n): \tan^{-1}\left(\frac{x}{1+1\cdot 2\cdot x^2}\right)+\tan^{-1}\left(\frac{x}{1+2\cdot 3\cdot x^2}\right)+\ldots+\tan^{-1}\left(\frac{x}{1+n(n+1)\,x^2}\right)=\tan^{-1}(n+1)x-\tan^{-1}x$ ...(i)

***Step* I** For $n=1$,

LHS of Eq. (i) $=\tan^{-1}\left(\frac{x}{1+1\cdot 2\cdot x^2}\right)$

$=\tan^{-1}\left(\frac{2x-x}{1+2x\cdot x}\right)=\tan^{-1}2x-\tan^{-1}x$

= RHS of Eq. (i)

Therefore, $P(1)$ is true.

***Step* II** Assume it is true for $n=k$.

$P(k): \tan^{-1}\left(\frac{x}{1+1\cdot 2\,x^2}\right)+\tan^{-1}\left(\frac{x}{1+2\cdot 3x^2}\right)+\ldots+\tan^{-1}\left(\frac{x}{[1+k(k+1)\,x^2]}\right)=\tan^{-1}(k+1)\,x-\tan^{-1}x$

***Step* III** For $n=k+1$,

$P(k+1): \tan^{-1}\left(\frac{x}{1+1\cdot 2\cdot x^2}\right)+\tan^{-1}\left(\frac{x}{1+2\cdot 3\cdot x^2}\right)+\ldots+\tan^{-1}\left(\frac{x}{1+k(k+1)\,x^2}\right)+\tan^{-1}\left(\frac{x}{1+(k+1)(k+2)\,x^2}\right)$

$=\tan^{-1}(k+2)\,x-\tan^{-1}x$

$\therefore$ LHS $=\tan^{-1}\left(\frac{x}{1+1\cdot 2\cdot x^2}\right)+\tan^{-1}\left(\frac{x}{1+2\cdot 3\cdot x^2}\right)+\ldots+\tan^{-1}\left(\frac{x}{1+k(k+1)\,x^2}\right)+\tan^{-1}\left(\frac{x}{1+(k+1)(k+2)\,x^2}\right)$

$=\tan^{-1}(k+1)\,x-\tan^{-1}x+\tan^{-1}\left(\frac{x}{1+(k+1)(k+2)\,x^2}\right)$ [by assumption step]

$=\tan^{-1}(k+1)\,x-\tan^{-1}x+\tan^{-1}\left(\frac{(k+2)x-(k+1)x}{1+(k+2)\,x\,(k+1)\,x}\right)$

$=\tan^{-1}(k+1)\,x-\tan^{-1}x+\tan^{-1}(k+2)\,x-\tan^{-1}(k+1)\,x$

$=\tan^{-1}(k+2)x-\tan^{-1}x=$ RHS

This shows that the result is true for $n=k+1$. Hence, by the principle of mathematical induction, the result is true for all $n\in N$.

● ***Ex. 11*** *Use the principle of mathematical induction to prove that for all $n\in N$.*

$$\sqrt{2+\sqrt{2+\sqrt{2+\ldots+\ldots+\sqrt{2}}}}=2\cos\left(\frac{\pi}{2^{n+1}}\right)$$

when the LHS contains n radical sign.

Sol. Let $P(n)=\sqrt{2+\sqrt{2+\sqrt{2+\ldots+\ldots+\sqrt{2}}}}=2\cos\left(\frac{\pi}{2^{n+1}}\right)$ ...(i)

***Step* I** For $n=1$,

LHS of Eq. (i) $=\sqrt{2}$ and RHS Eq. (i) $=2\cos\left(\frac{\pi}{2^2}\right)$

$=2\cos\left(\frac{\pi}{4}\right)=2\cdot\frac{1}{\sqrt{2}}=\sqrt{2}$

Therefore, $P(1)$ is true.

***Step* II** Assume it is true for $n=k$,

$P(k)=\underbrace{\sqrt{2+\sqrt{2+\sqrt{2+\ldots+\ldots+\sqrt{2}}}}}_{k \text{ radical sign}}=2\cos\left(\frac{\pi}{2^{k+1}}\right)$

***Step* III** For $n=k+1$,

$\therefore\ P(k+1)=\underbrace{\sqrt{2+\sqrt{2+\sqrt{2+\ldots+\ldots+\sqrt{2}}}}}_{(k+1) \text{ radical sign}}$

$=\sqrt{\{2+P(k)\}}$

$=\sqrt{2+2\cos\left(\frac{\pi}{2^{k+1}}\right)}$ [by assumption step]

$=\sqrt{2\left(1+\cos\left(\frac{\pi}{2^{k+1}}\right)\right)}$

$=\sqrt{2\left(1+2\cos^2\left(\frac{\pi}{2^{k+2}}\right)-1\right)}$

$=\sqrt{4\cos^2\left(\frac{\pi}{2^{k+2}}\right)}=2\cos\left(\frac{\pi}{2^{k+2}}\right)$

This shows that the result is true for $n=k+1$. Hence, by the principle of mathematical induction, the result is true for all $n\in N$.

● ***Ex. 12*** *Prove by mathematical induction that*

$$\frac{1}{1+x}+\frac{2}{1+x^2}+\frac{4}{1+x^4}+\ldots+\frac{2^n}{1+x^{2^n}}=\frac{1}{x-1}+\frac{2^{n+1}}{1-x^{2^{n+1}}}$$

where, $|x|\neq 1$ *and n is non-negative integer.*

Sol. Let $P(n): \frac{1}{1+x}+\frac{2}{1+x^2}+\frac{4}{1+x^4}+\ldots+\frac{2^n}{1+x^{2^n}}=\frac{1}{x-1}+\frac{2^{n+1}}{1-x^{2^{n+1}}}$ ...(i)

***Step* I** For $n = 1$,

$$\text{LHS of Eq. (i)} = \frac{1}{1+x} + \frac{2}{1+x^2}$$

$$= \frac{1}{x-1} - \frac{1}{x-1} + \frac{1}{1+x} + \frac{2}{1+x^2}$$

$$= \frac{1}{x-1} + \left(\frac{1}{1-x} + \frac{1}{1+x}\right) + \frac{2}{1+x^2}$$

$$= \frac{1}{x-1} + \frac{2}{1-x^2} + \frac{2}{1+x^2}$$

$$= \frac{1}{x-1} + 2\left(\frac{2}{(1-x^2)(1+x^2)}\right) = \frac{1}{x-1} + \frac{2^2}{1-x^2}$$

= RHS of Eq. (i)

***Step* II** Assume it is true for $n = k$, then

$$P(k): \frac{1}{1+x} + \frac{2}{1+x^2} + \frac{4}{1+x^4} + \ldots + \frac{2^k}{1+x^{2^k}}$$

$$= \frac{1}{x-1} + \frac{2^{k+1}}{1-x^{2^{k+1}}}$$

***Step* III** For $n = k + 1$,

$$P(k+1): \frac{1}{1+x} + \frac{2}{1+x^2} + \frac{4}{1+x^4} + \ldots + \frac{2^k}{1+x^{2^k}} + \frac{2^{k+1}}{1+x^{2^{k+1}}}$$

$$= \frac{1}{x-1} + \frac{2^{k+2}}{1-x^{2^{k+1}}}$$

$$\text{LHS} = \frac{1}{1+x} + \frac{2}{1+x^2} + \frac{4}{1+x^4} + \ldots + \frac{2k}{1+x^{2^k}} + \frac{2^{k+1}}{1+x^{2^{k+1}}}$$

$$= \frac{1}{x-1} + \frac{2^{k+1}}{1-x^{2^{k+1}}} + \frac{2^{k+1}}{1+x^{2^{k+1}}}$$

[by assumption step]

$$= \frac{1}{x-1} + 2^{k+1}\left(\frac{2}{(1-x^{2^{k+1}})(1+x^{2^{k+1}})}\right)$$

$$= \frac{1}{x-1} + \frac{2^{k+2}}{1-x^{2^{k+2}}} = \text{RHS}$$

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

● ***Ex. 13*** *Using the principle of mathematical induction to prove that* $\int_0^{\pi/2} \frac{\sin^2 nx}{\sin x}\, dx = 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{2n-1}$

Sol. Let $P(n): \int_0^{\pi/2} \frac{\sin^2 nx}{\sin x}\, dx = 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{2n-1}$ ...(i)

***Step* I** For $n = 1$,

$$\text{LHS of Eq. (i)} = \int_0^{\pi/2} \frac{\sin^2 x}{\sin x}\, dx = \int_0^{\pi/2} \sin x\, dx$$

$$= -[\cos x]_0^{\pi/2} = -(0-1) = 1$$

and RHS of Eq. (i) = 1

Therefore, $P(1)$ is true.

***Step* II** Assume it is true for $n = k$, then

$$P(k): \int_0^{\pi/2} \frac{\sin^2 kx}{\sin x}\, dx = 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{2k-1}$$

***Step* III** For $n = k + 1$,

$$P(k+1): \int_0^{\pi/2} \frac{\sin^2 (k+1)x}{\sin x}\, dx = 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{2k-1} + \frac{1}{2k+1}$$

$$\text{LHS} = \int_0^{\pi/2} \frac{\sin^2 (k+1)x}{\sin x}\, dx$$

$$= \int_0^{\pi/2} \frac{\sin^2 (k+1)x - \sin^2 kx + \sin^2 kx}{\sin x}\, dx$$

$$= \int_0^{\pi/2} \frac{\sin^2 (k+1)x - \sin^2 kx}{\sin x}\, dx + \int_0^{\pi/2} \frac{\sin^2 kx}{\sin x}\, dx$$

$$= \int_0^{\pi/2} \frac{\sin (2k+1)x \sin x}{\sin x}\, dx + P(k)$$

[by assumption step]

$$= \int_0^{\pi/2} \sin (2k+1)x\, dx + P(k)$$

$$= -\left[\frac{\cos (2k+1)x}{2k+1}\right]_0^{\pi/2} + P(k)$$

$$= -\frac{1}{(2k+1)}\left[\cos\left(\pi k + \frac{\pi}{2}\right) - 1\right] + P(k)$$

$$= -\frac{1}{(2k+1)}[-\sin \pi k - 1] + P(k)$$

$$= -\frac{1}{2k+1}[-0-1] + P(k)$$

$$= \frac{1}{(2k+1)} + 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{(2k-1)}$$

[by assumption step]

$$= 1 + \frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{(2k-1)} + \frac{1}{(2k+1)}$$

= RHS

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

● **Ex. 14** *Use induction to show that for all $n \in N$.*

$$\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}} < \frac{1+\sqrt{(4a+1)}}{2}$$

where 'a' is fixed positive number and n radical signs are taken on LHS.

Sol. Let $P(n): \sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}} < 1+\sqrt{\frac{(4a+1)}{2}}$

***Step* I** For $n = 1$, then $\sqrt{a} < \frac{1+\sqrt{(4a+1)}}{2}$

$\Rightarrow \quad 2\sqrt{a} < 1+\sqrt{(4a+1)}$

$\Rightarrow \quad 4a < 1+4a+1+2\sqrt{(4a+1)}$

$\Rightarrow \quad 2\sqrt{(4a+1)}+2>0$ which is true.

Therefore, $P(1)$ is true.

***Step* II** Assume it is true for $n = k$,

$$P(k): \underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}_{k \text{ radical signs}} < \frac{1+\sqrt{(4a+1)}}{2}$$

***Step* III** For $n = k+1$,

$$P(k+1): \underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}_{(k+1) \text{ radical signs}} < \frac{1+\sqrt{(4a+1)}}{2}$$

From assumption step

$$\underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}_{k \text{ radical signs}} < \frac{1+\sqrt{4a+1}}{2}$$

$$a+\underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}_{k \text{ radical signs}} < a+\frac{1+\sqrt{(4a+1)}}{2}$$

$$\Rightarrow \underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}}_{(k+1) \text{ radical signs}} < \sqrt{a+\frac{1+\sqrt{(4a+1)}}{2}}$$

$$= \sqrt{\frac{2a+1+\sqrt{(4a+1)}}{2}} = \sqrt{\frac{4a+2+2\sqrt{(4a+1)}}{4}}$$

$$= \sqrt{\frac{(\sqrt{(4a+1)})^2+1+2\sqrt{(4a+1)}}{4}}$$

$$= \sqrt{\left(\frac{1+\sqrt{(4a+1)}}{2}\right)^2} = \frac{1+\sqrt{(4a+1)}}{2}$$

$$\therefore \underbrace{\sqrt{a+\sqrt{a+\sqrt{a+\sqrt{a+\ldots+\sqrt{a}}}}}}_{(k+1) \text{ radical signs}} < \frac{1+\sqrt{(4a+1)}}{2}$$

which is true for $n = k+1$.

Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

● **Ex. 15** *Prove by induction that*

$$\left\{\prod_{r=0}^{n} f_r(x)\right\}' = \sum_{i=1}^{n}\{f_1(x) f_2(x)\ldots f_i'(x)\ldots f_n(x)\},$$

where dash denotes derivative with respect to x.

Sol. Let $P(n): \left\{\prod_{r=0}^{n} f_r(x)\right\}' = \sum_{i=1}^{n}\{f_1(x)f_2(x)\ldots f_i'(x)\ldots f_n(x)\}$ ...(i)

***Step* I** For $n = 1$,

LHS of Eq. (i) $= \left\{\prod_{r=1}^{1} f_r(x)\right\}' = \{f_1(x)\}' = f_1'(x)$

RHS of Eq. (i) $= \sum_{i=1}^{1}\{f_1(x)f_2(x)\ldots f_i'(x)\ldots f_1(x)\}$

$= f_1'(x)$

which is true for $n = 1$.

***Step* II** Assume it is true for $n = k$, then

$$P(k): \left\{\prod_{r=1}^{k} f_r(x)\right\}' = \sum_{i=1}^{k}\{f_1(x) f_2(x)\ldots f_i'(x)\ldots f_k(x)\}$$

***Step* III** For $n = k+1$,

$$P(k+1): \left\{\prod_{r=1}^{k+1} f_r(x)\right\}' = \sum_{i=1}^{k+1}\{f_1(x) f_2(x)\ldots f_i'(x)\ldots f_k(x)\}$$

$$\text{LHS} = \left\{\prod_{r=1}^{(k+1)} f_r(x)\right\}' = \left\{\prod_{r=1}^{k} f_r(x)\cdot f_{k+1}(x)\right\}'$$

$$= \prod_{r=1}^{k} f_r(x)\cdot f'_{k+1}(x) + f_{k+1}(x)\left\{\prod_{r=1}^{k} f_r(x)\right\}'$$

$$= \prod_{r=1}^{k} f_r(x)\cdot f'_{k+1}(x) + f_{k+1}(x)\cdot\sum_{i=1}^{k}\{f_1(x)\cdot f_2(x)\ldots f_i'(x)\ldots f_k(x)\}$$

[by assumption step]

$$= \{f_1(x) f_2(x)\ldots f_k(x)\} f'_{k+1}(x) + f_{k+1}(x)\sum_{i=1}^{k}\{f_1(x) f_2(x)\ldots f_i'(x)\ldots f_k(x)\}$$

$$= \sum_{i=1}^{k+1}\{f_1(x) f_2(x)\ldots f_i'(x)\ldots f_{k+1}(x)\}$$

= RHS

This shows that the result is true for $n = k+1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

Mathematical Induction Exercise 1 :
Single Option Correct Type Questions

- This section contains 3 **multiple choice questions**. Each question has four choices (a), (b), (c) and (d), out of which **ONLY ONE** is correct.

1. If $a_n = \sqrt{7+\sqrt{7+\sqrt{7+\ldots}}}$ having n radical signs. Then, by mathematical induction which one is true?
(a) $a_n > 7, \forall\ n \geq 1$
(b) $a_n > 3, \forall\ n \geq 1$
(c) $a_n < 4, \forall\ n \geq 1$
(d) $a_n < 3, \forall\ n \geq 1$

2. If $P(n) = 2 + 4 + 6 + \ldots + 2n, n \in N$, then $P(k) = k(k+1) + 2$
$\Rightarrow P(k+1) = (k+1)(k+2) + 2, \forall\ k \in N$. So, we can conclude that $P(n) = n(n+1) + 2$ for
(a) all $n \in N$ (b) $n > 1$
(c) $n > 2$ (d) Nothing can be said

3. The value of the natural number n such that the inequality $2^n > 2n + 1$ is valid, is
(a) for $n \geq 3$ (b) for $n < 3$ (c) for all n (d) for mn

Mathematical Induction Exercise 2 :
Statement I and II Type Questions

- **Directions** Question Number 4 to 6 Assertion-Reason type questions. Each of these questions contains two statements.
Statement-1 (Assertion) and
Statement-2 (Reason)
Each of these questions also four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below:
  (a) Statement-1 is true, Statement-2 is true; Statement-2 is correct explanation for Statement-1
  (b) Statement-1 is true, Statement-2 is true; Statement-2 is not correct explanation for Statement-1
  (c) Statement-1 is true, Statement-2 is false
  (d) Statement-1 is false, Statement-2 is true

4. **Statement-1** If $a_1 = 1, a_2 = 5$, then $a_n = 3^n - 2^n, \forall\ n \in N$ and $n \geq 1$.
Statement-2 $a_{n+2} = 5a_{n+1} - 6a_n, n \geq 1$.

5. **Statement-1** For all natural numbers n, $2 \cdot 7^n + 3 \cdot 5^n - 5$ is divisible by 24.
Statement-2 If $f(x)$ is divisible by x, then $f(x+1) - f(x)$ is divisible by $x + 1, \forall\ x \in N$.

6. **Statement-1** For all natural numbers n,
$0 \cdot 5 + 0 \cdot 55 + 0 \cdot 555 + \ldots$ upto n terms $= \frac{5}{9}\left\{n - \frac{1}{9}\left(1 - \frac{1}{10^n}\right)\right\}$
Statement-2 $a + ar + ar^2 + \ldots + ar^{n-1} = \frac{a(1-r^n)}{(1-r)}$, for $0 < r < 1$.

Mathematical Induction Exercise 3 :
Subjective Type Questions

- In this section, there are **10 subjective** questions.

7. Prove the following by using induction for all $n \in N$.
(i) $11^{n+2} + 12^{2n+1}$ is divisible by 133.
(ii) $n^7 - n$ is divisible by 42.
(iii) $3^{2n} + 24n - 1$ is divisible by 32.
(iv) $n(n+1)(n+5)$ is divisible by 6.
(v) $(25)^{n+1} - 24n + 5735$ is divisible by $(24)^2$.
(vi) $x^{2n} - y^{2n}$ is divisible by $x + y$.

8. Prove by induction that if n is a positive integer not divisible by 3, then $3^{2n} + 3^n + 1$ is divisible by 13.

9. Prove by induction that the product of three consecutive positive integers is divisible by 6.

10. Prove by induction that the sum of three successive natural numbers is divisible by 9.

11. Prove by induction that the even power of every odd integer when divided by 8 leaves the remainder 1.

12. Prove the following by using induction for all $n \in N$:

(i) $1+2+3+\ldots+n=\dfrac{n(n+1)}{2}$

(ii) $1^2+2^2+3^2+\ldots+n^2=\dfrac{n(n+1)(2n+1)}{6}$

(iii) $1\cdot3+3\cdot5+5\cdot7+\ldots+(2n-1)(2n+1)=\dfrac{n(4n^2+6n-1)}{3}$

(iv) $\dfrac{1}{2\cdot5}+\dfrac{1}{5\cdot8}+\dfrac{1}{8\cdot11}+\ldots+\dfrac{1}{(3n-1)(3n+2)}=\dfrac{n}{6n+4}$

(v) $1\cdot4\cdot7+2\cdot5\cdot8+3\cdot6\cdot9+\ldots$ upto n terms $=\dfrac{n}{4}(n+1)(n+6)(n+7)$

(vi) $\dfrac{1^2}{1\cdot3}+\dfrac{2^2}{3\cdot5}+\ldots+\dfrac{n^2}{(2n-1)(2n+1)}=\dfrac{n(n+1)}{2(2n+1)}$

13. Let $a_0=2, a_1=5$ and for $n\geq2, a_n=5a_{n-1}-6a_{n-2}$, then prove by induction that $a_n=2^n+3^n, \forall\ n\geq0, n\in N$.

14. If $a_1=1, a_{n+1}=\dfrac{1}{n+1}a_n, n\geq1$, then prove by induction that $a_{n+1}=\dfrac{1}{(n+1)!}, n\in N$.

15. If a, b, c, d, e and f are six real numbers such that

$$a+b+c=d+e+f$$
$$a^2+b^2+c^2=d^2+e^2+f^2$$

and $a^3+b^3+c^3=d^3+e^3+f^3$, prove by mathematical induction that

$a^n+b^n+c^n=d^n+e^n+f^n, \forall\ n\in N$.

16. Using mathematical induction, prove that

$$\tan^{-1}\left(\frac{1}{3}\right)+\tan^{-1}\left(\frac{1}{7}\right)+\ldots+\tan^{-1}\left(\frac{1}{n^2+n+1}\right)=\tan^{-1}\left(\frac{n}{n+2}\right).$$

Mathematical Induction Exercise 4 : Questions Asked in Previous 13 Year's Exam

- This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to year **2017**.

17. **Statement-1** For every natural number $n\geq2\ \dfrac{1}{\sqrt{1}}+\dfrac{1}{\sqrt{2}}+\ldots+\dfrac{1}{n}>\sqrt{n}$,

Statement-2 For every natural number $n\geq2\ \sqrt{n(n+1)}<n+1$

(a) Statement-1 is true, Statement-2 is true; Statement-2 is correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is false
(d) Statement-1 is false, Statement-2 is true **[AIEEE 2008, 3M]**

18. **Statement-1** For each natural number $n, (n+1)^7-n^7-1$ is divisible by 7.

Statement-2 For each natural number n, n^7-n is divisible by 7.

(a) Statement-1 is false, Statement-2 is true
(b) Statement-1 is true, Statement-2 is true; Statement-2 is correct explanation for Statement-1
(c) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(d) Statement-1 is true, Statement-2 is false **[AIEEE 2011, 4M]**

Answers

Chapter Exercise

1. (c) **2.** (d) **3.** (a) **4.** (a) **5.** (c) **6.** (b) **17.** (b) **18.** (b)

Solutions

1. Let $P(n): a_n = \sqrt{7+\sqrt{7+\sqrt{7+\ldots}}}$ (n radical sign)

***Step* I** For $n = 1$,

$P(1): a_1 = \sqrt{7} < 4$

***Step* II** Assume that $a_k < 4$ for all natural number, $n = k$

***Step* III** For $n = k+1$,

$P(k+1): a_{k+1} = \sqrt{7+\sqrt{7+\sqrt{7+\ldots}}}$

[$(k+1)$ radical sign]

$= \sqrt{7+a_k} < \sqrt{7+4}$ [$\because a_k < 4$]

< 4 [by assumption]

This shows that, $a_{k+1} < 4$, i.e. the result is true for $n = k+1$.
Hence, by the principle of mathematical induction

$a_n < 4, \forall n \geq 1$

2. It is obvious.

3. Check through options, the condition $2^n > 2n+1$ is valid for $n \geq 3$.

4. Let $P(n): a_n = 3^n - 2^n$

***Step* I** For $n = 1$,

LHS $= a_1 = 1$ [given]

and RHS $= 3^1 - 2^1 = 1$

$\therefore$ LHS = RHS

Hence, $P(1)$ is true.

For $n = 2$,

LHS $= a_2 = 5$ [given]

and RHS $= 3^2 - 2^2 = 5$

$\therefore$ LHS = RHS

Hence, $P(2)$ is also true.

Thus, $P(1)$ and $P(2)$ are true.

***Step* II** Let $P(k)$ and $P(k-1)$ are true

$\therefore$ $a_k = 3^k - 2^k$ and $a_{k-1} = 3^{k-1} - 2^{k-1}$

***Step* III** For $n = k+1$,

$a_{k+1} = 5a_k - 6a_{k-1}$ [from Statement-2]

$= 5(3^k - 2^k) - 6(3^{k-1} - 2^{k-1})$

$= 5\cdot 3^k - 5\cdot 2^k - 2\cdot 3^k + 3\cdot 2^k$

$= 3\cdot 3^k - 2\cdot 2^k = 3^{k+1} - 2^{k+1}$

which is true for $n = k+1$.

Hence, both statements are true and Statement-2 is a correct explanation of Statement-1.

5. Let $P(n): 2\cdot 7^n + 3\cdot 5^n - 5$

***Step* I** For $n = 1$,

$P(1): 2\cdot 7^1 + 3\cdot 5^1 - 5$

: 24 is divisible by 24.

***Step* II** Assume $P(k)$ is divisible by 24, then

$P(k): 2\cdot 7^k + 3\cdot 5^k - 5 = 24\lambda$, λ is positive integer.

***Step* III** For $n = k+1$,

$P(k+1) - P(k) = (2\cdot 7^{k+1} + 3\cdot 5^{k+1} - 5) - (2\cdot 7^k + 3\cdot 5^k - 5)$

$= 2\cdot 7^k(7-1) + 3\cdot 5^k(5-1)$

$= 12(7^k + 5^k)$

$=$ divisible by 24

$= 24\mu, \forall \mu \in I$

[$\because 7^k + 5^k$ is always divisible by 24]

$\therefore$ $P(k+1) = P(k) + 24\mu = 24\lambda + 24\mu$

$= 24(\lambda + \mu)$

Hence, $P(k+1)$ is divisible by 24.

Hence, Statement-1 is true and Statement-2 is false.

6. ***Step* I** For $n = 1$,

LHS $= 0.5$ and RHS $= \frac{5}{9}\left\{1 - \frac{1}{9}\left(1 - \frac{1}{10}\right)\right\} = \frac{5}{9}\left(1 - \frac{1}{10}\right) = \frac{5}{10} = 0.5$

$\therefore$ LHS = RHS

which is true for $n = 1$.

***Step* II** Assume it is true for $n = k$, then $0.5 + 0.55 + 0.555 + \ldots$ + upto k terms

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\}$

***Step* III** For $n = k+1$,

LHS $= 0.5 + 0.55 + 0.555 + \ldots +$ upto $(k+1)$ terms

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\} + (k+1)$ th terms

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\} + \underbrace{0.555\ldots5}_{(k+1) \text{ times}}$

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\} + \frac{1}{10^{k+1}}\left(\underbrace{555\ldots5}_{(k+1) \text{ times}}\right)$

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\} + \frac{5}{10^{k+1}}$

$(1 + 10 + 10^2 + \ldots + 10^k)$

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right)\right\} + \frac{5\cdot(10^{k+1} - 1)}{10^{k+1}\cdot(10-1)}$

$= \frac{5}{9}\left\{k - \frac{1}{9}\left(1 - \frac{1}{10^k}\right) + \frac{10^{k+1} - 1}{10^{k+1}}\right\}$

$= \frac{5}{9}\left\{(k+1) - \frac{1}{9} + \frac{1}{9\cdot 10^k} - \frac{1}{10^{k+1}}\right\}$

$= \frac{5}{9}\left\{(k+1) - \frac{1}{9} + \frac{(10-9)}{9\cdot 10^{k+1}}\right\}$

$= \frac{5}{9}\left\{(k+1) - \frac{1}{9}\left(1 - \frac{1}{10^{k+1}}\right)\right\} =$ RHS

which is true for $n = k+1$.

Hence, both statements are true but Statement-2 is not a correct explanation for Statement-1.

7. (i) Let $P(n) = 11^{n+2} + 12^{2n+1}$

***Step* I** For $n = 1$,

$$P(1) = 11^{1+2} + 12^{2\times 1+1} = 11^3 + 12^3$$
$$= (11 + 12)(11^2 - 11 \times 12 + 12^2)$$
$$= 23 \times 133, \text{ which is divisible by 133.}$$

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$, then

$P(k) = 11^{k+2} + 12^{2k+1}$ is divisible by 133.

$\Rightarrow$ $P(k) = 133r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$\therefore\ P(k+1) = 11^{(k+1)+2} + 12^{2(k+1)+1} = 11^{k+3} + 12^{2k+3}$$
$$= 11^{(k+1)+1} \cdot 11 + 12^{2k+1} \cdot 12^2$$
$$= 11 \cdot 11^{k+2} + 144 \cdot 12^{2k+1}$$

Now, $11^{k+2} + 12^{2k+1}\overline{)11 \cdot 11^{k+2} + 144 \cdot 12^{2k+1}}(11$

$$11 \cdot 11^{k+2} + 11 \cdot 12^{2k+1}$$
$$- \quad -$$
$$133 \cdot 12^{2k+1}$$

$$\therefore\ 11 \cdot 11^{(k+2)} + 144 \cdot 12^{2k+1}$$
$$= 11(11^{k+2} + 12^{2k+1}) + 133 \cdot 12^{2k+1}$$

i.e. $P(k+1) = 11P(k) + 133 \cdot 12^{2k+1}$

But we know that, $P(k)$ is divisible by 133. Also, $133 \cdot 12^{2k+1}$ is divisible by 133.

Hence, $P(k + 1)$ is divisible by 133. This shows that, the result is true for $n = k + 1$.

Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

(ii) Let $P(n) = n^7 - n$

***Step* I** For $n = 1$,

$P(1) = 1^7 - 1 = 0$, which is divisible by 42.

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$. Then,

$P(k) = k^7 - k$ is divisible by 42.

$\Rightarrow$ $P(k) = 42r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$P(k+1) = (k+1)^7 - (k+1)$$
$$= (1+k)^7 - (k+1)$$
$$= 1 + {}^7C_1 k + {}^7C_2 k^2 + {}^7C_3 k^3 + {}^7C_4 k^4 + {}^7C_5 k^5 + {}^7C_6 k^6 + {}^7C_7 k^7 - (k+1)$$
$$= (k^7 - k) + ({}^7C_1 k + {}^7C_2 k^2 + {}^7C_3 k^3 + {}^7C_4 k^4 + {}^7C_5 k^5 + {}^7C_6 k^6)$$

But by assumption $k^7 - k$ is divisible by 42.

Also, ${}^7C_1 k + {}^7C_2 k^2 + {}^7C_3 k^3 + {}^7C_4 k^4 + {}^7C_5 k^5 + {}^7C_6 k^6$

is divisible by 42. [$\because$ ${}^7C_r$, $1 \le r \le 6$ is divisible by 7]

Hence, $P(k + 1)$ is divisible by 42. This shows that, the result is true for $n = k + 1$.

$\therefore$ By the principle of mathematical induction, the result is true for all $n \in N$.

(iii) Let $P(n) = 3^{2n} + 24n - 1$

***Step* I** For $n = 1$,

$$P(1) = 3^{2\times 1} + 24 \times 1 - 1 = 3^2 + 24 - 1 = 9 + 24 - 1$$
$$= 32, \text{ which is divisible by 32.}$$

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$. Then,

$P(k) = 3^{2k} + 24k - 1$ is divisible by 32.

$\Rightarrow$ $P(k) = 32r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$P(k+1) = 3^{2(k+1)} + 24(k+1) - 1$$
$$= 3^{2k+2} + 24k + 24 - 1$$
$$= 3^2 \cdot 3^{2k} + 24k + 23$$
$$= 9 \cdot 3^{2k} + 24k + 23$$

Now, $3^{2k} + 24k - 1\overline{)9 \times 3^{2k} + 24k + 23}(9$

$$9 \cdot 3^{2k} + 216k - 9$$
$$- \quad - \quad +$$
$$-192k + 32$$

$$\therefore\ P(k+1) = 9(3^{2k} + 24k - 1) - 32(6k - 1)$$
$$= 9P(k) - 32(6k - 1)$$

$\therefore$ $P(k+1) = 9(32r) - 32(6k - 1)$ [by assumption step]

$$= 32(9r - 6k + 1),$$

which is divisible by 32, as $9r - 6k + 1$ is an integer.

Therefore, $P(k + 1)$ is divisible by 32. Hence, by the principle of mathematical induction $P(n)$ is divisible by 32, $\forall\ n \in N$.

(iv) Let $P(n) = n(n + 1)(n + 5)$

***Step* I** For $n = 1$,

$$P(1) = 1 \cdot (1+1)(1+5) = 1 \cdot 2 \cdot 6$$
$$= 12, \text{ which is divisible by 6.}$$

Therefore, the result is true for $n = 1$.

Step II Assume that the result is true for $n = k$. Then,

$\Rightarrow$ $P(k) = k(k + 1)(k + 5)$ is divisible by 6.
$P(k) = 6r$, r is an integer.

Step III For $n = k + 1$,

$$P(k+1) = (k+1)(k+1+1)(k+1+5)$$
$$= (k+1)(k+2)(k+6)$$

Now, $P(k+1) - P(k) = (k+1)(k+2)(k+6) - k(k+1)(k+5)$

$$= (k+1)\{k^2 + 8k + 12 - k^2 - 5k\}$$
$$= (k+1)(3k+12)$$
$$= 3(k+1)(k+4)$$

$\Rightarrow$ $P(k+1) = P(k) + 3(k+1)(k+4)$

which is divisible by 6 as $P(k)$ is divisible by 6 [by assumption step]

and clearly $3(k + 1)(k + 4)$ is divisible by 6, $\forall\ k \in N$.

Hence, the result is true for $n = k + 1$.

Therefore, by the principle of mathematical induction, the result is true for all $n \in N$.

(v) Let $P(n) = (25)^{n+1} - 24n + 5735$

***Step* I** For $n = 1$,

$$P(1) = (25)^2 - 24 + 5735 = 625 - 24 + 5735 = 6336$$
$$= 11 \times (24)^2, \text{ which is divisible by } (24)^2.$$

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$. Then,

$P(k) = (25)^{k+1} - 24k + 5735$ is divisible by $(24)^2$.

$\Rightarrow$ $P(k) = (24)^2 r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$P(k+1) = (25)^{(k+1)+1} - 24(k+1) + 5735$$
$$= (25)^{k+2} - 24k + 5711$$
$$= (25)(25)^{k+1} - 24k + 5711$$

Now, $P(k+1) - P(k)$

$= \{(25)(25)^{k+1} - 24k + 5711\} - \{(25)^{k+1} - 24k + 5735\}$

$= (24)(25)^{k+1} - 24$

$= 24\{(25)^{k+1} - 1\}$

$\Rightarrow$ $P(k+1) = P(k) + 24\{(25)^{k+1} - 1\}$

But by assumption $P(k)$ is divisible by $(24)^2$. Also, $24\{(25)^{k+1} - 1\}$ is clearly divisible by $(24)^2$, $\forall\ k \in N$. This shows that, the result is true for $n = k + 1$.

Hence, by the principle of mathematical induction, result is true for all $n \in N$.

(vi) Let $P(n) = x^{2n} - y^{2n}$

***Step* I** For $n = 1$,

$$P(1) = x^2 - y^2$$
$= (x - y)(x + y)$ which is divisible by $(x + y)$.

Therefore, the result is true for $n = 1$.

***Step* II** Assume that the result is true for $n = k$. Then,

$P(k) = x^{2k} - y^{2k}$ is divisible by $x + y$.

$\Rightarrow$ $P(k) = (x + y)r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$= x^2 \cdot x^{2k} - y^2 \cdot y^{2k}$$
$$= x^2 x^{2k} - x^2 y^{2k} + x^2 y^{2k} - y^2 y^{2k}$$
$$= x^2(x^{2k} - y^{2k}) + y^{2k}(x^2 - y^2)$$
$$= x^2(x + y)r + y^{2k}(x - y)(x + y)$$

[by assumption step]

$$= (x + y)\{x^2 r + y^{2k}(x - y)\}$$

which is divisible by $(x + y)$ as $x^2 r + y^{2k}(x - y)$ is an integer.

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

8. Let $P(n) = 3^{2n} + 3^n + 1$, $\forall\ n$ is a positive integer not divisible by 3.

***Step* I** For $n = 1$,

$$P(1) = 3^2 + 3 + 1 = 9 + 3 + 1$$
$$= 13, \text{ which is divisible by } 13.$$

Therefore, $P(1)$ is true.

***Step* II** Assume $P(n)$ is true for $n = k$, k is a positive integer not divisible by 3, then

$P(k) = 3^{2k} + 3^k + 1$, is divisible by 13.

$\Rightarrow$ $P(k) = 13r$, where r is an integer.

***Step* III** For $n = k + 1$,

$$P(k+1) = 3^{2(k+1)} + 3^{k+1} + 1$$
$$= 3^2 \cdot 3^{2k} + 3 \cdot 3^k + 1$$

Now, $3^{2k} + 3^k + 1 \overline{)\ 3^2 \cdot 3^{2k} + 3 \cdot 3^k + 1\ (3^2}$

$3^2 \cdot 3^{2k} + 3^2 \cdot 3^k + 3^2$

$- \quad - \quad -$

$-6 \cdot 3^k - 8$

$\Rightarrow$ $P(k+1) = 3^2(3^{2k} + 3^k + 1) - 6 \cdot 3^k - 8$

$$= 9P(k) - 2(3^{k+1} + 4)$$
$$= 9(13r) - 2(3^{k+1} + 4) \qquad \text{[by assumption step]}$$

which is divisible by 13 as $3^{k+1} + 4$ is also divisible by 13, $\forall\ k \in N$ and not divisible by 3. This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all natural numbers not divisible by 3.

9. Let $P(n) = n(n+1)(n+2)$, where n is a positive integer.

***Step* I** For $n = 1$,

$$P(1) = 1(1+1)(1+2) = 1 \cdot 2 \cdot 3$$
$$= 6, \text{ which is divisible by } 6.$$

Therefore, the result is true for $n = 1$.

***Step* II** Let us assume that the result is true for $n = k$, where k is a positive integer.

Then, $P(k) = k(k+1)(k+2)$ is divisible by 6.

$\Rightarrow$ $P(k) = 6r$, where r is an integer.

$a^2\ a^k + b^2 b^k \overline{)\ a^2\ }$ [infact positive integer]

***Step* III** For $n = k + 1$, where k is a positive integer.

$$P(k+1) = (k+1)(k+1+1)(k+2+1)$$
$$= (k+1)(k+2)(k+3)$$

Now, $P(k+1) - P(k) = (k+1)(k+2)(k+3) - k(k+1)(k+2)$

$$= (k+1)(k+2)(k+3-k)$$
$$= 3(k+1)(k+2)$$

$\Rightarrow$ $P(k+1) = P(k) + 3(k+1)(k+2)$

But we know that, $P(k)$ is divisible by 6. Also, $3(k+1)(k+2)$ is divisible by 6 for all positive integer. This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all positive integer.

10. Let $P(n) = n^3 + (n+1)^3 + (n+2)^3$, where $n \in N$.

***Step* I** For $n = 1$,

$$P(1) = 1^3 + 2^3 + 3^3 = 1 + 8 + 27$$
$$= 36, \text{ which is divisible by } 9.$$

***Step* II** Assume that $P(n)$ is true for $n = k$, then

$P(k) = k^3 + (k+1)^3 + (k+2)^3$, where $k \in N$.

$\Rightarrow$ $P(k) = 9r$, where r is a positive integer.

***Step* III** For $n = k + 1$,

$$P(k+1) = (k+1)^3 + (k+2)^3 + (k+3)^3$$

Now, $P(k+1) - P(k) = (k+1)^3 + (k+2)^3 + (k+3)^3 - \{k^3 + (k+1)^3 + (k+2)^3\}$

$$= (k+3)^3 - k^3$$

$$= k^3 + 9k^2 + 27k + 27 - k^3$$

$$= 9(k^2 + 3k + 3)$$

$$\Rightarrow \quad P(k+1) = P(k) + 9(k^2 + 3k + 3)$$

$$= 9r + 9(k^2 + 3k + 3)$$

$$= 9(r + k^2 + 3k + 3)$$

which is divisible by 9 as $(r + k^2 + 3k + 3)$ is a positive integer.

Hence, by the principle mathematical induction, $P(n)$ is divisible by 9 for all $n \in N$.

11. Let $P(n) : (2r+1)^{2n}$, $\forall\ n \in N$ and $r \in I$.

***Step* I** For $n = 1$,

$$P(1) : (2r+1)^2 = 4r^2 + 4r + 1$$

$$= 4r(r+1) + 1 = 8p + 1,\ p \in I$$

[$\because r(r+1)$ is an even integer]

Therefore, $P(1)$ is true.

***Step* II** Assume $P(n)$ is true for $n = k$, then

$P(k) : (2r+1)^{2k}$ is divisible by 8 leaves remainder 1.

$\Rightarrow \quad P(k) = 8m + 1$, $n \in I$, where m is a positive integer.

***Step* III** For $n = k + 1$,

$\therefore \quad P(k+1) = (2r+1)\,2(k+1)$

$$= (2r+1)^{2k}(2r+1)^2$$

$$= (8m+1)(8p+1) \qquad \text{[from Steps I and II]}$$

$$= 64\ mp + 8\ (m + p) + 1$$

$$= 8\ (8mp + m + p) + 1$$

which is true for $n = k + 1$ as $8mp + m + p$ is an integer. Hence, by the principle of mathematical induction, when $P(n)$ is divided by 8 leaves the remainder 1 for all $n \in N$.

12. (i) Let $P(n) : 1 + 2 + 3 + \ldots + n = \dfrac{n(n+1)}{2}$ ...(i)

***Step* I** For $n = 1$,

LHS of Eq. (i) $= 1$

RHS of Eq. (i) $= \dfrac{1(1+1)}{2} = 1$

LHS = RHS

Therefore, $P(1)$ is true.

***Step* II** Let us assume that the result is true for $n = k$. Then,

$$P(k) : 1 + 2 + 3 + \ldots + k = \frac{k(k+1)}{2}$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1) = 1 + 2 + 3 + \ldots + k + (k+1) = \frac{(k+1)(k+2)}{2}$$

$$\text{LHS} = 1 + 2 + 3 + \ldots + k + (k+1)$$

$$= \frac{k(k+1)}{2} + k + 1 \qquad \text{[by assumption step]}$$

$$= (k+1)\left(\frac{k}{2} + 1\right) = (k+1)\left(\frac{k+2}{2}\right)$$

$$= \frac{(k+1)(k+2)}{2}$$

$$= \text{RHS}$$

This shows that the result is true for $n = k + 1$. Therefore, by the principle of mathematical induction, the result is true for all $n \in N$.

(ii) Let $P(n) : 1^2 + 2^2 + 3^2 + \ldots + n^2 = \dfrac{(n+1)(2n+1)}{6}$ ...(i)

***Step* I** For $n = 1$,

LHS of Eq. (i) $= 1^2 = 1$

RHS of Eq. (i) $= \dfrac{1(1+1)(2\times 1+1)}{6}$

$$= \frac{1\cdot 2\cdot 3}{6} = 1$$

LHS = RHS

Therefore, $P(1)$ is true.

***Step* II** Let us assume that the result is true for $n = k$. Then,

$$P(k) : 1^2 + 2^2 + 3^2 + \ldots + k^2 = \frac{k(k+1)(2k+1)}{6}$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1) : 1^2 + 2^2 + 3^2 + \ldots + k^2 + (k+1)^2 = \frac{(k+1)(k+2)(2k+3)}{6}$$

$$\text{LHS} = 1^2 + 2^2 + 3^2 + \ldots + k^2 + (k+1)^2$$

$$= \frac{k(k+1)(2k+1)}{6} + (k+1)^2 \qquad \text{[by assumption step]}$$

$$= (k+1)\left\{\frac{k(2k+1)}{6} + (k+1)\right\}$$

$$= (k+1)\left\{\frac{2k^2 + 7k + 6}{6}\right\}$$

$$= (k+1)\left\{\frac{(k+2)(2k+3)}{6}\right\} = \frac{(k+1)(k+2)(2k+3)}{6}$$

$$= \text{RHS}$$

This shows that the result is true for $n = k + 1$. Therefore, by the principle of mathematical induction, the result is true for all $n \in N$.

(iii) Let $P(n) : 1\cdot 3 + 3\cdot 5 + 5\cdot 7 + \ldots + (2n-1)(2n+1)$

$$= \frac{n(4n^2 + 6n - 1)}{3} \qquad \text{...(i)}$$

***Step* I** For $n = 1$,

LHS of Eq. (i) $= 1\cdot 3 = 3$

RHS of Eq. (i) $= \dfrac{1(4\times 1^2 + 6\times 1 - 1)}{3} = \dfrac{4+6-1}{3} = 3$

$\therefore \quad$ LHS = RHS

Therefore, $P(1)$ is true.

***Step* II** Assume that the result is true for $n = k$. Then,

$$P(k) : 1\cdot 3 + 3\cdot 5 + 5\cdot 7 + \ldots + (2k-1)(2k+1) = \frac{k(4k^2 + 6k - 1)}{3}$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1): 1\cdot 3 + 3\cdot 5 + 5\cdot 7 + \ldots + (2k-1)(2k+1) + (2k+1)(2k+3)$$
$$= \frac{(k+1)\left[4(k+1)^2 + 6(k+1) - 1\right]}{3}$$
$$= \frac{(k+1)(4k^2 + 14k + 9)}{3}$$

$$\text{LHS} = 1\cdot 3 + 3\cdot 5 + 5\cdot 7 + \ldots + (2k-1)(2k+1) + (2k+1)(2k+3)$$
$$= \frac{k(4k^2 + 6k - 1)}{3} + (2k+1)(2k+3) \quad \text{[by assumption step]}$$
$$= \frac{4k^3 + 6k^2 - k}{3} + (4k^2 + 8k + 3)$$
$$= \frac{4k^3 + 18k^2 + 23k + 9}{3}$$
$$= \frac{(k+1)(4k^2 + 14k + 9)}{3} = \text{RHS}$$

This shows that the result is true for $n = k + 1$. Therefore, by the principle of mathematical induction, the result is true for all $n \in N$.

(iv) Let $P(n): \dfrac{1}{2\cdot 5} + \dfrac{1}{5\cdot 8} + \dfrac{1}{8\cdot 11} + \ldots + \dfrac{1}{(3n-1)(3n+2)}$

$$= \frac{n}{6n+4} \quad \ldots(i)$$

***Step* I** For $n = 1$,

$$\text{LHS of Eq. (i)} = \frac{1}{2\cdot 5} = \frac{1}{10}$$
$$\text{RHS of Eq. (i)} = \frac{1}{6\times 1 + 4} = \frac{1}{10}$$
$$\text{LHS} = \text{RHS}$$

Therefore, $P(1)$ is true.

***Step* II** Let us assume that the result is true for $n = k$. Then,

$$P(k): \frac{1}{2\cdot 5} + \frac{1}{5\cdot 8} + \frac{1}{8\cdot 11} + \ldots + \frac{1}{(3k-1)(3k+2)} = \frac{k}{6k+4}$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1): \frac{1}{2\cdot 5} + \frac{1}{5\cdot 8} + \frac{1}{8\cdot 11} + \ldots + \frac{1}{(3k-1)(3k+2)} + \frac{1}{(3k+2)(3k+5)}$$
$$= \frac{(k+1)}{6(k+1)+4} = \frac{(k+1)}{6k+10}$$

$$\text{LHS} = \frac{1}{2\cdot 5} + \frac{1}{5\cdot 8} + \frac{1}{8\cdot 11} + \ldots + \frac{1}{(3k-1)(3k+2)} + \frac{1}{(3k+2)(3k+5)}$$
$$= \frac{k}{6k+4} + \frac{1}{(3k+2)(3k+5)} \quad \text{[by assumption step]}$$
$$= \frac{k(3k+5)+2}{2(3k+2)(3k+5)} = \frac{3k^2 + 5k + 2}{2(3k+2)(3k+5)}$$
$$= \frac{(k+1)(3k+2)}{2(3k+2)(3k+5)} = \frac{k+1}{6k+10}$$
$$= \text{RHS}$$

This shows that the result is true for $n = k + 1$. Therefore, by the principle of mathematical induction, the result is true for all $n \in N$.

(v) Let $P(n): 1\cdot 4\cdot 7 + 2\cdot 5\cdot 8 + 3\cdot 6\cdot 9 + \ldots$ + upto n terms

$$= \frac{n}{4}(n+1)(n+6)(n+7)$$

i.e., $P(n): 1\cdot 4\cdot 7 + 2\cdot 5\cdot 8 + 3\cdot 6\cdot 9 + \ldots + n(n+3)(n+6)$

$$= \frac{n}{4}(n+1)(n+6)(n+7) \quad \ldots(i)$$

***Step* I** For $n = 1$,

$$\text{LHS of Eq. (i)} = 1\cdot 4\cdot 7 = 28$$
$$\text{RHS of Eq. (i)} = \frac{1}{4}(1+1)(1+6)(1+7) = \frac{2\cdot 7\cdot 8}{4} = 28$$
$$\text{LHS} = \text{RHS}$$

Therefore, $P(1)$ is true.

***Step* II** Let us assume that the result is true for $n = k$. Then,

$$P(k): 1\cdot 4\cdot 7 + 2\cdot 5\cdot 8 + 3\cdot 6\cdot 9 + \ldots + k(k+3)(k+6) = \frac{k}{4}(k+1)(k+6)(k+7)$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1): 1\cdot 4\cdot 7 + 2\cdot 5\cdot 8 + 3\cdot 6\cdot 9 + \ldots + k(k+3)(k+6) + (k+1)(k+4)(k+7)$$
$$= \frac{(k+1)}{4}(k+2)(k+7)(k+8)$$

$$\text{LHS} = 1\cdot 4\cdot 7 + 2\cdot 5\cdot 8 + 3\cdot 6\cdot 9 + \ldots + k(k+3)(k+6) + (k+1)(k+4)(k+7)$$
$$= \frac{k}{4}(k+1)(k+6)(k+7) + (k+1)(k+4)(k+7) \quad \text{[by assumption step]}$$
$$= (k+1)(k+7)\left\{\frac{k}{4}(k+6) + (k+4)\right\}$$
$$= (k+1)(k+7)\left\{\frac{k^2 + 6k + 4k + 16}{4}\right\}$$
$$= (k+1)(k+7)\left\{\frac{k^2 + 10k + 16}{4}\right\}$$
$$= (k+1)(k+7)\left\{\frac{(k+2)(k+8)}{4}\right\}$$
$$= \frac{(k+1)}{4}(k+2)(k+7)(k+8) = \text{RHS}$$

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

(vi) Let $P(n): \dfrac{1^2}{1\cdot 3} + \dfrac{2^2}{3\cdot 5} + \ldots + \dfrac{n^2}{(2n-1)(2n+1)}$

$$= \frac{n(n+1)}{2(2n+1)} \quad \ldots(i)$$

***Step* I** For $n = 1$,

$$\text{LHS of Eq. (i)} = \frac{1^2}{1\cdot 3} = \frac{1}{3}$$

$$\text{RHS of Eq. (i)} = \frac{1(1+1)}{2(2\times 1+1)} = \frac{2}{2(3)} = \frac{1}{3}$$

$$\text{LHS} = \text{RHS}$$

Therefore, $P(1)$ is true.

***Step* II** Let us assume that the result is true for $n = k$, then

$$P(k) = \frac{1^2}{1\cdot 3} + \frac{2^2}{3\cdot 5} + \ldots + \frac{k^2}{(2k-1)(2k+1)} = \frac{k(k+1)}{2(2k+1)}$$

***Step* III** For $n = k + 1$, we have to prove that

$$P(k+1): \frac{1^2}{1\cdot 3} + \frac{2^2}{3\cdot 5} + \ldots + \frac{k^2}{(2k-1)(2k+1)} + \frac{(k+1)^2}{(2k+1)(2k+3)} = \frac{(k+1)(k+2)}{2(2k+3)}$$

$$\text{LHS} = \frac{1^2}{1\cdot 3} + \frac{2^2}{3\cdot 5} + \ldots + \frac{k^2}{(2k-1)(2k+1)} + \frac{(k+1)^2}{(2k+1)(2k+3)}$$

$$= \frac{k(k+1)}{2(2k+1)} + \frac{(k+1)^2}{(2k+1)(2k+3)} \quad \text{[by assumption step]}$$

$$= \frac{(k+1)}{(2k+1)}\left\{\frac{k}{2} + \frac{k+1}{(2k+3)}\right\} = \frac{(k+1)}{(2k+1)}\left\{\frac{2k^2+5k+2}{2(2k+3)}\right\}$$

$$= \frac{(k+1)}{(2k+1)}\cdot\frac{(k+2)(2k+1)}{2(2k+3)} = \frac{(k+1)(k+2)}{2(2k+3)}$$

$$= \text{RHS}$$

This shows that, the result is true for $n = k + 1$. Therefore, by the principle of mathematical induction the result is true for all $n \in N$.

13. Let $P(n): a_n = 2^n + 3^n, \forall\ n \geq 0, n \in N$

and $a_0 = 2, a_1 = 5$ and for $n \geq 2$; $a_n = 5a_{n-1} - 6a_n - 2$

***Step* I** For $n = 0$,

$$a_0 = 2^0 + 3^0 = 1 + 10 = 2$$

which is true as $a_0 = 2$. [given]

Also, for $n = 1$, $\quad a_1 = 2^1 + 3^1 = 2 + 3 = 5$

which is also true as $a_1 = 5$. [given]

Hence, $P(0)$ and $P(1)$ are true.

***Step* II** Assume that $P(k-1)$ and $P(k)$ are true. Then,

$$a_{k-1} = 2^{k-1} + 3^{k-1} \quad \ldots(i)$$

where $\quad a_{k-1} = 5a_{k-2} - 6a_{k-3}$ and $a_k = 2^k + 3^k \quad \ldots(ii)$

where $\quad a_k = 5a_{k-1} - 6a_{k-2}$

***Step* III** For $n = k + 1$,

$$P(k+1): a_{k+1} = 2^{k+1} + 3^{k+1},\ \forall\ k \geq 0, k \in N.$$

where $\quad a_{k+1} = 5a_k - 6a_{k-1}$

Now, $\quad a_{k+1} = 5a_k - 6a_{k-1}$

$$= 5(2^k + 3^k) - 6(2^{k-1} + 3^{k-1})$$

[by using Eqs. (i) and (ii)]

$$= 5\cdot 2^k + 5\cdot 3^k - 6\cdot 2^{k-1} - 6\cdot 3^{k-1}$$

$$= 2^{k-1}(5\cdot 2 - 6) + 3^{k-1}(5\cdot 3 - 6)$$

$$= 2^{k-1}\cdot 4 + 3^{k-1}\cdot 9 = 2^{k+1} + 3^{k+1}$$

$$\Rightarrow \quad a_{k+1} = 2^{k+1} + 3^{k+1}$$

where $\quad a_{k+1} = 5a_k - 6a_{k-1}$

This shows that the result is true for $n = k + 1$. Hence, by the second principle of mathematical induction, the result is true for $n \in N, n \geq 0$.

14. Let $P(n): a_{n+1} = \frac{1}{(n+1)!}, n \in N \quad \ldots(i)$

where $a_1 = 1$ and $a_{n+1} = \frac{1}{(n+1)}a_n, n \geq 1 \quad \ldots(ii)$

***Step* I** For $n = 1$, from Eq. (i), we get

$$a_2 = \frac{1}{(1+1)!} = \frac{1}{2!}$$

But from Eq. (ii), we get $a_2 = \frac{1}{(1+1)}, a_1 = \frac{1}{2}(1) = \frac{1}{2}$

which is true.

Also, for $n = 2$ from Eq. (i), we get

$$a_3 = \frac{1}{3!} = \frac{1}{6}$$

But from Eq. (ii), we get $\quad a_3 = \frac{1}{3}, a_2 = \frac{1}{3}\cdot\frac{1}{2} = \frac{1}{6}$

which is also true.

Hence, $P(1)$ and $P(2)$ are true.

***Step* II** Assume that $P(k-1)$ and $P(k)$ are true. Then,

$$P(k-1): a_k = \frac{1}{k!} \quad \ldots(ii)$$

where, $a_k = \frac{1}{k}a_{k-1}, \quad k \geq 1 \quad \ldots(iv)$

and $\quad P(k): a_{k+1} = \frac{1}{(k+1)!} \quad \ldots(v)$

where $\quad a_{k+1} = \frac{1}{k+1}a_k, k \geq 1 \quad \ldots(vi)$

***Step* III** For $n = k + 1$,

$$P(k+1): a_{k+2} = \frac{1}{(k+2)!} \quad \ldots(vii)$$

where $\quad a_{k+2} = \frac{1}{(k+2)}a_{k+1} \quad \ldots(viii)$

Now, LHS of Eq. (vii) $= a_{k+2}$

$$= \frac{1}{(k+2)}a_{k+1} \quad \text{[using Eq. (viii)]}$$

$$= \frac{1}{(k+2)}\cdot\frac{1}{(k+1)}a_k \quad \text{[using Eq. (vi)]}$$

$$= \frac{1}{k+2}\cdot\frac{1}{k+1}\cdot\frac{1}{k}a_{k-1} \quad \text{[using Eq. (iv)]}$$

$$= \frac{1}{k+2}\cdot\frac{1}{k+1}\cdot\frac{1}{k}\cdot\frac{1}{k!} \quad \text{[using Eq. (iii)]}$$

$$= \frac{1}{(k+2)!} = \text{RHS of Eq. (vii)}$$

This shows that the result is true for $n = k + 1$. Hence, by the second principle of mathematical induction, the result is true for all $n \geq 1, n \in N$.

15. Let $P(n): a^n + b^n + c^n = d^n + e^n + f^n, \forall\, n \in N$ ...(i)

where $a + b + c = d + e + f$ ...(ii)

$a^2 + b^2 + c^2 = d^2 + e^2 + f^2$ ...(iii)

and $a^3 + b^3 + c^3 = d^3 + e^3 + f^3$ ...(iv)

***Step* I** For $n = 1$ from Eq. (i), we get

$P(1): a + b + c = d + e + f$ [given]

Hence, the result is true for $n = 1$.

Also, for $n = 2$ from Eq. (i), we get

$P(2): a^2 + b^2 + c^2 = d^2 + e^2 + f^2$ [given]

Hence, the result is true for $n = 2$.

Also, for $x = 3$, from Eq. (i), we get

$P(3): a^3 + b^3 + c^3 = d^3 + e^3 + f^3$ [given]

Hence, the result is true for $n = 3$.

Therefore, $P(1)$, $P(2)$ and $P(3)$ are true.

***Step* II** Assume that $P(k-2)$, $P(k-1)$ and $P(k)$ are true, then

$P(k-2): a^{k-2} + b^{k-2} + c^{k-2} = d^{k-2} + e^{k-2} + f^{k-2}$ ...(v)

$P(k-1): a^{k-1} + b^{k-1} + c^{k-1} = d^{k-1} + e^{k-1} + f^{k-1}$ ...(vi)

and $P(k): a^k + b^k + c^k = d^k + e^k + f^k$ ...(vii)

***Step* III** For $xn = k + 1$, we shall to prove that

$P(k+1): a^{k+1} + b^{k+1} + c^{k+1} = d^{k+1} + e^{k+1} + f^{k+1}$

LHS $= a^{k+1} + b^{k+1} + c^{k+1}$

$= (a^k + b^k + c^k)(a + b + c) - (a^{k-1} + b^{k-1} + c^{k-1})$

$(ab + bc + ca) + abc\,(a^{k-2} + b^{k-2} + c^{k-2})$

$= (d^k + e^k + f^k)(d + e + f) - (d^{k-1} + e^{k-1} + f^{k-1})$

$(de + ef + fd) + def(d^{k-2} + e^{k-2} + f^{k-2})$

[using Eqs. (ii), (iii), (iv), (v), (vi), (vii)]

$\therefore \quad (a + b + c)^2 = (d + e + f)^2$

$\Rightarrow \quad a^2 + b^2 + c^2 + 2(ab + bc + ca)$

$= d^2 + e^2 + f^2 + 2(de + ef + fd)$

$\Rightarrow \quad ab + bc + ca = de + ef + fd$

$[\because a^2 + b^2 + c^2 = d^2 + e^2 + f^2]$

and $a^3 + b^3 + c^3 - 3abc$

$= (d + e + f)(d^2 + e^2 + f^2 - de - ef - fd)$

$= d^3 + e^3 + f^3 - 3def$

$\Rightarrow \quad abc = def \qquad [\because a^3 + b^3 + c^3 = d^3 + e^3 + f^3]$

$= d^{k+1} + e^{k+1} + f^{k+1} = \text{RHS}$

This shows that the result is true for $n = k + 1$. Hence, by second principle of mathematical induction, the result is true for all $n \in N$.

16. Let $P(n): \tan^{-1}\left(\frac{1}{3}\right) + \tan^{-1}\left(\frac{1}{7}\right) + \ldots + \tan^{-1}\left(\frac{1}{n^2 + n + 1}\right)$

$= \tan^{-1}\left(\frac{n}{n+2}\right)$ ...(i)

***Step* I** For $n = 1$,

LHS of Eq. (i) $= \tan^{-1}\left(\frac{1}{3}\right) = \tan^{-1}\left(\frac{1}{1+2}\right)$

$= \text{RHS of Eq. (i)}$

Therefore, $P(1)$ is true.

***Step* II** Assume that $P(k)$ is true. Then,

$P(k): \tan^{-1}\left(\frac{1}{3}\right) + \tan^{-1}\left(\frac{1}{7}\right) + \ldots + \tan^{-1}\left(\frac{1}{k^2 + k + 1}\right)$

$= \tan^{-1}\left(\frac{k}{k+2}\right)$

***Step* III** For $n = k + 1$,

$P(k+1): \tan^{-1}\left(\frac{1}{3}\right) + \tan^{-1}\left(\frac{1}{7}\right) + \ldots + \tan^{-1}\left(\frac{1}{k^2 + k + 1}\right)$

$+ \tan^{-1}\left(\frac{1}{(k+1)^2 + (k+1) + 1}\right)$

$= \tan^{-1}\left(\frac{k+1}{k+3}\right)$ ...(ii)

LHS of Eq. (ii)

$= \tan^{-1}\left(\frac{1}{3}\right) + \tan^{-1}\left(\frac{1}{7}\right) + \ldots + \tan^{-1}\left(\frac{1}{k^2 + k + 1}\right)$

$+ \tan^{-1}\left(\frac{1}{(k+1)^2 + (k+1) + 1}\right)$

$= \tan^{-1}\left(\frac{k}{k+2}\right) + \tan^{-1}\left(\frac{1}{(k+1)^2 + (k+1) + 1}\right)$

[by assumption step]

$= \tan^{-1}\left(\frac{k}{1 + (k+1)}\right) + \tan^{-1}\left(\frac{1}{k^2 + 3k + 3}\right)$

$= \tan^{-1}\left(\frac{k}{1 + (k+1)}\right) + \tan^{-1}\left(\frac{1}{1 + (k+1)(k+2)}\right)$

$= \tan^{-1}\left(\frac{(k+1) - 1}{1 + (k+1)\cdot 1}\right) + \tan^{-1}\left(\frac{(k+2) - (k+1)}{1 + (k+2)(k+1)}\right)$

$= \tan^{-1}(k+1) - \tan^{-1}1 + \tan^{-1}(k+2) - \tan^{-1}(k+1)$

$= \tan^{-1}(k+2) - \tan^{-1}1$

$= \tan^{-1}\left(\frac{k+2-1}{1 + (k+2)\cdot 1}\right) = \tan^{-1}\left(\frac{k+1}{k+3}\right) = \text{RHS of Eq. (ii)}$

This shows that the result is true for $n = k + 1$. Hence, by the principle of mathematical induction, the result is true for all $n \in N$.

17. Let $P(n) = \frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \ldots + \frac{1}{\sqrt{n}}$

$\therefore \quad P(2) = \frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} = 1.707 > \sqrt{2}$

Let us assume that

$$P(k) = \frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \ldots + \frac{1}{\sqrt{k}} > \sqrt{k} \text{ is true for } n = k + 1.$$

$$\text{LHS} = \frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \ldots + \frac{1}{\sqrt{k}} + \frac{1}{\sqrt{k+1}}$$

$$> \sqrt{k} + \frac{1}{\sqrt{k+1}} = \frac{\sqrt{k(k+1)+1}}{\sqrt{(k+1)}} > \frac{k+1}{\sqrt{(k+1)}}$$

$$[\because \sqrt{k(k+1)+1} > k, \forall\ k \geq 0]$$

$$\therefore \quad P(k+1) > \sqrt{(k+1)}$$

By mathematical induction Statement-1 is true, $\forall\ n \geq 2$.

Now, let $\alpha(n) = \sqrt{n(n+1)}$

$$\therefore \qquad \alpha(2) = \sqrt{2(2+1)} = \sqrt{6} < 3$$

Let us assume that

$$\alpha(k) = \sqrt{k(k+1)} < (k+1) \text{ is true}$$

for $n = k + 1$

$$\text{LHS} = \sqrt{(k+1)(k+2)} < (k+2)$$

$$[\because (k+1) < (k+2)]$$

By mathematical induction Statement-2 is true but Statement-2 is not a correct explanation for Statement-1.

18. Let $P(n) = n^7 - n$

By mathematical induction for $n = 1$, $P(1) = 0$, which is divisible by 7

for $n = k$, $P(k) = k^7 - k$

Assume $P(k)$ is divisible by 7

$$\therefore \qquad k^7 - k = 7\lambda,\ \lambda \in I \qquad \ldots(i)$$

For $n = k + 1$,

$$P(k+1) = (k+1)^7 - (k+1)$$

$$= ({}^7C_0 k^7 + {}^7C_1 k^6 + {}^7C_2 k^5 + {}^7C_3 k^4 + \ldots + {}^7C_6 k + {}^7C_7) - (k+1)$$

$$= (k^7 - k) + 7(k^6 + 3k^5 + \ldots + k)$$

$$= 7\lambda + 7(k^6 + 3k^5 + \ldots + k) = \text{Divisible by 7}$$

$\therefore$ Statement-2 is true.

Also, let $F(n) = (n+1)^7 - n^7 - 1$

$$= \{(n+1)^7 - (n+1)\} - (n^7 - n)$$

$$= \text{Divisible by 7 from Statement-2}$$

Hence, both statements are true and Statement-2 is correct explanation of Statement-1.

Session 1

Definition of Set, Representation of Set, Different Types of Sets, Laws and Theorems, Venn Diagram (Euler-Venn Diagrams)

Introduction

The concept of set is fundamental in modern Mathematics. Today this concept is being used in different branches of Mathematics and widely used in the foundation of relations and functions. The theory of sets was developed by German Mathematician **Georg Cantor** (1845-1918).

Definition of Set

A set is well-defined collection of distinct objects. Sets are usually denoted by capital letters
$A, B, C, X, Y, Z, \ldots$.

Examples of sets

(i) The set of all complex numbers.

(ii) The set of vowels in the alphabets of English language.

(iii) The set of all natural numbers.

(iv) The set of all triangles in a plane.

(v) The set of all states in India.

(vi) The set of all months in year which has 30 days.

(vii) The set of all stars in space.

Elements of the Set

The elements of the set are denoted by small letters in the alphabets of English language, i.e. $a, b, c, x, y, z, \ldots$. If x is an element of a set A, we write $x \in A$ (read as 'x belongs to A').

If x is not an element of A, then we write $x \notin A$ (read as 'x does not belong to A').

For example,

If $A = \{1, 2, 3, 4, 5\}$, then $3 \in A, 6 \notin A$.

Representation of a Set

There are two methods for representing a set.

1. Tabulation or Roster or Enumeration Method

Under this method, the elements are enclosed in curly brackets or braces { } after separating them by commas.

Remark

1. The order of writing the elements of a set is immaterial, so $\{a, b, c\}, \{b, a, c\}, \{c, a, b\}$ all denote the same set.
2. An element of a set is not written more than once, i.e. the set {1, 2, 3, 4, 3, 3, 2, 1, 2, 1, 4} is identical with the set {1, 2, 3, 4}.

For example,

1. If A is the set of prime numbers less than 10, then
$$A = \{2, 3, 5, 7\}$$
2. If A is the set of all even numbers lying between 2 and 20, then
$$A = \{4, 6, 8, 10, 12, 14, 16, 18\}$$

2. Set Builder Method

Under this method, the stating properties which its elements are to satisfy, then we write
$$A = \{x\ P(x)\} \quad \text{or} \quad A = \{x : P(x)\}$$
and read as 'A is the set of elements x, such that x has the property P'.

Remark

1. " : " or " | " means 'such that'.
2. The other names of this method are property method, rule method and symbolic method.

For example,

1. If $A = \{1, 2, 3, 4, 5, 6, 7, 8\}$, then we can write
$$A = \{x \in N : x \leq 8\}.$$
2. A is the set of all odd integers lying between 2 and 51, then
$$A = \{x : 2 < x < 51, x \text{ is odd}\}.$$

Some Standard Sets

- N denotes set of all natural numbers $= \{1, 2, 3, \ldots\}$.
- Z or I denotes set of all integers
$= \{\ldots, -3, -2, -1, 0, 1, 2, 3, \ldots\}$.
- Z_0 or I_0 denotes set of all integers excluding zero
$= \{\ldots, -3, -2, -1, 1, 2, 3, \ldots\}$.
- Z^+ or I^+ denotes set of all positive integers
$= \{1, 2, 3, \ldots\} = N$.
- E denotes set of all even integers
$= \{\ldots, -6, -4, -2, 0, 2, 4, 6, \ldots\}$.
- O denotes set of all odd integers
$= \{\ldots, -5, -3, -1, 1, 3, 5, \ldots\}$.
- W denotes set of all whole numbers $= \{0, 1, 2, 3, \ldots\}$.
- Q denotes set of all rational numbers $= \{x : x = p/q$, where p and q are integers and $q \neq 0\}$.
- Q_0 denotes set of all non-zero rational numbers $\{x : x = p/q$, where p and q are integers and $p \neq 0$ and $q \neq 0\}$.
- Q^+ denotes set of all positive rational numbers $= \{x : x = p/q$, where p and q are both positive or negative integers$\}$
- R denotes set of all real numbers.
- R_0 denotes set of all non-zero real numbers.
- R^+ denotes set of all positive real numbers.
- $R - Q$ denotes set of all irrational numbers.
- C denotes set of all complex numbers
$= \{a + ib : a, b \in R$ and $i = \sqrt{-1}\}$.
- C_0 denotes set of all non-zero complex numbers
$= \{a + ib : a, b \in R_0$ and $i = \sqrt{-1}\}$.
- N_a denotes set of all natural numbers which are less than or equal to a, where a is positive integer
$= \{1, 2, 3, \ldots, a\}$.

Different Types of Sets

1. Null Set or Empty Set or Void Set

A set having no element is called a null set or empty set or void set. It is denoted by ϕ or $\{\ \}$.

Remark

1. ϕ is called the null set.
2. ϕ is unique.
3. ϕ is a subset of every set.
4. ϕ is never written within braces i.e., $\{\phi\}$ is not the null set.
5. $\{0\}$ is not an empty set as it contains the element 0 (zero).

For example,

1. $\{x : x \in N, 4 < x < 5\} = \phi$
2. $\{x : x \in R, x^2 + 1 = 0\} = \phi$
3. $\{x : x^2 = 25, x$ is even number$\} = \phi$

2. Singleton or Unit Set

A set having one and only one element is called singleton or unit set.

For example, $\{x : x - 3 = 4\}$ is a singleton set.

Since, $x - 3 = 4 \Rightarrow x = 7$

$\therefore$ $\{x : x - 3 = 4\} = \{7\}$

3. Subset

If every element of a set A is also an element of a set B, then A is called the subset of B, we write $A \subseteq B$ (read as A is subset of B or A is contained in B).

Thus, $A \subseteq B \Leftrightarrow [x \in A \Rightarrow x \in B]$

Remark

1. Every set is a subset of itself
i.e., $A \subseteq A$.
2. If $A \subseteq B$, $B \subseteq C$, then $A \subseteq C$.

For example,

1. If $A = \{2, 3, 4\}$ and $B = \{5, 4, 2, 3, 1\}$, then $A \subseteq B$.
2. The sets $\{a\}, \{b\}, \{a, b\}, \{b, c\}$ are the subsets of the set $\{a, b, c\}$.

4. Total Number of Subsets

If a set A has n elements, then the number of subsets of $A = 2^n$.

Example 1. Write the letters of the word ALLAHABAD in set form and find the number of subsets in it and write all subsets.

Sol. There are 5 different letters in the word ALLAHABAD i.e., A,L,H,B,D, then set is {A, B, D, H, L}, then number of subsets $= 2^5 = 32$ and all subsets are

ϕ, {A}, {B}, {D}, {H}, {L}, {A, B}, {A, D}, {A, H}, {A, L}, {B, D}, {B, H}, {B, L}, {D, H}, {D, L}, {H, L}, {A, B, D}, {A, B, H}, {A, B, L}, {A, D, H}, {A, D, L}, {A, H, L}, {B, D, H}, {B, D, L}, {B, H, L}, {D, H, L}, {A, B, D, H}, {A, B, D, L}, {B, D, H, L}, {A, D, H, L}, {A, B, H, L}, {A, B, D, H, L}.

5. Equal Sets

Two sets A and B are said to be equal, if every element of A is an element of B, and every element of B is an element of A. If A and B are equal, we write $A = B$.

It is clear that $A \subseteq B$ and $B \subseteq A \Leftrightarrow A = B$.

For example,

1. The sets {1, 2, 5} and {5, 2, 1} are equal.
2. $\{1, 2, 3\} = \{x : x^3 - 6x^2 + 11x - 6 = 0\}$

6. Power Set

The set of all the subsets of a given set A is said to be the power set A and is denoted by $P(A)$ or 2^A.

Symbolically, $P(A) = \{x : x \subseteq A\}$

Thus, $x \in P(A) \Leftrightarrow x \subseteq A$.

Remark

1. ϕ and A are both elements of $P(A)$.
2. If $A = \phi$, then $P(\phi) = \{\phi\}$, a singleton but ϕ is a null set.
3. If $A = \{a\}$, then $P(A) = \{\phi, \{a\}\}$

   For example, If $A = \{a, b, c\}$, then

   $P(A)$ or $2^A = \{\phi, \{a\}, \{b\}, \{c\}, \{a, b\}, \{b, c\}, \{c, a\}, \{a, b, c\}\}$

   Also, $n(P(A))$ or $n(2^A) = 2^3 = 8$
4. Since, $P(\phi) = \{\phi\}$

   $\therefore$ $P(P(\phi)) = \{\phi, \{\phi\}\}$

   and $P(P(P(\phi))) = \{\phi, \{\phi\}, \{\{\phi\}\}, \{\phi, \{\phi\}\}\}$
5. If A has n elements, then $P(A)$ has 2^n elements.

7. Super Set

The statement $A \subseteq B$ can be rewritten as $B \supseteq A$, then B is called the super set of A and is written as $B \supset A$.

8. Proper Subset

A set A is said to be proper subset of a set B, if every element of A is an element of B and B has atleast one element which is not an element of A and is denoted by $A \subset B$ (read as "A is a proper subset of B").

For example,

1. If $A = \{1, 2, 4\}$ and $B = \{5, 1, 2, 4, 3\}$, then $A \subset B$
   Since, $3, 5 \notin A$.
2. If $A = \{a, b, c\}$ and $B = \{c, b, a\}$, then $A \not\subset B$ (since, B does not contain any element which is not in A).
3. $N \subset I \subset Q \subset R \subset C$

9. Finite and Infinite Sets

A set in which the process of counting of elements comes to an end is called a finite set, otherwise it is called an infinite set.

For example,

1. Each one of the following sets is a finite set.
   (i) Set of universities in India.
   (ii) Set of Gold Medalist students in Civil Branch, sec A in A.M.I.E. (India).
   (iii) Set of natural numbers less than 500.
2. Each one of the following is an infinite set.
   (i) Set of all integers.
   (ii) Set of all points in a plane.
   (iii) $\{x : x \in R, 1 < x < 2\}$
   (iv) Set of all concentric circles with centre as origin.

10. Cardinal Number of a Finite Set

The number of distinct elements in a finite set A is called cardinal number and the cardinal number of a set A is denoted by $n(A)$.

For example,

If $A = \{-3, -1, 8, 9, 13, 17\}$, then $n(A) = 6$.

11. Comparability of Sets

Two sets A and B are said to be comparable, if either $A \subset B$ or $B \subset A$ or $A = B$, otherwise A and B are said to be incomparable.

For example,

1. The sets $A = \{1,2,3\}$ and $B = \{1,2,4,6\}$ are incomparable (since $A \not\subset B$ or $B \not\subset A$ or $A \neq B$)
2. The sets $A = \{1, 2, 4\}$ and $B = \{1, 4\}$ are comparable (since $B \subset A$).

12. Universal Set

All the sets under consideration are likely to be subsets of a set is called the universal set and is denoted by Ω or S or U.

For example,

1. The set of all letters in alphabet of English language $U = \{a, b, c, \ldots, x, y, z\}$ is the universal set of vowels in alphabet of English language.
   i.e., $A = \{a, e, i, o, u\}$.
2. The set of all integers $I = \{0, \pm 1, \pm 2, \pm 3, \ldots\}$ is the universal set of all even integers
   i.e., $\{0, \pm 2, \pm 4, \pm 6, \ldots\}$

13. Union of Sets

The union of two sets A and B is the set of all those elements which are either in A or in B or in both. This set is denoted by $A \cup B$ or $A + B$ (read as 'A union B' or 'A cup B' or 'A join B').

Symbolically, $A \cup B = \{x : x \in A \text{ or } x \in B\}$

or $A \cup B = \{x : x \in A \vee x \in B\}$

Clearly, $x \in A \cup B \Leftrightarrow x \in A$ or $x \in B$

For example,

1. If $A = \{1, 2, 3, 4\}$ and $B = \{4, 5, 6\}$,
   then $A \cup B = \{1, 2, 3, 4, 4, 5, 6\} = \{1, 2, 3, 4, 5, 6\}$
2. If $A = \{1,2,3\}$, $B = \{2, 3, 4, 5\}$, $C = \{7, 8\}$,
   then $A \cup B \cup C = \{1, 2, 3, 4, 5, 7, 8\}$

Remark

The union of a finite number of sets $A_1, A_2, A_3, \ldots, A_n$ is represented by $A_1 \cup A_2 \cup A_3 \cup \ldots \cup A_n$ or $\bigcup_{i=1}^{n} A_i$.

Symbolically, $\bigcup_{i=1}^{n} A_i = \{x : x \in A_i \text{ for atleast one } i\}$

14. Intersection of Sets

The intersection of two sets A and B is the set of all elements which are common in A and B. This set is denoted by $A \cap B$ or AB (read as 'A intersection B' or 'A cap B' or 'A meet B').

Symbolically, $A \cap B = \{x : x \in A \text{ and } x \in B\}$

or $A \cap B = \{x : x \in A \wedge x \in B\}$

Clearly, $x \in A \cap B \Leftrightarrow x \in A$ and $x \in B$

For example,

1. If $A = \{1, 2, 3\}$ and $B = \{3, 4, 5, 6\}$, then $A \cap B = \{3\}$.
2. If $A = \{1, 2, 3\}$, $B = \{2, 3, 4\}$ and $C = \{3, 4, 5\}$, then $A \cap B \cap C = \{3\}$

Remark

The intersection of a finite number of sets $A_1, A_2, A_3, \ldots, A_n$ represented by

$$A_1 \cap A_2 \cap A_3 \cap \ldots \cap A_n \quad \text{or} \quad \bigcap_{i=1}^{n} A_i.$$

Symbolically, $\bigcap_{i=1}^{n} A_i = \{x : x \in A_i \text{ for all } i\}$

15. Disjoint Sets

If the two sets A and B have no common element.

i.e., $A \cap B = \phi$, then the two sets A and B are called disjoint or mutually exclusive events.

For example, If $A = \{a, b, c\}$ and $B = \{1, 2, 3\}$, then $A \cap B = \phi$

Hence, A and B are disjoint sets.

Remark

If $S = \{a_1, a_2, a_3, \ldots, a_n\}$, so

number of ordered pairs of disjoint sets of S is $\frac{3^n + 1}{2}$.

($\because$ each element in either (A) or (B) or neither

$\therefore$ Total ways $= 3^n$ i.e., $A = B$, iff $A = B = \phi$ (1 case) otherwise A and B are interchangeable.

$\therefore$ Number of ordered pairs of disjoint sets of $S = 1 + \frac{3^n - 1}{2} = \frac{3^n + 1}{2}$.

16. Difference of Sets

If A and B be two given sets, then the set of all those elements of A which do not belong to B is called difference of sets A and B. It is written as $A - B$. It is also denoted by $A \sim B$ or $A \backslash B$ or ${}_{C_A}B$ (complement of B in A).

Symbolically, $A - B = \{x : x \in A \text{ and } x \notin B\}$

Clearly, $x \in A - B \Leftrightarrow x \in A$ and $x \notin B$.

Remark

1. $A - B \neq B - A$
2. The sets $A - B$, $B - A$ and $A \cap B$ are disjoint sets.
3. $A - B \subseteq A$ and $B - A \subseteq B$
4. $A - \phi = A$ and $A - A = \phi$

For example,

If $A = \{1, 2, 3, 4\}$ and $B = \{4, 5, 6, 7\}$, then $A - B = \{1, 2, 3\}$.

17. Symmetric Difference of Two Sets

Let A and B be two sets. The symmetric difference of sets A and B is the set $(A - B) \cup (B - A)$ or $(A \cup B) - (A \cap B)$ and is denoted by $A \Delta B$ or $A \oplus B$ (A direct sum B).

i.e., $A \oplus B$ or $A \Delta B = (A - B) \cup (B - A)$

and $A \oplus B$ or $A \Delta B = (A \cup B) - (A \cap B)$

Remark

1. $A \Delta B = \{x : x \in A \text{ and } x \notin B\}$
   or $A \Delta B = \{x : x \in B \text{ and } x \notin A\}$
2. $A \Delta B = B \Delta A$ (commutative)

For example,

Let $A = \{1,2,3,4,5\}$ and $B = \{1,3,5,7\}$,

then $A - B = \{2, 4\}$, $B - A = \{7\}$

$\therefore$ $A \Delta B = (A - B) \cup (B - A) = \{2, 4, 7\}$

18. Complement Set

Let U be the universal set and A be a set, such that $A \subset U$. Then, the complement of A with respect to U is denoted by A' or A^c or $C(A)$ or $U - A$.

Symbolically, A' or A^c or $C(A) = \{x : x \in U \text{ and } x \notin A\}$.

Clearly, $x \in A' \Leftrightarrow x \notin A$.

Remark

1. $U' = \phi$ and $\phi' = U$
2. $A \cup A' = U$ and $A \cap A' = \phi$

For example,

Let $U = \{1, 2, 3, 4, 5, 6, 7\}$ and $A = \{1, 3, 5, 7\}$.

Then, $A' = U - A = \{2, 4, 6\}$

Laws and Theorems

1. **Idempotent Laws**
For **any set A,**
(i) $A \cup A = A$ (ii) $A \cap A = A$
Proof
(i) Let $x \in A \cup A \Leftrightarrow x \in A$ or $x \in A$
$\Leftrightarrow x \in A$
Hence, $A \cup A = A$
(ii) Let $x \in A \cap A \Leftrightarrow x \in A$ and $x \in A$
$\Leftrightarrow x \in A$
Hence, $A \cap A = A$

2. **Identity Laws**
For **any set A,**
(i) $A \cup \phi = A$ (ii) $A \cap \phi = \phi$
(iii) $A \cup U = U$ (iv) $A \cap U = A$
Proof
(i) Let $x \in A \cup \phi \Leftrightarrow x \in A$ and $x \in \phi$
$\Leftrightarrow x \in A$
Hence, $A \cup \phi = A$
(ii) Let $x \in A \cap \phi \Leftrightarrow x \in A$ and $x \in \phi$
$\Leftrightarrow x \in \phi$
Hence, $A \cap \phi = \phi$
(iii) Let $x \in A \cup U \Leftrightarrow x \in A$ or $x \in U$
$\Leftrightarrow x \in U$
Hence, $A \cup U = U$
(iv) Let $x \in A \cap U \Leftrightarrow x \in A$ and $x \in U$
$\Leftrightarrow x \in A$
Hence, $A \cap U = A$

3. **Commutative Laws**
For any two sets A and B, we have
(i) $A \cup B = B \cup A$ (ii) $A \cap B = B \cap A$
Proof
(i) Let $x \in A \cup B \Leftrightarrow x \in A$ or $x \in B$
$\Leftrightarrow x \in B$ or $x \in A$
$\Leftrightarrow x \in B \cup A$
$\therefore \quad x \in A \cup B \Leftrightarrow x \in B \cup A$
Hence, $A \cup B = B \cup A$
(ii) Let $x \in A \cap B \Leftrightarrow x \in A$ and $x \in B$
$\Leftrightarrow x \in B$ and $x \in A$
$\Leftrightarrow x \in B \cap A$
$\therefore \quad x \in A \cap B \Leftrightarrow x \in B \cap A$
Hence, $A \cap B = B \cap A$.

4. **Associative Laws**
For any three sets A, B and C, we have
(i) $A \cup (B \cup C) = (A \cup B) \cup C$
(ii) $A \cap (B \cap C) = (A \cap B) \cap C$
Proof
(i) Let $x \in A \cup (B \cup C) \Leftrightarrow x \in A$ or $x \in B \cup C$
$\Leftrightarrow x \in A$ or $(x \in B$ or $x \in C)$
$\Leftrightarrow (x \in A$ or $x \in B)$ or $x \in C$
$\Leftrightarrow x \in A \cup B$ or $x \in C$
$\Leftrightarrow x \in (A \cup B) \cup C$
$\therefore \quad x \in A \cup (B \cup C) \Leftrightarrow x \in (A \cup B) \cup C$
Hence, $A \cup (B \cup C) = (A \cup B) \cup C$.
(ii) Let $x \in A \cap (B \cap C) \Leftrightarrow x \in A$ and $x \in B \cap C$
$\Leftrightarrow x \in A$ and $(x \in B$ and $x \in C)$
$\Leftrightarrow (x \in A$ and $x \in B)$ and $x \in C$
$\Leftrightarrow x \in A \cap B$ and $x \in C$
$\Leftrightarrow x \in (A \cap B) \cap C$
Hence, $A \cap (B \cap C) = (A \cap B) \cap C$.

5. **Distributive Laws**
For any three sets A, B and C, we have
(i) $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$
(ii) $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$
Proof
(i) Let $x \in A \cup (B \cap C) \Leftrightarrow x \in A$ or $x \in B \cap C$
$\Leftrightarrow x \in A$ or $(x \in B$ and $x \in C)$
$\Leftrightarrow (x \in A$ or $x \in B)$ and $(x \in A$ or $x \in C)$
$\Leftrightarrow x \in A \cup B$ and $x \in A \cup C$
$\Leftrightarrow x \in [(A \cup B) \cap (A \cup C)]$
$\therefore \quad x \in A \cup (B \cap C) \Leftrightarrow x \in (A \cup B) \cap (A \cup C)$
Hence, $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$.
(ii) Let $x \in A \cap (B \cup C) \Leftrightarrow x \in A$ and $x \in B \cup C$
$\Leftrightarrow x \in A$ and $(x \in B$ or $x \in C)$
$\Leftrightarrow (x \in A$ and $x \in B)$ or $(x \in A$ and $x \in C)$
$\Leftrightarrow x \in A \cap B$ or $x \in A \cap C$
$\Leftrightarrow x \in (A \cap B) \cup (A \cap C)$
$\therefore \quad x \in A \cap (B \cup C) \Leftrightarrow x \in (A \cap B) \cup (A \cap C)$
Hence, $A \cap (B \cup C) = (A \cup B) \cap (A \cup C)$.

6. **For any two sets A and B, we have**
(i) $P(A) \cap P(B) = P(A \cap B)$
(ii) $P(A) \cup P(B) \subseteq P(A \cup B)$
where, $P(A)$ is the power set of A.
Proof
(i) Let $x \in P(A) \cap P(B) \Leftrightarrow x \in P(A)$ or $x \in P(B)$
$\Leftrightarrow x \subseteq A$ or $x \subseteq B$
$\Leftrightarrow x \subseteq A \cap B$
$\Leftrightarrow x \in P(A \cap B)$
Hence, $P(A) \cap P(B) = P(A \cap B)$

(ii) Let $x \in P(A) \cup P(B) \Leftrightarrow x \in P(A)$ or $x \in P(B)$
$\Leftrightarrow x \subseteq A$ or $x \subseteq B$
$\Leftrightarrow x \subseteq A \cup B$
$\Leftrightarrow x \in P(A \cup B)$
Hence, $P(A) \cup P(B) \subseteq P(A \cup B)$

7. If A is any set, then $\boldsymbol{(A')' = A}$
Proof Let $x \in (A')' \Leftrightarrow x \notin A' \Leftrightarrow x \in A$
Hence, $(A')' = A$

8. **De-Morgan's Laws**
For any three sets A, B and C, we have
(i) $\boldsymbol{(A \cup B)' = A' \cap B'}$
(ii) $\boldsymbol{(A \cap B)' = A' \cup B'}$
(iii) $\boldsymbol{A - (B \cup C) = (A - B) \cap (A - C)}$
(iv) $\boldsymbol{A - (B \cap C) = (A - B) \cup (A - C)}$

Proof

(i) Let $x \in (A \cup B)' \Leftrightarrow x \notin A \cup B$
$\Leftrightarrow x \notin A$ and $x \notin B$
$\Leftrightarrow x \in A'$ and $x \in B'$
$\Leftrightarrow x \in A' \cap B'$
$\therefore \quad x \in (A \cup B)' \Leftrightarrow x \in A' \cap B'$
Hence, $(A \cup B)' = A' \cap B'$.

(ii) Let $x \in (A \cap B)' \Leftrightarrow x \notin A \cap B$
$\Leftrightarrow x \notin A$ or $x \notin B$
$\Leftrightarrow x \in A'$ or $x \in B'$
$\Leftrightarrow x \in A' \cup B'$
$\therefore \quad x \in (A \cap B)' \Leftrightarrow x \in A' \cup B'$
Hence, $(A \cap B)' = A' \cup B'$.

(iii) Let $x \in A - (B \cup C) \Leftrightarrow x \in A$ and $x \notin B \cup C$
$\Leftrightarrow x \in A$ and $(x \notin B$ and $x \notin C)$
$\Leftrightarrow (x \in A$ and $x \notin B)$ and $(x \in A$ and $x \notin C)$
$\Leftrightarrow x \in (A - B)$ and $x \in (A - C)$
$\Leftrightarrow x \in (A - B) \cap (A - C)$
Hence, $A - (B \cup C) = (A - B) \cap (A - C)$.

(iv) Let $x \in A - (B \cap C) \Leftrightarrow x \in A$ and $x \notin (B \cap C)$
$\Leftrightarrow x \in A$ and $(x \notin B$ or $x \notin C)$
$\Leftrightarrow (x \in A$ and $x \notin B)$ or $(x \in A$ and $x \notin C)$
$\Leftrightarrow x \in (A - B)$ or $x \in (A - C)$
$\Leftrightarrow x \in (A - B) \cup (A - C)$
Hence, $A - (B \cap C) = (A - B) \cup (A - C)$.

Aliter

$A - (B \cap C) = A \cap (B \cap C)' \quad [\because A - B = A \cap B']$
$= A \cap (B' \cap C)'$
$= (A \cap B') \cup (A \cap C')$
$= (A - B) \cup (A - C)$

More Results on Operations on Sets

For any two sets A and B, we have

1. $\boldsymbol{A \subseteq A \cup B, B \subseteq A \cup B, A \cap B \subseteq A, A \cap B \subseteq B}$

2. $\boldsymbol{A - B = A \cap B'}$
Proof
Let $x \in A - B \Leftrightarrow x \in A$ and $x \notin B$
$\Leftrightarrow x \in A$ and $x \in B'$
$\Leftrightarrow x \in A \cap B'$
Hence, $A - B = A \cap B'$

3. $\boldsymbol{(A - B) \cup B = A \cup B}$
Proof $(A - B) \cup B = (A \cap B') \cup B$
$= (A \cup B) \cap (B' \cup B)$ [from distributive law]
$= (A \cup B) \cap U$
$= A \cup B$
Hence, $(A - B) \cup B = A \cup B$

4. $\boldsymbol{(A - B) \cap B = \phi}$
Proof $(A - B) \cap B = (A \cap B') \cap B$
$= A \cap (B' \cap B)$ [from associative law]
$= A \cap \phi = \phi$
Hence, $(A - B) \cap B = \phi$

5. $\boldsymbol{A \subseteq B \Leftrightarrow B' \subseteq A'}$
Proof Only if part Let $A \subseteq B$ ...(i)
To prove $B' \subseteq A'$
Let $x \in B' \Rightarrow x \notin B$
$\Rightarrow x \notin A$ $[\because A \subseteq B]$
$\Rightarrow x \in A'$
Thus, $x \in B' \Rightarrow x \in A'$ $[\because B \subseteq A]$
Hence, $B' \subseteq A'$ ...(ii)
If part Let $B' \subseteq A'$ ...(iii)
To prove $A \subseteq B$
Let $x \in A \Rightarrow x \notin A'$
$\Rightarrow x \notin B'$ [from Eq.(iii)]
$\Rightarrow x \in B$
Hence, $A \subseteq B$ ...(iv)
From Eqs. (ii) and (iv), we get $A \subseteq B \Leftrightarrow B' \subseteq A'$

6. $\boldsymbol{A - B = B' - A'}$
Proof $A - B = (A \cap B')$
$= B' \cap A = B' \cap (A')' = B' - A'$
Hence, $A - B = B' - A'$

7. $\boldsymbol{(A \cup B) \cap (A \cup B') = A}$
Proof $(A \cup B) \cap (A \cup B') = A \cup (B \cap B')$
[by distributive law]
$= A \cup \phi = A$
Hence, $(A \cup B) \cap (A \cup B') = A$

8. $\boldsymbol{A \cup B = (A - B) \cup (B - A) \cup (A \cap B)}$
Proof $(A - B) \cup (B - A) \cup (A \cap B)$
$= [(A \cup B) - (A \cap B)] \cup (A \cap B)$

$=[(A \cup B) \cap (A \cap B)'] \cup (A \cap B)$
$=[(A \cup B) \cup (A \cap B)] \cap [(A \cap B)' \cup (A \cap B)]$
$=(A \cup B) \cap U = A \cup B$

Hence, $A \cup B = (A - B) \cup (B - A) \cup (A \cap B)$

9. $\boldsymbol{A - (A - B) = A \cap B}$

Proof $A - (A - B) = A - (A \cap B')$
$= A \cap (A \cap B')'$
$= A \cap (A' \cup B)$
$= (A \cap A') \cup (A \cap B)$
$= \phi \cup (A \cap B) = A \cap B$

Hence, $A - (A - B) = A \cap B$

10. $\boldsymbol{A - B = B - A \Leftrightarrow A = B}$

Proof **Only if part** Let $A - B = B - A$ ...(i)

To prove $A = B$

Let $x \in A \Leftrightarrow (x \in A$ and $x \notin B)$ or $(x \in A$ and $x \in B)$
$\Leftrightarrow x \in (A - B)$ or $x \in (A \cap B)$
$\Leftrightarrow x \in (B - A)$

or $x \in A \cap B$ [from Eq. (i)]
$\Leftrightarrow (x \in B$ and $x \notin A)$ or $(x \in B$ and $x \in A)$
$\Leftrightarrow x \in B$

Hence, $A = B$

If part Let $A = B$

To prove $A - B = B - A$

Now, $A - B = A - A = \phi$ $[\because B = A]$

and $B - A = A - A = \phi$ $[\because B = A]$

$\therefore$ $A - B = B - A$

Hence, $A = B \Rightarrow A - B = B - A$

11. $\boldsymbol{A \cup B = A \cap B \Leftrightarrow A = B}$

Proof **Only if part** Let $A \cup B = A \cap B$

Now, $x \in A \Rightarrow x \in A \cup B$

$\Rightarrow$ $x \in A \cap B$ $[\because A \cup B = A \cap B]$

$\Rightarrow$ $x \in B$

Thus, $A \subseteq B$ ...(i)

Again, $y \in B \Rightarrow y \in A \cup B$

$\Rightarrow$ $y \in A \cap B$ $[\because A \cup B = A \cap B]$

$\Rightarrow$ $y \in A$

Thus, $B \subseteq A$ ...(ii)

From Eqs. (i) and (ii), we have $A = B$

Thus, $A \cup B = A \cap B \Rightarrow A = B$.

If part Let $A = B$ ...(iii)

To prove $A \cup B = A \cap B$

Now, $A \cup B = A \cup A = A$ $[\because B = A]$...(iv)

and $A \cap B = A \cap A = A$ $[\because B = A]$...(v)

From Eqs. (iv) and (v), we have $A \cup B = A \cap B$

Hence, $A \cup B = A \cap B \Leftrightarrow A = B$

Example 2. ***Let*** A, B ***and*** C ***be three sets such that*** $A \cup B = A \cup C$ ***and*** $A \cap B = A \cap C$***. Show that*** $B = C$***.***

Sol. Given, $A \cup B = A \cup C$ ...(i)

and $A \cap B = A \cap C$ ...(ii)

To prove $B = C$.

From Eq. (i), $(A \cup B) \cap C = (A \cup C) \cap C$

$\Rightarrow$ $(A \cap C) \cup (B \cap C) = (A \cap C) \cup (C \cup C)$

$\Rightarrow$ $(A \cap B) \cup (B \cap C) = (A \cap C) \cup C$
$[\because A \cap C = A \cap B]$

$\Rightarrow$ $(A \cap B) \cup (B \cap C) = C$ $[\because A \cap C \subseteq C]$

Thus, $C = (A \cap B) \cup (B \cap C)$ ...(iii)

Again, from Eq. (i), $(A \cup B) \cap B = (A \cup C) \cap B$

$\Rightarrow$ $(A \cap B) \cup (B \cap B) = (A \cap B) \cup (C \cap B)$

$\Rightarrow$ $(A \cap B) \cup B = (A \cap B) \cup (B \cap C)$

$\Rightarrow$ $B = (A \cap B) \cup (B \cap C)$
$[\because A \cap B \subseteq B]$

Thus, $B = (A \cap B) \cup (B \cap C)$ ...(iv)

From Eqs. (iii) and (iv), we have $B = C$.

Example 3. Let A and B be any two sets. If for some set X, $A \cap X = B \cap X = \phi$ and $A \cup X = B \cup X$, prove that $A = B$.

Sol. Given, $A \cap X = B \cap X = \phi$ ...(i)

and $A \cup X = B \cup X$ ...(ii)

From Eq. (ii), $A \cap (A \cup X) = A \cap (B \cup X)$

$\Rightarrow$ $A = (A \cap B) \cup (A \cap X)$
$[\because A \subseteq A \cup X \ \therefore A \cap (A \cup X) = A]$

$\Rightarrow$ $A = (A \cap B) \cup \phi$ $[\because A \cap X = \phi]$

$\Rightarrow$ $A = (A \cap B)$

$\Rightarrow$ $A \subseteq B$ ...(iii)

Again, $A \cup X = B \cup X$

$\Rightarrow$ $B \cap (A \cup X) = B \cap (B \cup X)$

$\Rightarrow$ $(B \cap A) \cup (B \cap X) = B$
$[\because B \subseteq B \cup X \ \therefore B \cap (B \cup X) = B]$

$\Rightarrow$ $(B \cap A) \cup \phi = B$ $[\because B \cap X = \phi]$

$\Rightarrow$ $B \cap A = B$

$\Rightarrow$ $B \subseteq A$ ...(iv)

From Eqs. (iii) and (iv), we have $A = B$.

Example 4. If A and B are any two sets, prove that $P(A) = P(B) \Rightarrow A = B$.

Sol. Given, $P(A) = P(B)$ ...(i)

To prove $A = B$

Let $x \in A \Rightarrow$ there exists a subset X of A such that $x \in X$.

Now, $X \subseteq A \Rightarrow X \in P(A)$

$\Rightarrow$ $X \in P(B)$ [from Eq. (i)]

$\Rightarrow \quad X \subseteq B$

$\Rightarrow \quad x \in B \qquad [\because x \in X]$

Thus, $x \in A \Rightarrow x \in B$

$\therefore \quad A \subseteq B \qquad \ldots(ii)$

Let $y \in B \Rightarrow$ there exists a subset Y of B such that $y \in Y$.

Now, $Y \subseteq B \Rightarrow Y \in P(B)$

$\Rightarrow \quad Y \in P(A) \qquad [\because P(B) = P(A)]$

$\Rightarrow \quad Y \subseteq A$

$\Rightarrow \quad y \in A \qquad [\because y \in Y]$

Thus, $y \in B \Rightarrow y \in A$

$\therefore \quad B \subseteq A \qquad \ldots(iii)$

From Eqs. (ii) and (iii), we have $A = B$

Use of Sets in Logical Problems

M = Set of students which have Mathematics.

P = Set of students which have Physics.

C = Set of students which have Chemistry.

Applying the different operations on the above sets, then we get following important results.

M' = Set of students which have no Mathematics.

P' = Set of students which have no Physics.

C' = Set of students which have no Chemistry.

$M \cup P$ = Set of students which have atleast one subject Mathematics or Physics.

$P \cup C$ = Set of students which have atleast one subject Physics or Chemistry.

$C \cup M$ = Set of students which have atleast one subject Chemistry or Mathematics.

$M \cap P$ = Set of students which have both subjects Mathematics and Physics.

$P \cap C$ = Set of students which have both subjects Physics and Chemistry.

$C \cap M$ = Set of students which have both subjects Chemistry and Mathematics.

$M \cap P'$ = Set of students which have Mathematics but not Physics.

$P \cap C'$ = Set of students which have Physics but not Chemistry.

$C \cap M'$ = Set of students which have Chemistry but not Mathematics.

$(M \cup P)'$ = Set of students which have not both subjects Mathematics and Physics.

$(P \cup C)'$ = Set of students which have not both subjects Physics and Chemistry.

$(C \cup M)'$ = Set of students which have not both subjects Chemistry and Mathematics.

$(M \cap P \cap C)$ = Set of students which have all three subjects Mathematics, Physics and Chemistry.

$(M \cup P \cup C)$ = Set of all students which have three subjects.

Cardinal Number of Some Sets

If A, B and C are finite sets and U be the finite universal set, then

(i) $n(A') = n(U) - n(A)$

(ii) $n(A \cup B) = n(A) + n(B) - n(A \cap B)$

(iii) $n(A \cup B) = n(A) + n(B)$, if A and B are disjoint non-void sets.

(iv) $n(A \cap B') = n(A) - n(A \cap B)$

(v) $n(A' \cap B') = n(A \cup B)' = n(U) - n(A \cup B)$

(vi) $n(A' \cup B') = n(A \cap B)' = n(U) - n(A \cap B)$

(vii) $n(A - B) = n(A) - n(A \cap B)$

(viii) $n(A \cap B) = n(A \cup B) - n(A \cap B') - n(A' \cap B)$

(ix) $n(A \cup B \cup C) = n(A) + n(B) + n(C) - n(A \cap B) - n(B \cap C) - n(C \cap A) + n(A \cap B \cap C)$

(x) If $A_1, A_2, A_3, \ldots, A_n$ are disjoint sets, then
$n(A_1 \cup A_2 \cup A_3 \cup \ldots \cup A_n) = n(A_1) + n(A_2) + n(A_3) + \ldots + n(A_n)$

Example 5. If A and B be two sets containing 6 and 3 elements respectively, what can be the minimum number of elements in $A \cup B$? Also, find the maximum number of elements in $A \cup B$.

Sol. We have, $n(A \cup B) = n(A) + n(B) - n(A \cap B)$,

$n(A \cup B)$ is minimum or maximum according as $n(A \cap B)$ is maximum or minimum, respectively.

***Case* I** If $n(A \cap B)$ is minimum i.e., $n(A \cap B) = 0$ such that

$A = \{a, b, c, d, e, f\}$ and $B = \{g, h, i\}$

$\therefore \quad n(A \cup B) = n(A) + n(B) = 6 + 3 = 9$

***Case* II** If $n(A \cap B)$ is maximum i.e., $n(A \cap B) = 3$, such that

$A = \{a, b, c, d, e, f\}$ and $B = \{d, a, c\}$

$\therefore\ n(A \cup B) = n(A) + n(B) - n(A \cap B) = 6 + 3 - 3 = 6$

Example 6. Suppose $A_1, A_2, \ldots, A_{30}$ are thirty sets each with five elements and $B_1, B_2, \ldots, B_n$ are n sets each with three elements.

Let $\bigcup_{i=1}^{30} A_i = \bigcup_{j=1}^{n} B_j = S$

Assume that each element of S belongs to exactly ten of the A_i's and exactly to nine of the B_j's. Find n.

Sol. Given, A's are thirty sets with five elements each, so

$$\sum_{i=1}^{30} n(A_i) = 5 \times 30 = 150 \quad \ldots(i)$$

If the m distinct elements in S and each element of S belongs to exactly 10 of the A_i's, so we have

$$\sum_{i=1}^{30} n(A_i) = 10m \quad \ldots(ii)$$

$\therefore$ From Eqs. (i) and (ii), we get $10m = 150$

$$\therefore \quad m = 15 \quad \ldots(iii)$$

Similarly, $\sum_{j=1}^{n} n(B_j) = 3n$ and $\sum_{j=1}^{n} n(B_j) = 9m$

$$\therefore \quad 3n = 9m \implies n = \frac{9m}{3} = 3m$$

$$= 3 \times 15 = 45 \quad \text{[from Eq. (iii)]}$$

Hence, $n = 45$

Example 7. In a group of 1000 people, there are 750 who can speak Hindi and 400 who can speak Bengali. How many can speak Hindi only? How many can speak Bengali only? How many can speak both Hindi and Bengali?

Sol. Let H and B be the set of those people who can speak Hindi and Bengali respectively, then according to the problem, we have

$$n(H \cup B) = 1000,$$
$$n(H) = 750, n(B) = 400$$

We know that,

$$n(H \cup B) = n(H) + n(B) - n(H \cap B)$$
$$1000 = 750 + 400 - n(H \cap B)$$
$$\therefore \quad n(H \cap B) = 150$$

$\therefore$ Number of people speaking Hindi and Bengali both is 150.

Also, $n(H \cap B') = n(H) - n(H \cap B)$

$$= 750 - 150$$
$$= 600$$

Thus, number of people speaking Hindi only is 600.

Again, $n(B \cap H') = n(B) - n(B \cap H) = 400 - 150 = 250$

Thus, number of people speaking Bengali only is 250.

Example 8. A survey of 500 television watchers produced the following information, 285 watch football, 195 watch hockey, 115 watch basketball, 45 watch football and basketball, 70 watch football and hockey, 50 watch hockey and basketball, 50 do not watch any of the three games. How many watch all the three games? How many watch exactly one of the three games?

Sol. Let F, H and B be the sets of television watchers who watch Football, Hockey and Basketball, respectively.

Then, according to the problem, we have

$$n(U) = 500, \ n(F) = 285, n(H) = 195,$$
$$n(B) = 115, \ n(F \cap B) = 45,$$
$$n(F \cap H) = 70, n(H \cap B) = 50$$

and $n(F' \cup H' \cup B') = 50,$

where U is the set of all the television watchers.

Since, $n(F' \cup H' \cup B') = n(U) - n(F \cup H \cup B)$

$$\implies 50 = 500 - n(F \cup H \cup B)$$
$$\implies n(F \cup H \cup B) = 450$$

We know that,

$$n(F \cup H \cup B) = n(F) + n(H) + n(B) - n(F \cap H) - n(H \cap B) - n(B \cap F) + n(F \cap H \cap B)$$
$$\implies 450 = 285 + 195 + 115 - 70 - 50 - 45 + n(F \cap H \cap B)$$
$$\therefore \quad n(F \cap H \cap B) = 20$$

which is the number of those who watch all the three games. Also, number of persons who watch football only

$$= n(F \cap H' \cap B')$$
$$= n(F) - n(F \cap H) - n(F \cap B) + n(F \cap H \cap B)$$
$$= 285 - 70 - 45 + 20 = 190$$

The number of persons who watch hockey only

$$= n(H \cap F' \cap B')$$
$$= n(H) - n(H \cap F) - n(H \cap B) + n(H \cap F \cap B)$$
$$= 195 - 70 - 50 + 20 = 95$$

and the number of persons who watch basketball only

$$= n(B \cap H' \cap F')$$
$$= n(B) - n(B \cap H) - n(B \cap F) + n(H \cap F \cap B)$$
$$= 115 - 50 - 45 + 20 = 40$$

Hence, required number of those who watch exactly one of the three games

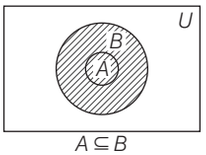
$$= 190 + 95 + 40 = 325$$

Venn Diagrams
(Euler-Venn Diagrams)

The diagram drawn to represent sets are called Venn diagrams or Euler Venn diagrams. Here, we represent the universal set U by points within rectangle and the subset A of the set U is represented by the interior of a circle. If a set A is a subset of a set B, then the circle representing A is drawn inside the circle representing B. If A and B are not equal but they have some common elements, then to represent A and B by two intersecting circles.

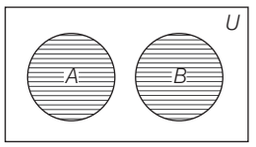
Venn Diagrams in Different Situations

1. Subset

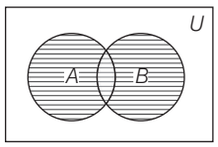


$A \subseteq B$

2. Union of sets

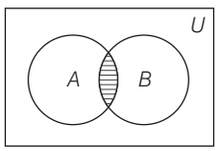


$A \cup B$, when $A \cap B = \phi$

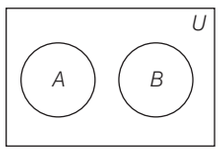


$A \cup B$, when neither $A \subseteq B$ nor $B \subseteq A$

3. Intersection of sets

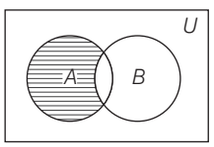


$A \cap B$, when neither $A \subseteq B$ nor $B \subseteq A$

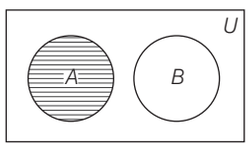


$A \cap B$, when $A \cap B = \phi$ (no shaded one)

4. Difference of sets

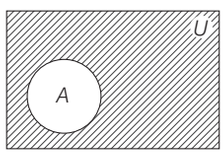


$A - B$, when neither $A \subseteq B$ nor $B \subseteq A$



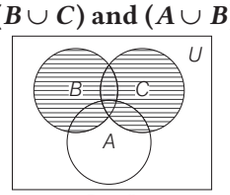
$A - B$, when $A - B = \phi$

5. Complement set

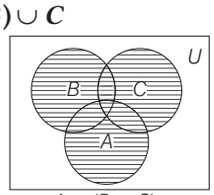


A' = shaded one

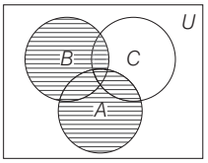
6. $A \cup (B \cup C)$ and $(A \cup B) \cup C$



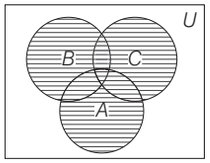
$B \cup C$



$A \cup (B \cup C)$



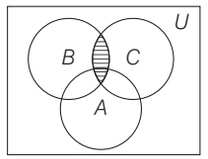
$A \cup B$



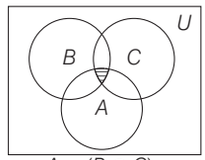
$(A \cup B) \cup C$

Hence, $A \cup (B \cup C) = (A \cup B) \cup C$ which is associative law for union.

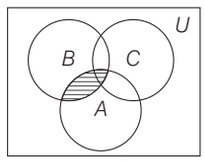
7. $A \cap (B \cap C)$ and $(A \cap B) \cap C$



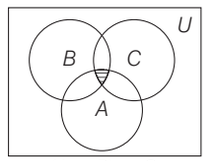
$B \cap C$



$A \cap (B \cap C)$



$A \cap B$



$(A \cap B) \cap C$

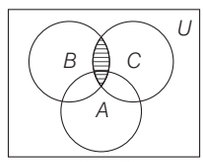
Hence, $A \cap (B \cap C) = (A \cap B) \cap C$ which is associative law for intersection.

8. Distributive law

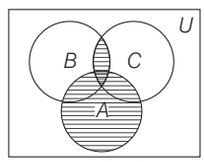
(i) $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$

(ii) $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$

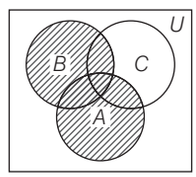
(i)



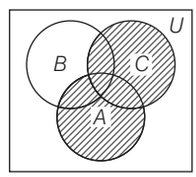
$(B \cap C)$



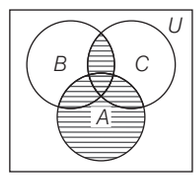
$A \cup (B \cap C)$



$(A \cup B)$



$(A \cup C)$

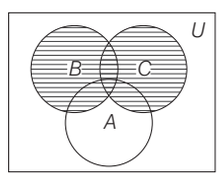


$(A \cup B) \cap (A \cup C)$

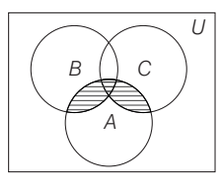
It is clear from diagrams that

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$$

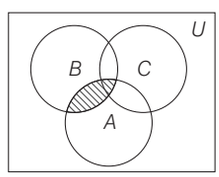
(ii)



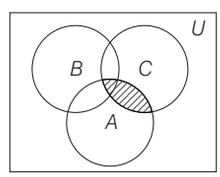
$(B \cup C)$



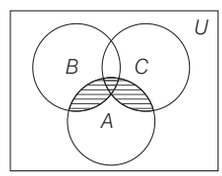
$A \cap (B \cup C)$



$(A \cap B)$



$(A \cap C)$

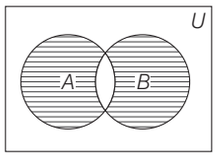


$(A \cap B) \cup (A \cap C)$

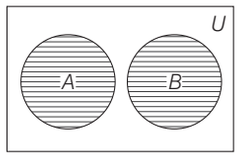
It is clear from diagrams that

$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$$

9. Symmetric difference



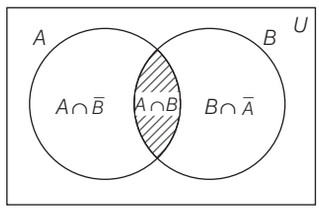
$A \Delta B$, when neither $A \subseteq B$ nor $B \subseteq A$ and $A \cap B \neq \phi$

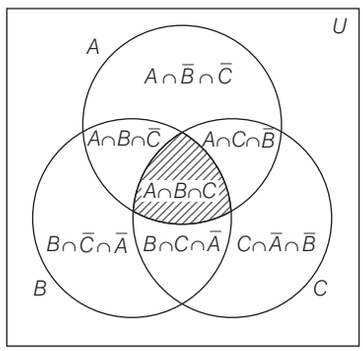


$A \Delta B$, when $A \cap B = \phi$

Remark

Remember with the help of figures.





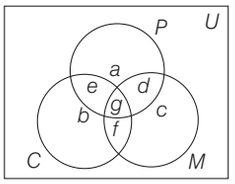
Example 9. A class has 175 students. The following table shows the number of students studying one or more of the following subjects in this case.

Subjects	Number of students
Mathematics	100
Physics	70
Chemistry	46
Mathematics and Physics	30
Mathematics and Chemistry	28
Physics and Chemistry	23
Mathematics, Physics and Chemistry	18

How many students are enrolled in Mathematics alone, Physics alone and Chemistry alone? Are there students who have not offered any one of these subjects?

Sol. Let P, C and M denotes the sets of students studying Physics, Chemistry and Mathematics, respectively.

Let a, b, c, d, e, f, g denote the elements (students) contained in the bounded region as shown in the diagram.



Then, $a + d + e + g = 170$

$c + d + f + g = 100$

$b + e + f + g = 46$

$d + g = 30$

$e + g = 23$

$f + g = 28$

$g = 18$

After solving, we get $g = 18$, $f = 10$, $e = 5$, $d = 12$, $a = 35$, $b = 13$ and $c = 60$

$\therefore \quad a + b + c + d + e + f + g = 153$

So, the number of students who have not offered any of these three subjects $= 175 - 153 = 22$

Number of students studying Mathematics only, $c = 60$

Number of students studying Physics only, $a = 35$

Number of students studying Chemistry only, $b = 13$

Aliter

Let P, C and M be the sets of students studying Physics, Chemistry and Mathematics, respectively. Then, we are given that

$n(P) = 70, n(C) = 46, n(M) = 100$

$n(M \cap P) = 30, n(M \cap C) = 28$

$n(P \cap C) = 23$

and $n(M \cap P \cap C) = 18$

$\therefore$ The number of students enrolled in Mathematics only

$= n(M \cap P' \cap C') = n(M \cap (P \cup C)')$

[by De-Morgan's law]

$= n(M) - n(M \cap (P \cup C))$

$= n(M) - \{n[(M \cap P) \cup (M \cap C)]\}$

[by distributive law]

$= n(M) - n(M \cap P) - (M \cap C) + n(M \cap P \cap C)$

$= 100 - 30 - 28 + 18 = 60$

Similarly, the number of students enrolled in Physics only,

$n(P \cap M' \cap C')$

$= n(P) - n(P \cap M) - n(P \cap C) + n(P \cap M \cap C)$

$= 70 - 30 - 23 + 18 = 35$

and the number of students enrolled in Chemistry only,

$n(C \cap M' \cap P') = n(C) - n(C \cap M) - n(C \cap P) + n$

$(C \cap M \cap P)$

$= 46 - 28 - 23 + 18 = 13$

and the number of students who have not offered any of the three subjects,

$n(M' \cap P' \cap C') = n(M \cap P \cap C)'$ [by De-Morgan's law]

$= n(U) - n(M \cup P \cup C)$

$= n(U) - \{n(M) + n(P) + n(C) - n(M \cap P)$

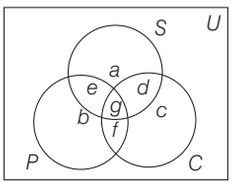
$- n(M \cap C) - n(P \cap C) + n(P \cap C \cap M)\}$

$= 175 - \{100 + 70 + 46 - 30 - 28 - 23 + 8\}$

$= 175 - 153 = 22$

Example 10. In a pollution study of 1500 Indian rivers the following data were reported. 520 were polluted by sulphur compounds, 335 were polluted by phosphates, 425 were polluted by crude oil, 100 were polluted by both crude oil and sulphur compounds, 180 were polluted by both sulphur compounds and phosphates, 150 were polluted by both phosphates and crude oil and 28 were polluted by sulphur compounds, phosphates and crude oil. How many of the rivers were polluted by atleast one of the three impurities?
How many of the rivers were polluted by exactly one of the three impurities?

Sol. Let S, P and C denote the sets of rivers polluted by sulphur compounds, by phosphates and by crude oil respectively, and let a, b, c, d, e, f, g denote the elements (impurities) contained in the bounded region as shown in the diagram.



Then, $a + d + e + g = 520$

$c + d + f + g = 425$

$b + e + f + g = 335 \implies d + g = 100$

$e + g = 180 \implies f + g = 150$

$g = 28$

After solving, we get

$g = 28, f = 122, e = 152, b = 33, d = 72, c = 203$ and $a = 268$

The number of rivers were polluted by atleast one of the three impurities

$= (a + b + c + d + e + f + g) = 878$

and the number of rivers were polluted by exactly one of the three impurities,

$a + b + c = 268 + 33 + 203 = 504$

Aliter

Let S, P and C denote the sets of rivers polluted by sulphur compounds, by phosphates and by crude oil, respectively.

Then, we are given that

$n(S) = 520, n(P) = 335, n(C) = 425, n(C \cap S) = 100,$

$n(S \cap P) = 180, n(P \cap C) = 150$ and $n(S \cap P \cap C) = 28.$

The number of rivers polluted by atleast one of the three impurities,

$n(S \cup P \cup C)$

$= n(S) + n(P) + n(C) - n(S \cap P)$

$- n(P \cap C) - n(C \cap S) + n(S \cap P \cap C)$

$= 520 + 335 + 425 - 180 - 150 - 100 + 28 = 878$

and the number of rivers polluted by exactly one of the three impurities,

$n\{(S \cap P' \cap C') \cup (P \cap C' \cap S') \cup (C \cap P' \cap S')$

$= n\{(S \cap (P \cup C)')\} \cup \{P \cap (C \cup S)')\} \cup \{C \cap P \cup S)'\}$

$= n(S \cap (P \cup C)') + n(P \cap (C \cup S)') + n(C \cap (P \cup S)')$

$= n(S) - n(S \cap P) - n(S \cap C)$

$+ n(S \cap P \cap C) + n(P) - n(P \cap C) - n(P \cap S)$

$+ n(S \cap P \cap C)$

$+ n(C) - n(C \cap P) - n(C \cap S) + n(S \cap P \cap C)$

$= n(S) + n(P) + n(C) - 2n(S \cap P) - 2n(S \cap C)$

$- 2n(P \cap C) + 3n(S \cap P \cap C)$

$= 520 + 335 + 425 - 360 - 200 - 300 + 84 = 504$

Exercise for Session 1

1. If $X = \{4^n - 3n - 1 : n \in N\}$ and $y = \{9(n-1) : n \in N\}$, then $X \cup Y$ equals

(a) X (b) Y (c) N (d) None of these

2. If $N_a = \{an : n \in N\}$, then $N_5 \cap N_7$ equals

(a) N (b) N_5 (c) N_7 (d) N_{35}

3. If A and B are two sets, then $A \cap (A \cup B)'$ equals

(a) A (b) B (c) ϕ (d) None of these

4. If U be the universal set and $A \cup B \cup C = U$, then $[(A - B) \cup (B - C) \cup (C - A)']$ equals

(a) $A \cup B \cup C$ (b) $A \cap B \cap C$ (d) $A \cup (B \cap C)$ (d) $A \cap (B \cup C)$

5. If A and B are two sets, then $(A - B) \cup (B - A) \cup (A \cap B)$ equals

(a) $A \cup B$ (b) $A \cap B$ (c) A (d) B'

6. If $A = \{x : x$ is a multiple of 4$\}$ and $B = \{x : x$ is a multiple of 6$\}$, then $A \subset B$ consists of all multiple of

(a) 4 (b) 8 (c) 12 (d) 16

7. A set contains $2n + 1$ elements. The number of subsets of this set containing more than n elements equals

(a) 2^{n-1} (b) 2^n (c) 2^{n+1} (d) 2^{2n}

8. If $A = \{\phi, \{\phi\}\}$, then the power set of A is

(a) A (b) $\{\phi, \{\phi\}, A\}$

(c) $\{\phi, \{\phi\}, \{\{\phi\}\}, A\}$ (d) None of these

9. Given $n(U) = 20, n(A) = 12, n(B) = 9, n(A \cap B) = 4$, where U is the universal set, A and B are subsets of U, then $n((A \cup B)')$ equals

(a) 3 (b) 9 (c) 11 (d) 17

10. A survey shows that 63% of the Indians like cheese, whereas 76% like apples. If x % of the Indians like both cheese and apples, then x can be

(a) 40 (b) 65 (c) 39 (d) None of these

11. In a class of 55 students, the number of students studying different subjects are 23 in Mathematics, 24 in Physics, 19 in Chemistry, 12 in Mathematics and Physics, 9 in Mathematics and Chemistry, 7 in Physics and Chemistry and 4 in all the three subjects. The number of students who have taken exactly one subject is

(a) 6 (b) 7 (c) 9 (d) 22

Session 2

Ordered Pair, Definition of Relation, Ordered Relation, Composition of Two Relations

Ordered Pair

If A be a set and $a, b \in A$, then the ordered pair of elements a and b in A denoted by (a, b), where a is called the first coordinate and b is called the second coordinate.

Remark

1. Ordered pairs (a, b) and (b, a) are different.
2. Ordered pairs (a, b) and (c, d) are equal iff $a = c$ and $b = d$.

Cartesian Product of Two Sets

The cartesian product to two sets A and B is the set of all those ordered pairs whose first coordinate belongs to A and second coordinate belongs to B. This set is denoted by $A \times B$ (read as 'A cross B' or 'product set of A and B').

Symbolically, $A \times B = \{(a, b) : a \in A \text{ and } b \in B\}$

or $A \times B = \{(a, b) : a \in A \wedge b \in B\}$

Thus, $(a, b) \in A \times B \Leftrightarrow a \in A \wedge b \in B$

Similarly, $B \times A = \{(b, a) : b \in B \wedge a \in A\}$

Remark

1. $A \times B \neq B \times A$
2. If A has p elements and B has q elements, then $A \times B$ has pq elements.
3. If $A = \phi$ and $B = \phi$, then $A \times B = \phi$.
4. Cartesian product of n sets $A_1, A_2, A_3, \ldots, A_n$ is the set of all ordered n-tuples $(a_1, a_2, \ldots, a_n)$ $a_i \in A_i$, $i = 1, 2, 3, \ldots, n$ and is denoted by $A_1 \times A_2 \times \ldots \times A_n$ or $\prod_{i=1}^{n} A_i$.

Example 11. ***If*** $A = \{1, 2, 3\}$ ***and*** $B = \{4, 5\}$***, find*** $A \times B$***,*** $B \times A$ ***and show that*** $A \times B \neq B \times A$***.***

Sol. $A \times B = \{1, 2, 3\} \times \{4, 5\} = \{(1, 4), (1, 5), (2, 4), (2, 5), (3, 4), (3, 5)\}$

and $B \times A = \{4, 5\} \times \{1, 2, 3\} = \{(4, 1), (4, 2), (4, 3), (5, 1), (5, 2), (5, 3)\}$

It is clear that $A \times B \neq B \times A$.

Example 12. If A and B be two sets and $A \times B = \{(3, 3), (3, 4), (5, 2), (5, 4)\}$, find A and B.

Sol. A = First coordinates of all ordered pairs = $\{3, 5\}$

and B = Second coordinates of all ordered pairs = $\{2, 3, 4\}$

Hence, $A = \{3, 5\}$ and $B = \{2, 3, 4\}$

Important Theorems on Cartesian Product

If A, B and C are three sets, then

(i) $A \times (B \cup C) = (A \times B) \cup (A \times C)$

(ii) $A \times (B \cap C) = (A \times B) \cap (A \times C)$

(iii) $A \times (B - C) = (A \times B) - (A \times C)$

(iv) $(A \times B) \cap (S \times T) = (A \cap S) \times (B \cap T)$, where S and T are two sets.

(v) If $A \subseteq B$, then $(A \times C) \subseteq (B \times C)$

(vi) If $A \subseteq B$, then $(A \times B) \cap (B \times A) = A^2$

(vii) If $A \subseteq B$ and $C \subseteq D$, then $A \times C \subseteq B \times D$

Example 13. ***If*** A ***and*** B ***are two sets given in such a way that*** $A \times B$ ***consists of 6 elements and if three elements of*** $A \times B$ ***are (1, 5), (2, 3) and (3, 5), what are the remaining elements?***

Sol. Since, $(1, 5), (2, 3), (3, 5) \in A \times B$, then clearly $1, 2, 3 \in A$ and $3, 5 \in B$.

$A \times B = \{1, 2, 3\} \times (3, 5)$

$= (1, 3), (1, 5), (2, 3), (2, 5), (3, 3), (3, 5)$

Hence, the remaining elements are $(1, 3), (2, 5), (3, 3)$.

Relations

Introduction of Relation

We use sentences depending upon the relationship of an object to the other object in our daily life such as

(i) 'Ram, Laxman, Bharat, Shatrughan' were the sons of Dashrath.
(ii) 'Sita' was the wife of Ram.
(iii) 'Laxman' was the brother of Ram.
(iv) 'Dashrath' was the father of Ram.
(v) 'Kaushaliya' was the mother of Ram.

If Ram, Laxman, Bharat, Shatrughan, Sita, Kaushaliya and Dashrath are represented by a, b, c, d, e, f and y respectively and A represents the set, then

$$A = \{a, b, c, d, e, f, y\}$$

Here, we see that any two elements of set A are related many ways, i.e. a, b, c, d are sons of y. 'a' is the son of y is represented by aRy. Similarly, b is the son of y, c is the son of y and d is also son of y are represented as $b\,R\,y$, $c\,R\,y$ and $d\,R\,y$, respectively.

If we write here $y\,R\,a$ it means that y is the son of a which is impossible, since a is the son of y. Hence, y and a cannot be related like this. Its generally represented as $y \not R a$. Hence, we can say that a and y are in definite order. a comes before R and y after R. Therefore, aRy may be represented as a order pair (a, y). Similarly, bRy, cRy and dRy are represented by $(b, y), (c, y)$ and (d, y), respectively. If all pairs will represented by a set, then we see that first element of each pair is the son of second element. Hence, the set of these pairs may be represented by set R, then

$$R = \{(a, y), (b, y), (c, y), (d, y)\}$$

Symbolically, $R = \{(x, y) : x, y \in A$, where x is son of $y\}$

It is clear that R is subset of $A \times A$

i.e., $R \subseteq A \times A$

Corollary In above example, if

$A = \{a, b, c, d\}$ and $B = \{e, f, y\}$, then

$R = \{(x, z) : x \in A, z \in B$, where x is son of $z\}$

It is clear that $R \subseteq A \times B$.

Definition of Relation

A relation (or binary relation) R, from a non-empty set A to another non-empty set B, is a subset of $A \times B$.

i.e., $R \subseteq A \times B$ or $R \subseteq \{(a, b) : a \in A, b \in B\}$

Now, if (a, b) be an element of the relation R, then we write aRb (read as 'a is related to b')

i.e., $(a, b) \in R \Leftrightarrow aRb$

and if (a, b) is not an element of the relation R, then we write $a \not R b$ (read as 'a is not related to b'),

i.e. $(a, b) \notin R \Leftrightarrow a \not R b$.

Remark

1. Any subset of $A \times A$ is said to be a relation on A.
2. If A has m elements and B has n elements, then $A \times B$ has $m \times n$ elements and total number of different relations from A to B is 2^{mn}.
3. If $R = A \times B$, then Domain $R = A$ and Range $R = B$.
4. The domain as well as range of the empty set ϕ is ϕ.
5. If $A = \text{Dom}\, R$ and $B = \text{Ran}\, R$, then we write $B = R\,[A]$.

For example,

Let $A = \{1, 2, 3\}$ and $B = \{3, 5, 7\}$, then
$A \times B = \{(1, 3), (1, 5), (1, 7), (2, 3), (2, 5), (2, 7), (3, 3), (3, 5), (3, 7)\}$.
But $R \subseteq A \times B$
i.e., every subset of $A \times B$ is a relation from A to B. If we consider the relation, $R = \{(1, 5), (1, 7), (3, 5), (3, 7)\}$
Then, $1\,R\,5; 1\,R\,7; 3\,R\,5; 3\,R\,7$
Also, $1\,R\,3; 2\,R\,3; 2\,R\,5; 2\,R\,7; 3\,R\,3;$
Clearly, Domain $R = \{1, 3\}$ and Range $R = \{5, 7\}$

For example,

Let $A = \{1, 2, 3\}$ and $B = \{4, 5\}$, then number of different relations from A to B is $2^{3\times 2} = 2^6 = 64$ because A has 3 elements and B has 2 elements.

Types of Relations from One Set to Another Set

1. Empty Relation

A relation R from A to B is called an empty relation or a void relation from A to B if $R = \phi$.

For example,

Let $A = \{2, 4, 6\}$ and $B = \{7, 11\}$
Let $R = \{(a, b) : a \in A, b \in B$ and $a - b$ is even$\}$
As, none of the numbers $2 - 7, 2 - 11, 4 - 7, 4 - 11, 6 - 7, 6 - 11$ is an even number, $R = \phi$.
Hence, R is an empty relation.

2. Universal Relation

A relation R from A to B is said to be the universal relation, if $R = A \times B$.

For example, Let $A = \{1, 2\}$, $B = \{1, 3\}$ and
$R = \{(1, 1), (1, 3), (2, 1), (2, 3)\}$
Here, $R = A \times B$
Hence, R is the universal relation from A to B.

Types of Relations on a Set

1. Empty Relation

A relation R on a set A is said to be an empty relation or a void relation, if $R = \phi$.

For example,

Let $A = \{1,3\}$ and $R = \{(a, b) : a, b \in A$ and $a + b$ is odd$\}$

Hence, R contains no element, therefore R is an empty relation on A.

2. Universal Relation

A relation R on a set A is said to be universal relation on A, if $R = A \times A$.

For example,

Let $A = \{1, 2\}$

and $R = [(1, 1), (1, 2), (2, 1), (2, 2)]$

Here, $R = A \times A$

Hence, R is the universal relation on A.

3. Identity Relation

A relation R on a set A is said to be the identity relation on A, if

$$R = [(a, b) : a \in A, b \in A \text{ and } a = b]$$

Thus, identity relation, $R = [(a, a) : \forall\, a \in A]$

Identity relation on set A is also denoted by I_A.

Symbolically, $I_A = [(a, a) : a \in A]$

For example,

Let $A = \{1, 2, 3\}$

Then, $I_A = \{(1, 1), (2, 2), (3, 3)\}$

Remark

In an identity relation on A every element of A should be related to itself only.

4. Inverse Relation

If R is a relation from a set A to a set B, then inverse relation of R to be denoted by R^{-1}, is a relation from B to A.

Symbolically, $R^{-1} = \{(b, a) : (a, b) \in R\}$

Thus, $(a, b) \in R \Leftrightarrow (b, a) \in R^{-1}, \forall\, a \in A, b \in B.$

Remark

1. Dom (R^{-1}) = Range (R) and Range (R^{-1}) = Dom (R)
2. $(R^{-1})^{-1} = R$

For example,

If $R = \{(1, 2), (3, 4), (5, 6)\}$, then

$R^{-1} = \{(2, 1), (4, 3), (6, 5)\}$

$\therefore (R^{-1})^{-1} = \{(1, 2), (3, 4), (5, 6)\} = R$

Here, dom $(R) = \{1, 3, 5\}$, range $(R) = \{2, 4, 6\}$

and dom $(R^{-1}) = \{2, 4, 6\}$, range $(R^{-1}) = \{1, 3, 5\}$

Clearly, dom (R^{-1}) = range (R)

and range (R^{-1}) = dom (R).

Various Types of Relations

1. Reflexive Relation

A relation R on a set A is said to be reflexive, if $a\, R\, a, \forall\, a \in A$

i.e., if $(a, a) \in R, \forall\, a \in A$

For example,

Let $A = \{1, 2, 3\}$

$R_1 = \{(1, 1), (2, 2), (3, 3)\}$

$R_2 = \{(1, 1), (2, 2), (3, 3), (1, 2), (2, 1), (1, 3)\}$

and $R_3 = \{(1, 1), (2, 2), (2, 3), (3, 2)\}$

Here, R_1 and R_2 are reflexive relations on A, R_3 is not a reflexive relation on A as $(3, 3) \notin R_3$, i.e. $3 \not R_3\ 3$.

Remark

The identity relation is always a reflexive relation but a reflexive relation may or may not be the identity relation. It is clear in the above example given, R_1 is both reflexive and identity relation on A but R_2 is a reflexive relation on A but not an identity relation on A.

2. Symmetric Relation

A relation R on a set A is said to be symmetric relation, if

$$a\, R\, b \Rightarrow b\, R\, a, \forall\, a, b \in A$$

i.e., if $(a, b) \in R \Rightarrow (b, a) \in R, \forall\, a, b \in A$

For example,

Let $A = \{1, 2, 3\}$

$R_1 = \{(1, 2), (2, 1)\}$

$R_2 = \{(1, 2), (2, 1), (1, 3), (3, 1)\}$

and $R_3 = \{(2, 3), (1, 3), (3, 1)\}$

Here, R_1 and R_2 are symmetric relations on A but R_3 is not a symmetric relation on A because $(2, 3) \in R_3$ and $(3, 2) \notin R_3$.

3. Anti-symmetric Relation

A relation R on a set A is said to be anti-symmetric,

if $a\, R\, b, b\, R\, a \Rightarrow a = b, \forall\, a, b \in A$

i.e., $(a, b) \in R$ and $(b, a) \in R \Rightarrow a = b, \forall\, a, b \in A$

For example,

Let R be the relation in N (natural number) defined by, ''x is divisor of y'', then R is anti-symmetric because x divides y and y divides $x \Rightarrow x = y$

4. Transitive Relation

A relation R on a set A is said to be a transitive relation, if $a\,R\,b$ and $b\,R\,c \Rightarrow aRc, \forall\ a, b, c \in A$

i.e., $(a, b) \in R$ and $(b, c) \in R \Rightarrow (a, c) \in R, \forall\ a, b, c \in A$

For example,

Let $A = \{1, 2, 3\}$

$R_1 = \{(1, 2), (2, 3), (1, 3), (3, 2)\}$

$R_2 = \{(2, 3), (3, 1)\}$

$R_3 = \{(1, 3), (3, 2), (1, 2)\}$

Then, R_1 is not transitive relation on A because $(2, 3) \in R_1$ and $(3, 2) \in R_1$ but $(2, 2) \notin R_1$. Again, R_2 is not transitive relation on A because $(2, 3) \in R_2$ and $(3, 1) \in R_2$ but $(2, 1) \notin R_2$. Finally R_3 is a transitive relation.

Example 14. ***Let*** $A = \{1, 2, 3\}$ ***and*** $R = \{(a, b) : a, b \in A,$ a ***divides*** b ***and*** b ***divides*** $a\}$***. Show that*** R ***is an identity relation on*** A***.***

Sol. Given, $A = \{1, 2, 3\}$

$a \in A, b \in B, a$ divides b and b divides a.

$\Rightarrow \quad a = b$

$\therefore \quad R = \{(a, a), a \in A\} = \{(1, 1), (2, 2), (3, 3)\}$

Hence, R is the identity relation on A.

Example 15. Let $A = \{3, 5\}, B = \{7, 11\}$.
Let $R = \{(a, b) : a \in A, b \in B, a - b$ is even$\}$.
Show that R is an universal relation from A to B.

Sol. Given, $A = \{3, 5\}, B = \{7, 11\}$.

Now, $R = \{(a, b) : a \in A, b \in B$ and $a - b$ is even$\}$
$= \{(3, 7), (3, 11), (5, 7), (5, 11)\}$

Also, $A \times B = \{(3, 7), (3, 11), (5, 7), (5, 11)\}$

Clearly, $R = A \times B$

Hence, R is an universal relation from A to B.

Example 16. Prove that the relation R defined on the set N of natural numbers by $xRy \Leftrightarrow 2x^2 - 3xy + y^2 = 0$ is not symmetric but it is reflexive.

Sol. (i) $2x^2 - 3x \cdot x + x^2 = 0, \forall\ x \in N$.

$\therefore\ x\ R\ x, \forall\ x \in N$, i.e. R is reflexive.

(ii) For $x = 1, y = 2, 2x^2 - 3xy + y^2 = 0$

$\therefore\ 1R2$

But $2 \cdot 2^2 - 3 \cdot 2 \cdot 1 + 1^2 = 3 \neq 0$

So, 2 is not related to 1 i.e., $2 \not R 1$

$\therefore$ R is not symmetric.

Example 17. Let N be the set of natural numbers and relation R on N be defined by $x\,R\,y \Leftrightarrow x$ divides y, $\forall\ x, y \in N$.
Examine whether R is reflexive, symmetric, anti-symmetric or transitive.

Sol. (i) x divides x i.e., $x\,R\,x, \forall\ x \in N$

$\therefore$ R is reflexive.

(ii) 1 divides 2 i.e., $1\ R\ 2$ but $2 \not R\ 1$ as 2 does not divide 1.

(iii) x divides y and y divides $x \Rightarrow x = y$

i.e., $x\,R\,y$ and $y\,R\,x \Rightarrow x = y$

$\therefore$ R is anti-symmetric relation.

(iv) $x\,R\,y$ and $y\,R\,z \Rightarrow x$ divides y and y divides z.

$\Rightarrow kx = y$ and $k'y = 2$, where k, k' are positive integers.

$\Rightarrow\ kk'x = z\ \Rightarrow\ x$ divides $z\ \Rightarrow\ x\,R\,z$

$\therefore$ R is transitive.

Equivalence Relation

A relation R on a set A is said to be an equivalence relation on A, when R is (i) reflexive (ii) symmetric and (iii) transitive. The equivalence relation denoted by ~.

Example 18. N ***is the set of natural numbers. The relation*** R ***is defined on*** $N \times N$ ***as follows***

$(a, b)\,R\,(c, d) \Leftrightarrow a + d = b + c$

Prove that R ***is an equivalence relation.***

Sol. (i) $(a, b)\,R\,(a, b) \Rightarrow a + b = b + a$

$\therefore$ R is reflexive.

(ii) $(a, b)\,R\,(c, d) \Rightarrow a + d = b + c$

$\Rightarrow \quad c + b = d + a\ \Rightarrow\ (c, d)\,R\,(a, b)$

$\therefore$ R is symmetric.

(iii) $(a, b)\,R\,(c, d)$ and $(c, d)\,R\,(e, f) \Rightarrow a + d = b + c$ and $c + f = d + e$

$\Rightarrow\ a + d + c + f = b + c + d + e$

$\Rightarrow \quad a + f = b + e\ \Rightarrow (a, b)\,R\,(e, f)$

$\therefore$ R is transitive.

Thus, R is an equivalence relation on $N \times N$.

Example 19. A relation R on the set of complex numbers is defined by $z_1\,R\,z_2 \Leftrightarrow \dfrac{z_1 - z_2}{z_1 + z_2}$ is real, show that R is an equivalence relation.

Sol. (i) $z_1 R z_1 \Rightarrow \dfrac{z_1 - z_1}{z_1 + z_1}, \forall z_1 \in C\ \Rightarrow\ 0$ is real

$\therefore$ R is reflexive.

(ii) $z_1 R z_2 \Rightarrow \dfrac{z_1 - z_2}{z_1 + z_2}$ is real

$\Rightarrow -\left(\dfrac{z_2 - z_1}{z_1 + z_2}\right)$ is real $\Rightarrow \left(\dfrac{z_2 - z_1}{z_1 + z_2}\right)$ is real

$\Rightarrow z_2 R z_1, \forall z_1, z_2 \in C$

$\therefore$ R is symmetric.

(iii) $\because z_1 R z_2 \Rightarrow \dfrac{z_1 - z_2}{z_1 + z_2}$ is real

$\Rightarrow \left(\overline{\dfrac{z_1 - z_2}{z_1 + z_2}}\right) = -\left(\dfrac{z_1 - z_2}{z_1 + z_2}\right)$

$\Rightarrow \left(\dfrac{\bar{z}_1 - \bar{z}_2}{\bar{z}_1 + \bar{z}_2}\right) + \left(\dfrac{z_1 - z_2}{z_1 + z_2}\right) = 0$

$\Rightarrow 2(z_1\bar{z}_1 - z_2\bar{z}_2) = 0 \Rightarrow |z_1|^2 = |z_2|^2$ ...(i)

Similarly, $z_2 R z_2 \Rightarrow |z_2|^2 = |z_3|^2$ ...(ii)

From Eqs. (i) and (ii), we get

$z_1 R z_2, z_2 R z_3$

$\Rightarrow |z_1|^2 = |z_3|^2$

$\Rightarrow z_1 R z_3$

$\therefore R$ is transitive.

Hence, R is an equivalence relation.

Ordered Relation

A relation R is called ordered, if R is transitive but not an equivalence relation.

Symbolically, $a R b, b R c \Rightarrow a R c, \forall a, b, c \in A$

For example,

Let $R = \{(1,2),(2,1),(2,3),(3,2),(1,3)\}$.

Here, R is symmetric.

Since, $(1,2) \in R \Rightarrow (2,1) \in R, (2,3) \in R \Rightarrow (3,2) \in R$

and R is transitive.

Since, $(1,2) \in R, (2,3) \in R \Rightarrow (1,3) \in R$

but R is not reflexive.

Since, $(1,1) \notin R, (2,2) \notin R, (3,3) \notin R$

Hence, R is not an equivalence relation.

$\therefore$ R is an ordered relation.

Partial Order Relation

A relation R is called partial order relation, if R is reflexive, transitive and anti-symmetric at the same time.

For example,

Let $R = \{(1,1),(2,2),(3,3),(1,2),(2,3),(1,3)\}$

$\therefore$ $R^{-1} = \{(1,1),(2,2),(3,3),(2,1),(3,2),(3,1)\}$

$R \cap R^{-1} = \{(1,1),(2,2),(3,3)\}$ = Identity

$\therefore$ R is anti-symmetric.

It is clear that R is reflexive.

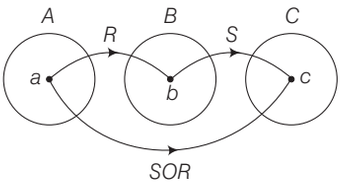
Since, $(1,1) \in R, (2,2) \in R, (3,3) \in R$ and R is transitive.

Since, $(1,2) \in R$ and $(2,3) \in R \Rightarrow (1,3) \in R$

Hence, R is partial order relation.

Composition of Two Relations

If A, B and C are three sets such that $R \subseteq A \times B$ and $S \subseteq B \times C$, then $(SOR)^{-1} = R^{-1}OS^{-1}$. It is clear that aRb, $bSc \Rightarrow aSORc$.



More generally,

$(R_1 O R_2 O R_3 O \ldots O R_n)^{-1} = R_n^{-1} O \ldots O R_3^{-1} O R_2^{-1} O R_1^{-1}$

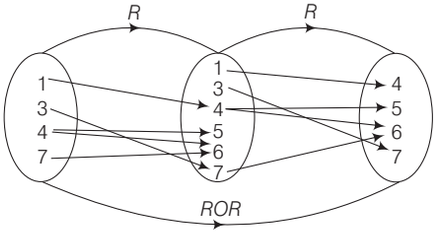
Example 20. ***Let R be a relation such that $R = \{(1,4),(3,7),(4,5),(4,6),(7,6)\}$, find***

(i) $R^{-1}OR^{-1}$ and (ii) $(R^{-1}OR)^{-1}$.

Sol. (i) We know that, $(ROR)^{-1} = R^{-1}OR^{-1}$

Dom $(R) = \{1, 3, 4, 7\}$

Range $(R) = \{4, 5, 6, 7\}$



We see that,

$1 \longrightarrow 4 \longrightarrow 5 \Rightarrow (1,5) \in ROR$

$1 \longrightarrow 4 \longrightarrow 6 \Rightarrow (1,6) \in ROR$

$3 \longrightarrow 7 \longrightarrow 6 \Rightarrow (3,6) \in ROR$

$\therefore$ $ROR = \{(1,5),(1,6),(3,6)\}$

Then, $R^{-1}OR^{-1} = (ROR)^{-1}$

$= \{(5,1),(6,1),(6,3)\}$

(ii) We know that, $(R^{-1}OR)^{-1} = R^{-1}O(R^{-1})^{-1} = R^{-1}OR$

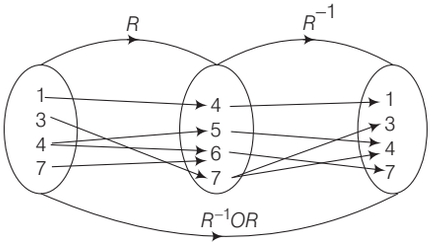
Since,

$R = \{(1,4),(3,7),(4,5),(4,6),(7,6)\}$

$\therefore$ $R^{-1} = \{(4,1),(7,3),(5,4),(6,4),(6,7)\}$

$\therefore$ Dom $(R) = \{1, 3, 4, 7\}$, Range $(R) = \{4, 5, 6, 7\}$

$\text{Dom}(R^{-1}) = \{4, 5, 6, 7\}$, $\text{Range}(R^{-1}) = \{1, 3, 4, 7\}$



We see that,

$1 \xrightarrow{R} 4 \xrightarrow{R^{-1}} 1 \Rightarrow (1, 1) \in R^{-1}OR$

$3 \xrightarrow{R} 7 \xrightarrow{R^{-1}} 3 \Rightarrow (3, 3) \in R^{-1}OR$

$4 \xrightarrow{R} 5 \xrightarrow{R^{-1}} 4 \Rightarrow (4, 4) \in R^{-1}OR$

$4 \xrightarrow{R} 6 \xrightarrow{R^{-1}} 4 \Rightarrow (4, 4) \in R^{-1}OR$

$4 \xrightarrow{R} 6 \xrightarrow{R^{-1}} 7 \Rightarrow (4, 7) \in R^{-1}OR$

$7 \xrightarrow{R} 6 \xrightarrow{R^{-1}} 4 \Rightarrow (7, 4) \in R^{-1}OR$

$7 \xrightarrow{R} 6 \xrightarrow{R^{-1}} 7 \Rightarrow (7, 7) \in R^{-1}OR$

$\therefore\ R^{-1}OR = \{(1, 1), (3, 3), (4, 4), (7, 7), (4, 7), (7, 4)\}$

Hence, $(R^{-1}OR)^{-1} = R^{-1}OR = \{(1, 1), (3, 3)$
$(4, 4), (7, 7), (4, 7), (7, 4)\}$

Theorems on Binary Relations

If R is a relation on a set A, then

(i) R is reflexive $\Rightarrow R^{-1}$ is reflexive.

(ii) R is symmetric $\Rightarrow R^{-1}$ is symmetric.

(iii) R is transitive $\Rightarrow R^{-1}$ is transitive.

Exercise for Session 2

1. If $A = \{2,3,5\}$, $B = \{2,5,6\}$, then $(A - B) \times (A \cap B)$ is

(a) {(3, 2), (3, 3), (3, 5)} (b) {(3, 2), (3, 5), (3, 6)}
(c) {(3, 2), (3, 5)} (d) None of these

2. If $n(A) = 4$, $n(B) = 3$, $n(A \times B \times C) = 24$, then $n(C)$ equals

(a) 1 (b) 2 (c) 17 (d) 288

3. The relation R defined on the set of natural numbers as $\{(a, b) : a \text{ differs from } b \text{ by } 3\}$ is given by

(a) {(1, 4), (2, 5), (3, 6), ...} (b) {(4, 1), (5, 2), (6, 3), ...} (c) {(1, 3), (2, 6), (3, 9), ...} (d) None of these

4. Let A be the non-void set of the children in a family. The relation 'x is a brother of y' on A, is

(a) reflexive (b) anti-symmetric (c) transitive (d) equivalence

5. Let $n(A) = n$, then the number of all relations on A, is

(a) 2^n (b) $2^{n!}$ (c) 2^{n^2} (d) None of these

6. If $S = \{1, 2, 3, \ldots, 20\}$, $K = \{a, b, c, d\}$, $G = \{b, d, e, f\}$. The number of elements of $(S \times K) \cup (S \times G)$ is

(a) 40 (b) 100 (c) 120 (d) 140

7. The relation R is defined on the set of natural numbers as $\{(a, b) : a = 2b\}$, then R^{-1} is given by

(a) {(2, 1) (4, 2) (6, 3), …} (b) {(1, 2) (2, 4) (3, 6), …} (c) R^{-1} is not defined (d) None of these

8. The relation $R = \{(1, 1), (2, 2), (3, 3), (1, 2), (2, 3), (1, 3)\}$ on set $A = \{1, 2, 3\}$ is

(a) reflexive but not symmetric (b) reflexive but not transitive
(c) symmetric and transitive (d) Neither symmetric nor transitive

9. The number of equivalence relations defined in the set $S = \{a, b, c\}$ is

(a) 5 (b) 3! (c) 2^3 (d) 3^3

10. If R be a relation $<$ from $A = \{1, 2, 3, 4\}$ to $B = \{1, 3, 5\}$, i.e. $(a, b) \in R \Leftrightarrow a < b$, then ROR^{-1}, is

(a) {(1, 3), (1, 5), (2, 3), (2, 5), (3,5), (4, 5)} (b) {(3, 1), (5, 1), (3, 2), (5, 2), (5, 3), (5, 4)}
(c) {(3, 3), (3, 5), (5, 3), (5, 5)} (d) {(3, 3), (3, 4), (4, 5)}

Session 3

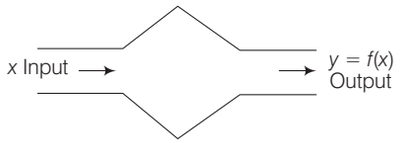
Definition of Functions, Domain, Codomain and Range, Composition of Mapping, Equivalence Classes, Partition of Set, Congruences

Functions

Introduction

If two variable quantities x and y according to some law are so related that corresponding to each value of x (considered only real), which belongs to set E, there corresponds one and only one finite value of the quantity y (i.e., unique value of y). Then, y is said to be a function (single valued) of x, defined by $y = f(x)$, where x is the **argument** or **independent variable** and y is the **dependent variable** defined on the set E.

For example, If r is the radius of the circle and A its area, then r and A are related by $A = \pi r^2$ or $A = f(r)$. Then, we say that the area A of the circle is the function of the radius r. **Graphically**,



Where, y is the image of x and x is the pre-image of y under f.

Remark

1. If to each value of x, which belongs to set E there corresponds one or more than one values of the quantity y. Then, y is called the multiple valued function of x defined on the set E.
2. The word 'FUNCTION' is used only for single valued function. *For example,* $y = \sqrt{x}$ is single valued functions but $y^2 = x$ is a multiple valued function.
   $\therefore\ y^2 = x \Rightarrow y = \pm\sqrt{x}$ for one value of x, y gives two values.

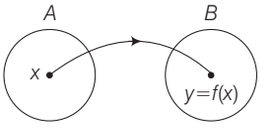
Definition of Functions

If A and B be two non-empty sets, then a function from A to B associates to each element x in A, a unique element $f(x)$ in B and is written as

$$f : A \to B \text{ or } A \xrightarrow{f} B$$

which is read as f is a mapping from A to B.

The other terms used for functions are **operators** or **transformations.**



Remark

1. If $x \in A$, $y = [f(x)] \in B$, then $(x, y) \in f$.
2. If $(x_1, y_1) \in f$ and $(x_2, y_2) \in f$, then $y_1 = y_2$.

Domain, Codomain and Range

Domain The set of A is called the domain of f (denoted by D_f).

Codomain The set of B is called the codomain of f (denoted by C_f).

Range The range of f denoted by R_f is the set consisting of all the images of the elements of the domain A.

Range of $f = [f(x) : x \in A]$

The range of f is always a subset of codomain B.

Onto and Into Mappings

In the mapping $f : A \to B$ such

$$f(A) = B$$

i.e., Range = Codomain

Then, the function is **Onto** and if $f(A) \subset B$, i.e. Range $\subset$ Codomain, then the function is **Into**.

Remark

Onto functions is also known as **surjective.**

Method to Test Onto or Into Mapping

Let $f : A \to B$ be a mapping. Let y be an arbitrary element in B and then $y = f(x)$, where $x \in A$. Then, express x in terms of y.

Now, if $x \in A, \forall\, y \in B$, then f is onto

and if $x \notin A, \forall\, y \in B$, then f is into.

For into mapping Find an element of B which is not f-image of any element of A.

One-one and Many-one Mapping

(i) The mapping $f : A \to B$ is called one-one mapping, if no two different elements of A have the same image in B. Such a mapping is also known as **injective mapping** or an **injection** or **monomorphism.**

Method to Test One-one If $x_1, x_2 \in A$,

then $f(x_1) = f(x_2)$

$\Rightarrow$ $x_1 = x_2$ and $x_1 \neq x_2$

$\Rightarrow$ $f(x_1) \neq f(x_2)$

(ii) The mapping $f : A \to B$ is called many-one mapping, if two or more than two different elements in A have the same image in B.

Method to Test Many-one

If $x_1, x_2 \in A$, then $f(x_1) = f(x_2)$

$\Rightarrow$ $x_1 \neq x_2$

From above classification, we conclude that function is of four types

(i) One-one onto (bijective)

(ii) One-one into

(iii) Many-one onto

(iv) Many-one into

Number of Functions (Mappings) at One Place in a Table

Let $f : A \to B$ be a mapping such that A and B are finite sets having m and n elements respectively, then

	Description of mappings
(i)	Total number of mappings from A to B
(ii)	Total number of one-one mappings from A to B
(iii)	Total number of many-one mappings from A to B
(iv)	Total number of onto (surjective) mappings from A to B
(v)	Total number of one-one onto (bijective) mappings from A to B
(vi)	Total number of into mappings from A to B

Example 21. Let N be the set of all natural numbers. Consider $f : N \to N : \ f(x) = 2x, \forall\, x \in N$. Show that f is one-one into.

Sol. Let $x_1, x_2 \in N$, then

$f(x_1) = f(x_2)$

$\Rightarrow$ $2x_1 = 2x_2 \ \Rightarrow \ x_1 = x_2$

$\therefore$ f is one-one.

Let $y = 2x$, then $x = \dfrac{y}{2}$

Now, if we put $y = 5$, then $x = \dfrac{5}{2} \notin N$.

This show that $5 \in N$ has no pre-image in N. So, f is into.

Hence, f is one-one and into.

Example 22. Show that the mapping $f : R \to R : f(x) = \cos x, \forall\, x \in R$ is neither one-one nor onto.

Sol. Let $x_1, x_2 \in R$.

Then, $f(x_1) = f(x_2) \ \Rightarrow \cos x_1 = \cos x_2$

$\Rightarrow$ $x_1 = 2n\pi \pm x_2 \ \Rightarrow \ x_1 \neq x_2$

$\therefore$ f is not one-one.

Let $y = \cos x$, but $-1 \leq \cos x \leq 1$

$\therefore$ $y \in [-1, 1]$

$[-1, 1] \subset R$

So, f is into (not onto).

Hence, f is neither one-one nor onto.

Constant Mapping

The mapping $f : A \to B$ is known as a constant mapping, if the range of B has only one element.

For all $x \in A$, $f(x) = a$, where as $a \in B$.

Identity Mapping

The mapping $f : A \to B$ is known as an identity mapping, if $f(a) = a, \forall\, a \in A$ and it is denoted by I_A.

Remark

I_A is bijective or bijection.

Equal Mapping

Let A and B be two mappings are $f : A \to B$ and $g : A \to B$ such that

$$f(x) = g(x), \forall\, x \in A$$

Then, the mappings f and g are equal and written as $f = g$.

Inclusion Mapping

The mapping $f : A \to B$ is known as inclusion mapping.

If $A \subseteq B$, then $f(a) = a, \forall\, a \in A$.

Equivalent or Equipotent or Equinumerous Set

The mapping $f : A \to B$ is known as equivalent sets, if A and B are both one-one and onto and written as $A \sim B$ which is read as 'A wiggle B'.

Inverse Mapping

If $f : A \to B$ be one-one and onto mapping, let $b \in B$, then there exist exactly one element $a \in A$ such that $f(a) = b$, so we may define

$$f^{-1} : B \to A : f^{-1}(b) = a$$
$$\Leftrightarrow \qquad f(a) = b$$

The function f^{-1} is called the inverse of f. A functions is invertible iff f is one-one onto.

Remark

1. $f^{-1}(b) \subseteq A$
2. If $f : A \to B$ and $g : B \to A$, then f and g are said to be invertible.

Example 23. Let $f : R \to R$ be defined by $f(x) = \cos(5x + 2)$. Is f invertible? Justify your answer.

Sol. For invertible of f, f must be bijective (i.e., one-one onto).

If $x_1, x_2 \in R$,

then $f(x_1) = f(x_2)$

$\Rightarrow \cos(5x_1 + 2) = \cos(5x_2 + 2)$

$\Rightarrow 5x_1 + 2 = 2n\pi \pm (5x_2 + 2)$

$\Rightarrow x_1 \neq x_2$

$\therefore$ f is not one-one.

But $-1 \le \cos(5x + 2) \le 1$

$\therefore -1 \le f(x) \le 1$

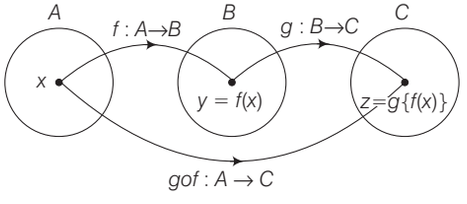
$\text{Range} = [-1, 1] \subset R$

$\therefore$ f is into mapping.

Hence, the function $f(x)$ is no bijective and so it is not invertible.

Composition of Mapping

Let A, B and C be three non-empty sets. Let $f : A \to B$ and $g : B \to C$ be two mappings, then $gof : A \to C$. This function is called the product or composite of f and g, given by $(gof)x = g\{f(x)\}, \forall\ x \in A$.



Important Remarks

1. (i) $(fog)x = f\{g(x)\}$ (ii) $(fof)x = f\{f(x)\}$
   (iii) $(gog)x = g\{g(x)\}$ (iv) $(fg)x = f(x) \cdot g(x)$
   (v) $(f \pm g)x = f(x) \pm g(x)$ (vi) $\left(\frac{f}{g}\right)x = \frac{f(x)}{g(x)}; g(x) \neq 0$
2. Let $h : A \to B$, $g : B \to C$ and $f : C \to D$ be any three functions. Then, $(fog)oh = fo(goh)$.
3. Let $f : A \to B$, $g : B \to C$ be two functions, then
   (i) f and g are injective $\Rightarrow gof$ is injective.
   (ii) f and g are surjective $\Rightarrow gof$ is surjective.
   (iii) f and g are bijective $\Rightarrow gof$ is bijective.
4. An injective mapping from a finite set to itself in bijective.

Example 24. If $f : R \to R$ and $g : R \to R$ be two mapping such that $f(x) = \sin x$ and $g(x) = x^2$, then
(i) prove that $fog \neq gof$.
(ii) find the values of $(fog)\frac{\sqrt{\pi}}{2}$ and $(gof)\left(\frac{\pi}{3}\right)$.

Sol. (i) Let $x \in R$

$\therefore \quad (fog)x = f\{g(x)\} \qquad [\because g(x) = x^2]$

$= f\{x^2\} = \sin x^2 \qquad \ldots(i)$

$[\because f(x) = \sin x]$

and $(gof)x = g\{f(x)\}$

$= g(\sin x) \qquad [\because f(x) = \sin x]$

$= \sin^2 x \qquad \ldots(ii)$

$[\because g(x) = x^2]$

From Eqs. (i) and (ii), we get $(fog)x \neq (gof)x, \forall\ x \in R$

Hence, $fog \neq gof$

(ii) From Eq. (i), $(fog)x = \sin x^2$

$\therefore \quad (fog)\frac{\sqrt{\pi}}{2} = \sin\frac{\pi}{4} = \frac{1}{\sqrt{2}}$

and from Eq. (ii), $(gof)x = \sin^2 x$

$\therefore \quad (gof)\frac{\pi}{3} = \sin^2\frac{\pi}{3} = \left(\frac{\sqrt{3}}{2}\right)^2 = \frac{3}{4}$

Example 25. If the mapping f and g are given by

$f = \{(1, 2), (3, 5), (4, 1)\}$

and $g = \{(2, 3), (5, 1), (1, 3)\}$,

write down pairs in the mapping fog and gof.

Sol. Domain $f = \{1, 3, 4\}$, Range $f = \{2, 5, 1\}$

Domain $g = \{2, 5, 1\}$, Range $g = \{1, 3\}$

$\because$ Range f = Dom $g = \{(2, 5, 1)\}$

$\therefore$ gof mapping is defined.

Then, gof mapping defined following way

$$\{1, 3, 4\} \xrightarrow{f} \{2, 5, 1\} \xrightarrow{g} \{1, 3\}$$
$$gof$$

We see that, $f(1) = 2,\ f(3) = 5,\ f(4) = 1$

and $g(2) = 3,\ g(5) = 1,\ g(1) = 3$

$\therefore \quad (gof)(1) = g\{f(1)\} = g(2) = 3$

$(gof)(3) = g\{f(3)\} = g(5) = 1$

$$(gof)(4) = g\{f(4)\} = g(1) = 3$$

Hence, $gof = \{(1, 3), (3, 1), (4, 3)\}$

Now, since Range of $f \subset$ Dom f

$\therefore$ fog is defined.

Then, fog mapping defined following way

$$\{2, 5, 1\} \xrightarrow{g} \{1, 3, 4\} \xrightarrow{f} \{2, 5, 1\}$$

$$fog$$

We see that, $g(2) = 3,\ g(5) = 1,\ g(1) = 3$

$$f(1) = 2,\ f(3) = 5,\ f(4) = 1$$

$\therefore$ $(fog)(2) = f\{g(2)\} = f(3) = 5$

$(fog)(5) = f\{g(5)\} = f(1) = 2$

$(fog)(1) = f\{g(1)\} = f(3) = 5$

Hence, $fog = \{(2,5),(5,2),(1,5)\}$

Equivalence Classes

If R be an equivalence relation on a set A, then $[a]$ is equivalence class of a with respect to R.

Symbolically, X_a or $[a] = \{x : x \in X, x\ R\ a\}$.

Remark

1. Square brackets[ ] are used to denote the equivalence classes.
2. $a \in [a]$ and $a \in [b] \Rightarrow [a] = [b]$
3. Either $[a] = [b]$ or $[a] \cap [b] = \phi$
4. Equivalence class of a also denoted by $E(a)$ or $\bar{a}$.
5. If $a \sim b$, $\frac{(a-b)}{m} = k$, the total number of equivalence class is m.

Example 26. Let $I = \{0, \pm 1, \pm 2, \pm 3, \pm 4, \ldots\}$ and $R = \{(a,b) : (a-b)/4 = k, k \in I\}$ is an equivalence relation, find equivalence class.

Sol. Given, $\frac{a-b}{4} = k$

$\Rightarrow$ $a = 4k + b$, where $0 \le b < 4$

It is clear b has only value in 0, 1, 2, 3.

(i) Equivalence class of $[0] = \{x : x \in I \text{ and } x \sim 0\}$
$= \{x : x - 0 = 4k\} = \{0, \pm 4, \pm 8, \pm 12, \ldots)$
where, $k = 0, \pm 1, \pm 2, \pm 3, \ldots$

(ii) Equivalence class of $[1] = \{x : x \in I \text{ and } x \sim 1\}$
$= \{x : x - 1 = 4k\} = \{x : x = 4k + 1\}$
$= \{\ldots, -11, -7, -3, 1, 5, 9, \ldots\}$

(iii) Equivalence class of $[2] = \{x : x \in I \text{ and } x \sim 2\}$
$= \{x : x - 2 = 4k\} = \{x : x = 4k + 2\}$
$= \{\ldots, -10, -6, -2, 2, 6, 10, \ldots\}$

(iv) Equivalence class of $[3] = \{x : x \in I \text{ and } x \sim 3\}$
$= \{x : x - 3 = 4k\} = \{x : x = 4k + 3\}$
$= \{\ldots, -9, -5, -1, 5, 9, 13, \ldots\}$

Continue this process, we see that the equivalence class

$$[4] = [0], [5] = [1], [6] = [2], [7] = [3], [8] = [0]$$

Hence, total equivalence relations are [0], [1], [2], [3] and also clear

(i) $I = [0] \cup [1] \cup [2] \cup [3]$
(ii) every equivalence is a non-empty.
(iii) for any two equivalence classes $[a] \cap [b] = \phi$.

Partition of a Set

If A be a non-empty set, then a partition of A, if

(i) A is a collection of non-empty disjoint subsets of A.
(ii) union of collection of non-empty sets is A.

i.e., If A be a non-empty set and A_1, A_2, A_3, A_4 are subsets of A, then the set $\{A_1, A_2, A_3, A_4\}$ is called partition, if

(i) $A_1 \cup A_2 \cup A_3 \cup A_4 = A$
(ii) $A_1 \cap A_2 \cap A_3 \cap A_4 = \phi$

For example,

If $A = \{0, 1, 2, 3, 4\}$ and $A_1 = \{0\}, A_2 = \{1\}, A_3 = \{4\}$ and $A_4 = \{2, 3\}$, then we see that for $P = \{A_1, A_2, A_3, A_4\}$

(i) all A_1, A_2, A_3, A_4 are non-empty subset of A
(ii) $A_1 \cup A_2 \cup A_3 \cup A_4 = \{0, 1, 2, 3, 4\} = A$ and
(iii) $A_i \cap A_j \ne \phi, \forall\ i \ne j\ (i, j = 1, 2, 3, 4)$
Hence, from definition $P = \{A_1, A_2, A_3, A_4\}$ is partition of A.

Congruences

Let m be a positive integer, then two integers a and b are said to be congruent modulo m, if $a - b$ is divisible by m.

i.e., $m \overline{)\ a - b\ (\lambda}$

$$\begin{array}{r} a - b \\ \underline{-\ \ +} \\ 0 \end{array}$$

$\therefore$ $a - b = m\lambda$, where λ is a positive integer.

The congruent modulo 'm' is defined on all $a\ b \in I$ by $a \equiv b \pmod m$, if $a - b = m\lambda$, $\lambda \in I_+$.

Example 27. Find congruent solutions of $155 \equiv 7 \pmod 4$.

Sol. Since, $\left(\frac{155-7}{4} = \frac{148}{4} = 37\right)$

and $a = 155, b = 7, m = 4$

$\therefore$ $\lambda = \frac{a-b}{4} = \frac{155-7}{4} = \frac{148}{4}$

[here, $a = 155, b = 7$]

$= 37$ (integer)

Example 28. Find all congruent solutions of $8x \equiv 6 \pmod{14}$.

Sol. Given, $8x \equiv 6 \pmod{14}$

$$\therefore \quad \lambda = \frac{8x-6}{14}, \text{ where } \lambda \in I_+$$

$$\therefore \quad 8x = 14\lambda + 6$$

$$\Rightarrow \quad x = \frac{14\lambda + 6}{8}$$

$$\Rightarrow \quad x = \frac{7\lambda + 3}{4}$$

$$= \frac{4\lambda + 3(\lambda + 1)}{4}$$

$$x = \lambda + \frac{3}{4}(\lambda + 1), \text{ where } \lambda \in I_+$$

and here greatest common divisor of 8 and 14 is 2, so there are two required solutions.

For $\lambda = 3$ and 7, $x = 6$ and 13.

Exercise for Session 3

1. The values of b and c for which the identity $f(x+1) - f(x) = 8x + 3$ is satisfied, where $f(x) = bx^2 + cx + d$, are

(a) $b = 2, c = 1$ (b) $b = 4, c = -1$ (c) $b = -1, c = 4$ (d) $b = -1, c = 1$

2. If $f(x) = \frac{x-1}{x+1}$, then $f(ax)$ in terms of $f(x)$ is equal to

(a) $\frac{f(x)+a}{1+af(x)}$ (b) $\frac{(a-1)f(x)+a+1}{(a+1)f(x)+a-1}$ (c) $\frac{(a+1)f(x)+a-1}{(a-1)f(x)+a+1}$ (d) None of these

3. If f be a function satisfying $f(x+y) = f(x) + f(y)$, $\forall\, x, y \in R$. If $f(1) = k$, then $f(n)$, $n \in N$ is equal to

(a) k^n (b) nk (c) k (d) None of these

4. If $g = \{(1,1), (2,3), (3,5), (4,7)\}$ is a function described by the formula $g(x) = \alpha x + \beta$, what values should be assigned to α and β?

(a) $\alpha = 1, \beta = 1$ (b) $\alpha = 2, \beta = -1$ (c) $\alpha = 1, \beta = -2$ (d) $\alpha = -2, \beta = -1$

5. The values of the parameter α for which the function $f(x) = 1 + \alpha x$, $\alpha \neq 0$ is the inverse of itself, is

(a) -2 (b) -1 (c) 1 (d) 2

6. If $f(x) = (a - x^n)^{1/n}$, where $a > 0$ and $n \in N$, then $fof(x)$ is equal to

(a) a (b) x (c) x^n (d) a^n

7. If $f(x) = (ax^2 + b)^3$, the function g such that $f(g(x)) = g(f(x))$, is given by

(a) $g(x) = \left(\frac{b - x^{1/3}}{a}\right)^{1/2}$ (b) $g(x) = \frac{1}{(ax^2+b)^3}$ (c) $g(x) = (ax^2 + b)^{1/3}$ (d) $g(x) = \left(\frac{x^{1/3} - b}{a}\right)^{1/2}$

8. Which of the following functions from I to itself are bijections?

(a) $f(x) = x^3$ (b) $f(x) = x + 2$ (c) $f(x) = 2x + 1$ (d) $f(x) = x^2 + x$

9. Let $f : R - \{n\} \to R$ be a function defined by $f(x) = \frac{x-m}{x-n}$, where $m \neq n$. Then,

(a) f is one-one onto (b) f is one-one into (c) f is many-one onto (d) f is many-one into

10. If $f(x + 2y, x - 2y) = xy$, then $f(x, y)$ equals

(a) $\frac{x^2 - y^2}{8}$ (b) $\frac{x^2 - y^2}{4}$ (c) $\frac{x^2 + y^2}{4}$ (d) $\frac{x^2 - y^2}{2}$

Shortcuts and Important Results to Remember

1. Every set is a subset of itself.
2. Null set is a subset of every set.
3. The set $\{0\}$ is not an empty set as it contains one element 0. The set $\{\phi\}$ is not an empty set as it contains one element ϕ.
4. The order of finite set A of n elements is denoted by $O(A)$ or $n(A)$.
5. Number of subsets of a set containing n elements is 2^n.
6. Number of proper subsets of a set containing n elements is $2^n - 1$.
7. If $A = \phi$, then $P(A) = \phi$; $\therefore\ n(P(A)) = 1$.
8. The order of an infinite set is undefined.
9. A natural number p is a prime number, if p is greater than one and its factors are 1 and p only.
10. Finite sets are equivalent sets only, when they have equal number of elements.
11. Equal sets are equivalent sets but equivalent sets may not be equal sets.
12. If A is any set, then $A \subseteq A$ is true but $A \subset A$ is false.
13. If $A \subseteq B$, then $A \cup B = B$
14. $A \subset B \Leftrightarrow A \subseteq B$ and $A \neq B$
15. $x \notin A \cup B \Leftrightarrow x \notin A$ and $x \notin B$
16. $x \notin A \cap B \Leftrightarrow x \notin A$ or $x \notin B$
17. If $A_1, A_2, \ldots, A_n$ is a finite family of sets, then their union is denoted by $\bigcup_{i=1}^{n} A_i$ or $A_1 \cup A_2 \cup A_3 \cup \ldots \cup A_n$.
18. If $A_1, A_2, A_3, \ldots, A_n$ is a finite family of sets, then their intersection is denoted by $\bigcap_{i=1}^{n} A_i$ or $A_1 \cap A_2 \cap A_3 \cap \ldots \cap A_n$.
19. $R - Q$ is the set of all irrational numbers.
20. Total number of relations from set A to set B is equal to $2^{n(A)n(B)}$.
21. The universal relation on a non-empty set is always reflexive, symmetric and transitive.
22. The identity relation on a non-empty set is always anti-symmetric.
23. The identity relation on a set is also called the diagonal relation on A.
24. For two relations R and S, the composite relations RoS, SoR may be void relations.
25. Every polynomial function $f : R \to R$ of degree odd is ONTO.
26. Every polynomial function $f : R \to R$ of degree even is INTO.
27. (i) The number of onto functions that can be defined from a finite set A containing n elements onto a finite set B containing 2 elements $= 2^n - 2$
    (ii) The number of onto functions that can be defined from a finite set A containing n elements onto a finite set B containing 3 elements $= 3^n - 3 \cdot 2^n + 3$
28. If a set A has n elements, then the number of binary relations on $A = n^{n^2}$.
29. If $fog = gof$, then either $f^{-1} = g$ or $g^{-1} = f$.
30. If f and g are bijective functions such that $f : A \to B$ and $g : B \to C$, then $gof : A \to C$ is bijective. Also, $(gof)^{-1} = f^{-1}og^{-1}$.
31. Let $f : A \to B$, $g : B \to C$ be two functions, then
    (i) f and g are injective $\Rightarrow gof$ is injective
    (ii) f and g are surjective $\Rightarrow gof$ is surjective
    (iii) f and g are bijective $\Rightarrow gof$ is bijective
32. Let $f : A \to B$, $g : B \to C$ be two functions, then
    (i) $gof : A \to C$ is injective $\Rightarrow f : A \to B$ is injective
    (ii) $gof : A \to C$ is surjective $\Rightarrow g : B \to C$ is surjective
    (iii) $gof : A \to C$ is injective and $g : B \to C$ is surjective $\Rightarrow$ $g : B \to C$ is injective
    (iv) $gof : A \to C$ is surjective and $g : B \to C$ is injective $\Rightarrow$ $f : A \to B$ is surjective
33. An injective mapping from a finite set to itself is bijective.

JEE Type Solved Examples :
Single Option Correct Type Questions

▪ This section contains **6 multiple choice examples**. Each example has four choices (a), (b), (c) and (d), out of which **ONLY ONE** is correct.

● ***Ex. 1*** *Two finite sets have m and n elements. The total number of subsets of the first set is 56 more than the total number of subsets of the second set. The values of m and n are*

(a) 7, 6 (b) 6, 3 (c) 5, 1 (d) 8, 7

Sol. (*b*) Since, $2^m - 2^n = 56 = 8 \times 7 = 2^3 \times 7$

$\Rightarrow \quad 2^n(2^{m-n} - 1) = 2^3 \times 7$

$\Rightarrow \quad n = 3$ and $2^{m-n} = 8 = 2^3 \Rightarrow n = 3$ and $m - n = 3$

$\Rightarrow \quad n = 3$ and $m - 3 = 3 \quad \Rightarrow n = 3$ and $m = 6$

● ***Ex. 2*** *If $aN = \{ax : x \in N\}$ and $bN \cap cN = dN$, where b, $c \in N$ are relatively prime, then*

(a) $d = bc$ (b) $c = bd$

(c) $b = cd$ (d) None of these

Sol. (a) bN = The set of positive integral multiples of b

cN = The set of positive integral multiples of c

$\therefore\ bN \cap cN$ = The set of positive integral multiples of bc

$= bcN \quad [\because\ b$ and c are prime$]$

$\therefore \quad d = bc$

● ***Ex. 3*** *In a town of 10000 families, it was found that 40% families buy newspaper A, 20% families buy newspaper B and 10% families buy newspaper C, 5% families buy newspapers A and B, 3% buy newspapers B and C and 4% buy newspapers A and C. If 2% families buy all the three newspapers, then number of families which buy A only is*

(a) 3100 (b) 3300 (c) 2900 (d) 1400

Sol. (*b*) $n(A) = 40\%$ of $10000 = 4000$

$n(B) = 20\%$ of $10000 = 2000$

$n(C) = 10\%$ of $10000 = 1000$

$n(A \cap B) = 5\%$ of $10000 = 500$

$n(B \cap C) = 3\%$ of $10000 = 300$

$n(C \cap A) = 4\%$ of $10000 = 400$

$n(A \cap B \cap C) = 2\%$ of $10000 = 200$

We want to find $n(A \cap B^c \cap C^c) = n[A \cap (B \cup C)^c]$

$= n(A) - n[A \cap (B \cup C)] = n(A) - n[(A \cap B) \cup (A \cap C)]$

$= n(A) - [n(A \cap B) + n(A \cap C) - n(A \cap B \cap C)]$

$= 4000 - [500 + 400 - 200] = 4000 - 700 = 3300$

● ***Ex. 4*** *Let R be the relation on the set R of all real numbers defined by aRb iff $|a - b| \le 1$. Then, R is*

(a) reflexive and symmetric (b) symmetric only

(c) transitive only (d) anti-symmetric only

Sol. (a) $\because\ |a - a| = 0 < 1 \ \Rightarrow\ a\ R\ a, \forall\ a \in R$

$\therefore\ R$ is reflexive.

Again, $aRb \ \Rightarrow\ |a - b| \le 1$

$\Rightarrow \quad |b - a| \le 1 \Rightarrow bRa$

$\therefore\ R$ is symmetric.

Again, $1\ R\ 2$ and $2R1$ but $2 \ne 1$

$\therefore\ R$ is not anti-symmetric.

Further, $1R2$ and $2R3$ but $1 \not R 3 \quad [\because\ |1 - 3| = 2 > 1]$

$\therefore\ R$ is not transitive.

● ***Ex. 5*** *The relation R defined on A = {1, 2, 3} by aRb, if $|a^2 - b^2| \le 5$. Which of the following is false?*

(a) $R = \{(1, 1), (2, 2), (3, 3), (2, 1), (1, 2), (2, 3), (3, 2)\}$

(b) $R^{-1} = R$

(c) Domain of $R = \{1, 2, 3\}$

(d) Range of $R = \{5\}$

Sol. (*d*) Let $a = 1$

Then, $|a^2 - b^2| \le 5 \ \Rightarrow\ |1 - b^2| \le 5$

$\Rightarrow \quad |b^2 - 1| \le 5 \ \Rightarrow\ b = 1, 2$

Let $a = 2$

Then, $|a^2 - b^2| \le 5$

$\Rightarrow \quad |4 - b^2| \le 5 \ \Rightarrow\ |b^2 - 4| \le 5$

$\therefore \quad b = 1, 2, 3$

Let $a = 3$

Then, $|a^2 - b^2| \le 5$

$\Rightarrow \quad |9 - b^2| \le 5 \ \Rightarrow\ |b^2 - 9| \le 5 \ \Rightarrow\ b = 2, 3$

$\therefore \quad R = \{(1, 1), (1, 2), (2, 1), (2, 2), (2, 3), (3, 2), (3, 3)\}$

$R^{-1} = \{(y, x) : (x, y) \in R\}$

$= \{(1, 1), (2, 1), (1, 2), (2, 2), (3, 2), (2, 3), (3, 3)\} = R$

Domain of $R = \{x : (x, y) \in R\} = \{1, 2, 3\}$

Range of $R = \{y : (x, y) \in R\} = \{1, 2, 3\}$

● ***Ex. 6*** *If $f(x) = \dfrac{1}{(1-x)}$, $g(x) = f\{f(x)\}$ and $h(x) = f[f\{f(x)\}]$. Then the value of $f(x) \cdot g(x) \cdot h(x)$ is*

(a) 6 (b) −1 (c) 1 (d) 2

Sol. (*b*) $\because\ g(x) = f\{f(x)\} = f\left(\dfrac{1}{1-x}\right) = \dfrac{1}{1 - \dfrac{1}{1-x}} = \dfrac{x-1}{x}$

and $h(x) = f[f\{f(x)\}] = f(g(x))$

$= \dfrac{1}{1 - g(x)} = \dfrac{1}{1 - \dfrac{x-1}{x}} = x$

$\therefore\ f(x) \cdot g(x) \cdot h(x) = \dfrac{1}{(1-x)} \cdot \dfrac{(x-1)}{x} \cdot x = -1$

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **3 multiple choice examples**. Each example has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

● ***Ex. 7*** *If I is the set of integers and if the relation R is defined over I by aRb, iff $a-b$ is an even integer, $a, b \in I$, the relation R is*

(a) reflexive (b) anti-symmetric
(c) symmetric (d) equivalence

Sol. (a, c, d)

$aRb \Leftrightarrow a-b$ is an even integer, $a, b \in I$

$a - a = 0$ (even integer)

$\therefore \quad (a, a) \in R, \ \forall \ a \in I$

$\therefore$ R is reflexive relation.

Let $(a, b) \in R \Rightarrow (a-b)$ is an even integer.

$\Rightarrow \quad -(b-a)$ is an even integer.

$\Rightarrow \quad (b-a)$ is an even integer.

$\Rightarrow \quad (b, a) \in R$

$\therefore$ R is symmetric relation.

Now, let $(a, b) \in R$ and $(b, c) \in R$

Then, $(a-b)$ is an even integer and $(b-c)$ is an even integer.

So, let $\quad a - b = 2x_1, \ x_1 \in I$

and $\quad b - c = 2x_2, \ x_2 \in I$

$\therefore \quad (a-b)+(b-c) = 2(x_1 + x_2)$

$\Rightarrow \quad (a-c) = 2(x_1 + x_2) \Rightarrow a - c = 2x_3$

$\therefore$ $(a-c)$ is an even integer.

$\therefore$ aRb and $bRc \Rightarrow aRc$ So, R is transitive relation.

Hence, R is an equivalence relation.

● ***Ex. 8*** *If $f(x) = \dfrac{a-x}{a+x}$, the domain of $f^{-1}(x)$ contains*

(a) $(-\infty, \infty)$ (b) $(-\infty, -1)$
(c) $(-1, \infty)$ (d) $(0, \infty)$

Sol. (b, c, d)

Let $\quad y = f(x) = \dfrac{a-x}{a+x} \Rightarrow ay + xy = a - x$

$\therefore \quad x = \dfrac{a(1-y)}{(1+y)} = f^{-1}(y) \Rightarrow f^{-1}(x) = \dfrac{a(1-x)}{(1+x)}$

$\therefore$ $f^{-1}(x)$ is not defined for $x = -1$.

Domain of $f^{-1}(x)$ belongs to $(-\infty, -1) \cup (-1, \infty)$.

Now, for $a = -1$, given function $f(x) = -1$, which is constant.

Then, $f^{-1}(x)$ is not defined.

$\therefore \quad a \neq -1$

● ***Ex. 9*** *If $f(x) = \dfrac{\sin([x]\pi)}{x^2 + x + 1}$, where $[\cdot]$ denotes the greatest integer function, then*

(a) f is one-one
(b) f is not one-one and non-constant
(c) f is constant function (d) f is zero function

Sol. (c, d)

$\because \quad \sin([x]\pi) = 0$

$\therefore \quad f(x) = 0 \quad [\because [x] \text{ is an integer}]$

$\Rightarrow$ $f(x)$ is a constant function and also $f(x)$ is a zero function.

JEE Type Solved Examples :
Passage Based Questions

■ This section contains **2 solved passages** based upon each of the passage **3 multiple choice** examples have to be answered. Each of these examples has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I
(Ex. Nos. 10 to 12)

If $A = \{x : |x| < 2\}$, $B = \{x : |x-5| \leq 2\}$,
$C = \{x : |x| > x\}$ and $D = \{x : |x| < x\}$

● ***10.*** *The number of integral values in $A \cup B$ is*

(a) 4 (b) 6
(c) 8 (d) 10

● ***11.*** *The number of integral values in $A \cap C$ is*

(a) 1 (b) 2
(c) 3 (d) 0

● ***12.*** *The number of integral values in $A \cap D$ is*

(a) 2 (b) 4
(c) 6 (d) 0

Sol. (Ex. Nos. 10 to 12)

$$A = \{x : |x| < 2\} = \{x : -2 < x < 2\} = (-2, 2)$$

$$B = \{x : |x - 5| \le 2\} = \{x : -2 \le x - 5 \le 2\}$$

$$= \{x : 3 \le x \le 7\} = [3, 7]$$

$$C = \{x : |x| > x\} = \{x : x < 0\} = (-\infty, 0)$$

and $D = \{x : |x| < x\} = \phi$

10. (*c*) $A \cup B = (-2, 2) \cup [3, 7]$

Integral values in $A \cup B$ are $-1, 0, 1, 3, 4, 5, 6, 7$.

$\therefore$ Number of integral values in $A \cup B$ is 8.

11. (*a*) $A \cap C = (-2, 2) \cap (-\infty, 0) = (-2, 0)$

Integral value in $A \cap C$ is -1.

$\therefore$ Number of integral values in $A \cap C$ is 1.

12. (*d*) $A \cap D = (-2, 2) \cap \phi = \phi$

$\therefore$ Number of integral values in $A \cap D$ is 0.

Passage II

(Ex. Nos. 13 to 15)

If $A = \{x : x^2 - 2x + 2 > 0\}$ *and* $B = \{x : x^2 - 4x + 3 \le 0\}$

● ***13.*** *$A \cap B$ equals*

(a) $[1, \infty)$ (b) $[1, 3]$

(c) $(-\infty, 3]$ (d) $(-\infty, 1) \cup (3, \infty)$

● ***14.*** *$A - B$ equals*

(a) $(-\infty, \infty)$ (b) $(1, 3)$

(c) $(3, \infty)$ (d) $(-\infty, 1) \cup (3, \infty)$

● ***15.*** *$A \cup B$ equals*

(a) $(-\infty, 1)$ (b) $(3, \infty)$

(c) $(-\infty, \infty)$ (d) $(1, 3)$

Sol. (Ex. Nos. 13 to 15)

$$A = \{x : x^2 - 2x + 2 > 0\} = \{x : (x - 1)^2 + 1 > 0\} = (-\infty, \infty)$$

$$B = \{x : x^2 - 4x + 3 \le 0\} = \{x : (x - 1)(x - 3) \le 0\}$$

$$= \{x : 1 \le x \le 3\} = [1, 3]$$

13. (*b*) $A \cap B = (-\infty, \infty) \cap [1, 3] = [1, 3]$

14. (*d*) $A - B = (-\infty, \infty) - [1, 3] = (-\infty, 1) \cup (3, \infty)$

15. (*c*) $A \cup B = (-\infty, \infty) \cup [1, 3] = (-\infty, \infty)$

JEE Type Solved Examples :
Single Integer Answer Type Questions

■ This section contains **2 examples.** The answer to each example is a **single digit integer** ranging from **0** to **9** (both inclusive).

● ***Ex. 16*** *If $f : R^+ \to A$, where $A = \{x : -5 < x < \infty\}$ is defined by $f(x) = x^2 - 5$ and if $f^{-1}(13) = \{-\lambda\sqrt{(\lambda - 1)}, \lambda\sqrt{(\lambda - 1)}\}$, the value of λ is*

Sol. (*3*) $f^{-1}(13) = \{x : f(x) = 13\} = \{x : x^2 - 5 = 13\}$

$$= \{x : x^2 = 18\} = \{x : x = \pm 3\sqrt{2}\}$$

$$= \{-3\sqrt{2}, 3\sqrt{2}\}$$

$$= \{-\lambda\sqrt{(\lambda - 1)}, \lambda\sqrt{(\lambda - 1)}\} \quad \text{[given]}$$

$\therefore \quad \lambda = 3$

● ***Ex. 17*** *If $A = \{2, 3\}$, $B = \{4, 5\}$ and $C = \{5, 6\}$, then $n\{(A \times B) \cup (B \times C)\}$ is*

Sol. (*8*) $\because A \times B = \{2, 3\} \times \{4, 5\}$

$$= \{(2, 4), (2, 5), (3, 4), (3, 5)\}$$

and $B \times C = \{4, 5\} \times \{5, 6\}$

$$= \{(4, 5), (4, 6), (5, 5), (5, 6)\}$$

$\therefore \quad (A \times B) \cup (B \times C) = \{(2, 4), (2, 5), (3, 4), (3, 5),$

$(4, 5), (4, 6), (5, 5), (5\ 6)\}$

Now, $n\{(A \times B) \cup (B \times C)\} = 8$

JEE Type Solved Examples : Matching Type Questions

■ This section contains **1 examples.** Example 18 have three statements (A, B and C) given in Column I and four statements (p, q, r and s) in **Column II.** Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II.**

● ***Ex. 18***

	Column I		Column II
(A)	$R = \{(x, y) : x < y\ ;\ x, y \in N\}$	(p)	Reflexive
(B)	$S = \{(x, y) : x + y = 10\ ;\ x, y \in N\}$	(q)	Symmetric
(C)	$T = \{(x, y) : x = y$ or $x - y = 1\ ;\ x, y \in N\}$	(r)	Transitive
(D)	$U = \{(x, y) : x^y = y^x;\ x, y \in N\}$	(s)	Equivalence

Sol. (A) → (r); (B) → (q); (C) → (p); (D) → (p, q, r, s)

(A) $\because \quad R = \{(x, y) : x < y;\ x, y \in N\}$

$x \not< x \ \therefore (x, x) \notin R$

So, R is not reflexive.

Now, $(x, y) \in R \Rightarrow x < y \not\Rightarrow y < x \Rightarrow (y, x) \notin R$

$\therefore$ R is not symmetric.

Let $(x, y) \in R$ and $(y, z) \in R$

$\Rightarrow \quad x < y$ and $y < z \Rightarrow x < z \Rightarrow (x, z) \in R$

$\therefore R$ is transitive.

(B) $\because\ S = \{(x, y) : x + y = 10\ ;\ x, y \in N\}$

$\therefore \quad x + x = 10 \Rightarrow 2x = 10 \Rightarrow x = 5$

So, each element of N is not related to itself by the relation $x + y = 10$.

$\therefore$ S is not reflexive.

Now, $(x, y) \in S \Rightarrow x + y = 10 \Rightarrow y + x = 10$

$\Rightarrow \quad (y, x) \in S$

$\therefore$ S is symmetric relation.

Now, let $(3, 7) \in S$ and $(7, 3) \in S \Rightarrow (3, 3) \notin S$

$\therefore$ S is not transitive.

(C) $\because\ T = \{(x, y) : x = y$ or $x - y = 1;\ x, y \in N\}$

$\therefore \quad x = x$

So, $\quad (x, x) \in T, \forall\ x \in N$

$\therefore \quad T$ is reflexive.

Let $\quad (3, 2) \in T$ and $3 - 2 = 1$

$\not\Rightarrow \quad 2 - 3 = -1 \Rightarrow (2, 3) \notin T$

$\therefore \quad T$ is not symmetric.

Now, let $\quad (3, 2) \in T$ and $(2, 1) \in T$

$\therefore \quad 3 - 2 = 1$ and $2 - 1 = 1$

Then, $\quad (3, 1) \notin T \qquad [\because 3 - 1 = 2 \neq 1]$

$\therefore \quad T$ is not transitive.

(D) $U = \{(x, y) : x^y = y^x;\ x, y \in N\}$

$\because \quad x^x = x^x$

$\therefore \quad (x, x) \in U$

$\therefore U$ is reflexive.

Now, $(x, y) \in U \Rightarrow x^y = y^x$

$\Rightarrow \quad y^x = x^y \Rightarrow (y, x) \in U$

$\therefore U$ is symmetric.

Now, let $(x, y) \in U$ and $(y, z) \in U$

$\Rightarrow \quad x^y = y^x$ and $y^z = z^y$

Now, $\quad (x^y)^z = (y^x)^z$

$\Rightarrow \quad (x^z)^y = (y^z)^x \Rightarrow (x^z)^y = (z^y)^x$

$\Rightarrow \quad (x^z)^y = (z^x)^y \Rightarrow x^z = z^x \Rightarrow (x, z) \in U$

$\therefore \quad U$ is transitive.

Hence, U is an equivalence relation.

JEE Type Solved Examples : Statement I and II Type Questions

■ **Directions** Example numbers 19 and 20 are Assertion-Reason type examples. Each of these examples contains two statements:

Statement-1 (Assertion) and

Statement-2 (Reason)

Each of these examples also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below:

(a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

(b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1

(c) Statement-1 is true; Statement-2 is false

(d) Statement-1 is false; Statement-2 is true

● ***Ex. 19*** **Statement-1** *If $A \cup B = A \cup C$ and $A \cap B = A \cap C$, then $B = C$.*

Statement-2 $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$

Sol. (*a*) We have, $B = B \cup (A \cap B)$

$= B \cup (A \cap C) \qquad [\because A \cap B = A \cap C]$

$= (A \cup C) \cap (B \cup C)$ $[\because A \cup B = A \cup C]$
$= (A \cap B) \cup C$
$= (A \cap C) \cup C$ $[\because A \cap B = A \cap C]$
$= C$

Hence, Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation of Statement-1.

● ***Ex. 20*** **Statement-1** *If U is universal set and $B = U - A$, then $n(B) = n(U) - n(A)$.*
Statement-2 *For any three arbitrary sets A, B and C, if $C = A - B$, then $n(C) = n(A) - n(B)$.*

Sol. (c) $\because$ $B = U - A = A'$
$\therefore$ $n(B) = n(A') = n(U) - n(A)$
So, Statement-1 is true.
But for any three arbitrary sets A, B and C, we cannot always have
$$n(C) = n(A) - n(B)$$
if $C = A - B$
As it is not specified A is universal set or not. In case not conclude
$$n(C) = n(A) - n(B)$$
Hence, Statement-2 is false.

Subjective Type Examples

■ In this section, there are **12 subjective** solved examples.

● ***Ex. 21.*** *If $A = A \cup B$, prove that $B = A \cap B$.*

Sol. $\because A = A \cap B$
$\therefore$ $A \subseteq A \cup B$ and $A \cup B \subseteq A$
Now, let $x \in B \Leftrightarrow x \in A \cup B$ [by definition of union]
$\Leftrightarrow$ $x \in A$ $[\because A \subseteq A \cup B]$
$\Leftrightarrow$ $x \in A \cap B$ $[\because A \subseteq A \cup B$, then also $A \subseteq A \cap B]$
$\therefore$ $B \subseteq A \cap B$ and $A \cap B \subseteq B$
Hence, $A \cap B = B$ **Hence proved.**

● ***Ex. 22*** *Find the smallest and largest sets of Y such that $Y \cup \{1, 2\} = \{1, 2, 3, 5, 9\}$.*

Sol. Smallest set of Y has three elements and largest set of Y has five elements, since RHS set has five elements.
$\therefore$ Smallest set of Y is $\{3, 5, 9\}$
and largest set of Y is $\{1, 2, 3, 5, 9\}$.

● ***Ex. 23*** *If P, Q and R are the subsets of a set A, then prove that $R \times (P^c \cup Q^c)^c = (R \times P) \cap (R \times Q)$.*

Sol. We know that from De-Morgan's law,
$$A^c \cap B^c = (A \cup B)^c \quad \ldots(i)$$
Replacing A by P^c and B by Q^c, then Eq. (i) becomes
$(P^c)^c \cap (Q^c)^c = (P^c \cup Q^c)^c$
$\Rightarrow$ $P \cap Q = (P^c \cup Q^c)^c$ $[\because (A^c)^c = A]$ ...(ii)
$\therefore R \times (P^c \cup Q^c)^c = R \times (P \cap Q)$ [from Eq. (ii)]
$= (R \times P) \cap (R \times Q)$ [by cartesian product]
Hence, $R \times (P^c \cup Q^c)^c = (R \times P) \cap (R \times Q)$

● ***Ex. 24*** *Check the following relations R and ρ for reflexive, symmetry and transitivity.*

(i) aRb iff b is divisible by a, where a and b are natural numbers.

(ii) $\alpha\rho\beta$ iff α is perpendicular to β, where α and β are straight lines in a plane.

Sol. (i) The relation R is reflexive, since a is divisible by a, R is not symmetric because b is divisible by a but a is not divisible by b. i.e., $aRb \nRightarrow bRa$
Again, R is transitive, since b is divisible by a and c is divisible by b, then always c is divisible by a.

(ii) The relation ρ is not reflexive as no line can be perpendicular to itself. The relation ρ is symmetric, since a line α is perpendicular to β, then β is perpendicular to α and the relation ρ is not transitive, since a line α is perpendicular to β and if β is perpendicular to γ (new line), then α is not perpendicular to γ (since, α is parallel to γ).

● ***Ex. 25*** *Let $f:[0,1] \to [0,1]$ be defined by $f(x) = \dfrac{1-x}{1+x}$; $0 \le x \le 1$ and $g:[0,1] \to [0,1]$ be defined by $g(x) = 4x(1-x), 0 \le x \le 1$.*
Determine the functions *fog* and *gof*.
Note that $[0,1]$ stands for the set of all real members x that satisfy the condition $0 \le x \le 1$.

Sol. $(fog)x = f\{g(x)\} = f\{4x(1-x)\}$ $[\because g(x) = 4x(1-x)]$
$$= \frac{1 - 4x(1-x)}{1 + 4x(1-x)} \qquad \left[\because f(x) = \frac{1-x}{1+x}\right]$$
$$= \frac{1 - 4x + 4x^2}{1 + 4x - 4x^2} = \frac{(2x-1)^2}{1 + 4x - 4x^2}$$

and $(gof)x = g\{f(x)\} = g\left\{\frac{1-x}{1+x}\right\}$ $\left[\because f(x) = \frac{1-x}{1+x}\right]$

$$= 4\left(\frac{1-x}{1+x}\right)\left(1-\frac{1-x}{1+x}\right) = 4\left(\frac{1-x}{1+x}\right)\left(\frac{2x}{1+x}\right)$$

$$= \frac{8x(1-x)}{(1+x)^2}$$

● ***Ex. 26*** *If A, B are two sets, prove that* $A \cup B = (A - B) \cup (B - A) \cup (A \cap B)$.

Hence or otherwise prove that

$$n(A \cup B) = n(A) + n(B) - n(A \cap B)$$

where, $n(A)$ denotes the number of elements in A.

Sol. Let $x \in A \cup B \Rightarrow x \in A$ or $x \in B$

$\Leftrightarrow (x \in A$ and $x \notin B)$ or $(x \in B$ and $x \notin A)$

or $(x \in A$ and $x \in B)$ [from definition of union]

$\Leftrightarrow$ $x \in (A - B)$ or $x \in (B - A)$ or $x \in A \cap B$

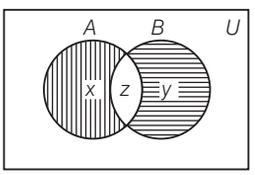
$\Leftrightarrow$ $x \in (A - B) \cup (B - A) \cup (A \cap B)$

$\therefore$ $A \cup B \subseteq (A - B) \cup (B - A) \cup (A \cap B)$

and $(A - B) \cup (B - A) \cup (A \cap B) \subseteq A \cup B$

Hence, $A \cup B = (A - B) \cup (B - A) \cup (A \cap B)$

Let the common elements in A and B are z and only element of A are x (represented by vertical lines in the Venn diagram) and only element of B are y (represented by horizontal lines in the Venn diagram)



$\therefore$ $n(A)$ = Total elements of $A = x + z$

$n(B)$ = Total elements of $B = y + z$

$n(A \cap B)$ = Common elements in A and $B = z$

Now, $n(A \cup B)$ = Total elements in complete region of A and B

$$= x + y + z$$
$$= (x + z) + (y + z) - z$$
$$= n(A) + n(B) - n(A \cap B)$$

Hence, $n(A \cup B) = n(A) + n(B) - n(A \cap B)$

● ***Ex. 27*** *Let* $A = \{\theta: 2\cos^2\theta + \sin\theta \le 2\}$ *and* $B = \{\theta: \pi / 2 \le \theta \le 3\pi / 2\}$. Then find $A \cap B$.

Sol. $\because$ $2\cos^2\theta + \sin\theta \le 2$

$\therefore$ $2(1 - \sin^2\theta) + \sin\theta \le 2$

$\Rightarrow$ $2\sin^2\theta - \sin\theta \ge 0$

$\Rightarrow$ $\sin\theta(2\sin\theta - 1) \ge 0$

$\Rightarrow$ $\sin\theta\left(\sin\theta - \frac{1}{2}\right) \ge 0$

$\therefore$ $\sin\theta \le 0$ and $\sin\theta \ge \frac{1}{2}$

Now, the values of θ which lie in the interval $\frac{\pi}{2} \le \theta \le \frac{3\pi}{2}$.

$\left[\because B = \left\{\theta: \frac{\pi}{2} \le \theta \le \frac{3\pi}{2}\right\}\right]$

So, θ satisfy $\sin\theta \le 0$ in the interval $\pi \le \theta \le \frac{3\pi}{2}$

and θ satisfy $\sin\theta \ge \frac{1}{2}$ in the interval $\frac{\pi}{2} \le \theta \le \frac{5\pi}{6}$.

$\therefore$ $A \cap B = \left\{\theta: \pi \le \theta \le \frac{3\pi}{2}\right\}$

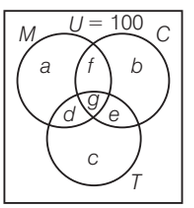
and $A \cap B = \left\{\theta: \frac{\pi}{2} \le \theta \le \frac{5\pi}{6}\right\}$

Hence, $A \cap B = \left\{\theta: \frac{\pi}{2} \le \theta \le \frac{5\pi}{6} \text{ or } \pi \le \theta \le \frac{3\pi}{2}\right\}$

$$= \left\{\theta: \theta \in \left[\frac{\pi}{2}, \frac{5\pi}{6}\right] \cup \left[\pi, \frac{3\pi}{2}\right]\right\}$$

● ***Ex. 28*** *An investigator interviewed* 100 *students to determine their preferences for the three drinks; milk* (M)*, coffee* (C) *and tea* (T)*. He reported the following:* 10 *students has all the three drinks M, C, T*; 20 *had M and C*; 30 *had C and T,* 25 *had M and T*; 12 *had M only;* 5 *had C only and* 8 *had T only. Using a Venn diagram, find how many did not take any of the three drinks?*

Sol. Given, M, C and T are the sets of drinks; milk, coffee and tea, respectively. Let us denote the number of drinks (students) contained in the bounded region as shown in the diagram by a, b, c, d, e, f and g, respectively.



Then, $g = 10$

$g + f = 20 \Rightarrow f = 10$ $[\because g = 10]$

$g + e = 30 \Rightarrow e = 20$

$d + g = 25 \Rightarrow d = 15$

and $a = 12, b = 5, c = 8$

Thus, total number of students taking drinks M or C or T

$$= a + b + c + d + e + f + g$$
$$= 12 + 5 + 8 + 15 + 20 + 10 + 10 = 80$$

Hence, the number of students taking none of them drinks

$$= 100 - 80 = 20$$

● ***Ex. 29*** *In a certain city, only two newspapers A and B are published. It is known that 25% of the city population reads A and 20% reads B, while 8% reads A and B. It is also known that 30% of those who read A but not B, look into advertisements and 40% of those who read B but not A, look into advertisements while 50% of those who read both A and B, look into advertisements. What per cent of the population read on advertisement?*

Sol. Let C = Set of people who read paper A
and D = Set of people who read paper B

Given, $n(C) = 25, n(D) = 20, n(C \cap D) = 8$

$\therefore \quad n(C \cap D') = n(C) - n(C \cap D)$

$= 25 - 8 = 17$

But total number of people who read A but not $B = 30\%$

$\therefore$ Percentage of people reading A but not $B = 30\%$ of 17

$$= \frac{30 \times 17}{100} = \frac{51}{10}$$

and $n(C' \cap D) = n(D) - n(C \cap D) = 20 - 8 = 12$

Also, total number of people who read B but not $A = 40\%$

$\therefore$ Percentage of people reading B but not $A = 40\%$ of 12

$$= \frac{40 \times 12}{100} = \frac{24}{5}$$

and given total people who read A and $B = 50\%$

$\therefore$ Total number of people who read A and $B = 50\%$ of 8

$$= \frac{50 \times 8}{100} = 4$$

$\therefore$ Percentage of people reading an advertisement

$$= \frac{51}{10} + \frac{24}{5} + 4 = 13.9\%$$

● ***Ex. 30*** *An analysis of 100 personal injury claims made upon a motor insurance company revealed that loss or injury in respect of an eye, an arm, a leg occurred in 30, 50 and 70 cases, respectively. Claims involving this loss or injury to two of these members numbered 44. How many claims involved loss or injury to all the three, we must assume that one or another of three members was mentioned in each of the 100 claims?*

Sol. Let the set of people having injuries in eyes, arms or legs be denoted by E, A and L, respectively. Then, according to the problem, we have

$$n(E \cup A \cup L) = 30, n(E) = 30$$

$$n(A) = 50, n(L) = 70$$

and $n[(E \cap A \cap L') \cup (E \cap A' \cap L) \cup (E' \cap A \cap L) = 44$

or $n(E \cap A \cap L') + n(E \cap A' \cap L) + n(E' \cap A \cap L) = 44$

[$\because$ each case is mutually exclusive]

or $n(E \cap A) - n(E \cap A \cap L) + n(E \cap L) - n(E \cap A \cap L) + n(E \cap L) - n(E \cap A \cap L) = 44$

$\Rightarrow \quad n(E \cap A) + n(E \cap L) + n(A \cap L) - 3n(E \cap A \cap L) = 44$ ...(i)

$\because \quad n(E \cup A \cup L) = 100$

$\therefore n(E) + n(A) + n(L) - n(E \cap A) - n(A \cap L) - n(E \cap L) + n(E \cap A \cap L) = 100$

$\Rightarrow \quad 30 + 50 + 70 - \{44 + 3n(E \cap A \cap L)\} + n(E \cap A \cap L) = 100$ [from Eq. (i)]

$\Rightarrow \quad 6 - 2n(E \cap A \cap L) = 0$

$\therefore \quad n(E \cap L \cap A) = 3$

Hence, there are three claims involved in loss or injury to all the three.

Aliter

Let E = Set of people having injuries in eyes

$\therefore \quad n(E) = 30$

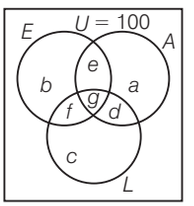
A = Set of people having injuries in arms

$\therefore \quad n(A) = 50$

and L = Set of people having injuries in legs

$\therefore \quad n(L) = 70$

Let us denote the number of injuries contained in the bounded region as shown in the diagram by a, b, c, d, e, f and g, respectively.



Then, $b + e + f + g = 30$ ...(i)

$a + d + e + g = 50$ ...(ii)

$c + d + f + g = 70$ ...(iii)

$d + e + f = 44$ ...(iv)

and $a + b + c + d + e + f + g = 100$ ...(v)

On adding Eqs. (i), (ii) and (iii), we get

$$a + b + c + 2(d + e + f) + 3g = 150$$

$\Rightarrow \quad 100 - d - e - f - g + 2(d + e + f) + 3g = 150$ [from Eq. (v)]

$\Rightarrow \quad d + e + f + 2g = 50$

$\Rightarrow \quad 44 + 2g = 50$ [from Eq. (iv)]

$\therefore \quad g = 3$

Hence, there are three claims involved loss or injury to all the three.

● ***Ex. 31*** *N is the set of natural number. The relation R is defined on $N \times N$ as follows:*

$$(a, b)\, R\, (c, d) \Leftrightarrow ad(b + c) = bc(a + d)$$

Prove that R is an equivalence relation.

Sol. **Reflexive**

Since, $(a, b)\ R\ (a, b) \Leftrightarrow ab(b + a) = ba(a + b), \forall\ a, b \in N$ is true.

Hence, R is reflexive.

Symmetric $(a, b)\ R\ (c, d)$

$\Leftrightarrow \quad ad(b + c) = bc(a + d)$

$\Leftrightarrow \quad bc(a + d) = ad(b + c)$

$\Leftrightarrow \quad cb(d + a) = da(c + b)$

$\Leftrightarrow \quad (c, d)\ R\ (a, b)$

Hence, R is symmetric.

Transitive

Since, $(a, b)\ R\ (c, d) \Leftrightarrow ad(b + c) = bc(a + d)$

$$\Leftrightarrow \quad \frac{b + c}{bc} = \frac{a + d}{ad}$$

$$\Leftrightarrow \quad \frac{1}{c} + \frac{1}{b} = \frac{1}{d} + \frac{1}{a}$$

$$\Leftrightarrow \quad \frac{1}{a} - \frac{1}{b} = \frac{1}{c} - \frac{1}{d}$$

$$\therefore \quad (a, b)\ R\ (c, d) \ \Leftrightarrow \ \frac{1}{a} - \frac{1}{b} = \frac{1}{c} - \frac{1}{d} \qquad \text{...(i)}$$

and similarly $(c, d)\ R\ (e, f) \Leftrightarrow \frac{1}{c} - \frac{1}{d} = \frac{1}{e} - \frac{1}{f}$ ...(ii)

From Eqs. (i) and (ii),

$$(a,b)R(c,d) \text{ and } (c,d)R(e,f) \Leftrightarrow \frac{1}{a} - \frac{1}{b} = \frac{1}{e} - \frac{1}{f}$$

$$\Leftrightarrow (a, b)\ R\ (e, f)$$

So, R is transitive. Hence, R is an equivalence relation.

● ***Ex. 32*** *The sets S and E are defined as given below:*

$S = \{(x, y): |x - 3| < 1 \text{ and } |y - 3| < 1\}$ *and*

$E = \{(x, y): 4x^2 + 9y^2 - 32x - 54y + 109 \le 0\}$.

Show that $S \subset E$.

Sol. **Graph of *S***

$\because\ |x - 3| < 1 \ \Rightarrow -1 < (x - 3) < 1 \ \Rightarrow\ 2 < x < 4$

Similarly, $|y - 3| < 1 \ \Rightarrow\ 2 < y < 4$

So, S consists of all points inside the square (not on $x \neq 2, 4$ and $y \neq 2, 4$) bounded by the lines $x = 2$, $y = 2$, $x = 4$ and $y = 4$.

Graph of *E*

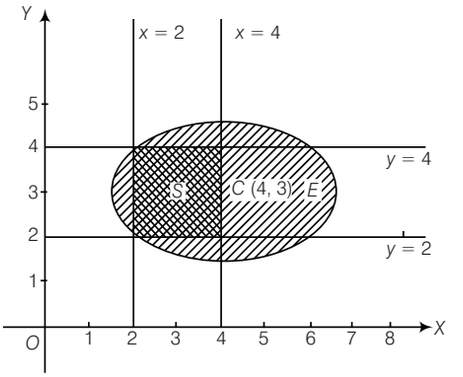
$\because \quad 4x^2 + 9y^2 - 32x - 54y + 109 \le 0$

$\Rightarrow \quad 4(x^2 - 8x) + 9(y^2 - 6y) + 109 \le 0$

$\Rightarrow \quad 4(x - 4)^2 + 9(y - 3)^2 \le 36$

$$\Rightarrow \quad \frac{(x - 4)^2}{3^2} + \frac{(y - 3)^2}{2^2} \le 1$$

So, E consists of all points inside and on the ellipse with centre $(4, 3)$ and semi-major and semi-minor axes are 3 and 2, respectively.



From the above graph, it is evident that the double hatched (which is S) is within the region represented by E. i.e., $S \subset E$

Sets, Relations and Functions Exercise 1 :
Single Option Correct Type Questions

■ This section contains **39 multiple choice questions.** Each question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct

1. If A and B are two sets, then $A \cap (A \cup B)$ equals
(a) A (b) B
(c) ϕ (d) None of these

2. If R is a relation from a set A to a set B and S is a relation from a set B to set C, then the relation SoR
(a) is from A to C (b) is from C to A
(c) does not exist (d) None of these

3. Let $R = \{(1, 3), (2, 2), (3, 2)\}$ and $S = \{(2, 1), (3, 2), (2, 3)\}$ be two relations on set $A = \{(1, 2, 3)\}$. Then, RoS is equal
(a) $\{(2, 3), (3, 2), (2, 2)\}$ (b) $\{(1, 3), (2, 2), (3, 2), (2, 1), (2, 3)\}$
(c) $\{(3, 2), (1, 3)\}$ (d) $\{(2, 3) (3, 2)\}$

4. If X and Y are two sets, then $X \cap (Y \cap X)'$ equals
(a) X (b) Y
(c) ϕ (d) None of these

5. For real numbers x and y, we write $x\ R\ y \Leftrightarrow x - y + \sqrt{2}$ is an irrational number. Then, the relation R is
(a) reflexive (b) symmetric
(c) transitive (d) None of these

6. Let $f(x) = (x + 1)^2 - 1, (x \geq -1)$. Then, the set $S = \{x : f(x) = f^{-1}(x)\}$ is
(a) $\left\{0, -1, \frac{-3 + i\sqrt{3}}{2}, \frac{-3 - i\sqrt{3}}{2}\right\}, i = \sqrt{-1}$
(b) $\{0, 1, -1\}$ (c) $\{0, -1\}$
(d) empty

7. The number of elements of the power set of a set containing n elements is
(a) 2^{n-1} (b) 2^n (c) $2^n - 1$ (d) 2^{n+1}

8. Which one of the following is not true?
(a) $A - B \subseteq A$ (b) $B' - A' \subseteq A$
(c) $A \subseteq A - B$ (d) $A \cap B' \subseteq A$

9. If $A = \{1, 2, 3\}$ and $B = \{3, 8\}$, then $(A \cup B) \times (A \cap B)$ is
(a) $\{(3, 1), (3, 2), (3, 3), (3, 8)\}$ (b) $\{(1, 3), (2, 3), (3, 3), (8, 3)\}$
(c) $\{(1, 2), (2, 2), (3, 3), (8, 8)\}$ (d) $\{(8, 3), (8, 2), (8, 1), (8, 8)\}$

10. Let $A = \{p, q, r\}$. Which of the following is not an equivalence relation on A?
(a) $R_1 = \{(p, q), (q, r), (p, r), (p, p)\}$
(b) $R_2 = \{(r, q), (r, p), (r, r), (q, q)\}$
(c) $R_3 = \{(p, p), (q, q), (r, r), (p, q)\}$
(d) None of the above

11. Let $A = \{x : x$ is a multiple of 3$\}$ and $B = \{x : x$ is a multiple of 5$\}$, then $A \cap B$ is given by
(a) $\{3, 6, 9\}$ (b) $\{5, 10, 15, 20, \ldots\}$
(c) $\{15, 30, 45, \ldots\}$ (d) None of these

12. Let $A = \{1, 2, 3\}$, $B = \{3, 4\}$ and $C = \{4, 5, 6\}$, then $A \cup (B \cap C)$ is
(a) $\{3\}$ (b) $\{1, 2, 3, 4\}$
(c) $\{1, 2, 5, 6\}$ (d) $\{1, 2, 3, 4, 5, 6\}$

13. Let $A = \{x, y, z\}$, $B = \{u, v, w\}$ and $f : A \to B$ be defined by $f(x) = u$, $f(y) = v, f(z) = w$. Then, f is
(a) surjective but not injective
(b) injective but not surjective
(c) bijective
(d) None of the above

14. If $A = \{2, 4\}$ and $B = \{3, 4, 5\}$, then $(A \cap B) \times (A \cup B)$ is
(a) $\{(2, 2), (3, 4), (4, 2), (5, 4)\}$ (b) $\{(2, 3), (4, 3), (4, 5)\}$
(c) $\{(2, 4), (3, 4), (4, 4), (4, 5)\}$ (d) $\{(4, 2), (4, 3), (4, 4), (5, 4)\}$

15. In the set $X = \{a, b, c, d\}$, which of the following functions in X?
(a) $R_1 = \{(b, a) (a, b), (c, d), (a, c)\}$
(b) $R_2 = \{(a, d) (d, c), (b, b), (c, c)\}$
(c) $R_3 = \{(a, b) (b, c), (c, d), (b, d)\}$
(d) $R_4 = \{(a, a) (b, b), (c, c), (a, d)\}$

16. The composite mapping fog of the map $f : R \to R$, $f(x) = \sin x$ and $g : R \to R$, $g(x) = x^2$ is
(a) $x^2 \sin x$ (b) $(\sin x)^2$ (c) $\sin x^2$ (d) $\sin x / x^2$

17. Which of the following is the empty set?
(a) $\{x : x$ is a real number and $x^2 - 1 = 0\}$
(b) $\{x : x$ is a real number and $x^2 + 1 = 0\}$
(c) $\{x : x$ is a real number and $x^2 - 9 = 0\}$
(d) $\{x : x$ is a real number and $x^2 = x + 2\}$

18. In order that a relation R defined on a non-empty set A is an equivalence relation. It is sufficient, if R
(a) is reflexive
(b) is symmetric
(c) is transitive
(d) possesses all the above three properties

19. Let $A = \{p, q, r, s\}$ and $B = \{1, 2, 3\}$. Which of the following relations from A to B is not a function?
(a) $R_1 = \{(p, 1), (q, 2), (r, 1), (s, 2)\}$
(b) $R_2 = \{(p, 1), (q, 2), (r, 1), (s, 1)\}$
(c) $R_3 = \{(p, 1), (q, 2), (r, 2), (r, 2)\}$
(d) $R_4 = \{(p, 2), (q, 3), (r, 2), (s, 2)\}$

20. n/m means that n is factor of m, then the relation f is
(a) reflexive and symmetric
(b) transitive and symmetric
(c) reflexive, transitive and symmetric
(d) reflexive, transitive and not symmetric

21. The solution of $8x \equiv 6 \pmod{14}$ are
(a) [8],[6] (b) [8],[14]
(c) [6],[13] (d) [8],[14],[16]

22. Let A be a set containing 10 distinct elements, the total number of distinct functions from A to A is
(a) 10! (b) 10^{10} (c) 2^{10} (d) $2^{10} - 1$

23. Let A and B be two non-empty subsets of set X such that A is not a subset of B, then
(a) A is a subset of the complement of B
(b) B is a subset of A
(c) A and B are disjoint
(d) A and the complement of B are non-disjoint

24. f and h are function from $A \to B$, where $A = \{a, b, c, d\}$ and $B = \{s, t, u\}$ defined as follows
$f(a) = t, f(b) = s, f(c) = s$
$f(d) = u, h(a) = s, h(b) = t$
$h(c) = s, h(a) = u, h(d) = u$
Which one of the following statement is true?
(a) f and h are functions
(b) f is a function and h is not a function
(c) f and h are not functions
(d) None of the above

25. Let I be the set of integer and $f : I \to I$ be defined as $f(x) = x^2$, $x \in I$, the function is
(a) bijection (b) injection
(c) surjection (d) None of these

26. Which of the four statements given below is different from others?
(a) $f : A \to B$
(b) $f : x \to f(x)$
(c) f is a mapping of A into B
(d) f is a function of A into B

27. The number of surjections from $A = \{1, 2, \ldots, n\}$, $n \geq 2$ onto $B = \{a, b\}$ is
(a) ${}^nP_2$ (b) $2^n - 2$
(c) $2^n - 1$ (d) None of these

28. Let $f : R \to R$ be defined by $f(x) = 3x - 4$, then $f^{-1}(x)$ is
(a) $\frac{1}{3}(x + 4)$ (b) $\frac{1}{3}x - 4$
(c) $3x + 4$ (d) not defined

29. $f : R \to R$ is a function defined by $f(x) = 10x - 7$. If $g = f^{-1}$, then $g(x)$ equals
(a) $\frac{1}{10x - 7}$ (b) $\frac{1}{10x + 7}$ (c) $\frac{x + 7}{10}$ (d) $\frac{x - 7}{10}$

30. Let R be a relation defined by $R = \{(a, b) : a \geq b\}$, where a and b are real numbers, then R is
(a) reflexive, symmetric and transitive
(b) reflexive, transitive but not symmetric
(c) symmetric, transitive but not reflexive
(d) neither transitive, nor reflexive, not symmetric

31. If sets A and B are defined as
$A = \{(x, y) : y = e^x, x \in R\}$ and $B = \{(x, y) : y = x, x \in R\}$.
(a) $B \subset A$ (b) $A \subset B$
(c) $A \cap B = \phi$ (d) $A \cup B$

32. If $f : A \to B$ is a bijective function, then $f^{-1}of$ is equal to
(a) fof^{-1}
(b) f
(c) f^{-1}
(d) I_A(the identity map of the set A)

33. If $f(y) = \frac{y}{\sqrt{(1 - y^2)}}$, $g(y) = \frac{y}{\sqrt{(1 + y^2)}}$, then $(fog)y$ is equal to
(a) $\frac{y}{\sqrt{(1 - y^2)}}$ (b) $\frac{y}{\sqrt{(1 + y^2)}}$ (c) y (d) $\frac{(1 - y^2)}{\sqrt{(1 - y^2)}}$

34. If $f : R \to R$ is defined by $f(x) = 2x + |x|$, then $f(3x) - f(-x) - 4x$ equals
(a) $f(x)$ (b) $-f(x)$ (c) $f(-x)$ (d) $2f(x)$

35. Let R and S be two non-void relations on a set A. Which of the following statement is false?
(a) R and S are transitive $\Rightarrow R \cup S$ is transitive.
(b) R and S are transitive $\Rightarrow R \cap S$ is symmetric.
(c) R and S are symmetric $\Rightarrow R \cup S$ is symmetric.
(d) R and S are reflexive $\Rightarrow R \cap S$ is reflexive.

36. Let $f : R \to R$, $g : R \to R$ be two functions given by $f(x) = 2x - 3$, $g(x) = x^3 + 5$. Then, $(fog)^{-1}(x)$ is equal to
(a) $\left(\frac{x + 7}{2}\right)^{1/3}$ (b) $\left(x - \frac{7}{2}\right)^{1/3}$ (c) $\left(\frac{x - 2}{7}\right)^{1/3}$ (d) $\left(\frac{x - 7}{2}\right)^{1/3}$

37. If $f(x) = ax + b$ and $g(x) = cx + d$, then $f(g(x)) = g(f(x)) \Leftrightarrow$
(a) $f(a) = g(c)$ (b) $f(b) = g(b)$
(c) $f(d) = g(b)$ (d) $f(c) = g(a)$

38. If $f : R \to R$, $g : R \to R$ be two given functions, then $f(x) = 2\min(f(x) - g(x), 0)$ equals
(a) $f(x) + g(x) - |g(x) - f(x)|$
(b) $f(x) + g(x) + |g(x) - f(x)|$
(c) $f(x) - g(x) + |g(x) - f(x)|$
(d) $f(x) - g(x) - |g(x) - f(x)|$

39. Let $f : R \to R$, $g : R \to R$ be two given functions, such that f is injective and g is surjective, then which of the following is injective?
(a) gof (b) fog (c) gog (d) fof

Sets, Relations and Functions Exercise 2 : More than One Correct Option Type Questions

- This section contains **3 multiple choice questions**. Each question has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

40. Let L be the set of all straight lines in the Euclidean plane. Two lines l_1 and l_2 are said to be related by the relation R iff l_1 is parallel to l_2. Then, the relation R is

(a) reflexive (b) symmetric
(c) transitive (d) equivalence

41. Let $X = \{1, 2, 3, 4, 5, 6\}$ and $Y = \{1, 3, 5, 7, 9\}$. Which of the following is/are relations from X to Y?

(a) $R_1 = \{(x, y) : y = 2 + x, x \in X, y \in Y\}$
(b) $R_2 = \{(1, 1), (2, 1), (3, 3), (4, 3), (5, 5)\}$
(c) $R_3 = \{(1, 1), (1, 3), (3, 5), (3, 7), (5, 7)\}$
(d) $R_4 = \{(1, 3), (2, 5), (2, 4), (7, 9)\}$

42. Let the function $f : R - \{-b\} \to R - \{1\}$ be defined by $f(x) = \dfrac{x + a}{x + b} (a \neq b)$, then

(a) f is one-one but not onto
(b) f is onto but not one-one
(c) f is both one-one and onto
(d) $f^{-1}(2) = a - 2b$

Sets, Relations and Functions Exercise 3 : Passage Based Questions

- This section contains **2 passages**. Based upon each of the passage **3 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Passage I
(Q. Nos. 43 to 45)

Let f and g be real valued functions defined as

$$f(x) = \begin{cases} 7x^2 + x - 8, & x \le 1 \\ 4x + 5, & 1 < x \le 7 \\ 8x + 3, & x > 7 \end{cases} \quad g(x) = \begin{cases} |x|, & x < -3 \\ 0, & -3 \le x < 2 \\ x^2 + 4, & x \ge 2 \end{cases}$$

43. The value of $(gof)(0) + (fog)(-3)$ is

(a) -8 (b) 0
(c) 8 (d) 16

44. The value of $2(fog)(7) - (gof)(6)$ is

(a) 9 (b) 11
(c) 13 (d) 15

45. The value of $4(gof)(2) - (fog)(9)$ is

(a) 0 (b) 2 (c) 5 (d) 9

Passage II
(Q. Nos. 46 to 48)

R_1 on Z defined by $(a, b) \in R_1$ iff $|a - b| \le 7$, R_2 on Q defined by $(a, b) \in R_2$ iff $ab = 4$ and R_3 on R defined by $(a, b) \in R_3$ iff $a^2 - 4ab + 3ab^2 = 0$.

46. Relation R_1 is

(a) reflexive and symmetric (b) symmetric and transitive
(c) reflexive and transitive (d) equivalence

47. Relation R_2 is

(a) reflexive (b) symmetric
(c) transitive (d) equivalence

48. Relation R_3 is

(a) reflexive (b) symmetric
(c) transitive (d) equivalence

Sets, Relations and Functions Exercise 4 : Single Integer Answer Type Questions

- This section contains **6 questions**. The answer to each question is a **single digit integer**, ranging from 0 to 9 (both inclusive).

49. In a group of 45 students, 22 can speak Hindi only and 12 can speak English only . If $(2\lambda + 1)$ student can speak both Hindi and English, the value of λ is

50. If $A = \left\{x \mid \cos x > -\dfrac{1}{2} \text{ and } 0 \le x \le \pi\right\}$ and $B = \left\{x \mid \sin x > \dfrac{1}{2} \text{ and } \dfrac{\pi}{3} \le x \le \pi\right\}$ and if $\pi\lambda \le A \cap B < \pi\mu$, the value of $(\lambda + \mu)$ is

51. If $S = R$, $A = \{x : -3 \le x < 7\}$ and $B = \{x : 0 < x < 10\}$, the number of positive integers in $A \Delta B$ is

52. Two finite sets have m and n elements. The total number of subsets of the first set is 48 more than the total number of subsets of the second set. The value of $m - n$ is

53. If two sets A and B are having 99 elements in common, the number of elements common to each of the sets $A \times B$ and $B \times A$ are $121\lambda^2$, the value of λ is

Sets, Relations and Functions Exercise 5 : Matching Type Questions

- This section contains **2 questions**. Questions 54 and 55 have three statements (A, B and C) given in **Column I** and four statements (p, q, r and s) in **Column II** and questions 70 and 71 have four statements (A, B, C and D) given in **Column I** and five statements (p, q, r, s and t) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

54. The functions defined have domain R.

Column I		Column II	
(A)	$7x + 1$	(p)	onto $[-1, 1]$ but not one-one $[0, \pi]$
(B)	$\cos x$	(q)	one-one on $[0, \pi]$ but not onto R
(C)	$\sin x$	(r)	one-one and onto R
(D)	$1 + \ln x$	(s)	one-one on $(0, \infty)$

55. The domain of the function $f(x)$ is denoted by D_f.

Column I		Column II	
(A)	$f(x) = \sqrt{(3 - x)} + \sin^{-1}\left(\frac{3 - 2x}{5}\right)$, then D_f is	(p)	$\bigcup_{k \in I} [2k\pi, (2k + 1)\pi]$
(B)	$f(x) = \log_{10}(1 - \log_{10}(x^2 - 5x + 16))$, then D_f is	(q)	$[-4, -\pi] \cup [0, \pi]$
(C)	$f(x) = \cos^{-1}\left(\frac{2}{2 + \sin x}\right)$, then D_f is	(r)	$(2, 3)$
(D)	$f(x) = \sqrt{(\sin x)} + \sqrt{(16 - x^2)}$, then D_f is	(s)	$[-1, 3]$

Sets, Relations and Functions Exercise 6 : Statement I and II Type Questions

- **Directions** Question numbers 56 to 59 are Assertion-Reason type questions. Each of these questions contains two statements :
  (a) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1.
  (b) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1.
  (c) Statement-1 is true, Statement-2 is false.
  (d) Statement-1 is false, Statement-2 is true.

56. **Statement-1** If a set A has n elements, then the number of binary relations on $A = n^{n^2}$.
Statement-2 Number of possible relations from A to $A = 2^{n^2}$.

57. **Statement-1** If $A = \{x \mid g(x) = 0\}$ and $B = \{x \mid f(x) = 0\}$, then $A \cap B$ be a root of $\{f(x)\}^2 + \{g(x)\}^2 = 0$.
Statement-2 $x \in A \cap B \Rightarrow x \in A$ or $x \in B$.

58. **Statement-1** $P(A) \cap P(B) = P(A \cap B)$, where $P(A)$ is power set of set A.
Statement-2 $P(A) \cup P(B) = P(A \cup B)$

59. **Statement-1** If Sets A and B have three and six elements respectively, then the minimum number of elements in $A \cup B$ is 6.
Statement-2 $A \cap B = 3$.

Sets, Relations and Functions Exercise 7 : Subjective Type Questions

- In this section, there are **15 subjective** questions.

60. Let $A = \{x : x \text{ is a natural number}\}$,
$B = \{x : x \text{ is an even natural number}\}$,
$C = \{x : x \text{ is an odd natural number}\}$
and $D = \{x : x \text{ is a prime number}\}$.
Find
(i) $A \cap B$ (ii) $A \cap C$
(iii) $B \cap D$ (iv) $C \cap D$

61. Let U be the set of all people and $M = \{\text{Males}\}$,
$S = \{\text{College students}\}$,
$T = \{\text{Teenagers}\}$, $W = \{\text{People having height more than five feet}\}$.
Express each of the following in the notation of set theory.
(i) College student having heights more than five feet.
(ii) People who are not teenagers and have their height less five feet.
(iii) All people who are neither males nor teenagers nor college students.

62. The set X consists of all points within and on the unit circle $x^2 + y^2 = 1$, whereas the set Y consists of all points on and inside the rectangular boundary $x = 0$, $x = 1$, $y = -1$ and $y = 1$. Determine $X \cup Y$ and $X \cap Y$. Illustrate your answer by diagrams.

63. In a group of children, 35 play football out of which 20 play football only, 22 play hockey; 25 play cricket out of which 11 play cricket only. Out of these 7 play cricket and football but not hockey, 3 play football and hockey but not cricket and 12 play football and cricket both.
How many play all the three games? How many play cricket and hockey but not football, how many play hockey only? What is the total number of children in the group?

64. Of the members of three athletic team in a certain school, 21 are on the basketball team, 26 on the hockey team and 29 on the football team. 14 play hockey and basketball, 15 play hockey and football, 12 play football and basketball and 8 play all the three games. How many members are there in all?

65. In a survey of 200 students of higher secondary school, it was found that 120 studied Mathematics; 90 studies Physics and 70 studied Chemistry; 40 studied Mathematics and Physics; 3 studied Physics and Chemistry; 50 studied Chemistry and Mathematics and 20 studied none of these subjects. Find the number of students who studied all the three subjects.

66. In a survey of population of 450 people, it is found that 205 can speak English, 210 can speak Hindi and 120 people can speak Tamil. If 100 people can speak both Hindi and English; 80 people can speak both English and Tamil, 35 people can speak Hindi and Tamil and 20 people can speak all the three languages, find the number of people who can speak English but not a Hindi or Tamil. Find also the number of people who can speak neither English nor Hindi nor Tamil.

67. A group of 123 workers went to a canteen for cold drinks, ice-cream and tea, 42 workers took ice-cream, 36 tea and 30 cold drinks. 15 workers purchased ice-cream and tea, 10 ice-cream and cold drinks, and 4 cold drinks and tea but not ice-cream, 11 took ice-cream and tea but not cold drinks. Determine how many workers did not purchase anything?

68. Let n be a fixed positive integer. Define a relation R on I (the set of all integers) as follows:
$a\ R\ b$ iff $n|(a - b)$ i.e., iff $(a - b)$ is divisible by n. Show that R is an equivalence relations on I.

69. N is the set of positive integers. The relation R is defined on $N \times N$ as follows:
$$(a, b)\ R\ (c, d) \Leftrightarrow ad = bc$$
Prove that R is an equivalence relation.

70. The following relations are defined on the set of real numbers.
(i) $a\ R\ b \Leftrightarrow |a - b| > 0$
(ii) $a\ R\ b \Leftrightarrow |a| = |b|$
(iii) $a\ R\ b \Leftrightarrow |a| \geq |b|$
(iv) $a\ R\ b \Leftrightarrow 1 + ab > 0$
(v) $a\ R\ b \Leftrightarrow |a| \leq b$
Find whether these relations are reflexive, symmetric or transitive.

71. Let $A = \{x : -1 \leq x \leq 1\} = B$ for each of the following functions from A to B. Find whether it is surjective, injective or bijective
(i) $f(x) = \dfrac{x}{2}$
(ii) $g(x) = |x|$
(iii) $h(x) = x|x|$
(iv) $k(x) = x^2$
(v) $l(x) = \sin \pi x$

72. If the functions f and g defined from the set of real numbers R to R such that $f(x) = e^x$ and $g(x) = 3x - 2$, then find functions fog and gof. Also, find the domain of the functions $(fog)^{-1}$ and $(gof)^{-1}$.

73. If $f(x) = \dfrac{x^2 - x}{x^2 + 2x}$, then find the domain and range of f. Show that f is one-one. Also, find the function $\dfrac{d(f^{-1}(x))}{dx}$ and its domain.

74. If the functions f, g and h are defined from the set of real numbers R to R such that

$$f(x) = x^2 - 1,\ g(x) = \sqrt{(x^2 + 1)},$$

$$h(x) = \begin{cases} 0, & \text{if } x \le 0 \\ x, & \text{if } x \ge 0 \end{cases}.$$

Then, find the composite function $hofog$ and determine whether the function fog is invertible and h is the identity function.

Sets, Relations and Functions Exercise 8 : Questions Asked in Previous 13 Year's Exam

■ This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to year **2017**.

75. Let $R = \{(3,3), (6,6), (9,9), (12,12), (6,12), (3,9)$ be a relation on the set $A = \{3, 6, 9, 12\}$.

The relation is **[AIEEE 2005, 3M]**

(a) an equivalence relation
(b) reflexive and symmetric only
(c) reflexive and transitive only
(d) reflexive only

76. Let W denotes the words in the English dictionary. Define the relation R by $R = \{(x, y) \in W \times W\}$ the words x and y have atleast one letter in common, then R is **[AIEEE 2006, 3M]**

(a) not reflexive, symmetric and transitive
(b) reflexive, symmetric and not transitive
(c) reflexive, symmetric and transitive
(d) reflexive, not symmetric and transitive

77. Let R be the real line, consider the following subsets of the plane $R \times R$ such that **[AIEEE 2008, 3M]**

$S = \{(x, y) : y = x + 1 \text{ and } 0 < x < 2\}$

$T = \{(x, y) : x - y \text{ is an integer}\}$.

Which one of the following is true?

(a) Both S and T are equivalence relations on R
(b) S is an equivalence relation on R but T is not
(c) T is an equivalence relation on R but S is not
(d) Neither S nor T is an equivalence relations on R

78. If A, B and C are three sets such that $A \cap B = A \cap C$ and $A \cup B = A \cup C$, then **[AIEEE 2009, 4M]**

(a) $A \cap B = \phi$ (b) $A = B$
(c) $A = C$ (d) $B = C$

79. Let $S = \{1, 2, 3, 4\}$. The total number of unordered pair of disjoint subsets of S is equal to **[IIT-JEE 2010, 5M]**

(a) 25 (b) 34 (c) 42 (d) 41

80. Consider the following relations.

$R = \{(x, y) \mid x, y$ are real numbers and $x = wy$ for some rational number $w\}$

$S = \left\{\left(\dfrac{m}{n}, \dfrac{p}{q}\right) \middle| m, n, p \text{ and } q \text{ are integers such that } n, q \ne 0 \text{ and } qm = pn\right\}$, then **[AIEEE 2010, 4M]**

(a) neither R nor S is an equivalence relation
(b) S is an equivalence relation but R is not an equivalence relation
(c) R and S both are equivalence relations
(d) R is an equivalence relation but S is not an equivalence relation

81. Let $P = \{\theta : \sin\theta - \cos\theta = \sqrt{2}\cos\theta\}$ and $Q = \{\theta : \sin\theta + \cos\theta = \sqrt{2}\sin\theta\}$ be two sets. Then, **[IIT-JEE 2011, 3M]**

(a) $P \subset Q$ and $A - P \ne \phi$ (b) $Q \not\subset P$
(c) $P \not\subset Q$ (d) $P = Q$

82. Let $f(x) = x^2$ and $g(x) = \sin x$ for all $x \in R$. Then, the set of all x satisfying $(fogogof)(x) = (gogof)(x)$, where $(fog)(x) = f(g(x))$ is **[IIT-JEE 2011, 3M]**

(a) $\pm\sqrt{n\pi}$, $n \in \{0, 1, 2, \ldots\}$

(b) $\pm\sqrt{n\pi}$, $n \in \{1, 2, 3, \ldots\}$

(c) $\dfrac{\pi}{2} + 2n\pi$, $n \in \{\ldots, -2, -1, 0, 1, 2, \ldots\}$

(d) $2n\pi$, $n \in \{\ldots, -2, -1, 0, 1, 2, \ldots\}$

83. Let R be the set of real numbers.

Statement-1 $A = \{(x, y) \in R \times R : y - x$ is an integer$\}$ is an equivalence relation on R.

Statement-2 $B = \{(x, y) \in R \times R : x = \alpha y$ for some rational number $\alpha\}$ is an equivalence relation on R. **[AIEEE 2011, 4M]**

(a) Statement-1 is true, Statement-2 is true; Statement-2 is not a correct explanation for Statement-1
(b) Statement-1 is true, Statement-2 is false
(c) Statement-1 is false, Statement-2 is true
(d) Statement-1 is true, Statement-2 is true; Statement-2 is a correct explanation for Statement-1

84. Let A and B be two sets containing 2 elements and 4 elements, respectively. The number of subsets of $A \times B$ having 3 or more elements, is **[JEE Main 2013, 4M]**
(a) 220 (b) 219 (c) 211 (d) 256

85. If $X = \{4^n - 3n - 1 : n \in N\}$ and $Y = \{9(n-1) : n = N\}$, where N is the set of natural numbers, then $X \cup Y$ is equal to **[JEE Main 2014, 4M]**
(a) X (b) Y (c) N (d) $Y - X$

86. Let A and B be two sets containing four and two elements, respectively. Then, the number of subsets of the set $A \times B$, each having atleast three elements is **[JEE Main 2015, 4M]**
(a) 275 (b) 510 (c) 219 (d) 256

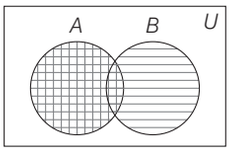
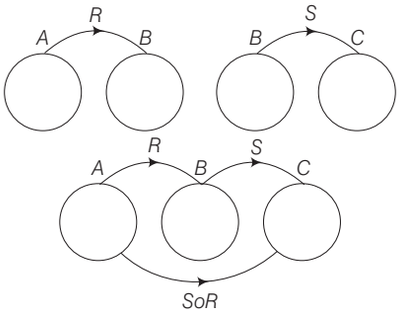
Solutions

1. By Venn diagram,



It is clear that $A \cap (A \cup B) = A$

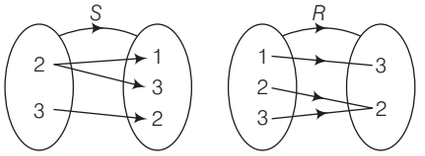
2.



SoR is the relation from A to C.

3. $R = \{(1, 3), (2, 2), (3, 2)\}$

$S = \{(2, 1), (3, 2), (2, 3)\}$



$RoS = \{(2, 3), (2, 2), (3, 2)\}$

4. $X \cap (Y \cap X)' = X \cap (Y' \cup X')$

$= (X \cap Y') \cup (X \cap X')$

$= (X \cap Y') \cup \phi = X \cap Y'$

$= X - (X \cap Y)$

5. $xRy \Leftrightarrow (x - y + \sqrt{2})$ is an irrational number.

Let $(x, x) \in R$.

Then, $x - x + \sqrt{2} = \sqrt{2}$ which is an irrational number.

$\therefore \quad x\ R\ x, \forall\ x \in R$

$\therefore$ R is an reflexive relation.

$x\ R\ y \Rightarrow (x - y + \sqrt{2})$ is an irrational number.

$\Rightarrow\ -(y - x - \sqrt{2})$ is an irrational number.

$\Rightarrow (y - x - \sqrt{2})$ is an irrational number.

$y\ R\ x \Rightarrow (y - x + \sqrt{2})$ is an irrational number.

So, $xRy \not\Rightarrow yRx \therefore R$ is not a symmetric relation.

Let $(1, 2) \in R$, then $(1 - 2 + \sqrt{2})$ is an irrational number.

$\Rightarrow \quad (\sqrt{2} - 1)$ is an irrational number.

and $(2, 3) \in R$, then $(2 \ -3 + \sqrt{2})$ is an irrational number.

$\Rightarrow \quad (\sqrt{2} - 1)$ is an irrational number.

$(1, 3) \in R \Rightarrow (1 - 3 + \sqrt{2})$ is an irrational number.

$\Rightarrow \quad (\sqrt{2} - 2)$ is an irrational number.

So, $(1, 2) \in R$ and $(2, 3) \in R \not\Rightarrow (1, 3) \in R$ (by any way)

$\therefore$ R is not transitive relation.

6. $f(x) = (x + 1)^2 - 1 \qquad [\because x \geq 1]$

$= x^2 + 1 + 2x - 1 = x^2 + 2x$

$S = \{x : f(x) \equiv f^{-1}(x)\}$

S is the set of point of intersection of $(y = x)$ and tf.

Now, solve $y = x$ and $f(x) = x^2 + 2x$

$$x^2 + 2x = x$$

$$x^2 + x = 0$$

$$x(x + 1) = 0$$

$$x = 0 \text{ or } x = -1$$

7. Let set A contains n elements.

Power set of A is the set of all subsets.

$\therefore$ Number of subsets of $A = {}^nC_o + {}^nC_1 + {}^nC_2 + \ldots + {}^nC_n = 2^n$

$\therefore$ Power set of A contains 2^n elements.

8. By Venn diagram, it is clear that

$A - B \subseteq A$ and $B' - A' \subseteq A$ and $A \cap B' \subseteq A$

but $A \not\subseteq A - B$

9. $A = \{1, 2, 3\}$

$$B = \{3, 8\}$$

$$A \cup B = \{1, 2, 3, 8\}$$

$$A \cap B = \{3\}$$

$$(A \cup B) \times (A \cap B) = \{1, 2, 3, 8\} \times \{3\}$$

$$= \{(1, 3), (2, 3), (3, 3) (8, 3)\}$$

10. $A = \{p, q, r\}$

$R_1 = \{(p, q), (q,r), (p, r), (p, p)\}$

$(q, q) \notin R_1$, so R_1 is not reflexive relation.

So, R_1 is not an equivalence relation.

$$R_2 = \{(r, q), (r, p), (r, r), (q, q)\}$$

Here, $(p, p) \notin R_2$, so R_2 is not reflexive relation.

So, R_2 is not an equivalence relation.

$$R_3 = \{(p, p), (q, q), (r, r), (p, q)\}$$

R_3 is an reflexive relation.

$(p, a) \in R_3$ but $(q, p) \notin R_3$

R_3 is not symmetric relation.

So, R_3 is not equivalence relation.

11. $A = \{x : x$ is a multiple of 3$\}$

$A = \{x : x = 3m, m \in N\}$

$B = \{x : x$ is a multiple of 5$\}$

$B = \{x : x = 5n, n \in N\}$

$A \cap B = \{x : x$ is a multiple of both 3 and 5$\}$

$$= \{15, 30, 45, \ldots\}$$

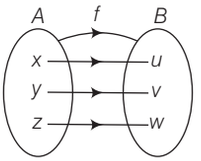
12. $A = \{1, 2, 3\}, B = \{3, 4\}, C = \{4, 5, 6\}$

$\Rightarrow \quad B \cap C = \{4\}$

and $A \cup (B \cap C) = \{1, 2, 3, 4\}$

13. $A = \{x, y, z\}, B = \{u, v, w\}$

Now, $f : A \to B$



f is one-one and f is onto.

14. $A = \{2, 4\}$

$B = \{3, 4, 5\}$

$A \cap B = \{4\}$

$A \cup B = \{2, 3, 4, 5\}$

$(A \cap B) \times (A \cup B) = \{(4, 2), (4, 3), (4, 4), (4, 5)\}$

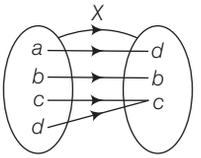
15. $X = \{a, b, c, d\}$

$R_1 = \{(b, a), (a, b), (c, d), (a, c)\}$

$(a, b) \in R_1$ and $(a, c) \in R$,

$\therefore R_1$ is not a function.

$R_2 = \{(a, d), (d, c), (b, b), (c, c)\}$



Hence, R_2 is a function.

16. $f : R \to R$

$\Rightarrow \quad f(x) = \sin x$ and $g : R \to R$

$\Rightarrow \quad g(x) = x^2$

Range of g is $R^+ \cup \{0\}$, which is the subset of domain of f.

$\therefore$ Composition of fog is possible.

$$fog = f(g(x)) = f(x^2)$$
$$= \sin x^2$$

17. $x^2 - 1 = 0$

$\Rightarrow \quad x = -1, 1$

$\therefore$ x is real, q $\quad x^2 + 1 = 0$

$\Rightarrow \quad x = \pm i$

$\therefore$ x is not real, $\quad x^2 - 9 = 0$

$\Rightarrow \quad x = \pm 3$

$\therefore$ x is real $\quad x^2 - x - 2 = 0$

$\Rightarrow \quad x = 2, -1$

$\therefore$ x is real.

18. By definition for equivalent relation.

R should be reflexive, symmetric, transitive.

19. $\because$ x - coordinates of two brackets are same.

20. $\frac{n}{m}$ means that n is a factor of m.

So, f is reflexive.

$\because$ A number is a factor of itself.

Now, if n is a factor of m, then m is not a factor of n

$\therefore$ f is not symmetric. Let n is a factor of m and m is a factor of s, then it is true that n is a factor of s.

$\therefore$ f is transitive.

21. $\lambda = \frac{8x - 6}{14}$, where $\lambda \in I_+$

$\therefore \quad 8x = 14\lambda + 6 \Rightarrow x = \frac{14\lambda + 6}{8}$

$\Rightarrow \quad x = \frac{7\lambda + 3}{4} = \lambda + \frac{3}{4}(\lambda + 1)$, when $\lambda \in I$

and here greatest common divisor of 8 and 14 is 2, so there are two required solutions.

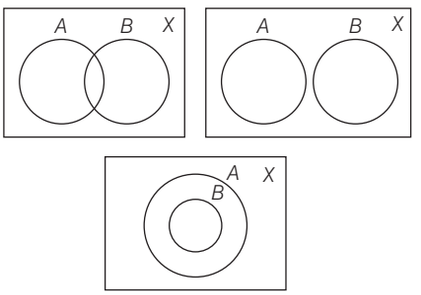
for $\lambda = 3$ and $\lambda = 7$, $x = 6, 13$ or $x = [6][13]$

22. $n(A) = 10$

Total number of distinc Functions from A to $A = 10^{10}$.

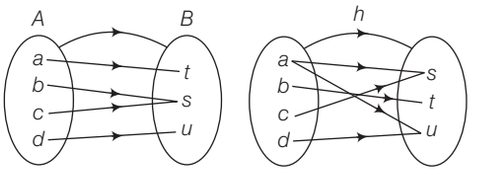
23. $A \subseteq X$ and $B \subseteq X$ and $A \subseteq B$

In all 3 possible cases,



24. $A = \{a, b, c, d\}$

$B = \{s, t, u\}$



It is clear that f is a function.

But in relation h, a have h image s and u.

So, h is not a function.

25. $f(x) = x^2, x \in Z$

$f(1) = 1$

$f(-1) = 1$

$\therefore$ f is not one-one

Range of f is set of whole number.

Which is a subset of Z.

$\therefore f$ is not onto.

26. It is obvious.

27. $A = \{1, 2, ..., n\}\ n \geq 2$

$B = \{a, b\}$

Number of into functions from A to $B = 2$

Total Numer of functions from A to $B = [n(B)]^{n(A)} = 2^n$

$\therefore$ Total Number of onto functions from A to $B = 2^n - 2$

28. $f : R \to R$

$\Rightarrow \qquad f(x) = 3x - 4$

f is one-one onto function.

$\therefore$ Let $\qquad y = 3x - 4$

$$x = \frac{y+4}{3}$$

Replace x by $y \Rightarrow y = \frac{x+4}{3} = f^{-1}(x)$

29. $f : R \to R$

$\Rightarrow \qquad f(x) = 10x - 7$

It is clear that f is one-one and onto.

$\therefore$ Let $\qquad y = 10x - 7$

$\therefore \qquad x = \frac{y+7}{10} = f^{-1}(y)$

$$g(x) = f^{-1}(x) = \frac{x+7}{10}$$

30. $R = \{(a, b) : a \geq b\}$

We know that, $a \geq a$

$\therefore \qquad (a, a) \in R, \forall\ a \in R$

R is a reflexive relation.

Let $(a, b) \in R$

$\Rightarrow \qquad a \geq b$

$\not\Rightarrow \qquad b \leq a$

$\not\Rightarrow \qquad (b, a) \in R$

So, R is not symmetric relation.

Now, let $(a, b) \in R$ and $(b, c) \in R$.

$\Rightarrow \qquad a \geq b$ and $b \geq c$

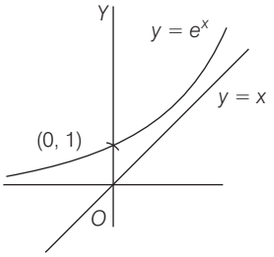
$\Rightarrow \qquad a \geq c$

$\Rightarrow \qquad (a, c) \in R$

$\therefore$ R is a transitive relation.

31. $A = \{(x, y) : y = e^x,\ x \in R\}$

$B = \{(x, y) : y = x,\ x \in R\}$

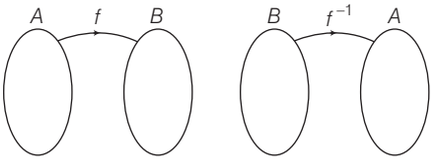


$\therefore \qquad A \subset B$

32. $f : A \to B$

f is a function, then f^{-1} is also a bijective function.

Composite function $(f^{-1}\ of) = I_A$



33. $f(y) = \frac{y}{\sqrt{(1-y^2)}},\ g(y) = \frac{y}{\sqrt{(1+y^2)}}$

and $\qquad (fog)y = f(g(y)) = f\left(\frac{y}{\sqrt{(1+y^2)}}\right)$

$$= \frac{\frac{y}{\sqrt{(1+y^2)}}}{\sqrt{1 - \frac{y^2}{(1+y^2)}}} = \frac{\frac{y}{\sqrt{(1+y^2)}}}{\frac{1}{\sqrt{(1+y^2)}}} = y$$

34. $f : R \to R$

$$f(x) = 2x + |x|$$

When $x \geq 0$, then $f(x) = 2x + x = 3x$

When $x < 0$, then $f(x) = 2x - x = x$

Now, when $x \geq 0$

$f(3x) - f(-x) - 4x = 3(3x) - (-x) - 4x = 9x + x - 4x$

$= 6x \qquad [\because x \geq 0]$

$= 2(3x) = 2f(x) \qquad [\therefore -x \leq 0]$

When $x < 0$,

$f(3x) - f(-x) - 4x = 3x - (-3x) - 4x = 2x = 2f(x)$

35. Let $A = \{1, 2, 3\}$, $R = \{(1, 1)\ (1, 2)\}$

and $S = \{(2, 2), (2, 3)\}$

be the transitive relation on A.

Then, $R \cup S = \{(1, 1,)\ (1, 2)(2, 2)\ (2, 3)\}$

$R \cup S$ is not transitive, because $(1, 2) \in R \cup S$

and $(2, 3) \in R \cup S$ but $(1, 3) \notin R \cup S$.

36. $f : R \to R$

$g : R \to R$

$f(x) = 2x - 3$

$g(x) = x^3 + 5$

$\Rightarrow \qquad (fog)(x) = f(g(x)) = f(x^3 + 5) = 2(x^3 + 5) - 3$

$= 2x^3 + 7$

Now, let $\ y = 2x^3 + 7$

$2x^3 = y - 7$

$$x = \left(\frac{y-7}{2}\right)^{1/3}$$

Replacing x by y, we get

$$y = \left(\frac{x-7}{2}\right)^{1/3}$$

$\therefore \qquad (fog)^{-1}(x) = \left(\frac{x-7}{2}\right)^{1/3}$

37. $f(x) = ax + b$

$g(x) = cx + d$

$f(g(x)) = g(f(x))$

$f(cx + d) = g(ax + b)$

$a(cx + d) + b = c(ax + b) + d$

$acx + ad + b = acx + bc + d$

$ad + b = cb + d$

$f(d) = g(b)$

38. $f : R \to R,\ g : R \to R$

$f(x) = 2 \min f(x) - g(x), 0)$

Let $f(x) - g(x) > 0$, then

$F(x) = f(x) - g(x) - |f(x) - g(x)|$ and $f(x) - g(x) < 0$, then

$F(x) = 2[f(x) - g(x)] = [f(x) - g(x)] - |f(x) - g(x)|$

39. $f : R \to R$ and $g : R \to R$ such that f is injective and $+g$ is surjective.

Then, g may be one-one or many-one.

If g is one-one, then gof is one-one.

fog is one-one

gog is one-one

But if g is many-one, then gof is not one-one.

fog is not one-one.

gog is many-one

Now, fof is one-one

40. Relation R on the set of all straight lines in the plane is of parallel line.

A line is parallel to itself. So, R is reflexive.

If l_1 is parallel to l_2, then l_2 is parallel to l_1.

$\therefore$ R is symmetric relation. $[l_1, l_2 \in L]$

Let $l_1, l_2, l_3 \in L$

l_1 is parallel to l_2 and l_2 is parallel to l_3.

Then, l_1 is parallel to l_3.

$\therefore$ R is transitive relation.

So, R is equivalence relation.

41. $X = \{1, 2, 3, 4, 5\}$

$Y = \{1, 3, 5, 7, 9\}$

(a) $R_1 = \{(x, y) : y = 2 + x,\ x \in X,\ y \in Y\}$

$x = 1$	$y = 2$
$x = 2$	$y = 4$
$x = 3$	$y = 5$
$x = 4$	$y = 6$
$x = 5$	$y = 7$

So, R_1 is a relation from X to Y.

(b) $R_2 = \{(1, 1), (2, 1), (3, 3)\ (4, 3), (5, 5)\}$

$R_2 \subseteq X \times Y$

(c) $R_3 = \{(1, 1), (1, 3), (3, 5)\ (5, 7)\}$

$R_3 \subseteq X \times Y$

(d) $R_4 \not\subseteq X \times Y$

42. $f : R - \{-b\} \to R - \{1\}$

$$f(x) = \frac{x + a}{x + b} \qquad [a \neq b]$$

Let $x_1, x_2 \in D_f$

$$f(x_1) = f(x_2)$$

$$\Rightarrow \quad \frac{x_1 + a}{x_1 + b} = \frac{x_2 + a}{x_2 + b}$$

$\Rightarrow x_1x_2 + bx_1 + ax_2 + ab = x_1x_2 + ax_1 + bx_2 + ab$

$\Rightarrow \quad b(x_1 - x_2) = a(x_1 - x_2)$

$\Rightarrow \quad (x_1 - x_2)(b - a) = 0$

$\Rightarrow \quad x_1 = x_2 \qquad [\because a \neq b]$

$\therefore f$ is one-one function.

Now, let $\quad y = \dfrac{x + a}{x + b}$

$xy + by = x + a$

$x(y - 1) = a - by$

$x = \dfrac{a - by}{y - 1}$ and $f^{-1}(y) = \dfrac{a - by}{y - 1}$

$\because \quad y \in R - \{1\}$

$\therefore$ x is defined, $\forall y \in R - \{1\}$

$$f^{-1}(2) = \frac{a - 2b}{2 - 1} = a - 2b$$

Sol. (Q. Nos. 43 to 45)

43. $(gof)(0) = g(f(0)) = g(7(0)^2 + 0 - 8)$

$= g(-8) = |-8| = 8$

and $\quad (fog)(-3) = f(g(-3)) = f(0) = 7(0)^2 + 0 - 8 = -8$

$\therefore \quad (gof)(0) + (fog)(-3) = -8 + 8 = 0$

44. $(fog)(7) = f(g(7)) = f(7^2 + 4) = f(53)$

$= 8(53) + 3 = 427$

and $\quad (gof)(6) = g(f(6)) = g(4 \times 6 + 5) + g(29)$

$= (29)^2 + 4 = 845$

$\therefore \quad 2(fog)(7) - (gof)(6) = 2 \times 427 - 845 = 9$

45. $(gof)(2) = g(f(2)) = g(4 \times 2 + 5) = g(13)$

$= (13)^2 + 4 = 173$

and $\quad (fog)(g) = f(g(9)) = f(9^2 + 4) = f(85)$

$= 8 \times 85 + 3 = 683$

$\therefore \quad 4(gof)(2) - (fog)(9) = 4 \times 173 - 683 = 9$

Sol. (Q. Nos. 46-48)

46. We have, $(a, b) \in R_1$ iff $|a - b| \leq 7$, where $a, b \in z$

Reflexivity Let $a \in z$

$\Rightarrow \quad a - a = 0$

$\Rightarrow \quad |a - a| \leq 7$

$\Rightarrow \quad 0 \leq 7$

$\Rightarrow \quad (a, a) \in R_1$

$\therefore$The relation R_1 is reflexive.

Symmetry

$(a, b) \in R_1$

$\Rightarrow \quad |a - b| \leq 7 \Rightarrow |-(b - a)| \leq 7$

$\Rightarrow \quad |b - a| \leq 7 \Rightarrow (b, a) \in R_1$

$\therefore$The relation R_1 is symmetric.

Transitivity We have $(2, 6), (6, 10) \in R_1$ because

$|2 - 6| = 4 \leq 7$ and $|6 - 10| = 4 \leq 7$

Also, $\quad |2 - 10| = 8 \not\leq 7$

$\therefore \quad (2, 10) \notin R_1$

Hence, the relation R_1 is not transitive.

47. We have $(a, b) \in R_2$ iff $ab = 4$, where $a, b \in Q$

Reflexivity $5 \in Q$ and $(5)(5) = 25 \neq 4$

$\therefore \quad (5, 5) \notin R_2$

The relation R_2 is not reflexive.

Symmetry

$(a, b) \in R_2$

$\Rightarrow \quad ab = 4 \Rightarrow ba = 4$

$\Rightarrow \quad (b, a) \in R_2$

$\therefore$ The relation R_2 is symmetric.

Transitivity We have $\left(8, \frac{1}{2}\right), \left(\frac{1}{2}, 8\right) \in R_2$ because

$$8\left(\frac{1}{2}\right) = 4 \quad \text{and} \quad \left(\frac{1}{2}\right)(8) = 4$$

Also, $8(8) = 64 \neq 4$

$\therefore \quad (8, 8) \notin R_2$

$\therefore$ The relation R_2 is not transitive.

48. We have, $(a, b) \in R_3$ iff $a^2 - 4ab + 3b^2 = 0$ where $a, b \in R$

Reflexivity

$\therefore \quad a^2 - 4a \cdot a + 3d^2 = 4a^2 - 4a^2 = 0$

$\therefore \quad (a, a) \in R_3$

$\therefore$ The relation R_3 is reflexive.

Symmetry

$(a, b) \in R_3$

$\Rightarrow \quad a^2 - 4ab + 3b^2 = 0$, we get $a = b$ and $a = 3b$

and $(b, a) \in R_3$

$\Rightarrow \quad b^2 - 4ab + 3a^2 = 0$

we get $b = a$ and $b = 3a$

$\therefore \quad (a, b) \in R_3 \Rightarrow (b, a) \in R_3$

$\therefore$ The relation R_3 is not symmetric.

Transitivity We have $(3, 1), \left(1, \frac{1}{3}\right) \in R_3$

because $(3)^2 - 4(3)(1) + 3(1)^2 = 9 - 12 + 3 = 0$

and $(1)^2 - 4(1)\left(\frac{1}{3}\right) + 3\left(\frac{1}{3}\right)^2 = 1 - \frac{4}{3} + \frac{1}{3} = 0$

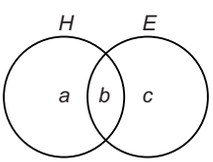
Also, $\left(3, \frac{1}{3}\right) \notin R_3$, because

$$(3)^2 - 4 \cdot (3)\left(\frac{1}{3}\right) + 3\left(\frac{1}{3}\right)^2 = 9 - 4 + \frac{1}{3} = \frac{16}{3} \neq 0$$

$\therefore$ The relation R_3 is not transitive.

49. Given, $a = 22$,

$c = 12$



and $a + b + c = 45$

$\Rightarrow \quad 22 + b + 12 = 45$

$\therefore \quad b = 11 = 2\lambda + 1$

$\Rightarrow \quad \lambda = 5$

50. $\therefore \quad \cos x > -\frac{1}{2}$ and $0 \leq x \leq \pi$

$\Rightarrow \quad -\frac{2\pi}{3} < x < \frac{2\pi}{3}$ and $0 \leq x \leq \pi$

$\Rightarrow \quad 0 \leq x < \frac{2\pi}{3}$

$\therefore \quad A = \left[0, \frac{2\pi}{3}\right]$

Again, $\sin x > \frac{1}{2}$ and $\frac{\pi}{3} \leq x \leq \pi$

$\Rightarrow \quad \frac{\pi}{6} < x < \frac{5\pi}{6}$ and $\frac{\pi}{3} \leq x \leq \pi$

$\Rightarrow \quad \frac{\pi}{3} \leq x < \frac{5\pi}{6}$

$B = \left[\frac{\pi}{3}, \frac{5\pi}{6}\right)$

Now, $A \cap B = \left[\frac{\pi}{3}, \frac{2\pi}{3}\right)$

$\frac{\pi}{3} \leq A \cap B < \frac{2\pi}{3}$

Here $\lambda = \frac{1}{3}$ and $\mu = \frac{2}{3}$

$\lambda + \mu = 1$

51. Here, $A = [-3, 7), B = (0, 10)$

and $S = (-\infty, \infty)$

$\therefore \quad A - B = [-3, 0]$ and $B - A = [7, 10)$

$\therefore \quad A \Delta B = (A - B) \cup (B - A) = [-3, 0] \cup [7, 10)$

$\therefore$ Positive integers are 7, 8, 9.

Number of positive integers = 3

52. As $2^m - 2^n = 48 = 16 \times 3 = 2^4 \times 3$

$\Rightarrow \quad 2^n(2^{m-n} - 1) = 2^4 (2^2 - 1)$

$\therefore \quad n = 4$ and $m - n = 2$

$n = 4$ and $m = 6$

Now, $m - n = 2$

53. $n((A \times B) \cap (B \times A)) = n((A \cap B) \times (B \cap A))$

$= n(A \cap B) \cdot n(B \cap A)$

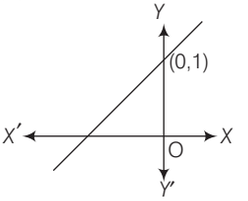
$= n(A \cap B) \cdot n(A \cap B)$

$= 99 \times 99 = 121 \times 9^2$

$\therefore \quad \lambda = 9$

54. (A) $y = 7x + 1$

$f(x) = 7x + 1$



Let $x_1, x_2 \in D_f$,

then $f(x_1) = f(x_2)$

$\Rightarrow \quad 7x_1 + 1 = 7x_2 + 1 \Rightarrow x_1 = x_2$

f is one-one, $\forall\, x \in R$

Now, $y = 7x + 1 \Rightarrow x = \dfrac{y-1}{7}$

for each $y \in R$, we get $x \in R$

f is onto function

(B) $y = \cos x$

for $x \in [0, \pi], y \in [-1, 1]$

$\therefore f$ is one-one on $[0\ \pi]$,

$\forall\ x \in R, y \in [-1, 1]$

y is not onto R.

(C) $y = \sin x$ or $f(x) = \sin x$

for $x \in [0, \pi], y \in [0, 1]$

$$f\left(\frac{\pi}{3}\right) = \frac{\sqrt{3}}{2} \text{ and } f\left(\frac{2\pi}{3}\right) = \frac{\sqrt{3}}{2}$$

$\therefore f$ is not one-one on $(0, \pi)$,

$\forall\ x \in R$ and $y \in [-1, 1]$

$\therefore f$ is onto $[-1, 1]$.

(D) $y = 1 + \text{In}\, x$ and $f(x) = 1 + \text{In}\, x$

y is defined for $x \in (0, \infty)$

Let $x_1, x_2 \in D_f$

then $f(x_1) = f(x_2)$

$\Rightarrow 1 + \text{In}\, x_1 = 1 + \text{In}\, x_2$

$\Rightarrow x_1 = x_2$

$\therefore f$ is one-one, $\forall\ x \in (0, \infty)$

55. **(A)** Let $y = \sqrt{3 - x} + \sin^{-1}\left(\dfrac{3-2x}{5}\right)$

For y to be defined $3 - x \geq 0$ on $-1 \leq \dfrac{3-2x}{5} \leq 1$

$x \leq 3$ ...(i)

$-5 \leq 3 - 2x \leq 5$

and $-1 \leq x \leq 4$ ...(ii)

From Eqs. (i) and (ii), we get

$x \in [-1, 3]$

(B) Let $y = \log_{10}\{1 - \log_{10}(x^2 - 5x + 16)\}$ for y to be defined

$x^2 - 5x + 16 > 0$ and $1 - \log_{10}(x^2 - 5x + 16) > 0$

$\left(x - \dfrac{5}{2}\right)^2 + \dfrac{39}{4} > 0$ and $\log_{10}(x^2 - 5x + 16) < 1$

which is true, $\forall\ x \in R$ ...(i)

$\Rightarrow x^2 - 5x + 16 < 10$

$\Rightarrow x^2 - 5x + 6 < 0 \Rightarrow (x-3)(x-2) < 0$

$\Rightarrow 2 < x < 3$ ...(ii)

From Eqs. (i) and (ii), $x \in (2, 3)$

(C) Let $y = \cos^{-1}\dfrac{2}{2 + \sin x}$, for y to be defined

$$-1 \leq \frac{2}{2 + \sin x} \leq 1 \qquad \left[\because -1 < \sin x \leq 1 \atop 1 < 2 + \sin x \leq 3\right]$$

Multiplying by $(2 + \sin x)$

$-(2 + \sin x) \leq 2 \leq 2 + \sin x$

$\Rightarrow -2 - \sin x \leq 2 \quad | \quad 2 \leq 2 + \sin x$

$\Rightarrow -\sin x \leq 4 \quad | \quad \sin x \geq 0$

$\Rightarrow \sin x \geq -4 \quad | \quad 2n\pi \leq x \leq (2n+1)\pi, n \in z$ ...(i)

We know that $\sin x \in [-1, 1]$

$\therefore x \in R$ ... (ii)

From Eqs. (i) and (ii); $x \in [2k\pi, (2k+1)\pi]$

Domain $= \underset{k \in I}{\cup} [2k\pi, (2k + 1\pi)]$

(D) $y = \sqrt{\sin x} + \sqrt{16 - x^2}$ for y to be defined

$\sin x \geq 0 \quad | \quad 16 - x^2 \geq 0$

$x \in [2k\pi, (2k+1)\pi], k \in I$ ...(i) $\quad | \quad -4 \leq x \leq 4$ ...(ii)

From Eqs. (i) and (ii), we get

$x \in [-4, -\pi] \cup [0, \pi]$

56. Let

$A = \{a_1, a_2, a_3, \ldots, a_n\}$

Then, the number of binary relations on $A = n^{(n \times n)} = n^{n^2}$

and number of relations form A to $A = 2^{n \times n} = 2^{n^2}$

Both statements are true but Statement-2 is not a correct explanation for Statement-1.

57. Let $\alpha \in (A \cap B) \Rightarrow \alpha \in A$ and $\alpha \in B$

$\Rightarrow g(\alpha) = 0$

and $f(\alpha) = 0$

$\Rightarrow \{f(\alpha)\}^2 + \{g(\alpha)\}^2 = 0$

$\Rightarrow \alpha$ is a root of $\{f(x)\}^2 + \{g(x)\}^2 = 0$

Hence, Statement-1 is true and Statement-2 is false.

58. Let $x \in P(A \cap B)$

$\Leftrightarrow x \subseteq (A \cap B)$

$\Leftrightarrow x \subseteq A$ and $x \subseteq B$

$\Leftrightarrow x \in P(A)$ and $x \in P(B)$

$\Leftrightarrow x \in P(A) \cap P(B)$

$\therefore P(A \cap B) \subseteq P(A) \cap P(B)$

and $P(A) \cap P(B) \subseteq P(A \cap B)$

Hence, $P(A) \cap P(B) = P(A \cap B)$

Now, consider sets $A = \{1\}, B = \{2\} \Rightarrow A \cup B = \{1, 2\}$

$\therefore P(A) = \{\phi, \{1\}\}, P(B) = \{\phi, \{2\}\}$.

and $P(A \cup B) = \{\phi\ \{1\}, \{2\}, \{1, 2\} \neq P(A) \cup P(B)\}$

Hence, Statement-1 is true and Statement-2 is false.

59. $n(A \cup B) = n(A) + n(B) - n(A \cap B)$

$= 3 + 6 - n(A \cap B) = 9 - n(A \cap B)$

As maximum number of element in $(A \cap B) = 3$

$\therefore$ Minimum number of elements in $(A \cap B) = 9 - 3 = 6$

Both statements are true; Statement-2 is a correct explanation for Statement-1.

60. $A = \{x : x \text{ is a natural number}\}$

$B = \{x : x \text{ is an even natural number}\}$

$C = \{x : x \text{ is an odd natural number}\}$

$D = \{x : x \text{ is a prime number}\}$

(i) $A \cap B = \{x : x = 2n, n \in N\} = B$

(ii) $A \cap C = \{x : x$ is an odd natural number$\} = C$

(iii) $B \cap D = \{x : x$ is prime natural number$\} = \{2\}$

(iv) $C \cap D = \{x : x$ is odd prime natural number$\}$

61. $U =$ Set of all people

$M =$ {Males}

$S =$ {College students}

$T =$ {Teenagers}

$W =$ {People having height more than 5 feet}

(i) College students having heights more than 5 feet $= S \cap W$

(ii) People who are not teenagers and having their heights less than 5 feet $= T' \cap W'$

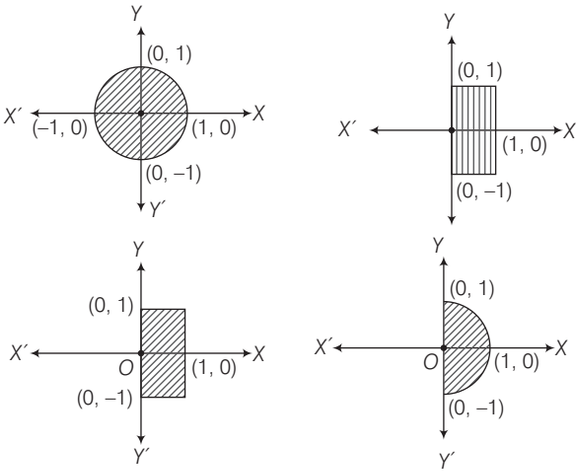
(iii) All people who are neither males nor teenagers nor college students $= (M \cup T \cup S)'$

62. $X = \{(x, y) : x^2 + y^2 \le 1\}$

$Y = \{(x, y) : 0 \le x \le 1, -1 \le y \le 1\}$

$X \cup Y = \{(x, y) : x^2 + y^2 \le 1$ or $0 \le x \le 1$ and $-1 \le y \le 1\}$

$X \cap Y = \{(x, y) : x^2 + y^2 \le 1$ and $x \ge 0\}$

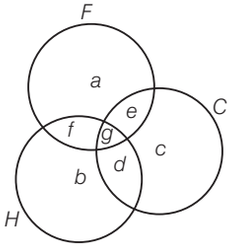


63. Given, $a = 20$ ...(i)

$e + f + g = 15$ ...(ii)

$b + d + f + g = 22$ ...(iii)

$c = 11$ ...(iv)



$c + d + e + g = 25$ ...(v)

$\Rightarrow \quad d + e + g = 14$ ...(vi)

$e = 7$ ...(vii)

$f = 3$ ...(viii)

From Eqs. (vii), (viii) and (ix),

$e + g = 12$ ...(ix)

$e = 7, f = 3, g = 5$

From Eq. (vi), $d = 2$

From Eq. (iii) $b + 2 + 3 + 5 = 22$

$\therefore \quad b = 12$

Hence, $a = 20, b = 12, c = 11, d = 2, e = 7, f = 3, g = 5$

Number of children play all the three games $= g = 5$

Number of children play cricket and hockey but not football $= d = 2$

Number of children play hockey only $= b = 12$

Total number of children in the group

$= a + b + c + d + e + f + g = 60$

64. $a + f + e + g = 21$ ...(i)

$b + d + f + g = 26$ ...(ii)

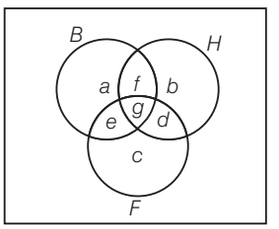
$c + d + e + g = 29$ ...(iii)

$f + g = 14$ ...(iv)

$g + d = 15$ ...(v)

$e + g = 12$ ...(vi)

$g = 8$ ...(vii)



From Eqs. (vii) and (vi), $e = 4$

Form Eqs. (vii) and (v), $d = 7$

From Eqs. (vii) and (iv), $f = 6$

From Eq. (iii), $c + 7 + 4 + 8 = 29 \Rightarrow c = 29 - 19 = 10 = c$

From Eq. (ii), $b + 7 + 6 + 8 = 26 \Rightarrow b = 26 - 21 \Rightarrow \ b = 5$

From Eq. (i), $a + 6 + 4 + 8 = 21 \Rightarrow a = 21 - 18 \Rightarrow \ a = 3$

$n(B) + n(H) + n(F) = a + b + c + d + e + f + g$

$= 3 + 5 + 10 + 7 + 4 + 6 + 8 = 43$

65. $a + e + f + g = 120$ ...(i)

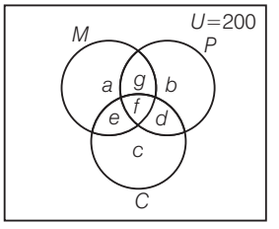
$b + d + f + g = 90$ ...(ii)

$e + f + c + d = 70$ ...(iii)

$g + f = 40$ ...(iv)

$f + d = 30$ ...(v)

$e + f = 50$ ...(vi)



$U - (a + b + c + d + e + f + g) = 20$

$\Rightarrow \quad a + b + c + d + e + f + g = 180$ ...(vii)

From Eqs. (i) and (iv), $a + e = 80$ ...(viii)

From Eqs. (ii) and (iv), $b + d = 50$ ...(ix)

From Eqs. (iii) and (v), $e + c = 40$ ...(x)

from Eqs (viii), (ix) & (x), $a + b + c + d + e + e = 197$ ...(xi)

from (xi), (vii) and (iv), $197 - e + 40 = 180$

$170 - e + 40 = 180$

$e = 210 - 180 = 30$

From Eq. (vi), $e + f = 50$

$\Rightarrow \quad 30 + f = 50$

$\Rightarrow \quad f = 20$

66. $b + e + f + g = 205$ ...(i)

$a + d + f + g = 210$ ...(ii)

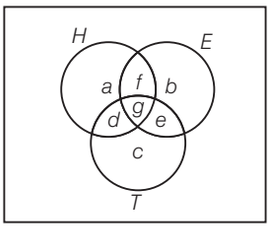
$c + d + e + g = 120$ ...(iii)

$f + g = 100$ ...(iv)

$e + g = 800$ ...(v)

$d + g = 35$ ... (vi)

$g = 20$ ...(vii)



From Eqs. (vi) and (vii), $d = 15$

From Eqs. (vii) and (v), $e = 60$

From Eqs. (vii) and (iv), $f = 80$

From Eq. (i), $b + 60 + 80 + 20 = 205 \Rightarrow b = 205 - 160$

$\Rightarrow b = 45$ = Can speak English but not Hindi or Tamil.

From Eq. (ii) $a + 15 + 80 + 20 = 210$

$\Rightarrow \quad a + 115 = 210 \Rightarrow a = 95$

From Eq. (iii), $c + 15 + 60 + 20 = 120$

$\Rightarrow \quad c = 120 - 95 \Rightarrow c = 25$

People who can speak neither E nor H nor T

$= 450 - (95 + 45 + 25 + 15 + 60 + 80 + 20)$

$= 450 - 340 = 110$

67. $c + f + g + e = 42$ ...(i)

$b + d + g + e = 36$ ...(ii)

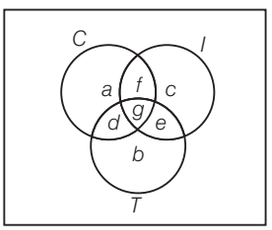
$a + f + d + g = 30$ ...(iii)

$g + e = 15$ ...(iv)

$f + g = 10$ ...(v)

$d = 4$ ...(vi)

$e = 11$ ...(vii)



From (iv) and (vii), $g + 11 = 15 \Rightarrow g = 4$ ...(viii)

From (v) and (viii), $f + 4 = 10 \Rightarrow f = 6$ ...(ix)

From (i), $c + 6 + 4 + 11 = 42 \Rightarrow c = 21$ ...(x)

From (ii), $b + 4 + 4 + 11 = 36 \Rightarrow b = 17$ ...(xi)

From (iii), $a + 6 + 4 + 4 = 30 \Rightarrow a = 16$ ...(xii)

Number of required persons

$= 123 - (16 + 17 + 21 + 4 + 11 + 6 + 4)$

$= 123 - 79$

$= 44$

68. aRb iff $n\,|(a - b)|$ i.e. $(a - b)$ is divisible by n.

Reflexivity $a - a = 0$ which is divisible by n.

So, $(a, a) \in R, \forall\ a \in I$

$\therefore$ R is reflexive relation.

Symmetry Let $(a, b) \in R$

Then, $(a, b) \in R \Rightarrow (a - b)$ is divisible by n.

$\Rightarrow \quad -(b - a)$ is divisible by n.

$\Rightarrow \quad (b - a)$ is divisible by n.

$\Rightarrow \quad (b, a) \in R$

$\therefore$ R is symmetric relation.

Transitivity Let $(a, b) \in R, (b, c) \in R$, then $(a - b)$ and $(b - c)$ are divisible by n.

$\Rightarrow \quad a - b = nk_1$ and $b - c = nk_2 \qquad [k_1, k_2 \in I]$

$\Rightarrow \quad (a - b) + (b - c) = n(k_1 + k_2)$

$\Rightarrow \quad a - c = n\,(k_1 + k_2)$

$\Rightarrow$ $(a - c)$ is divisible by n.

$\Rightarrow \quad (a, c) \in R$

$\therefore$ R is transitive relation.

$\therefore$ R is an equivalence relation.

69. R defined on $N \times N$ such that

$(a, b)\ R\ (c, d) \Leftrightarrow ad = bc$

Reflexivity Let $(a, b) \in N \times N$

$\Rightarrow \quad a, b \in N \ \Rightarrow \ ab = ba$

$\Rightarrow \quad (a, b)\ R\ (a, b)$

$\therefore$ R is reflexive on, $N \times N$.

Symmetry Let $(a, b), (c, d) \in N \times N$,

then $(a, b)\ R\ (c, d) \Rightarrow ad = bc$

$\Rightarrow \quad cb = da$

$\Rightarrow \quad (c, d)\ R\ (a, b)$

$\therefore$ R is symmetric on $N \times N$.

Transitivity Let $(a, b), (c, d), (e, f) \in N \times N$

Then, $(a, b)\ R\ (c, d) \Rightarrow ad = bc$ ...(i)

$(c, d)\ R\ (e, f) \Rightarrow cf = de$ ...(ii)

From Eqs. (i) and (ii), $(ad)\,(cf) = (bc)\,(de)$

$\Rightarrow \quad af = be$

$\Rightarrow \quad (a, b)\ R\ (e, f)$

$\therefore$ R is transitive relation on $N \times N$.

$\therefore$ R is equivalence relation on $N \times N$.

70. (i) $aRb \Leftrightarrow |a-b| > 0$

Reflexivity $a - a = 0$

$\therefore \quad (a, a) \notin R$

$\therefore$ R is not reflexive

Symmetry $(a, b) \in R \Rightarrow |a-b| > 0$

$\Rightarrow \quad |-(b-a) > 0|$

$\Rightarrow \quad |b-a| > 0$

$\Rightarrow \quad (b, a) \in R$

$\therefore$ R is symmetric relation

Transitivity $(a, b) \in R$ and $(b, c) \in R$

$\Rightarrow \quad |a-b| > 0$ and $|b-c| > 0$

$\Rightarrow \quad |a-b| + |b-c| > 0$ [by addition]

Now, let $a > b$ and $b > c$, then $a > c$

$|a-b| + |b-c| = a - b + b - c = a - c > 0$

$\Rightarrow \quad |a-c| > 0$

If $a < b$ and $b > c$, then

$|a-b| + |b-c| = -(a-b) + (b-c) = -a + 2b - c$

$\not\Rightarrow \quad |a-c| > 0$

$\therefore$ R is not transitive relation.

(ii) $aRb \Leftrightarrow |a| = |b|$

Reflexivity We have, $|a| = |a|$

$\Rightarrow \quad aRa \forall a$

$\therefore$ R is reflecxive relation.

Symmetry $aRb \Rightarrow |a| = |b|$

$\Rightarrow \quad |b| = |a|$

$\Rightarrow \quad bRa$

$\therefore$ R is symmetric relation.

Transitivity $(a, b) \in R$ and $(b, c) \in R$

$\Rightarrow \quad |a| = |b|$ and $|b| = |c|$

$\Rightarrow \quad |a| = |c|$

$\Rightarrow \quad (a, c) \in R$

$\therefore$ R is transitive relation.

(iii) $aRb \Leftrightarrow |a| \geq |b|$

Reflexivity For any $a \in R$, we have $|a| \geq |a|$

So, $aRa \ \forall \ a$

$\therefore$ R is reflexive relation.

Symmetry $aRb \Rightarrow |a| \geq |b|$

$\Rightarrow \quad |b| \leq |a|$

$\therefore$ R is not symmetric relation.

Transitivity aRb and $bRc \Rightarrow |a| \geq |b|$ and $|b| \geq |c|$

$\Rightarrow \quad |a| \geq |c|$

$\Rightarrow \quad a \ R \ c$

$\therefore$ R is transitive relation.

(iv) $aRb \Leftrightarrow 1 + ab > 0, \forall \ a, b \in R$

Reflexivity Let $a \notin R \Rightarrow 1 + a \cdot a = 1 + a^2 > 0$

$\Rightarrow \quad (a, a) \in R$

$\therefore$ R is reflexive on R.

Symmetry Let $(a, b) \in R$, then $(a, b) \in R$

$\Rightarrow \quad 1 + ab > 0$

$\Rightarrow \quad 1 + ba > 0$

$\Rightarrow \quad (b, a) \in R$

$\therefore$ R is symmetric on R.

Transitivity We observe that $\left(1, \frac{1}{2}\right) \in R$ and $\left(\frac{1}{2}, -1\right) \in R$ but $(1, -1) \notin R$ because

$1 + (1)(-1) = 0 \not> 0$

$\therefore$ R is not transitive on R.

(v) $aRb \Leftrightarrow |a| \leq b$

Reflexivity Let $-1 \in R$, then $|-1| \not\leq (-1)$

$\therefore$ R is not reflexive relation

Symmetry Now, let $-3 \, R \, 4$, then $|4| \not\leq -3$

$\Rightarrow \quad 4 \not R -3$

$\therefore R$ is not symmetric relation

Transitivity aRb and $bRc \Rightarrow |a| \leq b$ and $|b| \leq c$

Then, $|a| \leq c \ \Rightarrow aRc$

$\therefore$ R is transitive relation.

71. $A = \{x : -1 \leq x \leq\}$

$B = \{x : -1 \leq x \leq\}$

(i) $f(x) = \frac{x}{2}$

Let $x_1, x_2 \in A$

$\therefore \quad f(x_1) = f(x_2) \Rightarrow \frac{x_1}{2} = \frac{x_2}{2}$

$\Rightarrow \quad x_1 = x_2$

$\therefore$ f is one-one function.

Now, let $y = \frac{x}{2} \Rightarrow x = 2y$

$\Rightarrow \quad -1 \leq y \leq 1$

$\Rightarrow \quad -2 \leq 2y \leq 2 \Rightarrow -2 \leq x \leq 2$

Let $x \in [-1, 1]$

$\therefore$ There are some value of y for which x does not exist. So, f not onto.

(ii) $g(x) = |x|$

For $x = -1, g(-1) = 1$

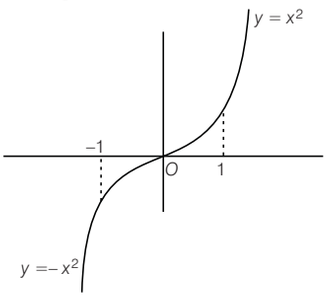
and for $x = 1, g(1) = 1$

$\therefore$ f is not one-one function

Let $y = |x|$, then $y \geq 0$

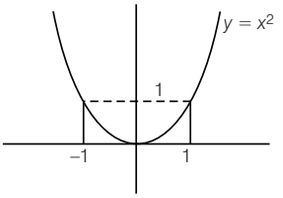
$\therefore$ f is not onto.

(iii) $h(x) = x|x| = \begin{cases} x^2, & x \geq 0 \\ -x^2, & x < 0 \end{cases}$



From figure, it is clear tat h is one-one and onto i.e., bijective.

(iv) $k(x) = x^2$



$k(1) = 1$

and $k(-1) = 1$

So, k is many-one function.

From figure, $y \in (0, 1)$

$\therefore$ y is not onto function.

(v) $y = l(x) = \sin \pi x$

for $x = 1$, $l(1) = \sin \pi = 0$

for $x = -1$, $l(-1) = \sin(-\pi) = 0$

$\therefore l$ is not one-one.

Now, $-1 \le x \le 1$

$\Rightarrow$ $-\pi \le \pi\ x \le \pi$

$\Rightarrow$ $-1 \le \sin \pi\ x \le 1$

$\therefore$ y is onto function.

Hence, l is surjective function.

72. $(fog)x = f(3x - 2) = e^{3x-2}$

and $(gof)x = g(e^x) = 3e^x - 2$

Let $(fog)x = y \Rightarrow e^{3x-2} = y$

$\Rightarrow$ $3x - 2 = \log_e y \Rightarrow x = \dfrac{2 + \log_e y}{3}$

$\Rightarrow (fog)^{-1}(y) = \dfrac{2 + \log_e y}{3}$

$\Rightarrow y > 0$ So, domain of $(fog)^{-1}$ is $(0, \infty)$.

Now, again let $(gof)x = 3e^x - 2$

$\Rightarrow$ $y = 3e^x - 2 \Rightarrow e^x = \dfrac{y + 2}{3}$

$\therefore$ $x = \log_e\left(\dfrac{y + 2}{3}\right)$

$\Rightarrow$ $(gof)^{-1}(y) = \log_e\left(\dfrac{y + 2}{3}\right)$

Clearly, $y + 2 > 0 \Rightarrow y > -2$

$\therefore$ Domain of $(gof)^{-1}$ is $(-2, \infty)$.

73. $f(x) = \dfrac{x^2 - x}{x^2 + 2x}$ ...(i)

$f(x) = \dfrac{x(x-1)}{x(x+2)}$

$f(x) = \dfrac{(x-1)}{(x+2)},\ x \ne 0$ ...(ii)

$D_f = \{x : x^2 + 2x \ne 0\}$ [from Eq. (i)]

$= \{x : x \in R - \{0, -2\}\}$

Now, let $y = \dfrac{x-1}{x+2}$

$\Rightarrow$ $yx + 2y = x - 1 \Rightarrow x(y - 1) = -(1 + 2y)$

$\Rightarrow$ $x = \dfrac{1 + 2y}{1 - y}$

Now, for $y = 1$, x is not defined.

Now, $x = 0,\ f(x) = -\dfrac{1}{2}$

$\therefore$ $R_f = R - \left\{1, -\dfrac{1}{2}\right\}$

Now, let $x_1, x_2 \in D_f$

Then, $f(x_1) = f(x_2) \Rightarrow \dfrac{x_1 - 1}{x_1 + 2} = \dfrac{x_2 - 1}{x_2 + 2}$

$\Rightarrow$ $x_1x_2 + 2x_1 - x_2 - 2 = x_1x_2 - x_1 + 2x_2 - 2$

$\Rightarrow$ $x_1 = x_2$

$\therefore f$ is one-one function.

Now, let $y = \dfrac{x-1}{x+2}$

Then, $x = \dfrac{1 + 2y}{1 - y}$

$\Rightarrow$ $f^{-1}(y) = \dfrac{1 + 2y}{1 - y}$ $[\because f(x) = y \Rightarrow x = f^{-1}(y)]$

Replace y by x, we get $f^{-1}(x) = \dfrac{1 + 2x}{1 - x}$

$\Rightarrow$ $\dfrac{d}{dx}\{f^{-1}(x)\} = \dfrac{(1-x)\,2 - (1+2x)(-1)}{(1-x)^2}$

$= \dfrac{2 - 2x + 1 + 2x}{(1-x)^2}$

$\Rightarrow$ $\dfrac{d}{dx}\{f^{-1}(x)\} = \dfrac{3}{(1-x)^2}$

$\therefore$ Domain of $\dfrac{d}{dx}\{f^{-1}(x)\} = R - \{1\}$

74. $f(x) = x^2 - 1$

$g(x) = \sqrt{x^2 + 1};\ h(x) = \begin{cases} 0, & \text{if } x \le 0 \\ x, & \text{if } x \ge 0 \end{cases}$

$\therefore$ $(hofog)(x) = (hof)\{g(x)\}$

$= (hof)\sqrt{x^2 + 1}$

$= h\{f\sqrt{(x^2 + 1)}\}$

$= h\{\sqrt{(x^2 + 1)^2} - 1\} = h(x^2 + 1 - 1)$

$= h(x^2) = x^2$ $[\because x^2 \ge 0]$

and $(fog)(x) = f\{g(x)\}$

$= f(\sqrt{x^2 + 1}) = \left(\sqrt{x^2 + 1}\right)^2 - 1 = x^2 + 1 - 1 = x^2$

Let $y = (fog)x = x^2,\ \forall\ x \in R$

If $x = 1$, then $y = 1$

If $x = -1$, then $y = 1$

So, fog is not one-one, so it is not invertible $h(x) = \begin{cases} 0, & x \le 0 \\ x, & x \ge 0 \end{cases}$

For $x = -1$, $h(-1) = 0$ and for $x = -2$, $h(-2) = 0$

$\therefore$ h is not identity function.

75. Here, (3, 3), (6, 6), (9, 9), (12, 12) So, it is Reflexive and
(3, 6), (6, 12), (3, 12) So, it is Transitive
Here, reflexive and transitive only.

76. Clearly, $(x, x) \in R, \forall\ x \in W$
So, R is reflexive.
Let $(x, y) \in R$, then $(y, x) \in R$ as x and y have atleast one letter in common. So, R is symmetric. But R is not transitive.
e.g. Let x = INDIA, y = BOMBAY and z = JUHU
Then, $(x, y) \in R$ and $(y, z) \in R$ but $(x, z) \notin R$

77. $T = \{(x, y) : x - y \in I\}$
As $0 \in I$, so T is a reflexive relation.
If $x - y \in I \Rightarrow y - x \in I$
$\therefore T$ is symmetric also.
If $x - y = I$ and $y - z = I2$
Then, $x - z = (x - y) + (y - z) = I_1 + I_2 \in I$
$\therefore$ T is also transitive.
Hence, T is an equivalence relation. Clearly, $x \neq x + 1 \Rightarrow (x, x) \notin S$
$\therefore S$ is not reflexive.

78. $\because\ A \cap B = A \cap C \Rightarrow B = C$ and $A \cup B = A \cup C \Rightarrow B = C$
Hence, $B = C$

79. For disoint sets, $A \cap B = \phi$
Each element in either A or B or neither.
$\therefore$ Total ways $= 3^4 = 81$; $A = B$ iff $A = B = \phi$
Otherwise, A and B are interchangable
$\therefore$ Number of unordered pair for disoint subsets of

$$S = \frac{3^4 + 1}{2} = 41$$

80. xRy need not implies yRx.

$S : \frac{m}{n} S \frac{P}{q} \Leftrightarrow qm = pm \Rightarrow \frac{m}{s} S \frac{m}{n}$ is reflexive.

$\frac{m}{n} S \frac{p}{q} \Rightarrow \frac{p}{q} S \frac{m}{n}$ is symmetric.

and $\frac{m}{n} S \frac{p}{q}, \frac{p}{q} S \frac{r}{t} \Rightarrow qm = pn,\ pt = qr$

$\Rightarrow$ $mt = nr \Rightarrow \frac{m}{n} S \frac{r}{t}$ is transitive.

$\therefore$ S is an equivalence relation.

81. $P : \sin\theta - \cos\theta = \sqrt{2}\cos\theta \Rightarrow \tan\theta = \sqrt{2} + 1$

$Q : \sin\theta + \cos\theta = \sqrt{2}\sin\theta \Rightarrow \tan\theta = \frac{1}{\sqrt{2} - 1} = \sqrt{2} + 1$

$\therefore$ $P = Q$

82. $\because (fogogof)(x) = (gogof)(x)$

$\therefore$ $(\sin\sin x^2)^2 = \sin\sin x^2 \Rightarrow \sin\sin x^2 = 0$ or 1

$\Rightarrow$ $x = +\sqrt{n\pi}, n \in \{0, 1, 2, 3, \ldots\}$

83. **Statement-1** $A = \{(x, y) \in R \times R : y - x$ is an integer$\}$

(a) **Reflexive** $xRy : (x - x)$ is an integer
which is true.
Hence it is reflexive.

(b) **Symmetric** $xRy : (x - y)$ is an integer.
$\Rightarrow -(y - x)$ is also an integer.
$\therefore$ $(y - x)$ is also an integer.
$\Rightarrow$ $y\ R\ x$
Hence, it is symmetric.

(c) **Transitive** $x\ R\ y$ and $y\ R\ z$
$\Rightarrow (x - y)$ and $(y - z)$ are integere and.
$\Rightarrow (x - y) + (y - z)$ is an integer.
$\Rightarrow (x - z)$ is an integer.
$\Rightarrow x\,R\,z$
$\therefore$ It is transitive
Hence, it is equvalence relation.

Statement-2
$B = \{(x, y) \in R \times R : x = \alpha y$ for some reational number $\alpha\}$
If $\alpha = 1$, then
$xRy : x = y$ (To check equivalence)

(a) **Reflexive** $xRx : x = x$ (True)
$\therefore$Reflexive

(b) **Symmetric** $xRy : x = y \Rightarrow y = x \Rightarrow yRx$
$\therefore$ Symmetric

(c) **Transitive** xRy and $yRz \Rightarrow x = y$
and $y = z \Rightarrow x = z \Rightarrow xRz$
$\therefore$ Transitive
Hence, it is equivalence relation.
$\therefore$Both are true but Statement-2 is not correct explanation of Statement-2

84. $\because A \times B$ has 8 elements.
$\therefore$Number of subsets $= 2^8 = 256$
Number of subsets with zero element $= {}^8C_0 = 1$
Number of subsets with one element $= {}^8C_1 = 8$
Number of subsets with one elements $= {}^8C_2 = 28$
Hence, Number of subsets of $A \times B$ having 3 or more elements
$= 256 - (1 + 8 + 28) = 256 - 37 = 219$

85. Since, $4^n - 3n - 1 = (1 + 3)^n - 3n - 1$
$= (1 + {}^nC_1 \cdot 3 + {}^nC_2 \cdot 3^2 + {}^nC_3 \cdot 3^3 + \ldots + {}^nC_n \cdot 3^n) - 3n - 1$
$= 3^2({}^nC_2 + {}^nC_3 \cdot 3 + \ldots + {}^nC_n \cdot 3^{n-2})$
$\Rightarrow 4^n - 3n - 1$ is a multiple of 9 for $n \geq 2$
For $n = 1$, $4^n - 3n - 1 = 4 - 3 - 1 = 0$
For $n = 2$, $4^n - 3n - 1 = 16 - 6 - 1 = 9$
$\therefore 4^n - 3n - 1$ is multiple of 9 for all $n \in N$.
It is clear that X contains elements, which are multiples of 9 and Y contains all multiples of 9.
$\therefore$ $X \subseteq Y$ i.e., $X \cup Y = Y$

86. $n(A) = 4, n(B) = 2 \Rightarrow n(A \times B) = 8$
The number of subsets of $A \times B$ having at least three elements
$= {}^8C_3 + {}^8C_4 + {}^8C_5 + \ldots + {}^8C_8$
$= 2^8 - ({}^8C_0 + {}^8C_1 + {}^8C_2)$
$= 256 - (1 + 8 + 28) = 219$

PREFACE

IF YOU CONTINUOUSLY PUT YOUR EFFORTS ON AN ASPECT, YOU HAVE VERY GOOD CHANCE TO GET POSITIVE OUTCOME i.e. ***SUCCESS***

It is a matter of great pride and honour for me to have received such an overwhelming response to the previous editions of this book from the readers. In a way, this has inspired me to revise this book thoroughly as per the changed pattern of JEE Main & Advanced. I have tried to make the contents more relevant as per the needs of students, many topics have been re-written, a lot of new problems of new types have been added in etcetc. All possible efforts are made to remove all the printing errors that had crept in previous editions. The book is now in such a shape that the students would feel at ease while going through the problems, which will in turn clear their concepts too.

A Summary of changes that have been made in Revised & Enlarged Edition

- Theory has been completely updated so as to accommodate all the changes made in JEE Syllabus & Pattern in recent years.
- The most important point about this new edition is, now the whole text matter of each chapter has been divided into small sessions with exercise in each session. In this way the reader will be able to go through the whole chapter in a systematic way.
- Just after completion of theory, Solved Examples of all JEE types have been given, providing the students a complete understanding of all the formats of JEE questions & the level of difficulty of questions generally asked in JEE.
- Along with exercises given with each session, a complete cumulative exercises have been given at the end of each chapter so as to give the students complete practice for JEE along with the assessment of knowledge that they have gained with the study of the chapter.
- Last 13 Years questions asked in JEE Main & Adv, IIT-JEE & AIEEE have been covered in all the chapters.

However I have made the best efforts and put my all Coordinate Geometry teaching experience in revising this book. Still I am looking forward to get the valuable suggestions and criticism from my own fraternity i.e. the fraternity of JEE teachers.

I would also like to motivate the students to send their suggestions or the changes that they want to be incorporated in this book. All the suggestions given by you all will be kept in prime focus at the time of next revision of the book.

Dr. SK Goyal

CONTENTS

1. COORDINATE SYSTEM AND COORDINATES 1-71

LEARNING PART

Session 1

- Introduction
- Coordinate Axes
- Rectangular Cartesian Coordinates of a Point
- Polar Coordinates of a Point
- Relation between the Polar and Cartesian Coordinates

Session 2

- Distance between Two Points
- Choice of Axes
- Distance between Two Points in Polar Coordinates

Session 3

- Section formulae
- Centroid of a Triangle
- Incentre
- Some Standard Results
- Area of Triangle

Session 4

- Locus and Its Equation
- Change of Axes the Transformations of Axes
- Removal of the Term xy from $F(x,y) = ax^2 + 2hxy + by^2$ without Changing the Origin

PRACTICE PART

- JEE Type Examples
- Chapter Exercises

2. THE STRAIGHT LINES 73-190

LEARNING PART

Session 1

- Definition
- Angle of Inclination of a Line
- Slope or Gradient of a Line
- Angle Between Two Lines
- Lines Parallel to Coordinate Axes
- Intercepts of a Line on Axes
- Different Forms of the Equation of a Straight Line
- Reduction of General Equation to Standard Form
- The Distance Form or Symmetric Form or Parametric Form of a Line

Session 2

- Position of Two Points Relative to a Given Line
- Position of a Point which lies Inside a Triangle
- Equations of Lines Parallel and Perpendicular to a Given Line
- Distance Between Two Parallel Lines
- Distance of a Point From a Line
- Area of Parallelogram

Session 3
- Points of Intersection of Two Lines
- Concurrent Lines
- Family of Lines
- How to Find Circumcentre and Orthocentre by Slopes

Session 4
- Equations of Straight Lines Passing Through a Given Point and Making a Given Angle with a Given Line
- A Line Equally Inclined with Two Lines
- Equation of the Bisectors
- Bisector of the Angle Containing The Origin
- Equation of that Bisector of the Angle Between Two Lines Which Contains a Given Point

5. PARABOLA 363-459

LEARNING PART

Session 1

- Introduction
- Conic Section
- Section of a Right Circular Cone by Different Planes
- Conic Section : Definition
- Equation of Conic Section
- Recognisation of Conics
- How to Find the Centre of Conics
- Parabola : Definition
- Standard Equation of Parabola
- Some Terms Related to Parabola
- Other forms of Parabola with Latusrectum $4a$
- Smart Table
- General Equation of a Parabola
- Equation of Parabola if Equation of axis, Tangent at Vertex and Latusrectum are given
- The Generalised form $(y\text{-}k)^2 = 4a\,(x\text{-}h)$
- Parabolic Curve

Session 2

- Position of a Point (x_1, y_1) with respect to a Parabola $y^2 = 4ax$
- Parametric Relation between the Coordinates of the Ends of a Focal Chord of a Parabola
- Intersection of a Line and a Parabola
- Equation of Tangent in Different Forms
- Point of Intersection of Tangents at any Two Points on the Parabola
- Equation of Normals in Different Forms
- Point of Intersection of Normals at any Two Points on the Parabola
- Relation Between 't_1' and 't_2' if Normal at 't_1' meets the Parabola Again at 't_2'
- Co-normal Points
- Circle Through Co-normal Points

Session 3

- Pair of Tangents $SS1 = T^2$
- Chord of Contact
- Equation of the Chord Bisected at a Given Point
- Diameter
- Lengths of Tangent, Subtangent, Normal and Subnormal
- Some Standard Properties of the Parabola
- Reflection Property of a Parabola
- Study of Parabola of the Form $(ax + by)^2 + 2gx + 2fy + c = 0$

PRACTICE PART

- JEE Type Examples

6. ELLIPSE 461-553

LEARNING PART

Session 1

- Ellipse Definition
- Standard Equation of Ellipse
- The Foci and Two Directrices of an Ellipse
- Tracing of the Ellipse
- Some Terms Related to an Ellipse
- Focal Distances of a Point
- The Shape of the Ellipse,
- when $b>a$ $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$,
- Mechanical Construction of an Ellipse
- Smart Table

Session 2

- Position of a Point with Respect to an Ellipse
- Intersection of a Line and an Ellipse
- Equation of Tangent in Different Forms
- Equations of Normals in Different Forms
- Properties of Eccentric Angles of the Co-normal Points
- Co-normal Points Lie on a Fixed Curve
- Smart Table

Session 3

- Pair of Tangents
- Chord of Contact
- Chord Bisected at a Given Point
- Diameter
- Conjugate Diameters
- Properties of Conjugate Diameters
- Equi-Conjugate Diameters
- Director Circle
- Sub-Tangent and Sub-Normal
- Concyclic Points
- Some Standard Properties of the Ellipse
- Reflection Property of an Ellipse
- Equation of an Ellipse Referred to Two Perpendicular Lines

PRACTICE PART

- JEE Type Examples
- Chapter Exercises

7. HYPERBOLA 555-638

LEARNING PART

Session 1

- Hyperbola : Definition
- Standard Equation of Hyperbola
- The Foci and Two Directrices of a Hyperbola
- Tracing of the Hyperbola
- Some Terms Related to Hyperbola
- Focal Distances of a Point
- Conjugate Hyperbola
- Position of a Point with Respect to a Hyperbola
- Intersection of a Line and a Hyperbola

Session 2

- Equations of Tangents in Different Forms
- Equations of Normals in Different Forms
- Pair of Tangents
- Chord of Contact
- Equation of the Chord Bisected at a Given Point

Session 3

- Diameter
- Conjugate Diameters
- Properties of Hyperbola
- Intersection of Conjugate Diameters and Hyperbola
- Director Circle
- Asymptotes
- Rectangular Hyperbola
- The Rectangular Hyperbola $xy = c^2$
- Study of Hyperbola $xy = c^2$
- Properties of Rectangular Hyperbola $xy = c^2$
- Reflection Property of a Hyperbola
- Equation of a Hyperbola Referred to Two Perpendicular Lines

PRACTICE PART

- JEE Type Examples
- Chapter Exercises

SYLLABUS

JEE MAIN

Cartesian system of rectangular coordinates in a plane, distance formula, section formula, locus and its equation, translation of axes, slope of a line, parallel and perpendicular lines, intercepts of a line on the coordinate axes.

Straight Lines

Various forms of equations of a line, intersection of lines, angles between two lines, conditions for concurrence of three lines, distance of a point from a line, equations of internal and external bisectors of angles between two lines, coordinates of centroid, orthocentre and circumcentre of a triangle, equation of family of lines passing through the point of intersection of two lines.

Circles, Conic Sections

Standard form of equation of a circle, general form of the equation of a circle, its radius and centre, equation of a circle when the end points of a diameter are given, points of intersection of a line and a circle with the centre at the origin and condition for a line to be tangent to a circle, equation of the tangent. Sections of cones, equations of conic sections (parabola, ellipse and hyperbola) in standard forms, condition for $y=mx+c$ to be a tangent and point (s) of tangency.

JEE ADVANCED

Analytical Geometry

Two Dimensions Cartesian Coordinates, distance between two points, section formulae, shift of origin.

Equation of a straight line in various forms, angle between two lines, distance of a point from a line. Lines through the point of intersection of two given lines, equation of the bisector of the angle between two lines, concurrency of lines, centroid, orthocentre, incentre and circumcentre of a triangle.

Equation of a circle in various forms, equations of tangent, normal and chord.

Parametric equations of a circle, intersection of a circle with a straight line or a circle, equation of a circle through the points of intersection of two circles and those of a circle and a straight line.

Equations of a parabola, ellipse and hyperbola in standard form, their foci, directrices and eccentricity, parametric equations, equations of tangent and normal.

CHAPTER

01

Coordinate System and Coordinates

Learning Part

Session 1

- Introduction
- Rectangular Cartesian Coordinates of a Point
- Relation between the Polar and Cartesian Coordinates
- Coordinate Axes
- Polar Coordinates of a Point

Session 2

- Distance between Two Points
- Distance between Two Points in Polar Coordinates
- Choice of Axes

Session 3

- Section formulae
- Incentre
- Area of Triangle
- Centroid of a Triangle
- Some Standard Results

Session 4

- Locus and Its Equation
- Change of Axes or the Transformations of Axes
- Removal of the Term xy from $F(x, y) = ax^2 + 2hxy + by^2$ without Changing the Origin
- Position of a Point Which Lies Inside a Triangle

Practice Part

- JEE Type Examples
- Chapter Exercises

Arihant on Your Mobile !

Exercises with the symbol can be practised on your mobile. See inside cover page to activate for free.

Session 1

Introduction, Coordinate Axes, Rectangular Cartesian Coordinates of a Point, Polar Coordinates of a Point, Relation between the Polar and Cartesian Coordinates

Introduction

The great philospher and mathematician of France **Rane Descartes** (1596-1665) published a book 'La Geometric' in 1637.

Descartes gave a new idea i.e. each point in a plane is expressed by an ordered pair of algebraic real numbers like $(x, y), (r, \theta)$ etc., called coordinates of the point.

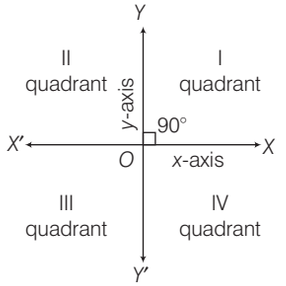
The point (x, y) is called cartesian coordinates and (r, θ) is called polar coordinates of the point. Then represents different forms of equations which are developed for all types of straight lines and curves.

Thus the Coordinate Geometry (or Analytical Geometry) is that branch of mathematics in which geometrical problems are solved with the help of Algebra.

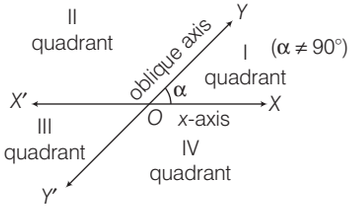
Coordinate Axes

The position of a point in a plane is determined with reference to two intersecting straight lines called the **coordinate axes** and their point of intersection is called the **origin** of coordinates.

If these two axes of reference (generally we call them x and y axes) cut each other at right angle, they are called **rectangular axes** otherwise they are called **oblique axes**. The axes divide the coordinate plane in four quadrants.



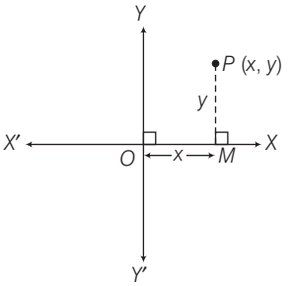
(a) **Rectangular axes**



(b) **Oblique axes**

Rectangular Cartesian Coordinates of a Point

Let $X'OX$ and $Y'OY$ be two perpendicular axes in the plane of paper intersecting at O. Let P be any point in the plane of the paper. Draw PM perpendicular to OX. Then the lengths OM and PM are called the rectangular cartesian coordinates or briefly the coordinates of P.



Let $OM = x$ and $MP = y$

Then, the position of the point P in the plane with respect to the coordinate axes is represented by the ordered pair (x, y). The ordered pair (x, y) is called the coordinates of point P.

i.e. $OM = x$-coordinate or abscissa of the point P

and $MP = y$-coordinate or ordinate of the point P.

Remarks

1. The ordinate of every point on X-axis is 0.
2. The abscissa of every point on Y-axis is 0.
3. The abscissa and ordinate of the origin $O(0, 0)$ are both zero.
4. The abscissa and ordinate of a point are at perpendicular distance from Y-axis and X-axis respectively.
5. Table for conversion sign of coordinates :

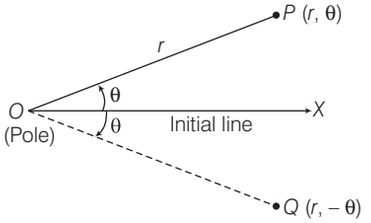
Quadrants	XOY (I)	$X'OY$ (II)	$X'OY'$ (III)	XOY' (IV)
Sign of x coordinates	+	−	−	+
Sign of y coordinates	+	+	−	−
Sign of (x, y)	(+, +)	(−, +)	(−, −)	(+, −)

6. Equation of X-axis, $y = 0$ and equation of Y-axis, $x = 0$.

Polar Coordinates of a Point

If $OP = r$ (radius vector)

and $\angle XOP = \theta$ (vectorial angle)



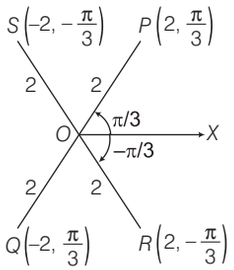
Then, the ordered pair of real numbers (r, θ) called the polar coordinates of the point P.

Remarks

1. r may be positive or negative according as θ is measured in anticlockwise or clockwise direction. θ lies between $-\pi$ to π i.e. $-\pi < \theta \leq \pi$. If it is greater than π, then we subtract 2π from it and if it is less than $-\pi$, then we add 2π, to it. It is also known as principal value of P.
2. Always taken θ in radian.

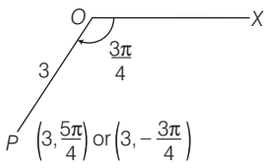
Example 1. Draw the polar coordinates $\left(2, \frac{\pi}{3}\right), \left(-2, \frac{\pi}{3}\right), \left(-2, -\frac{\pi}{3}\right)$ and $\left(2, -\frac{\pi}{3}\right)$ on the plane.

Sol.



Example 2. Draw the polar coordinate $\left(3, \frac{5\pi}{4}\right)$ on the plane.

Sol. Here, $\theta = \frac{5\pi}{4} > \pi$



then, $\theta - 2\pi = \frac{5\pi}{4} - 2\pi = -\frac{3\pi}{4}$

$\therefore \quad \left(3, \frac{5\pi}{4}\right)$ is same $\left(3, -\frac{3\pi}{4}\right)$

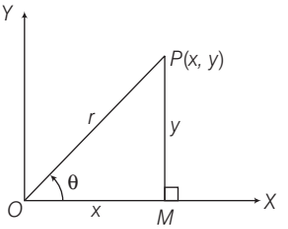
Relation between the Polar and Cartesian Coordinates

Let $P(x, y)$ be the cartesian coordinates with respect to axes OX and OY and (r, θ) be its polar coordinates with respect to pole O and initial line OX.

It is clear from figure

$$OM = x = r\cos\theta \quad \ldots (i)$$

and $$MP = y = r\sin\theta \quad \ldots (ii)$$



Squaring and adding Eqs. (i) and (ii), we get

$$x^2 + y^2 = r^2 \quad \text{or} \quad r = \sqrt{(x^2 + y^2)}$$

Dividing Eqs. (ii) by (i), then

$$\tan\theta = \left(\frac{y}{x}\right) \text{ or } \theta = \tan^{-1}\left(\frac{y}{x}\right)$$

i.e. $$(r\cos\theta, r\sin\theta) \Rightarrow (x, y) \quad \ldots (iii)$$

and $$\left(\sqrt{(x^2 + y^2)}, \tan^{-1}\left(\frac{y}{x}\right)\right) \Rightarrow (r, \theta) \quad \ldots (iv)$$

If r and θ are known then we can find (x, y) from Eq. (iii) and if x and y are known then we can find (r, θ) from Eq. (iv).

$\because \quad \theta = \tan^{-1}\left(\frac{y}{x}\right)$

If $\alpha = \tan^{-1}\left|\frac{y}{x}\right|$

Then, values of θ in four quadrants

Quadrant	I	II	III	IV
θ	α	$\pi - \alpha$	$-\pi + \alpha$	$-\alpha$

Example 3. Find the cartesian coordinates of the points whose polar coordinates are

(i) $\left(5, \pi - \tan^{-1}\left(\frac{4}{3}\right)\right)$ (ii) $\left(5\sqrt{2}, \frac{\pi}{4}\right)$

Sol. (i) Given, $r = 5, \theta = \pi - \tan^{-1}\left(\frac{4}{3}\right)$

Now, $x = r\cos\theta = 5\cos\left(\pi - \tan^{-1}\left(\frac{4}{3}\right)\right)$

$= -5\cos\left(\tan^{-1}\left(\frac{4}{3}\right)\right)$

$= -5\cos\left(\cos^{-1}\left(\frac{3}{5}\right)\right) = -5\times\frac{3}{5} = -3$

and $y = r\sin\theta = 5\sin\left(\pi - \tan^{-1}\left(\frac{4}{3}\right)\right)$

$= 5\sin\left(\tan^{-1}\left(\frac{4}{3}\right)\right)$

$= 5\sin\left(\sin^{-1}\left(\frac{4}{5}\right)\right) = 5\times\frac{4}{5} = 4$

Hence, cartesian coordinates of the given point will be $(-3, 4)$.

(ii) Given, $r = 5\sqrt{2}, \theta = \frac{\pi}{4}$

Now, $x = r\cos\theta = 5\sqrt{2}\cos\left(\frac{\pi}{4}\right) = 5\sqrt{2}\times\frac{1}{\sqrt{2}} = 5$

and $y = r\sin\theta = 5\sqrt{2}\sin\left(\frac{\pi}{4}\right) = 5\sqrt{2}\times\frac{1}{\sqrt{2}} = 5$

Hence, cartesian coordinates of the given point, will be $(5, 5)$.

Example 4. Find the polar coordinates of the points whose cartesian coordinates are

(i) $(-2, -2)$ (ii) $(-3, 4)$

Sol. (i) Given, $x = -2, y = -2$

$\therefore$ $r = \sqrt{(x^2 + y^2)} = \sqrt{(4+4)} = 2\sqrt{2}$

and $\alpha = \tan^{-1}\left|\frac{y}{x}\right| = \tan^{-1}\left|\frac{-2}{-2}\right| = \tan^{-1}1 = \frac{\pi}{4}$

Since, point $(-2, -2)$ lies in III quadrant.

$\therefore$ $\theta = -\pi + \alpha = -\pi + \frac{\pi}{4} = -\frac{3\pi}{4}$

Hence, polar coordinates of the given points will be $\left(2\sqrt{2}, -\frac{3\pi}{4}\right)$.

Remark : If we find θ, from the equation,

$\tan\theta = \frac{y}{x} = \frac{-2}{-2} = 1$

then, $\theta = \frac{\pi}{4}$ and then

$(x, y) = (r\cos\theta, r\sin\theta) = \left(2\sqrt{2}\times\frac{1}{\sqrt{2}}, 2\sqrt{2}\times\frac{1}{\sqrt{2}}\right)$

$= (2, 2) \neq (-2, -2)$

(ii) Given, $x = -3, y = 4$

$\therefore$ $r = \sqrt{(x^2 + y^2)} = \sqrt{(9+16)} = 5$

and $\alpha = \tan^{-1}\left|\frac{y}{x}\right| = \tan^{-1}\left|\frac{4}{-3}\right| = \tan^{-1}\left(\frac{4}{3}\right)$

Since, point $(-3, 4)$ lies in II quadrant

$\therefore$ $\theta = \pi - \alpha = \pi - \tan^{-1}\left(\frac{4}{3}\right)$

Hence, polar coordinates of the given points, will be $\left(5, \pi - \tan^{-1}\left(\frac{4}{3}\right)\right)$.

Example 5. Transform the equation $r^2 = a^2\cos 2\theta$ into cartesian form.

Sol. $\because$ $r = \sqrt{(x^2 + y^2)}$ and $\theta = \tan^{-1}\left(\frac{y}{x}\right)$

or $r^2 = (x^2 + y^2)$ and $\tan\theta = \frac{y}{x}$

Given, $r^2 = a^2\cos 2\theta = a^2\left(\frac{1 - \tan^2\theta}{1 + \tan^2\theta}\right)$

or $(x^2 + y^2) = a^2\left(\frac{1 - \frac{y^2}{x^2}}{1 + \frac{y^2}{x^2}}\right)$

or $(x^2 + y^2)^2 = a^2(x^2 - y^2)$

This is the required equation in cartesian form.

Aliter :

$r^2 = a^2\cos 2\theta$

or $r^2 = a^2(\cos^2\theta - \sin^2\theta)$

$\because$ $x = r\cos\theta$ and $y = r\sin\theta$

and $r^2 = x^2 + y^2$

then $r^2 = a^2\left(\frac{x^2}{r^2} - \frac{y^2}{r^2}\right)$

or $r^4 = a^2(x^2 - y^2)$

or $(x^2 + y^2)^2 = a^2(x^2 - y^2)$.

Example 6. Transform the equation $x^2 + y^2 = ax$ into polar form.

Sol. $\because$ $x = r\cos\theta,\ y = r\sin\theta$

Given, $x^2 + y^2 = ax$

$\Rightarrow$ $r^2 = a(r\cos\theta)$

or $r = a\cos\theta$

This is the required equation in polar form.

Exercise for Session 1

1. The polar coordinates of the point whose cartesian coordinates are $(-1, -1)$ is

(a) $\left(\sqrt{2}, \frac{\pi}{4}\right)$ (b) $\left(\sqrt{2}, \frac{3\pi}{4}\right)$ (c) $\left(\sqrt{2}, -\frac{\pi}{4}\right)$ (d) $\left(\sqrt{2}, -\frac{3\pi}{4}\right)$

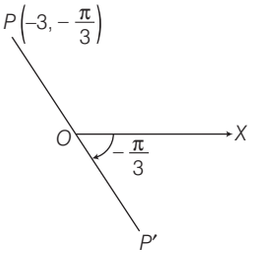
2. The cartesian coordinates of the point whose polar coordinates are $\left(13, \pi - \tan^{-1}\left(\frac{5}{12}\right)\right)$ is

(a) (12, 5) (b) (–12, 5) (c) (–12, – 5) (d) (12, – 5)

3. The transform equation of $r^2 \cos^2\theta = a^2 \cos 2\theta$ to cartesian form is $(x^2 + y^2)\, x^2 = a^2\lambda$, then value of λ is

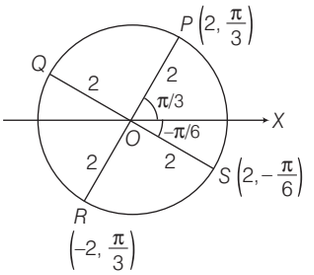
(a) $y^2 - x^2$ (b) $x^2 - y^2$ (c) xy (d) x^2y^2

4. The coordinates of P' in the figure is



(a) $\left(3, \frac{\pi}{3}\right)$ (b) $\left(3, -\frac{\pi}{3}\right)$ (c) $\left(-3, -\frac{\pi}{3}\right)$ (d) $\left(-3, \frac{\pi}{3}\right)$

5. The cartesian coordinates of the point Q in the figure is



(a) $(\sqrt{3}, 1)$ (b) $(-\sqrt{3}, 1)$ (c) $(-\sqrt{3}, -1)$ (d) $(\sqrt{3}, -1)$

6. A point lies on X-axis at a distance 5 units from Y-axis. What are its coordinates ?

7. A point lies on *Y-axis at a distance 4 units from X*-axis. What are its coordinates ?

8. A point lies on negative direction of X-axis at a distance 6 units from Y-axis. What are its coordinates ?

9. Transform the equation $y = x \tan\alpha$ to polar form.

10. Transform the equation $r = 2a \cos\theta$ to cartesian form.

Session 2

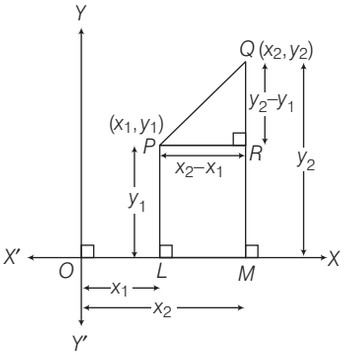
Distance between Two Points, Choice of Axes, Distance between Two Points in Polar Coordinates

Distance Between Two Points

Theorem : The distance between two points $P(x_1, y_1)$ and $Q(x_2, y_2)$ is given by

$$|PQ| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Proof : Let $P(x_1, y_1)$ and $Q(x_2, y_2)$ be any two points in the plane. Let us assume that the points P and Q are both in 1st quadrant (for the sake of exactness).



From P and Q draw PL and QM perpendiculars to X-axis. From P draw PR perpendicular to QM and join PQ. Then

$$OL = x_1,\ OM = x_2,\ PL = y_1,\ QM = y_2$$

$\therefore$ $PR = LM = OM - OL = x_2 - x_1$

and $QR = QM - RM = QM - PL = y_2 - y_1$

Since, PRQ is a right angled triangle, therefore by pythagoras theorem.

$$(PQ)^2 = (PR)^2 + (QR)^2$$

$\therefore$ $|PQ| = \sqrt{(PR)^2 + (QR)^2}$ ($\because PQ$ is always positive)

$$= \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

$\therefore$ The distance PQ between the points $P(x_1, y_1)$ and $Q(x_2, y_2)$ is given by $\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$

or $\sqrt{(\text{difference in x coordinates})^2 + (\text{difference in y coordinates})^2}$

or $\sqrt{(\text{difference of abscissaes})^2 + (\text{difference of ordinates})^2}$

Notations : We shall denote the distance between two points P and Q of the coordinate plane, either by $|PQ|$ or by $\overline{PQ}$.

***Corollary* 1 :** The above formula is true for all positions of the points (i.e. either point or both points are not in the 1st quadrant) keeping in mind, the proper signs of their coordinates.

***Corollary* 2 :** The distance of the point $P(x, y)$ from the origin $O(0, 0)$ is given by

$$|OP| = \sqrt{(x - 0)^2 + (y - 0)^2} = \sqrt{(x^2 + y^2)}$$

***Corollary* 3 :** The above formula can also be used as

$$\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$$

***Corollary* 4 :** (i) If PQ is parallel to X-axis, then $y_1 = y_2$ and so

$$|PQ| = \sqrt{(x_2 - x_1)^2} = |x_2 - x_1|$$

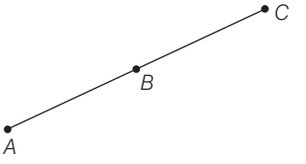
(ii) If PQ is parallel to Y-axis, then $x_1 = x_2$ and so

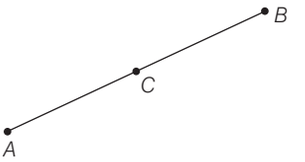
$$|PQ| = \sqrt{(y_2 - y_1)^2} = |y_2 - y_1|$$

***Corollary* 5 :** If distance between two points is given, then use $\pm$ sign.

Remarks

1. If three points $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ are collinear, then $|AB| \pm |BC| = |AC|$





2. When three points are given and it is required to :

(i) an **Isosceles triangle**, show that two of its sides (or two angles) are equal.

(ii) an **Equilateral triangle**, show that its all sides are equal or each angle is of 60°.

(iii) a **Right angle triangle**, show that the sum of the squares of two sides is equal to the square of the third side.

(iv) an **Isosceles right angled triangle**, show that two of its sides are equal and the sum of the squares of two equal sides is equal to the square of the third side.

(v) a **Scalene triangle**, show that its all sides are unequal.

3. When four points are given and it is required to

(i) a **Square**, show that the four sides are equal and the diagonals are also equal.

(ii) a **Rhombus, (or equilateral trapezium)** show that the four sides are equal and the diagonals are not equal.

(iii) a **Rectangle**, show that the opposite sides are equal and the diagonals are also equal.

(iv) a **Parallelogram**, show that the opposite sides are equal and the diagonals are not equal.

(v) a **Trapezium**, show that the two sides are parallel and the other two sides are not parallel.

(vi) An Isosceles Trapezium, show that the two sides are parallel and the other two sides are not parallel but equal.

4. If A, B, C be the vertices of a triangle and we have to find the coordinates of the circumcentre then, let the circumcentre be $P(x, y)$ and use $PA^2 = PB^2$ and $PA^2 = PC^2$ this will give two equations in x and y then solve these two equations and (x, y).

Important Remarks for Objective Questions

(i) If (x_1, y_1) and (x_2, y_2) are the ends of the hypotenuse of a right angled isosceles triangle, then the third vertex is given by

$$\left(\frac{(x_1 + x_2) \pm (y_1 - y_2)}{2}, \frac{(y_1 + y_2) \mp (x_1 - x_2)}{2}\right)$$

(ii) If two vertices of an equilateral triangle are (x_1, y_1) and (x_2, y_2), then coordinates of the third vertex are

$$\left(\frac{x_1 + x_2 \mp \sqrt{3}(y_2 - y_1)}{2}, \frac{y_1 + y_2 \pm \sqrt{3}(x_2 - x_1)}{2}\right)$$

Example 7. Prove that the distance of the point $(a\cos\alpha, a\sin\alpha)$ from the origin is independent of α.

Sol. Let $P \equiv (a\cos\alpha, a\sin\alpha)$ and $O \equiv (0, 0)$

$$\text{then} \quad |OP| = \sqrt{(a\cos\alpha - 0)^2 + (a\sin\alpha - 0)^2}$$
$$= \sqrt{(a^2\cos^2\alpha + a^2\sin^2\alpha)}$$
$$= \sqrt{a^2(\cos^2\alpha + \sin^2\alpha)} = \sqrt{a^2}$$
$$= |a|, \text{ which is independent of } \alpha.$$

Example 8. Find the distance between the points $(a\cos\alpha, a\sin\alpha)$ and $(a\cos\beta, a\sin\beta)$, where $a > 0$.

Sol. Let $P \equiv (a\cos\alpha, a\sin\alpha)$ and $Q \equiv (a\cos\beta, a\sin\beta)$

$$\text{then} \quad |PQ| = \sqrt{(a\cos\alpha - a\cos\beta)^2 + (a\sin\alpha - a\sin\beta)^2}$$
$$= \sqrt{a^2\{(\cos\alpha - \cos\beta)^2 + (\sin\alpha - \sin\beta)^2\}}$$
$$= \sqrt{a^2\{\cos^2\alpha + \cos^2\beta - 2\cos\alpha\cos\beta + \sin^2\alpha + \sin^2\beta - 2\sin\alpha\sin\beta\}}$$
$$= \sqrt{a^2\{1 + 1 - 2(\cos\alpha\cos\beta + \sin\alpha\sin\beta)\}}$$
$$= \sqrt{a^2(2 - 2\cos(\alpha - \beta))}$$
$$= \sqrt{2a^2(1 - \cos(\alpha - \beta))}$$
$$= \sqrt{\left(2a^2 \cdot 2\sin^2\left(\frac{\alpha - \beta}{2}\right)\right)}$$
$$= \sqrt{4a^2\sin^2\left(\frac{\alpha - \beta}{2}\right)}$$
$$= \left|2a\sin\left(\frac{\alpha - \beta}{2}\right)\right|$$
$$= 2a\left|\sin\left(\frac{\alpha - \beta}{2}\right)\right| \qquad (\because a > 0)$$

Example 9. If the point (x, y) be equidistant from the points $(6, -1)$ and $(2, 3)$, prove that $x - y = 3$.

Sol. Let $P \equiv (x, y)$, $A \equiv (6, -1)$ and $B \equiv (2, 3)$

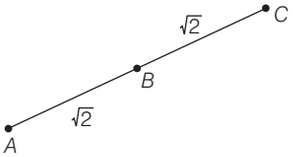
By the given condition, $PA = PB$

$$\Rightarrow \quad \sqrt{(x-6)^2 + (y+1)^2} = \sqrt{(x-2)^2 + (y-3)^2}$$
$$\text{or} \quad (x-6)^2 + (y+1)^2 = (x-2)^2 + (y-3)^2$$
$$\text{or} \quad x^2 - 12x + 36 + y^2 + 2y + 1 = x^2 - 4x + 4 + y^2 - 6y + 9$$
$$\text{or} \quad 8x - 8y = 24$$
$$\text{or} \quad x - y = 3$$

Example 10. Using distance formula, show that the points $(1, 5), (2, 4)$ and $(3, 3)$ are collinear.

Sol. Let $A \equiv (1, 5)$, $B \equiv (2, 4)$ and $C \equiv (3, 3)$ be the given points, then

$$|AB| = \sqrt{(1-2)^2 + (5-4)^2} = \sqrt{2}$$



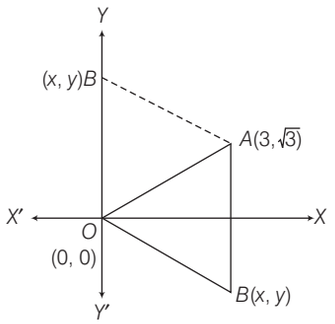
$$|BC| = \sqrt{(2-3)^2 + (4-3)^2} = \sqrt{2}$$
$$\text{and} \quad |AC| = \sqrt{(1-3)^2 + (5-3)^2} = 2\sqrt{2}$$
$$\text{Clearly,} \quad |AB| + |BC| = \sqrt{2} + \sqrt{2} = 2\sqrt{2} = |AC|.$$

Hence, A, B, C are collinear.

Example 11. An equilateral triangle has one vertex at the point $(0, 0)$ and another at $(3, \sqrt{3})$. Find the coordinates of the third vertex.

Sol. Let $O \equiv (0, 0)$ and $A \equiv (3, \sqrt{3})$ be the given points and let $B \equiv (x, y)$ be the required point. Then

$$OA = OB = AB$$



$$\Rightarrow \quad (OA)^2 = (OB)^2 = (AB)^2$$

$$\Rightarrow \quad (3-0)^2 + (\sqrt{3}-0)^2 = (x-0)^2 + (y-0)^2$$

$$= (x-3)^2 + (y-\sqrt{3})^2$$

$$\Rightarrow \quad 12 = x^2 + y^2 = x^2 + y^2 - 6x - 2\sqrt{3}y + 12$$

Taking first two members then

$$x^2 + y^2 = 12 \qquad \ldots(i)$$

and taking last two members, then

$$6x + 2\sqrt{3}y = 12 \text{ or } y = \sqrt{3}(2 - x) \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$x^2 + 3(2-x)^2 = 12$$

or $$4x^2 - 12x = 0$$

$$\Rightarrow \quad x = 0, 3$$

Putting $x = 0, 3$ in Eq. (ii), we get $y = 2\sqrt{3}, -\sqrt{3}$

Hence, the coordinates of the third vertex B are $(0, 2\sqrt{3})$ or $(3, -\sqrt{3})$.

Short Cut Method : According to important note :

$$\left(\frac{x_1 + x_2 \mp \sqrt{3}(y_2 - y_1)}{2}, \frac{y_1 + y_2 \pm \sqrt{3}(x_2 - x_1)}{2}\right)$$

i.e. $$\left(\frac{0 + 3 \mp \sqrt{3}(\sqrt{3} - 0)}{2}, \frac{0 + \sqrt{3} \pm \sqrt{3}(3 - 0)}{2}\right)$$

or $$\left(\frac{3 \mp 3}{2}, \frac{\sqrt{3} \pm 3\sqrt{3}}{2}\right)$$

$$\Rightarrow \quad (0, 2\sqrt{3}) \text{ or } (3, -\sqrt{3})$$

Example 12. Show that four points $(1, -2)$, $(3, 6)$, $(5, 10)$ and $(3, 2)$ are the vertices of a parallelogram.

Sol. Let $A \equiv (1, -2)$, $B \equiv (3, 6)$, $C \equiv (5, 10)$ and $D \equiv (3, 2)$ be the given points. Then

$$|AB| = \sqrt{(1-3)^2 + (-2-6)^2} = \sqrt{4 + 64} = 2\sqrt{17}$$

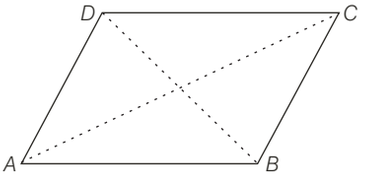
$$|BC| = \sqrt{(3-5)^2 + (6-10)^2} = \sqrt{4 + 16} = 2\sqrt{5}$$

$$|CD| = \sqrt{(5-3)^2 + (10-2)^2} = \sqrt{4 + 64} = 2\sqrt{17}$$

$$|AD| = \sqrt{(1-3)^2 + (-2-2)^2} = \sqrt{4 + 16} = 2\sqrt{5}$$

$$|AC| = \sqrt{(1-5)^2 + (-2-10)^2} = \sqrt{16 + 144} = 4\sqrt{10}$$

and $$|BD| = \sqrt{(3-3)^2 + (6-2)^2} = 4$$



Clearly, $|AB| = |CD|$, $|BC| = |AD|$ and $|AC| \neq |BD|$

Hence, $ABCD$ is a parallelogram.

Example 13. Let the opposite angular points of a square be $(3, 4)$ and $(1, -1)$. Find the coordinates of the remaining angular points.

Sol. Let $A(3, 4)$ and $C(1, -1)$ be the given angular points of a square $ABCD$ and let $B(x, y)$ be the unknown vertex. Then

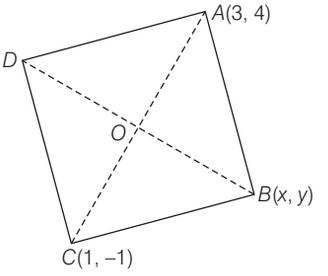
$$AB = BC$$

$$\Rightarrow \quad (AB)^2 = (BC)^2$$

$$\Rightarrow \quad (x-3)^2 + (y-4)^2 = (x-1)^2 + (y+1)^2$$

$$\Rightarrow \quad 4x + 10y - 23 = 0$$

$$\Rightarrow \quad x = \left(\frac{23 - 10y}{4}\right) \qquad \ldots(i)$$



Also, in ΔABC,

$$(AB)^2 + (BC)^2 = (AC)^2$$

$$\Rightarrow \quad (x-3)^2 + (y-4)^2 + (x-1)^2 + (y+1)^2$$

$$= (3-1)^2 + (4+1)^2$$

$$\Rightarrow \quad x^2 + y^2 - 4x - 3y - 1 = 0 \qquad \ldots(ii)$$

Substituting the value of x from Eqs. (i) into (ii), we get

$$\left(\frac{23 - 10y}{4}\right)^2 + y^2 - 4\left(\frac{23 - 10y}{4}\right) - 3y - 1 = 0$$

$$\Rightarrow \quad 4y^2 - 12y + 5 = 0$$

or $$(2y - 1)(2y - 5) = 0$$

$$\therefore \quad y = \frac{1}{2} \text{ or } \frac{5}{2}$$

Putting $y = \frac{1}{2}$ in Eq. (i), we get $x = \frac{9}{2}$,

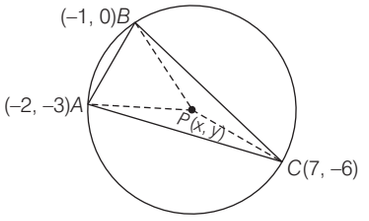
and putting $y = \frac{5}{2}$ in Eq. (i), we get $x = -\frac{1}{2}$

Hence, the required vertices of the square are $\left(\frac{9}{2}, \frac{1}{2}\right)$ and $\left(-\frac{1}{2}, \frac{5}{2}\right)$.

Example 14. Find the circumcentre of the triangle whose vertices are $(-2, -3)$, $(-1, 0)$ and $(7, -6)$. Also find the radius of the circumcircle.

Sol. Let $A \equiv (-2, -3)$, $B \equiv (-1, 0)$ and $C \equiv (7, -6)$.

Let $P \equiv (x, y)$ be the circumcentre of ΔABC.



Since, P is the circumcentre

$$\therefore \quad |PA| = |PB| = |PC| \Rightarrow (PA)^2 = (PB)^2 = (PC)^2$$

$$(x+2)^2 + (y+3)^2 = (x+1)^2 + (y-0)^2$$

$$= (x-7)^2 + (y+6)^2$$

$$\Rightarrow \quad x^2 + y^2 + 4x + 6y + 13 = x^2 + y^2 + 2x + 1$$

$$= x^2 + y^2 - 14x + 12y + 85$$

Taking first two members, we get

$$x + 3y + 6 = 0 \qquad \ldots(i)$$

and taking 1st and last member then, we get

$$3x - y - 12 = 0 \qquad \ldots(ii)$$

Solving Eqs. (i) and (ii), we get

$$x = 3, y = -3$$

Hence, circumcentre is $(3, -3)$.

Radius of the circumcircle

$$= PB = \sqrt{(3+1)^2 + (-3-0)^2}$$

$$= \sqrt{16+9} = 5 \text{ units}$$

Example 15. If the line segment joining the points $A(a,b)$ and $B(c,d)$ subtends an angle θ at the origin O, prove that

$$\cos\theta = \frac{ac+bd}{\sqrt{(a^2+b^2)(c^2+d^2)}}$$

or $$OA.OB\cos\theta = ac + bd$$

Sol. Let $OA = r_1$ and $OB = r_2$

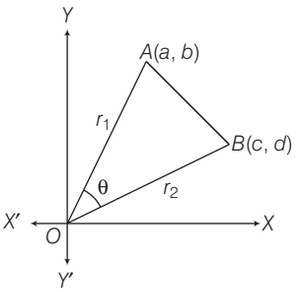
Now, $$r_1 = |OA| = \sqrt{(a^2 + b^2)} \qquad \ldots(i)$$

and $$r_2 = |OB| = \sqrt{(c^2 + d^2)} \qquad \ldots(ii)$$

Also, $$|AB| = \sqrt{(a-c)^2 + (b-d)^2}$$

$$= \sqrt{a^2 + b^2 + c^2 + d^2 - 2ac - 2bd}$$

$$= \sqrt{r_1^2 + r_2^2 - 2(ac + bd)}$$ [from Eqs. (i) and (ii)]



By using **Cosine formula** in ΔAOB

$$\cos\theta = \frac{(OA)^2 + (OB)^2 - (AB)^2}{2 \cdot OA \,.\, OB}$$

$$= \frac{r_1^2 + r_2^2 - (r_1^2 + r_2^2 - 2(ac + bd))}{2r_1 r_2}$$

$$= \frac{2(ac+bd)}{2r_1 r_2} = \frac{(ac+bd)}{r_1 r_2} \qquad \ldots(iii)$$

$$= \frac{(ac+bd)}{\sqrt{(a^2+b^2)}\sqrt{(c^2+d^2)}}$$ [from Eqs. (i) and (ii)]

$$= \frac{(ac+bd)}{\sqrt{(a^2+b^2)(c^2+d^2)}}$$

Also from Eq. (iii),

$$r_1 r_2 \cos\theta = ac + bd \quad \text{or} \quad OA.OB\cos\theta = ac + bd$$

Choice of Axes

For simplification we carefully choose the axes or the origin. Some situations are given below :

(i) If two lines are perpendicular then point of intersection is taken as origin and these lines must be taken as the coordinate axes.

(ii) If two fixed points A and B are given then we take $|AB| = 2a$ and the mid-point of AB as origin 'O', line AOB as X-axis and the line perpendicular to AB through O is taken as Y-axis then the coordinates of the fixed points are $(\pm a, 0)$. Similarly if AOB as Y-axis and the line perpendicular to AB through O is taken as X-axis then the coordinates of the fixed points are $(0, \pm a)$.

(iii) If there is a symmetry of any kind then take the coordinates of the points in a general way i.e. (x_i, y_i), $i = 1, 2, 3, \ldots$ etc.

Example 16. Show that the triangle, the coordinates of whose vertices are given by integers, can never be an equilateral triangle.

Sol. Let $A \equiv (0, 0)$, $B \equiv (a, 0)$ and $C \equiv (b, c)$ be the vertices of equilateral triangle ABC where a, b, c are integers then,

$$|AB| = |BC| = |CA|$$

$$\Rightarrow \quad (AB)^2 = (BC)^2 = (CA)^2$$

$$\Rightarrow \quad a^2 = (a-b)^2 + c^2 = b^2 + c^2$$

From first two members, we get

$$b^2 + c^2 = 2ab \qquad \ldots(i)$$

and taking first and third members, then

$$b^2 + c^2 = a^2 \qquad \ldots(ii)$$

From Eqs. (i) and (ii) we get

$$a = 2b \qquad (\because a \neq 0)$$

From Eq. (ii), $b^2 + c^2 = (2b)^2$

or $c^2 = 3b^2$

or $c = \pm b\sqrt{3}$

which is impossible, since b and c are integers.

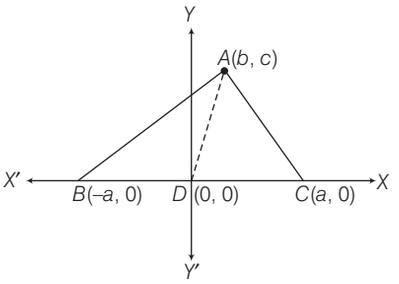
Example 17. In any triangle ABC, show that

$$AB^2 + AC^2 = 2(AD^2 + BD^2)$$

where, D is the middle point of BC.

Sol. Let D as the origin and DC and DY as the X and Y-axes respectively. Let $BC = 2a$, then

$B \equiv (-a, 0)$, $C \equiv (a, 0)$ and let $A \equiv (b, c)$



Now, LHS $= AB^2 + AC^2$

$$= (b+a)^2 + (c-0)^2 + (b-a)^2 + (c-0)^2$$

$$= 2(a^2 + b^2 + c^2) \qquad \ldots(i)$$

and RHS $= 2(AD^2 + BD^2)$

$$= 2\{(b-0)^2 + (c-0)^2 + a^2\}$$

$$= 2(a^2 + b^2 + c^2) \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

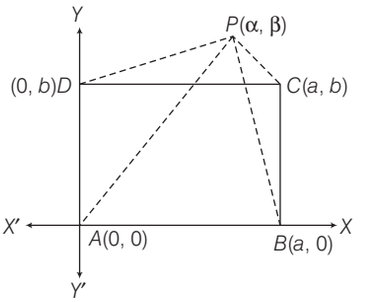
$$AB^2 + AC^2 = 2(AD^2 + BD^2)$$

Example 18. Let $ABCD$ be a rectangle and P be any point in its plane. Show that $PA^2 + PC^2 = PB^2 + PD^2$

Sol. Let A as the origin and AB and AD as the X and Y-axes respectively. Let $AB = a$ and $AD = b$, then

$B \equiv (a, 0)$, $D \equiv (0, b)$ and $C \equiv (a, b)$

Let $P \equiv (\alpha, \beta)$



Now, LHS $= PA^2 + PC^2$

$$= (\alpha - 0)^2 + (\beta - 0)^2 + (\alpha - a)^2 + (\beta - b)^2$$

$$= 2\alpha^2 + 2\beta^2 - 2a\alpha - 2b\beta + a^2 + b^2 \qquad \ldots(i)$$

and RHS $= PB^2 + PD^2$

$$= (\alpha - a)^2 + (\beta - 0)^2 + (\alpha - 0)^2 + (\beta - b)^2$$

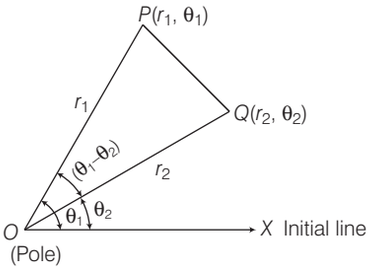
$$= 2\alpha^2 + 2\beta^2 - 2a\alpha - 2b\beta + a^2 + b^2 \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$PA^2 + PC^2 = PB^2 + PD^2$$

Distance between Two Points in Polar Coordinates

Let O be the pole and OX be the initial line. Let P and Q be two given points whose polar coordinates are (r_1, θ_1) and (r_2, θ_2) respectively.



Then, $OP = r_1$, $OQ = r_2$

and $\angle POX = \theta_1$, $\angle QOX = \theta_2$

$\therefore$ $\angle POQ = \theta_1 - \theta_2$

By using **Cosine formula** in ΔPOQ,

$$\cos(\angle POQ) = \frac{(OP)^2 + (OQ)^2 - (PQ)^2}{2(OP)(OQ)}$$

or $$\cos(\theta_1 - \theta_2) = \frac{r_1^2 + r_2^2 - (PQ)^2}{2\, r_1 r_2}$$

$\therefore$ $$|PQ| = \sqrt{(r_1^2 + r_2^2 - 2\, r_1 r_2 \cos(\theta_1 - \theta_2))}$$

Remark

Always taking θ_1 and θ_2 in radians.

Example 19. Prove that the points $(0, 0)$, $\left(3, \frac{\pi}{2}\right)$ and $\left(3, \frac{\pi}{6}\right)$ are the vertices of an equilateral triangle.

Sol. Let $A \equiv (0, 0)$, $B \equiv \left(3, \frac{\pi}{2}\right)$ and $C \equiv \left(3, \frac{\pi}{6}\right)$

Here, given coordinates are in polar form

$\therefore$ $$|AB| = \sqrt{(0^2 + 3^2 - 2 \cdot 0 \cdot 3 \cos\left(\frac{\pi}{2} - 0\right)} = 3 \text{ units}$$

$$|BC| = \sqrt{\left(3^2 + 3^2 - 2 \cdot 3 \cdot 3 \cos\left(\frac{\pi}{2} - \frac{\pi}{6}\right)\right)}$$

$$= \sqrt{\left(18 - 18 \sin\frac{\pi}{6}\right)} = \sqrt{(18 - 9)} = 3 \text{ units}$$

and $$|CA| = \sqrt{\left(3^2 + 0^2 - 2 \cdot 3 \cdot 0 \cos\left(\frac{\pi}{6} - 0\right)\right)} = 3 \text{ units}$$

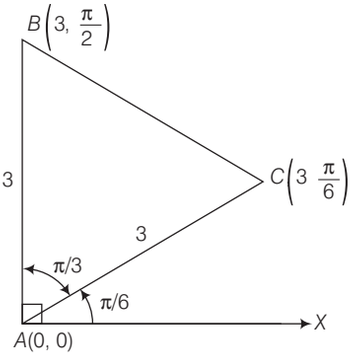
$\therefore$ $$|AB| = |BC| = |CA|$$

Hence, points A, B, C are the vertices of an equilateral triangle.

Aliter :

$\because$ $$\angle BAX = \frac{\pi}{2}$$

and $$\angle CAX = \frac{\pi}{6}$$



$\therefore$ $$\angle BAC = \frac{\pi}{2} - \frac{\pi}{6} = \frac{\pi}{3}$$

$\because$ In $\Delta\, ABC$

$$AB = AC$$

$\therefore$ $$\angle ACB = \angle ABC = \alpha \quad \text{(say)}$$

$\therefore$ $$\alpha + \alpha + \frac{\pi}{3} = \pi$$

or $$\alpha = \frac{\pi}{3}$$

Hence, $$|AB| = |BC| = |CA|.$$

Exercise for Session 2

1. If the distance between the points $(a, 2)$ and $(3, 4)$ be 8, then a equals to

(a) $2 + 3\sqrt{15}$ (b) $2 - 3\sqrt{15}$ (c) $2 \pm 3\sqrt{15}$ (d) $3 \pm 2\sqrt{15}$

2. The three points $(-2, 2)$, $(8, -2)$ and $(-4, -3)$ are the vertices of

(a) an isosceles triangle (b) an equilateral triangle (c) a right angled triangle (d) None of these

3. The distance between the points $\left(3, \frac{\pi}{4}\right)$ and $\left(7, \frac{5\pi}{4}\right)$ is

(a) 8 (b) 10 (c) 12 (d) 14

4. Let $A(6, -1)$, $B(1, 3)$ and $C(x, 8)$ be three points such that $AB = BC$, then the value of x are

(a) 3, 5 (b) –3, 5 (c) 3, – 5 (d) –3, – 5

5. The points $(a + 1, 1)$, $(2a + 1, 3)$ and $(2a + 2, 2a)$ are collinear, if

(a) $a = -1, 2$ (b) $a = \frac{1}{2}, 2$ (c) $a = 2, 1$ (d) $a = -\frac{1}{2}, 2$

6. If $A \equiv (3, 4)$ and B is a variable point on the lines $|x| = 6$. If $AB \leq 4$ then the number of positions of B with integral coordinates is

(a) 5 (b) 6 (c) 10 (d) 12

7. The number of points on X-axis which are at a distance c units $(c < 3)$ from $(2, 3)$ is

(a) 1 (b) 2 (c) 0 (d) 3

8. The point on the axis of y which its equidistant from $(-1, 2)$ and $(3, 4)$, is

(a) (0, 3) (b) (0, 4) (c) (0, 5) (d) (0, – 6)

9. Find the distance between the points $(at_1^2, 2at_1)$ and $(at_2^2, 2at_2)$, where t_1 and t_2 are the roots of the equation $x^2 - 2\sqrt{3}x + 2 = 0$ and $a > 0$.

10. If $P(at^2, 2at)$, $Q\left(\frac{a}{t^2}, -\frac{2a}{t}\right)$ and $S(a, 0)$ be any three points, show that $\frac{1}{SP} + \frac{1}{SQ}$ is independent of t.

11. Prove that the points $(3, 4)$, $(8, -6)$ and $(13, 9)$ are the vertices of a right angled triangle.

12. Show that the points $(0, -1)$, $(6, 7)$, $(-2, 3)$ and $(8, 3)$ are the vertices of a rectangle.

13. Find the circumcentre and circumradius of the triangle whose vertices are $(-2, 3)$, $(2, -1)$ and $(4, 0)$.

14. The vertices of a triangle are $A(1, 1)$, $B(4, 5)$ and $C(6, 13)$. Find $\cos A$.

15. Two opposite vertices of a square are $(2, 6)$ and $(0, -2)$. Find the coordinates of the other vertices.

16. If the point (x, y) is equidistant from the points $(a + b, b - a)$ and $(a - b, a + b)$, prove that $bx = ay$.

17. If a and b are real numbers between 0 and 1 such that the points $(a, 1)$, $(1, b)$ and $(0, 0)$ form an equilateral triangle, find a and b.

18. An equilateral triangle has one vertex at $(3, 4)$ and another at $(-2, 3)$. Find the coordinates of the third vertex.

19. If P be any point in the plane of square $ABCD$, prove that

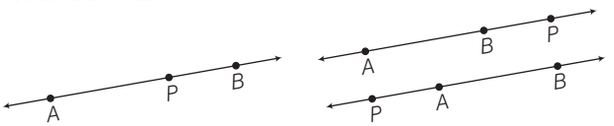
$$PA^2 + PC^2 = PB^2 + PD^2$$

Session 3

Section Formula, Centroid of a Triangle, Incentre, Some Standard Results, Area of Triangle

Section Formula

Definition : If P be any point on the line AB between A and B then we say that P divides segment AB *internally* in the ratio $AP : PB$.



Also, if P be any point on the line AB but not between A and B (P may be to the right or the left of the points A, B) then P divides AB *externally* in the ratio $AP : PB$

Note

$$\frac{AP}{PB} = \begin{cases} \text{Positive, in internally division} \\ \text{Negative, in externally division} \end{cases}$$

(i) Formula for Internal Division

Theorem : If the point $P(x, y)$ divides the line segment joining the points $A(x_1, y_1)$ and $B(x_2, y_2)$ internally in the ratio $m : n$, then prove that

$$x = \frac{mx_2 + nx_1}{m + n}$$

$$y = \frac{my_2 + ny_1}{m + n}$$

Proof : The given points are $A(x_1, y_1)$ and $B(x_2, y_2)$. Let us assume that the points A and B are both in 1st quadrant (for the sake of exactness). Since $P(x, y)$ divides AB internally in the ratio $m : n$ i.e. $AP : PB = m : n$. From A, B and P draw AL, BM and PN perpendiculars to X-axis. From A and P draw AH and PJ perpendiculars to PN and BM respectively, then

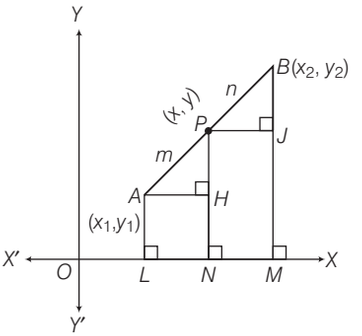
$OL = x_1, ON = x, OM = x_2, AL = y_1, PN = y$ and $BM = y_2$

$$\therefore \quad AH = LN = ON - OL = x - x_1$$

$$PJ = NM = OM - ON = x_2 - x$$

$$PH = PN - HN = PN - AL = y - y_1$$

and $$BJ = BM - JM = BM - PN = y_2 - y$$



Clearly, the Δs AHP and PJB are similar and therefore, their sides are proportional

$$\therefore \quad \frac{AH}{PJ} = \frac{PH}{BJ} = \frac{AP}{PB}$$

or $$\frac{x - x_1}{x_2 - x} = \frac{y - y_1}{y_2 - y} = \frac{m}{n}$$

(i) (ii) (iii)

From Eqs. (i) and (iii), we have

$$\frac{x - x_1}{x_2 - x} = \frac{m}{n}$$

$$\Rightarrow \quad nx - nx_1 = mx_2 - mx$$

$$\Rightarrow \quad (m + n)\, x = mx_2 + nx_1$$

$$\therefore \quad x = \frac{mx_2 + nx_1}{m + n}$$

and from Eqs. (ii) and (iii), we have

$$\frac{y - y_1}{y_2 - y} = \frac{m}{n}$$

$$\Rightarrow \quad ny - ny_1 = my_2 - my$$

$$\Rightarrow \quad (m + n)\, y = my_2 + ny_1$$

$$\therefore \quad y = \frac{my_2 + ny_1}{m + n}$$

Thus, the coordinates of P are

$$\left(\frac{mx_2 + nx_1}{m + n}, \frac{my_2 + ny_1}{m + n} \right).$$

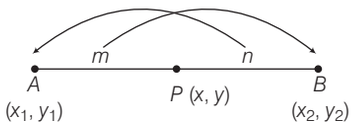
***Corollary* 1 :** The above section formula is true for all positions of the points (i.e. either point or both points are not in the 1st quadrant), keeping in mind, the proper signs of their coordinates.

***Corollary* 2 :** If P is the mid-point of AB then $m = n$, the coordinates of the middle-point of AB are

$$\left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$$

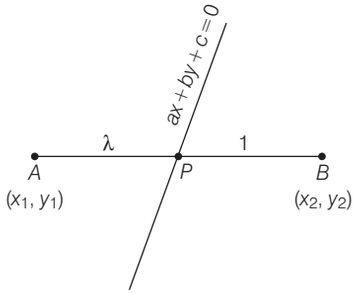
Remarks

1. If $P(\alpha, \beta)$ be the mid-point of AB and if coordinates of A are (λ, μ) then the coordinates of B are $(2\alpha - \lambda, 2\beta - \mu)$, i.e. (Double the x-co-ordinate of mid point – x-coordinate of given point, Double the y-co-ordinate of mid point – y-coordinate of given point).
2. The following diagram will help to remember the section formula.



3. For finding ratio, use ratio $\lambda : 1$, then coordinates of P are $\left(\frac{x_1 + \lambda x_2}{1 + \lambda}, \frac{y_1 + \lambda y_2}{1 + \lambda}\right)$. If λ is positive then divides internally and if λ is negative, then divides externally.
4. The straight line $ax + by + c = 0$ divides the joint of points $A(x_1, y_1)$ and $B(x_2, y_2)$ in the ratio

$$\frac{AP}{PB} = \frac{\lambda}{1} = -\frac{(ax_1 + by_1 + c)}{(ax_2 + by_2 + c)}$$



If ratio is positive, then divides internally and if ratio is negative then divides externally.

Proof : Coordinates of P are $\left(\frac{x_1 + \lambda x_2}{1 + \lambda}, \frac{y_1 + \lambda y_2}{1 + \lambda}\right)$

$\because P$ lies on the line $ax + by + c = 0$, then

$$a\left(\frac{x_1 + \lambda x_2}{1 + \lambda}\right) + b\left(\frac{y_1 + \lambda y_2}{1 + \lambda}\right) + c = 0$$

or $$(ax_1 + by_1 + c) + \lambda(ax_2 + by_2 + c) = 0$$

or $$\frac{\lambda}{1} = -\frac{(ax_1 + by_1 + c)}{(ax_2 + by_2 + c)}$$

5. The line joining the points (x_1, y_1) and (x_2, y_2) is divided by the X-axis in the ratio $-\frac{y_1}{y_2}$ and by Y-axis in the ratio $-\frac{x_1}{x_2}$.
6. In square, rhombus, rectangle and parallelogram diagonals bisect to each other.

Example 20. Find the coordinates of the point which divides the line segment joining the points $(5, -2)$ and $(9, 6)$ in the ratio $3 : 1$.

Sol. Let the required point be (x, y), then

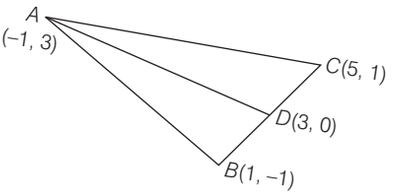
$$x = \left(\frac{3 \times 9 + 1 \times 5}{3 + 1}\right) = 8$$

and $$y = \left(\frac{3 \times 6 + 1 \times (-2)}{3 + 1}\right) = 4$$

Thus, the coordinates of the required point are $(8, 4)$.

Example 21. Find the length of median through A of a triangle whose vertices are $A(-1, 3), B(1, -1)$ and $C(5, 1)$.

Sol. Let D be the mid-point of BC, then coordinates of D are $\left(\frac{1+5}{2}, \frac{-1+1}{2}\right)$ i.e. $(3, 0)$



$\therefore$ Median $AD = \sqrt{(3+1)^2 + (0-3)^2}$

$= \sqrt{16 + 9} = \sqrt{25}$

$= 5$ units

Example 22. Determine the ratio in which $y - x + 2 = 0$ divides the line joining $(3, -1)$ and $(8, 9)$.

Sol. Suppose the line $y - x + 2 = 0$ divides the line segment joining $A(3, -1)$ and $B(8, 9)$ in the ratio $\lambda : 1$ at point P, then the coordinates of the point P are $\left(\frac{8\lambda + 3}{\lambda + 1}, \frac{9\lambda - 1}{\lambda + 1}\right)$.

But P lies on $y - x + 2 = 0$ therefore

$$\left(\frac{9\lambda - 1}{\lambda + 1}\right) - \left(\frac{8\lambda + 3}{\lambda + 1}\right) + 2 = 0$$

$\Rightarrow$ $9\lambda - 1 - 8\lambda - 3 + 2\lambda + 2 = 0$

$\Rightarrow$ $3\lambda - 2 = 0$ or $\lambda = \frac{2}{3}$

So, the required ratio is $\frac{2}{3} : 1$, i.e. $2 : 3$ (internally) since here λ is positive.

Shortcut method

According to Remark 4 :

$$\lambda = -\left(\frac{-1 - 3 + 2}{9 - 8 + 2}\right) = \frac{2}{3}$$

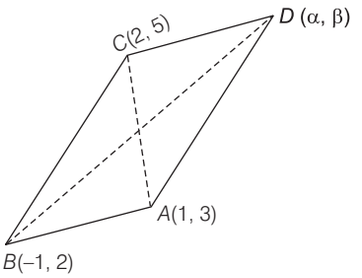
or $\lambda : 1 = 2 : 3$

Example 23. The coordinates of three consecutive vertices of a parallelogram are (1, 3), (–1, 2) and (2, 5). Then find the coordinates of the fourth vertex.

Sol. Let the fourth vertex be $D(\alpha, \beta)$. Since $ABCD$ is a parallelogram, the diagonals bisect to each other.
i.e. mid-point of BD = mid-point of AC

$$\therefore \quad \left(\frac{\alpha-1}{2}, \frac{\beta+2}{2}\right) = \left(\frac{2+1}{2}, \frac{5+3}{2}\right)$$

or $$\left(\frac{\alpha-1}{2}, \frac{\beta+2}{2}\right) = \left(\frac{3}{2}, 4\right)$$



On equating abscissaes and ordinates, we get

$$\frac{\alpha-1}{2} = \frac{3}{2} \quad \text{or} \quad \alpha - 1 = 3 \quad \text{or} \quad \alpha = 4$$

and $$\frac{\beta+2}{2} = 4 \quad \text{or} \quad \beta + 2 = 8 \quad \text{or} \quad \beta = 6$$

Hence, the coordinates of the fourth vertex $D(\alpha, \beta)$ is $(4, 6)$.

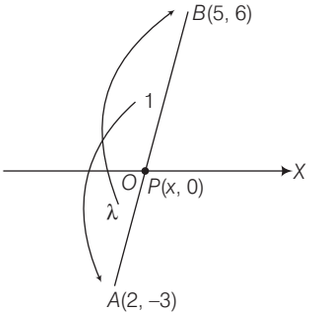
Example 24. In what ratio does X-axis divide the line segment joining $(2, -3)$ and $(5, 6)$?

Sol. Let the given points be $A(2, -3)$ and $B(5, 6)$. Let AB be divided by the X-axis at $P(x, 0)$ in the ratio $\lambda : 1$ internally. Considering the ordinate of P, then

$$0 = \frac{\lambda \times 6 + 1 \times (-3)}{\lambda + 1}$$

or $$\lambda = \frac{1}{2}$$

$\therefore$ The ratio is $\frac{1}{2} : 1$ i.e. $1 : 2$ (Internally)



Shortcut Method

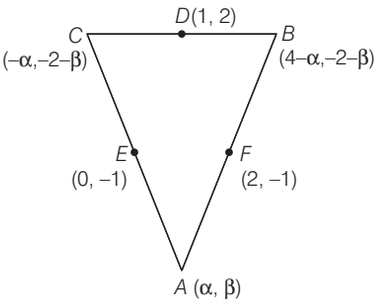
According to Remark 5 :

$$\frac{\lambda}{1} = -\frac{y_1}{y_2} = \frac{-(-3)}{6} = \frac{1}{2}$$

$\therefore$ The ratio is $\frac{1}{2} : 1$ i.e. $1 : 2$ (internally)

Example 25. The mid-points of the sides of a triangle are $(1, 2), (0, -1)$ and $(2, -1)$. Find the coordinates of the vertices of a triangle with the help of two unknowns.

Sol. Let $D(1, 2)$, $E(0, -1)$ and $F(2, -1)$ be the mid-points of BC, CA and AB respectively.
Let the coordinates of A be (α, β) then coordinates of B and C are $(4 - \alpha, -2 - \beta)$ and $(-\alpha, -2 - \beta)$ respectively (see note 1)
$\because$ D is the mid-point of B and C



then $$1 = \frac{4 - \alpha - \alpha}{2}$$

$\Rightarrow$ $$1 = 2 - \alpha \quad \text{or} \quad \alpha = 1$$

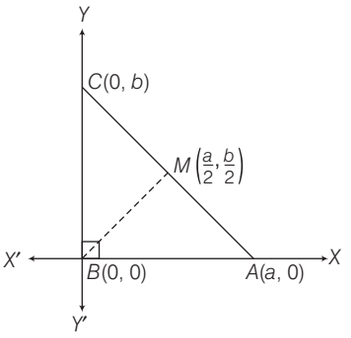
and $$2 = \frac{-2 - \beta - 2 - \beta}{2}$$

$\Rightarrow$ $$2 = -2 - \beta \quad \text{or} \quad \beta = -4$$

Hence, coordinates of A, B and C are $(1, -4), (3, 2)$ and $(-1, 2)$ respectively.

Example 26. Prove that in a right angled triangle the mid-point of the hypotenuse is equidistant from its vertices.

Sol. Let the given right angled triangle be ABC, with right angled at B. We take B as the origin and BA and BC as the X and Y-axes respectively.
Let $BA = a$ and $BC = b$
then $A \equiv (a, 0)$ and $C \equiv (0, b)$
Let M to be the mid-point of the hypotenuse AC, then coordinates of M are $\left(\frac{a}{2}, \frac{b}{2}\right)$



$$\therefore \quad |AM| = \sqrt{\left(a-\frac{a}{2}\right)^2+\left(0-\frac{b}{2}\right)^2} = \frac{\sqrt{(a^2+b^2)}}{2} \quad \text{... (i)}$$

$$|BM| = \sqrt{\left(0-\frac{a}{2}\right)^2+\left(0-\frac{b}{2}\right)^2} = \frac{\sqrt{(a^2+b^2)}}{2} \quad \text{...(ii)}$$

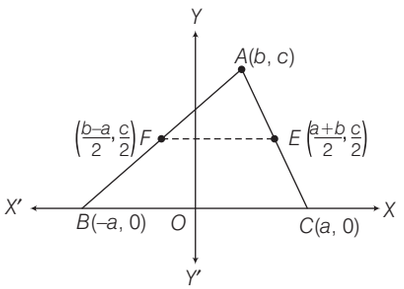
and $$|CM| = \sqrt{\left(0-\frac{a}{2}\right)^2+\left(b-\frac{b}{2}\right)^2} = \frac{\sqrt{(a^2+b^2)}}{2} \quad \text{...(iii)}$$

From Eqs. (i), (ii) and (iii), we get

$$|AM| = |BM| = |CM|$$

Example 27 Show that the line joining the mid-points of any two sides of a triangle is half the third side.

Sol. We take O as the origin and OC and OY as the X and Y-axes respectively.



Let $BC = 2a$, then $B \equiv (-a, 0)$, $C \equiv (a, 0)$

Let $A \equiv (b, c)$, if E and F are the mid-points of sides AC and AB respectively.

Then, $$E \equiv \left(\frac{a+b}{2}, \frac{c}{2}\right) \text{ and } F \equiv \left(\frac{b-a}{2}, \frac{c}{2}\right)$$

Now, $$FE = \sqrt{\left(\frac{a+b}{2}-\frac{b-a}{2}\right)^2+\left(\frac{c}{2}-\frac{c}{2}\right)^2} = a$$

$$= \frac{1}{2}(2a) = \frac{1}{2}(BG)$$

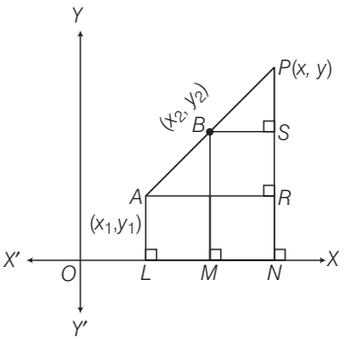
Hence, the line joining the mid-points of any two sides of a triangle is half the third side.

(ii) Formula for External Division

Theorem : If the point $P(x, y)$ divides the line joining the points $A(x_1, y_1)$ and $B(x_2, y_2)$ externally in the ratio $m : n$ then prove that

$$x = \frac{mx_2 - nx_1}{m-n}, \; y = \frac{my_2 - ny_1}{m-n}$$

Proof : The given points are $A(x_1, y_1)$ and $B(x_2, y_2)$. Let us assume that the points A and B are both in the 1st quadrant (for the sake of exactness). Let $P(x, y)$ be the point which divides AB externally in the ratio $m : n$, so that $\frac{AP}{BP} = \frac{m}{n}$.



From A, B and P draw AL, BM and PN perpendiculars on X-axis. Also, from A and B draw AR and BS perpendiculars on PN,

then $$AR = LN = ON - OL = x - x_1$$

$$BS = MN = ON - OM = x - x_2$$

$$PR = PN - RN = PN - AL = y - y_1$$

and $$PS = PN - SN = PN - BM = y - y_2$$

Clearly, the Δs APR and BPS are similar and therefore their sides are proportional.

$$\therefore \quad \frac{AP}{PB} = \frac{AR}{BS} = \frac{PR}{PS}$$

or $$\frac{m}{n} = \frac{x-x_1}{x-x_2} = \frac{y-y_1}{y-y_2}$$

(i) (ii) (iii)

From Eqs. (i) and (ii), we have

$$\frac{m}{n} = \frac{x-x_1}{x-x_2}$$

$$\Rightarrow \quad mx - mx_2 = nx - nx_1$$

$$\Rightarrow \quad (m-n)x = mx_2 - nx_1$$

or $$x = \frac{mx_2 - nx_1}{m-n}$$

Also, from Eqs. (i) and (iii), we have

$$\frac{m}{n}=\frac{y-y_1}{y-y_2}$$

$$\Rightarrow \quad my-my_2=ny-ny_1$$

$$\Rightarrow \quad (m-n)\,y=my_2-ny_1$$

or $$y=\frac{my_2-ny_1}{m-n}$$

Thus, the coordinates of P are $\left(\frac{mx_2-nx_1}{m-n}, \frac{my_2-ny_1}{m-n}\right)$.

(Here, $m \neq n$)

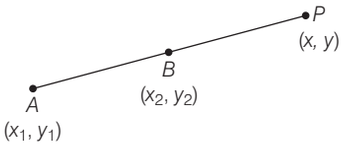
***Corollary* 1 :** The above formula is true for all positions of the points, keeping in mind, the proper signs of their coordinates.

***Corollary* 2 :** The above coordinates can also be expressed as

$$\left(\frac{mx_2+(-n)\,x_1}{m+(-n)}, \frac{my_2+(-n)\,y_1}{m+(-n)}\right)$$

and this can be thought of as the coordinates of the point dividing AB internally in the ratio $m:-n$

***Corollary* 3 :** $\because \quad \frac{AP}{PB}=\frac{m}{n}$



or $$\frac{AP}{PB}-1=\frac{m}{n}-1$$

or $$\frac{AP-PB}{PB}=\frac{m-n}{n}$$

or $$\frac{AB}{PB}=\frac{m-n}{n}$$

Now, we can say that B divides AP in the ratio $m-n:n$ internally.

i.e. $$x_2=\frac{(m-n)\,x+nx_1}{(m-n)+n} \quad \Rightarrow \quad x=\frac{mx_2-nx_1}{m-n}$$

and $$y_2=\frac{(m-n)\,y+ny_1}{(m-n)+n} \quad \Rightarrow \quad y=\frac{my_2-ny_1}{m-n}$$

***Corollary* 4 :** (for proving A, B and C are collinear)

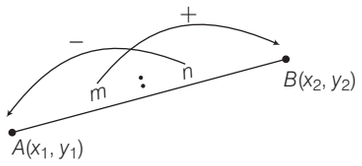
If A, B, C three points are collinear then let C divides AB in the ratio $\lambda:1$ internally.

If $\lambda =+$ ve rational, then divide internally

and if $\lambda =-$ ve rational, then divide externally.

Remarks

1. The following diagram will help to remember the section formula



2. Let $\frac{m}{n}=\lambda$, then $\left(\frac{mx_2-nx_1}{m-n}, \frac{my_2-ny_1}{m-n}\right)$

or $$\left(\frac{\frac{m}{n}x_2-x_1}{\frac{m}{n}-1}, \frac{\frac{m}{n}y_2-y_1}{\frac{m}{n}-1}\right) \quad \text{or} \quad \left(\frac{\lambda x_2-x_1}{\lambda-1}, \frac{\lambda y_2-y_1}{\lambda-1}\right)$$

Example 28. Find the coordinates of a point which divides externally the line joining $(1,-3)$ and $(-3,9)$ in the ratio $1:3$.

Sol. Let the coordinates of the required point be $P(x, y)$,

Then, $$x=\left(\frac{1\times(-3)-3\times 1}{1-3}\right)$$

and $$y=\left(\frac{1\times 9-3\times(-3)}{1-3}\right)$$

i.e. $$x=3 \quad \text{and} \quad y=-9$$

Hence, the required point is $(3,-9)$.

Example 29. The line segment joining $A(6,3)$ to $B(-1,-4)$ is doubled in length by having its length added to each end. Find the coordinates of the new ends.

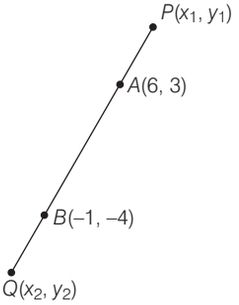
Sol. Let P and Q be the required new ends

Let the coordinates of P be (x_1, y_1)

Given, $$AB=2AP$$

$$\Rightarrow \quad \frac{AB}{AP}=\frac{2}{1}$$

i.e. A divides BP internally in the ratio $2:1$.



Then, $$6=\frac{2\times x_1+1\times(-1)}{2+1}$$

$\Rightarrow \quad 19 = 2x_1$ or $x_1 = \frac{19}{2}$

and $\quad 3 = \frac{2 \times y_1 + 1 \times (-4)}{2+1}$

$\Rightarrow \quad 13 = 2y_1$ or $y_1 = \frac{13}{2}$

$\therefore$ Coordinates of P are $\left(\frac{19}{2}, \frac{13}{2}\right)$.

Also, let coordinates of Q be (x_2, y_2)

Given, $\quad AB = 2BQ \Rightarrow \frac{AB}{BQ} = \frac{2}{1}$

i.e. B divides AQ internally in the ratio 2 : 1

Then $\quad -1 = \frac{2 \times x_2 + 1 \times 6}{2+1}$

$\Rightarrow \quad -9 = 2x_2$ or $x_2 = -\frac{9}{2}$

and $\quad -4 = \frac{2 \times y_2 + 1 \times 3}{2+1}$

$\Rightarrow \quad -15 = 2y_2$ or $y_2 = -\frac{15}{2}$

$\therefore$ Coordinates of Q are $\left(-\frac{9}{2}, -\frac{15}{2}\right)$

Aliter : $\because \quad AB = 2AP$

$\Rightarrow \quad \frac{AB}{AP} = \frac{2}{1} \Rightarrow \frac{AB}{AP} + 1 = \frac{2}{1} + 1$

$\Rightarrow \quad \frac{AB + AP}{AP} = \frac{3}{1} \Rightarrow \frac{BP}{AP} = \frac{3}{1}$

$\therefore$ P divides AB externally in the ratio 1 : 3

Then, $\quad x_1 = \frac{1 \times (-1) - 3 \times 6}{1-3} = \frac{19}{2}$

and $\quad y_1 = \frac{1 \times (-4) - 3 \times 3}{1-3} = \frac{13}{2}$

$\therefore$ Coordinates of P are $\left(\frac{19}{2}, \frac{13}{2}\right)$

Also, $\quad AB = 2BQ$

$\Rightarrow \quad \frac{AB}{BQ} = \frac{2}{1} \Rightarrow \frac{AB}{BQ} + 1 = \frac{2}{1} + 1$

$\Rightarrow \quad \frac{AB + BQ}{BQ} = \frac{3}{1} \Rightarrow \frac{AQ}{BQ} = \frac{3}{1}$

$\therefore$ Q divides AB externally in the ratio 3 : 1

then, $\quad x_2 = \frac{3 \times (-1) - 1 \times 6}{3-1} = -\frac{9}{2}$

and $\quad y_2 = \frac{3 \times (-4) - 1 \times 3}{3-1} = -\frac{15}{2}$

$\therefore$ Coordinates of Q are $\left(-\frac{9}{2}, -\frac{15}{2}\right)$.

Example 30. Using section formula show that the points $(1, -1), (2, 1)$ and $(4, 5)$ are collinear.

Sol. Let $A \equiv (1, -1)$, $B \equiv (2, 1)$ and $C \equiv (4, 5)$

Suppose C divides AB in the ratio $\lambda : 1$ internally, then

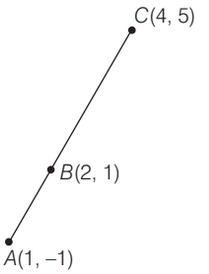
$$4 = \frac{\lambda \times 2 + 1 \times 1}{\lambda + 1}$$

$\Rightarrow \quad 4\lambda + 4 = 2\lambda + 1$

or $\quad \lambda = -\frac{3}{2}$

i.e. C divides AB in the ratio 3 : 2 (externally).

Hence, A, B, C are collinear.



Example 31. Find the ratio in which the point $(2, y)$ divides the line segment joining $(4, 3)$ and $(6, 3)$ and hence find the value of y.

Sol. Let $A \equiv (4, 3)$, $B \equiv (6, 3)$ and $P \equiv (2, y)$

Let P divides AB internally in the ratio $\lambda : 1$

then, $\quad 2 = \frac{6\lambda + 4}{\lambda + 1} \Rightarrow 2\lambda + 2 = 6\lambda + 4$

$\Rightarrow \quad -4\lambda = 2$ or $\lambda = -\frac{1}{2}$

$\therefore$ P divides AB externally in the ratio 1 : 2 ($\because \lambda$ is negative)

Now, $y = \frac{1 \times 3 - 2 \times 3}{1 - 2} = 3$

(iii) Harmonic Conjugates

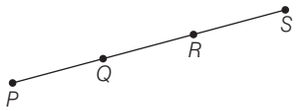
If four points in a line, then the system is said to form a range. Let four points say P, Q, R, S.

If the range (PQ, RS) has a cross ratio equal to -1, then it is called harmonic.

i.e. $\quad \frac{PR}{RQ} \cdot \frac{SQ}{SP} = -1 \Rightarrow \frac{PR}{RQ} = -\frac{SP}{SQ} = \lambda$ (say)

$\therefore \quad \frac{PR}{RQ} = \frac{\lambda}{1} \Rightarrow PR : RQ = \lambda : 1$ (internally)

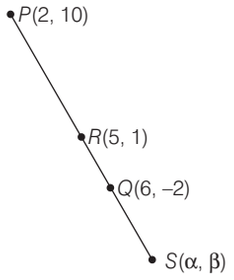
and $\quad \frac{SP}{SQ} = -\frac{\lambda}{1} \Rightarrow PS : SQ = \lambda : 1$ (externally)



Hence, R and S are called the **harmonic conjugates** to each other with respect to the points P and Q.

Example 32 Find the harmonic conjugates of the point $R(5,1)$ with respect to the points $P(2,10)$ and $Q(6,-2)$.

Sol. Let $S(\alpha, \beta)$ (be the harmonic conjugates of the point $R(5,1)$). Suppose R divides PQ in the ratio $\lambda : 1$ internally, then S divides PQ in the ratio $\lambda : 1$ externally, then



$$5 = \frac{6\lambda + 2}{\lambda + 1} \Rightarrow 5\lambda + 5 = 6\lambda + 2$$

$\therefore \quad \lambda = 3$

Also, $\quad 1 = \dfrac{-2\lambda + 10}{\lambda + 1}$

$$\lambda + 1 = -2\lambda + 10 \Rightarrow 3\lambda = 9$$

$\therefore \quad \lambda = 3$

Now, $\quad \alpha = \dfrac{3 \times 6 - 1 \times 2}{3 - 1} = 8$

and $\quad \beta = \dfrac{3 \times (-2) - 1 \times 10}{3 - 1}$

$$= -8$$

Hence, harmonic conjugates of $R(5,1)$ is $S(8,-8)$.

Centroid of a Triangle

Definition : The point of intersection of the medians of a triangle is called the centroid of the triangle and it divides the median internally in the ratio 2 : 1.

Theorem : Prove that the coordinates of the centroid of the triangle whose vertices are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) are

$$\left(\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3}\right)$$

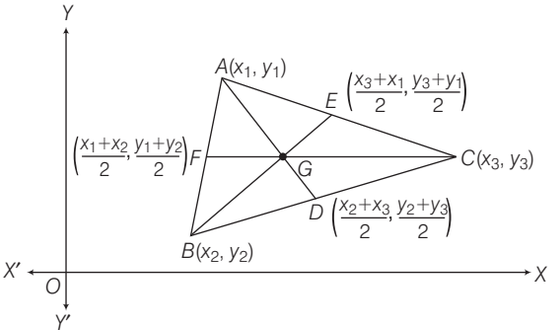
Also, deduce that the medians of a triangle are concurrent.

Proof : Let $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ be the vertices of the triangle ABC. Let us assume that the points A, B and C are in the 1st quadrant (for the sake of exactness) whose medians are AD, BE and CF respectively so D, E and F are respectively the mid-points of BC, CA and AB then the coordinates of D, E, F are

$$D \equiv \left(\frac{x_2 + x_3}{2}, \frac{y_2 + y_3}{2}\right)$$

$$E \equiv \left(\frac{x_3 + x_1}{2}, \frac{y_3 + y_1}{2}\right)$$

and $\quad F \equiv \left(\dfrac{x_1 + x_2}{2}, \dfrac{y_1 + y_2}{2}\right)$



The coordinates of a point dividing AD in the ratio 2 : 1 are

$$\left(\frac{2 \cdot \left(\dfrac{x_2 + x_3}{2}\right) + 1 \cdot x_1}{2+1}, \frac{2 \cdot \left(\dfrac{y_2 + y_3}{2}\right) + 1 \cdot y_1}{2+1}\right)$$

or $\quad \left(\dfrac{x_1 + x_2 + x_3}{3}, \dfrac{y_1 + y_2 + y_3}{3}\right)$

and the coordinates of a point dividing BE in the ratio 2 : 1 are

$$\left(\frac{2 \cdot \left(\dfrac{x_3 + x_1}{2}\right) + 1 \cdot x_2}{2+1}, \frac{2 \cdot \left(\dfrac{y_3 + y_1}{2}\right) + 1 \cdot y_2}{2+1}\right)$$

or $\quad \left(\dfrac{x_1 + x_2 + x_3}{3}, \dfrac{y_1 + y_2 + y_3}{3}\right)$

Similarly the coordinates of a point dividing CF in the ratio 2 : 1 are

$$\left(\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3}\right)$$

$\therefore$ The common point which divides AD, BE and CF in the ratio 2 : 1 is

$$\left(\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3}\right)$$

Hence, medians of a triangle are concurrent and the coordinates of the centroid are

$$\left(\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3}\right)$$

Important Theorem

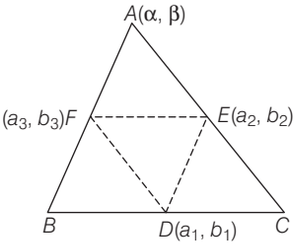
Centroid of the triangle obtained by joining the middle points of the sides of a triangle is the same as the centroid of the original triangle.

Or

If $(a_1, b_1), (a_2, b_2)$ and (a_3, b_3) are the mid-points of the sides of a triangle, then its centroid is given by

$$\left(\frac{a_1 + a_2 + a_3}{3}, \frac{b_1 + b_2 + b_3}{3}\right)$$

Proof : Let D, E, F are the mid-points of BC, CA and AB respectively now let coordinates of A are (α, β) then coordinates of B and C are $(2a_3 - \alpha, 2b_3 - \beta)$ and $(2a_2 - \alpha, 2b_2 - \beta)$ are respectively.



$\because$ $D(a_1, b_1)$ is the mid-point of B and C, then

$$2a_1 = 2a_3 - \alpha + 2a_2 - \alpha \quad \Rightarrow \quad \alpha = a_2 + a_3 - a_1$$

and $$2b_1 = 2b_3 - \beta + 2b_2 - \beta \quad \Rightarrow \quad \beta = b_2 + b_3 - b_1$$

Now, coordinates of B are $(2a_3 - \alpha, 2b_3 - \beta)$

or $$(a_3 + a_1 - a_2, b_3 + b_1 - b_2)$$

and coordinates of C are $(2a_2 - \alpha, 2b_2 - \beta)$

or $$(a_2 + a_1 - a_3, b_2 + b_1 - b_3)$$

Hence, coordinates of A, B and C are

$$A \equiv (a_2 + a_3 - a_1, b_2 + b_3 - b_1),$$
$$B \equiv (a_3 + a_1 - a_2, b_3 + b_1 - b_2)$$

and $$C \equiv (a_2 + a_1 - a_3, b_2 + b_1 - b_3)$$

$\therefore$ Coordinates of centroid of triangle ABC are

$$\left(\frac{a_1 + a_2 + a_3}{3}, \frac{b_1 + b_2 + b_3}{3}\right)$$

which is same as the centroid of triangle DEF.

***Corollary* 1 (Finger Rule) :** If mid-points of the sides of a triangle are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3), then coordinates of the original triangle are

$$(x_2 + x_3 - x_1, y_2 + y_3 - y_1),$$
$$(x_3 + x_1 - x_2, y_3 + y_1 - y_2)$$

and $$(x_1 + x_2 - x_3, y_1 + y_2 - y_3).$$

***Corollary* 2 :** If two vertices of a triangle are (x_1, y_1) and (x_2, y_2) and the coordinates of centroid are (α, β), then coordinates of the third vertex are

$$(3\alpha - x_1 - x_2, 3\beta - y_1 - y_2)$$

***Corollary* 3 :** According to important theorem Δs ABC and DEF are similar

$$\therefore \quad \frac{\text{Area of } \Delta ABC}{\text{Area of } \Delta DEF} = \frac{(BC)^2}{(EF)^2}$$

$$= \frac{4\{(a_2 - a_3)^2 + (b_2 - b_3)^2\}}{\{(a_2 - a_3)^2 + (b_2 - b_3)^2\}} = 4$$

$\therefore$ Area of $\Delta ABC = 4 \times$ Area of ΔDEF

i.e. Area of a triangle is four times the area of the triangle formed by joining the mid-points of its sides.

Example 33. Two vertices of a triangle are $(-1, 4)$ and $(5, 2)$. If its centroid is $(0, -3)$, find the third vertex.

Sol. Let the third vertex be (x, y) then the coordinates of the centroid of triangle are

$$\left(\frac{-1 + 5 + x}{3}, \frac{4 + 2 + y}{3}\right) \text{ i.e. } \left(\frac{4 + x}{3}, \frac{6 + y}{3}\right)$$

Now, $$\left(\frac{4 + x}{3}, \frac{6 + y}{3}\right) = (0, -3)$$

$$\Rightarrow \quad \frac{4 + x}{3} = 0 \quad \text{and} \quad \frac{6 + y}{3} = -3$$

$$\Rightarrow \quad 4 + x = 0 \quad \text{and} \quad y + 6 = -9$$

or $$x = -4 \quad \text{and} \quad y = -15$$

Hence, the third vertex is $(-4, -15)$.

Shortcut Method

According to corollary 2

$$(x, y) = (3 \times 0 - (-1) - 5, 3 \times (-3) - 4 - 2)$$
$$= (-4, -15)$$

Example 34. ***The vertices of a triangle are*** $(1, 2), (h, -3)$ ***and*** $(-4, k)$. ***Find the value of*** $\sqrt{\{(h+k)^2 + (h+3k)^2\}}$. ***If the centroid of the triangle be at the point*** $(5, -1)$.

Sol. Here, $$\frac{1 + h - 4}{3} = 5 \quad \text{and} \quad \frac{2 - 3 + k}{3} = -1$$

then, we get $h = 18, k = -2$

$$\therefore \quad = \sqrt{(h + k)^2 + (h + 3k)^2}$$
$$= \sqrt{(18 - 2)^2 + (18 - 6)^2}$$
$$= \sqrt{(16^2 + 12^2)} = 20$$

Example 35. If $D(-2, 3)$, $E(4, -3)$ and $F(4, 5)$ are the mid-points of the sides BC, CA and AB of triangle ABC, then find $\sqrt{(|AG|^2 + |BG|^2 - |CG|^2)}$ where, G is the centroid of ΔABC.

Sol. Let the coordinates of A be (α, β)

then coordinates of B are $(8 - \alpha, 10 - \beta)$

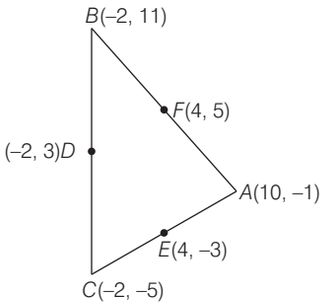
and coordinates of C are $(8 - \alpha, -6 - \beta)$

$\because$ D is the mid-point of BC, then

$$\frac{8 - \alpha + 8 - \alpha}{2} = -2$$

and $$\frac{10 - \beta - 6 - \beta}{2} = 3$$

i.e. $\alpha = 10$ and $\beta = -1$



$\therefore$ Coordinates of A, B, C are $(10, -1)$, $(-2, 11)$ and $(-2, -5)$ respectively.

Now, coordinates of centroid

$$G \equiv \left(\frac{10 - 2 - 2}{3}, \frac{-1 + 11 - 5}{3}\right)$$

i.e. $$G \equiv \left(2, \frac{5}{3}\right)$$

$\therefore$ $$AG = \sqrt{(10 - 2)^2 + \left(-1 - \frac{5}{3}\right)^2}$$

$$= \sqrt{\left(64 + \frac{64}{9}\right)} = \frac{8}{3}\sqrt{(10)}$$

$$BG = \sqrt{(-2 - 2)^2 + \left(11 - \frac{5}{3}\right)^2}$$

$$= \sqrt{16 + \frac{(28)^2}{9}} = \frac{4}{3}\sqrt{(58)}$$

and $$CG = \sqrt{(-2 - 2)^2 + \left(-5 - \frac{5}{3}\right)^2}$$

$$= \sqrt{\left(16 + \frac{400}{9}\right)} = \frac{4}{3}\sqrt{(34)}$$

Hence, $\sqrt{(|AG|^2 + |BG|^2 - |CG|^2)}$

$$= \sqrt{\left(\frac{64}{9} \times 10 + \frac{16}{9} \times 58 - \frac{16}{9} \times 34\right)}$$

$$= \sqrt{\frac{32}{9}(20 + 29 - 17)}$$

$$= \sqrt{\left(\frac{32}{9} \times 32\right)} = \frac{32}{3}$$

Example 36. If G be the centroid of the ΔABC and O be any other point in the plane of the triangle ABC, then show that

$OA^2 + OB^2 + OC^2 = GA^2 + GB^2 + GC^2 + 3GO^2$.

Sol. Let G be the origin and GO be X-axis.

$O \equiv (a, 0)$, $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$

and $C \equiv (x_3, y_3)$

Now, LHS $= OA^2 + OB^2 + OC^2$

$$= (x_1 - a)^2 + y_1^2 + (x_2 - a)^2 + y_2^2 + (x_3 - a)^2 + y_3^2$$

$$= (x_1^2 + x_2^2 + x_3^2) + (y_1^2 + y_2^2 + y_3^2)$$

$$- 2a(x_1 + x_2 + x_3) + 3a^2$$

$$= \sum x_1^2 + \sum y_1^2 - 0 + 3a^2 \qquad \left(\because \frac{x_1 + x_2 + x_3}{3} = 0 \text{ i.e., } x_1 + x_2 + x_3 = 0\right)$$

$$= \sum x_1^2 + \sum y_1^2 + 3a^2 \qquad \text{...(i)}$$

and RHS $= GA^2 + GB^2 + GC^2 + 3GO^2$

$$= x_1^2 + y_1^2 + x_2^2 + y_2^2 + x_3^2 + y_3^2 + 3\{(a - 0)^2\}$$

$$= \sum x_1^2 + \sum y_1^2 + 3a^2 \qquad \text{... (ii)}$$

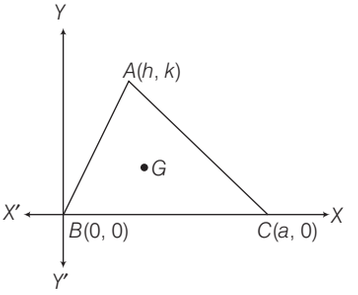
Hence, from Eqs. (i) and (ii), we get

$OA^2 + OB^2 + OC^2 = GA^2 + GB^2 + GC^2 + 3GO^2$.

Example 37. If G be the centroid of ΔABC, show that

$$AB^2 + BC^2 + CA^2 = 3(GA^2 + GB^2 + GC^2).$$

Sol. We take B as the origin and BC and BY as the X and Y-axes respectively.



Let $BC = a$, then $B \equiv (0, 0)$ and $C \equiv (a, 0)$
and let $A \equiv (h, k)$
then, coordinates of G will be

$$\left(\frac{h+0+a}{3}, \frac{k+0+0}{3}\right), \text{ i.e. } \left(\frac{h+a}{3}, \frac{k}{3}\right)$$

Take ΔABC as in 1st quadrant (for the sake of exactness).

Now, LHS $= (AB)^2 + (BC)^2 + (CA)^2$

$$= (h-0)^2 + (k-0)^2 + a^2 + (h-a)^2 + (k-0)^2$$

$$= 2h^2 + 2k^2 - 2ah + 2a^2 \quad \text{... (i)}$$

$$\text{RHS} = 3((GA)^2 + (GB)^2 + (GC)^2)$$

$$= 3\left\{\left(\frac{a+h}{3} - h\right)^2 + \left(\frac{k}{3} - k\right)^2 + \left(\frac{a+h}{3} - 0\right)^2 + \left(\frac{k}{3} - 0\right)^2 + \left(\frac{a+h}{3} - a\right)^2 + \left(\frac{k}{3} - 0\right)^2\right\}$$

$$= \frac{3}{9}\{(a-2h)^2 + (-2k)^2 + (a+h)^2 + k^2 + (h-2a)^2 + k^2\}$$

$$= \frac{1}{3}\{6a^2 + 6h^2 + 6k^2 - 6ah\}$$

$$= 2h^2 + 2k^2 - 2ah + 2a^2 \quad \text{... (ii)}$$

Hence, from Eqs. (i) and (ii), we get

$$AB^2 + BC^2 + CA^2 = 3(GA^2 + GB^2 + GC^2)$$

Example 38. The vertices of a triangle are $(1, a), (2, b)$ and $(c^2, -3)$

(i) Prove that its centroid can not lie on the Y-axis.

(ii) Find the condition that the centroid may lie on the X-axis.

Sol. Centroid of the triangle is

$$G \equiv \left(\frac{1+2+c^2}{3}, \frac{a+b-3}{3}\right) \text{ i.e. } \left(\frac{3+c^2}{3}, \frac{a+b-3}{3}\right)$$

(i) $\because$ G will lie on Y-axis, then

$$\frac{3+c^2}{3} = 0$$

$$\Rightarrow \quad c^2 = -3$$

or $\quad c = \pm i\sqrt{3}$

$\because$ Both values of c are imaginary.

Hence, G can not lie on Y-axis.

(ii) $\because$ G will lie on X-axis, then $\frac{a+b-3}{3} = 0$

$$\Rightarrow \quad a + b - 3 = 0$$

or $\quad a + b = 3$

Incentre

Definition : The point of intersection of internal angle bisectors of triangle is called the incentre of the triangle.

Theorem : Prove that the coordinates of the incentre of a triangle whose vertices are $A(x_1, y_1), B(x_2, y_2), C(x_3, y_3)$ are

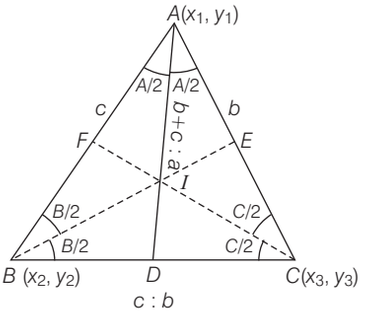
$$\left(\frac{ax_1 + bx_2 + cx_3}{a+b+c}, \frac{ay_1 + by_2 + cy_3}{a+b+c}\right)$$

where, a, b, c are the lengths of sides BC, CA and AB respectively.

Also, prove that the internal bisectors of the angles of a triangle are concurrent.

Proof : Given $A \equiv (x_1, y_1), B(x_2, y_2), C \equiv (x_3, y_3)$ be the vertices of ΔABC and $BC = a, CA = b$ and $AB = c$. Let AD be the bisector of A. We know that the bisector of an angle of a triangle divides the opposite side in the ratio of the sides containing the triangle.

$$\therefore \quad \frac{BD}{DC} = \frac{AB}{AC} = \frac{c}{b} \quad \text{... (i)}$$



Hence, D divides BC in the ratio $c : b$

$\therefore$ Coordinates of D are $\left(\frac{cx_3 + bx_2}{c+b}, \frac{cy_3 + by_2}{c+b}\right)$

From Eq. (i), $\quad \frac{DC}{BD} = \frac{b}{c}$ or $\frac{DC}{BD} + 1 = \frac{b}{c} + 1$

or $\quad \frac{DC + BD}{BD} = \left(\frac{b+c}{c}\right)$ or $\frac{a}{BD} = \left(\frac{b+c}{c}\right)$

$$\therefore \quad BD = \frac{ac}{(b+c)}$$

Also, in ΔABD, BI is the bisector of B.

Then, $\quad \frac{AI}{ID} = \frac{AB}{BD} = \frac{c}{\left(\frac{ac}{b+c}\right)} = \frac{b+c}{a}$

$\therefore$ I divides AD in the ratio $b+c:a$

$\therefore$ Coordinates of I are

$$\left(\frac{(b+c)\cdot\frac{cx_3+bx_2}{c+b}+a\cdot x_1}{b+c+a},\ \frac{(b+c)\cdot\frac{cy_3+by_2}{c+b}+b\cdot y_1}{b+c+a}\right)$$

i.e. $$\left(\frac{ax_1+bx_2+cx_3}{a+b+c},\frac{ay_1+by_2+cy_3}{a+b+c}\right)$$

Similarly we can show that the coordinates of the point which divides BE internally in the ratio $c+a:b$ and the coordinates of the point which divides CF internally in the ratio $a+b:c$ will be each

$$\left(\frac{ax_1+bx_2+cx_3}{a+b+c},\frac{ay_1+by_2+cy_3}{a+b+c}\right)$$

and $$CE=\frac{ab}{(c+a)},\ AE=\frac{bc}{(c+a)},$$

$$AF=\frac{bc}{a+b},\ BF=\frac{ac}{a+b}$$

Thus, the three internal bisectors of the angles of a triangle meet in a point I.

$$I\equiv\left(\frac{ax_1+bx_2+cx_3}{a+b+c},\frac{ay_1+by_2+cy_3}{a+b+c}\right)$$

***Corollary* 1 :** If ΔABC is equilateral, then $a=b=c$

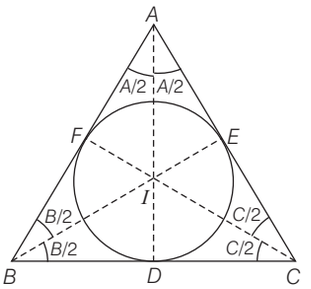
$$\text{incentre}=\left(\frac{x_1+x_2+x_3}{3},\frac{y_1+y_2+y_3}{3}\right)=\text{centroid}$$

i.e. incentre and centroid coincide in equilateral, triangle.

***Corollary* 2 :** $AE=AF=s-a$

$BD=BF=s-b$

$CD=CE=s-c$



where, $$s=\frac{a+b+c}{2}$$

and $$|BC|=a,|CA|=b,|AB|=c$$

Proof : Let $AE=AF=\alpha$

($\because$ Lengths of tangents are equal from a point to a circle)

$BD=BF=\beta$

$CD=CE=\gamma$

Also, $a=BC=BD+DC=\beta+\gamma$ ....(i)

$b=CA=CE+AE=\gamma+\alpha$ ...(ii)

and $c=AB=AF+BF=\alpha+\beta$ ...(iii)

Adding all, we get

$a+b+c=2(\alpha+\beta+\gamma)$

or $2s=2(\alpha+\beta+\gamma)$

$\therefore$ $s=\alpha+\beta+\gamma$

From Eqs. (i), (ii) and (iii), we get

$\alpha=s-a,\beta=s-b,\gamma=s-c$

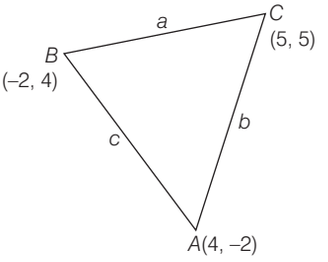
Example 39. Find the coordinates of incentre of the triangle whose vertices are $(4,-2)$, $(-2,4)$ and $(5,5)$.

Sol. Let $A(4,-2)$, $B(-2,4)$ and $C(5,5)$ be the vertices of the given triangle. Then

$$a=BC=\sqrt{(-2-5)^2+(4-5)^2}=\sqrt{50}=5\sqrt{2}$$

$$b=CA=\sqrt{(5-4)^2+(5+2)^2}=\sqrt{50}=5\sqrt{2}$$

and $$c=AB=\sqrt{(4+2)^2+(-2-4)^2}=\sqrt{72}=6\sqrt{2}$$



Let (x,y) be the coordinates of incentre of ΔABC. Then

$$x=\frac{ax_1+bx_2+cx_3}{a+b+c}$$

$$=\frac{5\sqrt{2}\times4+5\sqrt{2}\times(-2)+6\sqrt{2}\times5}{5\sqrt{2}+5\sqrt{2}+6\sqrt{2}}$$

$$=\frac{20\sqrt{2}-10\sqrt{2}+30\sqrt{2}}{16\sqrt{2}}$$

$$=\frac{40}{16}=\frac{5}{2}$$

and $$y=\frac{ay_1+by_2+cy_3}{a+b+c}$$

$$=\frac{5\sqrt{2}\times(-2)+5\sqrt{2}\times4+6\sqrt{2}\times5}{5\sqrt{2}+5\sqrt{2}+6\sqrt{2}}$$

$$=\frac{40}{16}=\frac{5}{2}$$

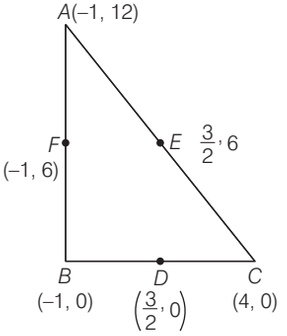
$\therefore$ The coordinates of the incentre are $\left(\frac{5}{2},\frac{5}{2}\right)$

Example 40. *If* $\left(\frac{3}{2}, 0\right), \left(\frac{3}{2}, 6\right)$ *and* $(-1, 6)$ *are mid-points of the sides of a triangle, then find*

(i) Centroid of the triangle

(ii) Incentre of the triangle

Sol. Let $A \equiv (\alpha, \beta)$, then coordinates of $B \equiv (-2-\alpha, 12-\beta)$ and coordinates of $C \equiv (3-\alpha, 12-\beta)$. But mid-point of BC is $\left(\frac{3}{2}, 0\right)$



then $3 = -2-\alpha+3-\alpha$

$\Rightarrow \quad \alpha = -1$

and $0 = 12-\beta+12-\beta$

$\Rightarrow \quad \beta = 12$

$\therefore$ Coordinates of vertices are

$A \equiv (-1, 12)$, $B \equiv (-1, 0)$ and $C \equiv (4, 0)$

(i) Centroid : The centroid of ΔABC is

$$\left(\frac{x_1+x_2+x_3}{3}, \frac{y_1+y_2+y_3}{3}\right)$$

or $\left(\frac{-1-1+4}{3}, \frac{12+0+0}{3}\right)$ i.e. $\left(\frac{2}{3}, 4\right)$

(ii) Incentre : We have

$$a = BC = \sqrt{(-1-4)^2+(0-0)^2} = 5$$

$$b = CA = \sqrt{(4+1)^2+(0-12)^2} = 13$$

and $c = AB = \sqrt{(-1+1)^2+(12-0)^2} = 12$

$\therefore$ The incentre of ΔABC is

$$\left(\frac{ax_1+bx_2+cx_3}{a+b+c}, \frac{ay_1+by_2+cy_3}{a+b+c}\right)$$

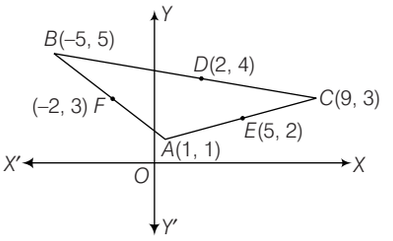
or $\left(\frac{5\times(-1)+13\times(-1)+12\times4}{5+13+12}, \frac{5\times12+13\times0+12\times0}{5+13+12}\right)$

i.e. $(1, 2)$

Example 41. If a vertex of a triangle be (1, 1) and the middle points of two sides through it be (– 2, 3) and (5, 2), then find the centroid and the incentre of the triangle.

Sol. Let coordinate of A be (1, 1) and mid-points of AB and AC are F and E.

$\therefore \quad F \equiv (-2, 3)$ and $E \equiv (5, 2)$



Hence, coordinates of B and C are $(2\times(-2)-1, (2\times3-1)$ and $(2\times2-(-5), 2\times4-5)$ respectively.

i.e. $B \equiv (-5, 5)$ and $C \equiv (9, 3)$

Then, centroid is $\left(\frac{1-5+9}{3}, \frac{1+5+3}{3}\right)$ i.e., $\left(\frac{5}{3}, 3\right)$

Also, $a = |BC| = \sqrt{(-5-9)^2+(5-3)^2} = \sqrt{200} = 10\sqrt{2}$

$b = |CA| = \sqrt{(9-1)^2+(3-1)^2} = \sqrt{68} = 2\sqrt{17}$

and $c = |AB| = \sqrt{(1+5)^2+(1-5)^2} = \sqrt{52} = 2\sqrt{13}$

Then, incentre is

$$\left(\frac{10\sqrt{2}\times1+2\sqrt{17}\times(-5)+2\sqrt{13}\times9}{10\sqrt{2}+2\sqrt{17}+2\sqrt{13}}, \frac{10\sqrt{2}\times1+2\sqrt{17}\times5+2\sqrt{13}\times3}{10\sqrt{2}+2\sqrt{17}+2\sqrt{13}}\right)$$

i.e. $\left(\frac{5\sqrt{2}-5\sqrt{17}+9\sqrt{13}}{5\sqrt{2}+\sqrt{17}+\sqrt{13}}, \frac{5\sqrt{2}+5\sqrt{17}+3\sqrt{13}}{5\sqrt{2}+\sqrt{17}+\sqrt{13}}\right)$

Example 42. If G be the centroid and I be the incentre of the triangle with vertices $A(-36, 7), B(20, 7)$ and $C(0, -8)$ and $GI = \frac{25}{3}\sqrt{(205)}\,\lambda$, then find the value of λ.

Sol. Coordinates of centroid are

$$G \equiv \left(-\frac{16}{3}, 2\right)$$

and $a = |BC| = \sqrt{(20-0)^2+(7+8)^2}$

$= \sqrt{625} = 25$

$b = |CA| = \sqrt{(0+36)^2+(-8-7)^2}$

$= \sqrt{1521} = 39$

$c = |AB| = \sqrt{(-36-20)^2+(7-7)^2}$

$= \sqrt{(56)^2} = 56$

Therefore, the coordinates of incentre are

$$I \equiv \left(\frac{25\times(-36)+39\times20+56\times0}{25+39+56}, \frac{25\times7+39\times7+56\times(-8)}{25+39+56}\right)$$

i.e., $I \equiv (-1, 0)$

$\therefore \quad GI = \sqrt{\left(-\frac{16}{3}+1\right)^2 + (2-0)^2} = \frac{\sqrt{(205)}}{3}$

but given $\quad GI = \frac{25}{3}\sqrt{(205)}\,\lambda$

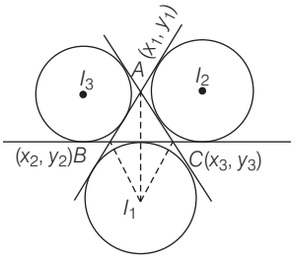
$\therefore \quad \frac{1}{3}\sqrt{(205)} = \frac{25}{3}\sqrt{(205)}\,\lambda$

$\Rightarrow \quad \lambda = \frac{1}{25}$

Some Standard Results

1. Excentres of a Triangle

This is the point of intersection of the external bisectors of the angles of a triangle.



The circle opposite to the vertex A is called the escribed circle opposite A or the circle escribed to the side BC. If I_1 is the point of intersection of internal bisector of $\angle BAC$ and external bisector of $\angle ABC$ and $\angle ACB$, then

$$I_1 \equiv \left(\frac{ax_1 - bx_2 - cx_3}{a-b-c}, \frac{ay_1 - by_2 - cy_3}{a-b-c}\right)$$

or $$I_1 \equiv \left(\frac{-ax_1 + bx_2 + cx_3}{-a+b+c}, \frac{-ay_1 + by_2 + cy_3}{-a+b+c}\right)$$

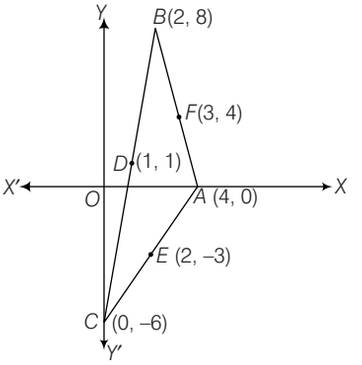
Similarly, $$I_2 \equiv \left(\frac{ax_1 - bx_2 + cx_3}{a-b+c}, \frac{ay_1 - by_2 + cy_3}{a-b+c}\right)$$

and $$I_3 \equiv \left(\frac{ax_1 + bx_2 - cx_3}{a+b-c}, \frac{ay_1 + by_2 - cy_3}{a+b-c}\right)$$

where, $|BC| = a, |CA| = b$ and $|AB| = c$

Example 43. If the coordinates of the mid-points of sides BC, CA and AB of triangle ABC are $(1, 1), (2, -3)$ and $(3, 4)$, then find the excentre opposite to the vertex A.

Sol. Let $D(1, 1)$, $E(2, -3)$ and $F(3, 4)$ are the mid-points of the sides of the triangle BC, CA and AB respectively. Let $A \equiv (\alpha, \beta)$



then $\quad B \equiv (6-\alpha, 8-\beta)$

and $\quad C \equiv (4-\alpha, -6-\beta)$

Also, D is the mid-point of B and C, then

$$1 = \frac{6-\alpha+4-\alpha}{2} \Rightarrow \alpha = 4$$

and $$1 = \frac{8-\beta-6-\beta}{2} \Rightarrow \beta = 0$$

$\therefore$ $A \equiv (4, 0)$, $B \equiv (2, 8)$ and $C \equiv (0, -6)$, then

$$a = |BC| = \sqrt{(2-0)^2 + (8+6)^2} = \sqrt{200} = 10\sqrt{2}$$

$$b = |CA| = \sqrt{(0-4)^2 + (-6-0)^2} = \sqrt{52} = 2\sqrt{13}$$

and $$c = |AB| = \sqrt{(4-2)^2 + (0-8)^2} = \sqrt{68} = 2\sqrt{17}$$

Hence, the coordinates of the excentre opposite to A are

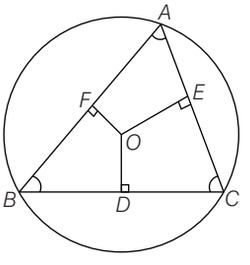
$$\left(\frac{-ax_1 + bx_2 + cx_3}{-a+b+c}, \frac{ay_1 + by_2 + cy_3}{-a+b+c}\right)$$

i.e., $$\left(\frac{-10\sqrt{2}\times 4 + 2\sqrt{13}\times 2 + 2\sqrt{17}\times 0}{-10\sqrt{2} + 2\sqrt{13} + 2\sqrt{17}}, \frac{-10\sqrt{2}\times 0 + 2\sqrt{13}\times 8 + 2\sqrt{17}\times(-6)}{-10\sqrt{2} + 2\sqrt{13} + 2\sqrt{17}}\right)$$

or $$\left(\frac{-20\sqrt{2} + 2\sqrt{13}}{-5\sqrt{2} + \sqrt{13} + \sqrt{17}}, \frac{8\sqrt{13} - 6\sqrt{17}}{-5\sqrt{2} + \sqrt{13} + \sqrt{17}}\right)$$

2. Circumcentre of a Triangle

The circumcentre of a triangle is the point of intersection of the perpendicular bisectors of the sides of a triangle (i.e., the lines through the mid-point of a side and perpendicular to it). Let $A(x_1, y_1), B(x_2, y_2)$ and $C(x_3, y_3)$ be the vertices of ΔABC and if angles of ΔABC are given, then coordinates of circumcentre



are $\left(\frac{x_1 \sin 2A + x_2 \sin 2B + x_3 \sin 2C}{\sin 2A + \sin 2B + \sin 2C}, \frac{y_1 \sin 2A + y_2 \sin 2B + y_3 \sin 2C}{\sin 2A + \sin 2B + \sin 2C}\right)$

Or

$\left(\frac{ax_1 \cos A + bx_2 \cos B + cx_3 \cos C}{a\cos A + b\cos B + c\cos C}, \frac{ay_1 \cos A + by_2 \cos B + cy_3 \cos C}{a\cos A + b\cos B + c\cos C}\right)$

where, $|BC| = a, |CA| = b$ and $|AB| = c$

Example 44. In a ΔABC with vertices $A(1, 2)$, $B(2, 3)$ and $C(3, 1)$ and $\angle A = \angle B = \cos^{-1}\left(\frac{1}{\sqrt{10}}\right)$, $\angle C = \cos^{-1}\left(\frac{4}{5}\right)$, then find the circumcentre of ΔABC.

Sol. Since, $\angle A = \angle B = \cos^{-1}\left(\frac{1}{\sqrt{10}}\right)$

$\Rightarrow \quad \cos A = \cos B = \frac{1}{\sqrt{10}}$

then, $\sin A = \sin B = \frac{3}{\sqrt{10}}$

$\therefore \quad \sin 2A = \sin 2B = 2 \times \frac{3}{\sqrt{10}} \times \frac{1}{\sqrt{10}} = \frac{3}{5}$

and $\angle C = \cos^{-1}\left(\frac{4}{5}\right)$

$\Rightarrow \quad \cos C = \frac{4}{5}$ then, $\sin C = \frac{3}{5}$

$\therefore \quad \sin 2C = 2 \times \frac{3}{5} \times \frac{4}{5} = \frac{24}{25}$

Let the circumcenter be (x, y), then

$$x = \frac{x_1 \sin 2A + x_2 \sin 2B + x_3 \sin 2C}{\sin 2A + \sin 2B + \sin 2C} = \frac{1 \times \frac{3}{5} + 2 \times \frac{3}{5} + 3 \times \frac{24}{25}}{\frac{3}{5} + \frac{3}{5} + \frac{24}{25}} = \frac{13}{6}$$

and $$y = \frac{y_1 \sin 2A + y_2 \sin 2B + y_3 \sin 2C}{\sin 2A + \sin 2B + \sin 2C} = \frac{2 \times \frac{3}{5} + 3 \times \frac{3}{5} + 1 \times \frac{24}{25}}{\frac{3}{5} + \frac{3}{5} + \frac{24}{25}} = \frac{11}{6}$$

Hence, coordinates of circumcenter are $\left(\frac{13}{6}, \frac{11}{6}\right)$.

Two Important Tricks for Circumcentre

(a) If angles of triangle ABC are not given and the vertices $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ are given, then the circumcentre of the ΔABC is given by

$$\left(\frac{(x_1 + x_2) + \lambda(y_1 - y_2)}{2}, \frac{(y_1 + y_2) - \lambda(x_1 - x_2)}{2}\right)$$

Here, we observe that

$$P = \begin{bmatrix} x_1 - x_3 & y_1 - y_3 \\ x_2 - x_3 & y_2 - y_3 \end{bmatrix}$$

$$\therefore \quad \lambda = \frac{\vec{\mathbf{R}}_1 \cdot \vec{\mathbf{R}}_2}{|P|}$$

(b) If the angle C is given instead of coordinates of the vertex C and the vertices $A(x_1, y_1)$, $B(x_2, y_2)$ of ΔABC are given, then the circumcentre of ΔABC is given by

$$\left(\frac{(x_1 + x_2) \pm \cot C(y_1 - y_2)}{2}, \frac{(y_1 + y_2) \pm \cot C(x_1 - x_2)}{2}\right)$$

Remark

Circumcentre of the right angled triangle ABC, right angled at A is $\frac{B + C}{2}$.

Example 45. Find the circumcentre of the triangle whose vertices are (2, 2), (4, 2) and (0, 4).

Sol. Let the given points are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) respectively.

for the matrix

$$P = \begin{bmatrix} x_1 - x_3 & y_1 - y_3 \\ x_2 - x_3 & y_2 - y_2 \end{bmatrix} = \begin{bmatrix} 2 & -2 \\ 4 & -2 \end{bmatrix}$$

$$\therefore \quad \lambda = \frac{\vec{\mathbf{R}}_1 \cdot \vec{\mathbf{R}}_2}{|P|} = \frac{2 \times 4 + (-2) \times (-2)}{2 \times (-2) - 4 \times (-2)} = \frac{12}{4} = 3$$

$\therefore$ Circumcentre of the triangle

$$\equiv \left(\frac{(x_1 + x_2) + \lambda(y_1 - y_2)}{2}, \frac{(y_1 + y_2) - \lambda(x_1 - x_2)}{2}\right)$$

$$\equiv \left(\frac{2 + 4 + 3(2 - 2)}{2}, \frac{2 + 2 - 3(2 - 4)}{2}\right)$$

$$\equiv (3, 5)$$

Example 46. Find the circumcentre of triangle ABC if $A \equiv (7, 4)$, $B \equiv (3, -2)$ and $\angle C = \frac{\pi}{3}$.

Sol. Here, $x_1 = 7, y_1 = 4, x_2 = 3, y_2 = -2$ and $\angle C = \frac{\pi}{3}$

$\therefore$ The circumcentre of ΔABC

$$\equiv \left(\frac{(x_1 + x_2) \pm \cot C(y_1 - y_2)}{2}, \frac{(y_1 + y_2) \mp \cot C(x_1 - x_2)}{2} \right)$$

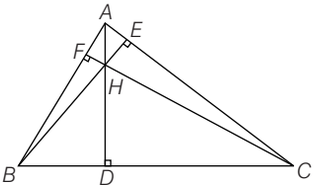
$$\equiv \left(\frac{(7+3) \pm \frac{1}{\sqrt{3}}(4+2)}{2}, \frac{(4-2) \mp \frac{1}{\sqrt{3}}(7-3)}{2} \right)$$

$$\equiv \left(5 + \sqrt{3}, 1 - \frac{2}{\sqrt{3}} \right) \text{ or } \left(5 - \sqrt{3}, 1 + \frac{2}{\sqrt{3}} \right)$$

3. Orthocentre of a Triangle

The orthocentre of a triangle is the point of intersection of altitudes
(i.e., the lines through the vertices and perpendicular to opposite sides).

Let $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ be the vertices of ΔABC and if angles of ΔABC are given, then coordinates of orthocentre are



$$\left(\frac{x_1 \tan A + x_2 \tan B + x_3 \tan C}{\tan A + \tan B + \tan C}, \frac{y_1 \tan A + y_2 \tan B + y_3 \tan C}{\tan A + \tan B + \tan C} \right)$$

or $$\left(\frac{ax_1 \sec A + bx_2 \sec B + cx_3 \sec C}{a \sec A + b \sec B + c \sec C}, \frac{ay_1 \sec A + by_2 \sec B + cy_3 \sec C}{a \sec A + b \sec B + c \sec C} \right)$$

where, $|BC| = a, |CA| = b$ and $|AB| = c$

Important trick for orthocentre :

orthocentre of the triangle whose vertices are (0, 0), (x_1, y_1) is given by

$$(\lambda(y_2 - y_1), -\lambda(x_2 - x_1))$$

where, $$\lambda = \frac{x_1 x_2 + y_1 y_2}{x_1 y_2 - x_2 y_1}$$

Remarks

1. The orthocentre of a triangle having vertices (α, β), (β, α) and (α, α) is (α, α).
2. The orthocentre of a triangle having vertices is $\left(-\frac{1}{\alpha\beta\gamma}, -\alpha\beta\gamma \right)$
3. The orthocentre of right angled triangle ABC, right angled at A is A.

Example 47. Find the orthocentre of ΔABC if $A \equiv (0, 0), B \equiv (3, 5)$ and $C \equiv (4, 7)$.

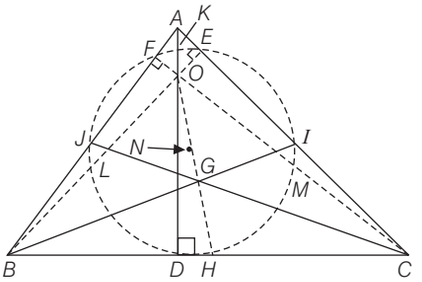
Sol. Here, $x_1 = 3, y_1 = 5, x_2 = 4, y_2 = 7$

$$\therefore \quad \lambda = \frac{3 \times 4 + 5 \times 7}{3 \times 7 - 4 \times 5} = 47$$

$\Rightarrow$ Orthocentre of $\Delta ABC \equiv (47(7-5), -47(4-3))$
$\equiv (94, -47)$

4. Nine Point Centre of a Triangle

If a circle passing through the feet of perpendiculars (i.e., D, E, F) mid-points of sides BC, CA, AB respectively (i.e., H, I, J) and the $n\,x$
mid-points of the line joining the orthocentre O to the angular points A, B, C (i.e., K, L, M) thus the nine points $D, E, F, H, I, J, K, L, M$ all lie on a circle.



This circle is known as nine point circle and its centre is called the nine point centre. The nine-point centre of a triangle is collinear with the circumcentre and the orthocentre and bisects the segments joining them and radius of nine point circle of a triangle is half the radius of the circumcircle.

***Corollary* 1 :** The orthocentre, the nine point centre, the centroid and the circumcentre therefore all lie on a straight line.

Corollary* 2 :** If O is orthocentre, N is nine point centre, G is centroid and C is circumcentre, then to remember it see ***ONGC (i.e. Oil Natural Gas Corporation) in left of G are 2 and in right is 1, therefore G divides O and C in the ratio 2 : 1 (internally).

***Corollary* 3 :** N is the mid-point of O and C

***Corollary* 4 :** Radius of nine point circle $= \frac{1}{2} \times$ Radius of circumcircle

Remarks

1. The distance between the orthocentre and circumcentre in an equilateral triangle is zero.
2. If the circumcentre and centroid of a triangle are respectively (α, β) (γ, δ) then orthocentre will be $(3\gamma - 2\alpha, 3\delta - 2\beta)$.

Example 48. If a triangle has its orthocentre at (1,1) and circumcentre at $\left(\frac{3}{2}, \frac{3}{4}\right)$, then find the centroid and nine point centre.

Sol. Since, centroid divides the orthocentre and circumcentre in the ratio 2 : 1 (internally) and if centroid $G(x, y)$, then

$$O(1,1) \overset{2}{\text{———}} G(x,y) \overset{1}{\text{———}} C\left(\frac{3}{2}, \frac{3}{4}\right)$$

$$x = \frac{2 \times \frac{3}{2} + 1 \times 1}{2+1} = \frac{4}{3}$$

and $$y = \frac{2 \times \frac{3}{4} + 1 \times 1}{2+1} = \frac{5}{6}$$

$\therefore$ Centroid is $\left(\frac{4}{3}, \frac{5}{6}\right)$ and nine point centre is the mid-point of orthocentre and circumcentre.

$\therefore$ Nine point centre is $\left(\frac{1+\frac{3}{2}}{2}, \frac{1+\frac{3}{4}}{2}\right)$, i.e. $\left(\frac{5}{4}, \frac{7}{8}\right)$.

Example 49. The vertices of a triangle are $A(a, a\tan\alpha), B(b, b\tan\beta)$ and $C(c, c\tan\gamma)$. If the circumcentre of ΔABC coincides with the origin and $H(\bar{x}, \bar{y})$ is the orthocentre, then show that $\frac{\bar{y}}{\bar{x}} = \left(\frac{\sin\alpha + \sin\beta + \sin\gamma}{\cos\alpha + \cos\beta + \cos\gamma}\right)$.

Sol. If R be the circumradius and O be the circumcentre

$\therefore$ $OA = OB = OC = R$

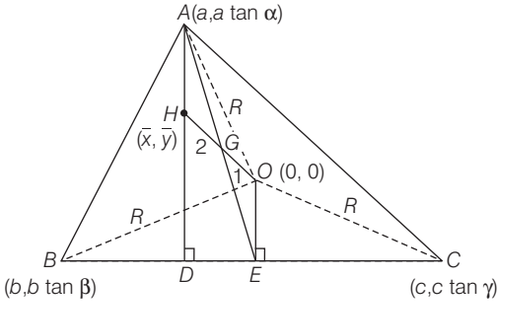
or $\sqrt{(a^2 + a^2\tan^2\alpha)} = \sqrt{(b^2 + b^2\tan^2\beta)}$

$= \sqrt{(c^2 + c^2\tan^2\gamma)} = R$

or $a\sec\alpha = b\sec\beta = c\sec\gamma = R$

or $a = R\cos\alpha, b = R\cos\beta, c = R\cos\gamma$

then, $a\tan\alpha = R\cos\alpha \cdot \frac{\sin\alpha}{\cos\alpha} = R\sin\alpha$



Similarly,

$b\tan\beta = R\sin\beta$ and $c\tan\gamma = R\sin\gamma$

$\therefore$ Coordinates of the vertices of a triangle are :

$A(R\cos\alpha, R\sin\alpha), B(R\cos\beta, R\sin\beta)$

and $C(R\cos\gamma, R\sin\gamma)$

$\therefore$ Centroid

$$(G) \equiv \left(\frac{R(\cos\alpha + \cos\beta + \cos\gamma)}{3}, \frac{R(\sin\alpha + \sin\beta + \sin\gamma)}{3}\right)$$

Since, G divides H and O in the ratio 2 : 1 (internally), then

$$\frac{R}{3}(\cos\alpha + \cos\beta + \cos\gamma) = \frac{2\cdot 0 + 1\cdot\bar{x}}{2+1}$$

or $$\frac{R}{3}(\cos\alpha + \cos\beta + \cos\gamma) = \frac{\bar{x}}{3} \quad \text{...(i)}$$

and $$\frac{R}{3}(\sin\alpha + \sin\beta + \sin\gamma) = \frac{2\cdot 0 + 1\cdot\bar{y}}{2+1}$$

or $$\frac{R}{3}(\sin\alpha + \sin\beta + \sin\gamma) = \frac{\bar{y}}{3} \quad \text{...(ii)}$$

Dividing Eqs. (ii) by (i), then we get

$$\frac{\bar{y}}{\bar{x}} = \left(\frac{\sin\alpha + \sin\beta + \sin\gamma}{\cos\alpha + \cos\beta + \cos\gamma}\right)$$

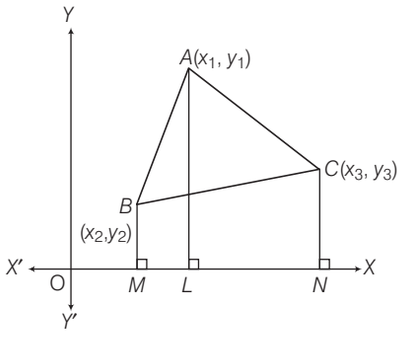
Area of a Triangle

Theorem : The area of a triangle, the coordinates of whose vertices are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) is

$$\frac{1}{2}|x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)|$$

or $$\frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}\right|$$

Proof : Let ABC be a triangle with vertices $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$. Let us assume that the points A, B and C are in 1st quadrant (for the sake of exactness). Draw AL, BM and CN perpendicular on X-axis. Let Δ be the required area of the triangle ABC, then



Δ = Area of triangle ABC

= [Area of trapezium $ABML$ + Area of trapezium $ALNC$ − Area of trapezium $BMNC$]

[$\because$ Area of trapezium $= \frac{1}{2}$ (Sum of parallel sides) × (Distance between them)]

$$\therefore \Delta = \left[\frac{1}{2}(BM + AL)(ML) + \frac{1}{2}(AL + CN)(LN) - \frac{1}{2}(BM + CN)(MN)\right]$$

$$= \left[\frac{1}{2}(BM + AL)(OL - OM) + \frac{1}{2}(AL + CN)(ON - (OL) - \frac{1}{2}(BM + CN)(ON - OM)\right]$$

$$= \left[\frac{1}{2}(y_2 + y_1)(x_1 - x_2) + \frac{1}{2}(y_1 + y_3)(x_3 - x_1) - \frac{1}{2}(y_2 + y_3)(x_3 - x_2)\right]$$

$$= \frac{1}{2}[x_1(y_2 + y_1 - y_1 - y_3) + x_2(-y_2 - y_1 + y_2 + y_3) + x_3(y_1 + y_3 - y_2 - y_3)]$$

$$= \frac{1}{2}[x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)]$$

The area of triangle ABC will come out to be a positive quantity only when the vertices A, B, C are taken in anticlockwise direction and if points A, B, C are taken in clockwise direction then the area will be negative and if the points A, B, C are taken arbitrary then the area will be positive or negative, the numerical value being the same in all cases.

Thus in general (i.e., 
)

$$\text{Area of } \Delta ABC = \frac{1}{2}|x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)|$$

This expression can be written in determinant form as follows

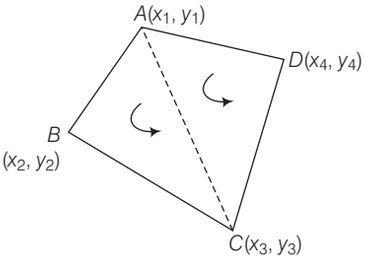
$$\frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}\right|$$

***Corollary* 1 :** Area of triangle can also be found by easy method

$$\Delta = \left|\frac{1}{2}\begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_2 & y_2 \\ x_3 & y_3 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_3 & y_3 \\ x_1 & y_1 \end{vmatrix}\right|$$

and **Area of quadrilateral *ABCD* :** The area of a quadrilateral can be found out by dividing the quadrilateral into two triangles.

$\therefore$ Area of quadrilateral $ABCD$



= Area of ΔABC + Area of ΔDAC

$$= \frac{1}{2}\begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_2 & y_2 \\ x_3 & y_3 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_3 & y_3 \\ x_1 & y_1 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_4 & y_4 \\ x_1 & y_1 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_1 & y_1 \\ x_3 & y_3 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix}$$

$$= \left|\frac{1}{2}\begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_2 & y_2 \\ x_3 & y_3 \end{vmatrix} + \frac{1}{2}\begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix}\right| + \frac{1}{2}\begin{vmatrix} x_4 & y_4 \\ x_1 & y_1 \end{vmatrix}$$

$$\left(\because \begin{vmatrix} x_3 & y_3 \\ x_1 & y_1 \end{vmatrix} = -\begin{vmatrix} x_1 & y_1 \\ x_3 & y_3 \end{vmatrix}\right)$$

$\therefore$ **Area of polygon whose vertices are $(x_1, y_1), (x_2, y_2), (x_3, y_3), \ldots, (x_n, y_n)$ is**

$$\frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} + \begin{vmatrix} x_2 & y_2 \\ x_3 & y_3 \end{vmatrix} + \begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix} + \ldots\ldots + \begin{vmatrix} x_n & y_n \\ x_1 & y_1 \end{vmatrix}\right|$$

Or

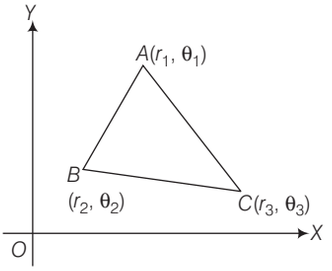
Stair Method Repeat first coordinates one time in last for down arrow use positive sign and for up arrow use negative sign.

$\therefore$ Area of polygon $= \frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \\ x_3 & y_3 \\ \cdots & \cdots \\ \cdots & \cdots \\ x_n & y_n \\ x_1 & y_1 \end{vmatrix}\right|$

$$= \frac{1}{2}|\{(x_1y_2 + x_2y_3 + \ldots + x_ny_1) - (y_1x_2 + y_2x_3 + \ldots + y_nx_1)\}|$$

***Corollary* 2 :** If the coordinates of the vertices of the triangle are given in polar form i.e.,

$A(r_1, \theta_1), B(r_2, \theta_2), C(r_3, \theta_3)$.



Then, area of triangle

$$= \frac{1}{2} | r_1 r_2 \sin(\theta_1 - \theta_2) + r_2 r_3 \sin(\theta_2 - \theta_3) + r_3 r_1 \sin(\theta_3 - \theta_1) |$$

$$= \frac{1}{2} | \sum r_1 r_2 \sin(\theta_1 - \theta_2) |$$

***Corollary* 3 :** If $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + c_2 = 0$ and $a_3x + b_3y + c_3 = 0$ are the sides of a triangle, then the area of the triangle is given by (without solving the vertices)

$$\Delta = \frac{1}{2 | C_1 C_2 C_3 |} \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}^2$$

where, C_1, C_2, C_3 are the cofactors of c_1, c_2, c_3 in the determinant

Here, $$C_1 = \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix} = (a_2 b_3 - a_3 b_2)$$

$$C_2 = \begin{vmatrix} a_3 & b_3 \\ a_1 & b_1 \end{vmatrix} = (a_3 b_1 - a_1 b_3)$$

and $$C_3 = \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = (a_1 b_2 - a_2 b_1)$$

and $$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = c_1 C_1 + c_2 C_2 + c_3 C_3$$

Or

$$\text{Area of triangle} = \frac{\Delta^2}{2 | \Delta_1 \Delta_2 \Delta_3 |}$$

where, $$\Delta = \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}, \Delta_1 = \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}, \Delta_2 = \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix}$$

and $$\Delta_3 = \begin{vmatrix} a_3 & b_3 \\ a_1 & b_1 \end{vmatrix}$$

***Corollary* 4 :** Area of the triangle formed by the lines of the form $y = m_1x + c_1, y = m_2x + c_2$ and $y = m_3x + c_3$ is

$$\Delta = \frac{1}{2} \left| \frac{(c_2 - c_3)^2}{(m_2 - m_3)} + \frac{(c_3 - c_1)^2}{(m_3 - m_1)} + \frac{(c_1 - c_2)^2}{(m_1 - m_2)} \right|$$

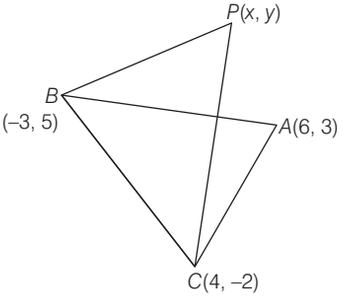
Remarks

1. If area of a triangle is given then, use ± sign.
2. The points $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ are collinear, then area of $(\Delta ABC) = 0$.
3. Four given points will be collinear, then area of the quadrilateral is zero.
4. Area of the triangle formed by the points (x_1, y_1), (x_2, y_2) and (x_3, y_3) is $\Delta = \frac{1}{2} \left| \begin{vmatrix} x_1 - x_3 & x_2 - x_3 \\ y_1 - y_3 & y_2 - y_3 \end{vmatrix} \right|$
5. If one vertex (x_3, y_3) is at (0, 0) then, $\Delta = \frac{1}{2} | x_1y_2 - x_2y_1 |$

Example 50. The coordinates of A, B, C are $(6, 3), (-3, 5)$ and $(4, -2)$ respectively and P is any points (x, y). Show that the ratio of the areas of the triangles PBC and ABC is $\frac{|x + y - 2|}{7}$.

Sol. We have

$$\frac{\text{Area of } \Delta PBC}{\text{Area of } \Delta ABC} = \frac{\frac{1}{2} | \{x(5 + 2) - 3(-2 - y) + 4(y - 5)\} |}{\frac{1}{2} | \{6(5 + 2) - 3(-2 - 3) + 4(3 - 5)\} |}$$



$$= \frac{| 7x + 7y - 14 |}{| 49 |} = \frac{7 | x + y - 2 |}{49} = \frac{| x + y - 2 |}{7}$$

Example 51. Find the area of the pentagon whose vertices are $A(1, 1), B(7, 21), C(7 - 3), D(12, 2)$ and $E(0, -3)$.

Sol. The required area

$$= \frac{1}{2} \left| \begin{vmatrix} 1 & 1 \\ 7 & 21 \end{vmatrix} + \begin{vmatrix} 7 & 21 \\ 7 & -3 \end{vmatrix} + \begin{vmatrix} 7 & -3 \\ 12 & 2 \end{vmatrix} + \begin{vmatrix} 12 & 2 \\ 0 & -3 \end{vmatrix} + \begin{vmatrix} 0 & -3 \\ 1 & 1 \end{vmatrix} \right|$$

$$= \frac{1}{2} | (21 - 7) + (-21 - 147) + (14 + 36) + (-36 - 0) + (0 + 3) |$$

$$= \frac{1}{2} | -137 | = \frac{137}{2} \text{ sq units}$$

Example 52. Show that the points $(a,0),(0,b)$ and (1, 1) are collinear, if $\frac{1}{a}+\frac{1}{b}=1$

Sol. Let $A\equiv(a,0)$, $B\equiv(0,b)$ and $C\equiv(1,1)$

Now, points A,B,C will be collinear, if area of $\Delta ABC=0$

or $$\frac{1}{2}\left|\begin{vmatrix}a&0\\0&b\end{vmatrix}+\begin{vmatrix}0&b\\1&1\end{vmatrix}+\begin{vmatrix}1&1\\a&0\end{vmatrix}\right|=0$$

$\Rightarrow$ $$|(ab-0)+(0-b)+(0-a)|=0$$

or $$ab-a-b=0$$

or $$a+b=ab \text{ or } \frac{1}{a}+\frac{1}{b}=1$$

Example 53. Prove that the coordinates of the vertices of an equilateral triangle can not all be rational.

Sol. Let $A(x_1,y_1)$, $B(x_2,y_2)$ and $C(x_3,y_3)$ be the vertices of a triangle ABC. If possible let x_1,y_1,x_2,y_2,x_3,y_3 be all rational.

Now, area of $\Delta ABC=\frac{1}{2}|x_1(y_2-y_3)+x_2(y_3-y_1)+x_3(y_1-y_2)|$

$=$ Rational ...(i)

Since, ΔABC is equilateral

$\therefore$ Area of $\Delta ABC=\frac{\sqrt{3}}{4}(\text{side})^2$

$=\frac{\sqrt{3}}{4}(AB)^2$

$=\frac{\sqrt{3}}{4}\{(x_1-x_2)^2+(y_1-y_2)^2\}$

$=$ Irrational ...(ii)

From Eqs. (i) and (ii),

Rational = Irrational

which is contradiction.

Hence, x_1,y_1,x_2,y_2,x_3,y_3 cannot all be rational.

Example 54. The coordinates of two points A and B are (3, 4) and $(5,-2)$ respectively. Find the coordinates of any point P if $PA=PB$ and area of ΔAPB is 10.

Sol. Let coordinates of P be (h,k).

$\because$ $PA=PB \Rightarrow (PA)^2=(PB)^2$

$\Rightarrow$ $(h-3)^2+(k-4)^2=(h-5)^2+(k+2)^2$

$\Rightarrow$ $(h-3)^2-(h-5)^2+(k-4)^2-(k+2)^2=0$

$\Rightarrow$ $(2h-8)(2)+(2k-2)(-6)=0$

$\Rightarrow$ $(h-4)-3(k-1)=0$

$\Rightarrow$ $h-3k-1=0$ ...(i)

Now, Area of $\Delta PAB=\frac{1}{2}\left|\begin{vmatrix}h&k&1\\3&4&1\\5&-2&1\end{vmatrix}\right|=10$

or $6h+2k-26=\pm20$

$\Rightarrow$ $6h+2k-46=0$ or $6h+2k-6=0$

$\Rightarrow$ $3h+k-23=0$ or $3h+k-3=0$

Solving $h-3k-1=0$ and $3h+k-23=0$,

we get $h=7,k=2$

Solving $h-3k-1=0$ and $3h+k-3=0$,

we get $h=1,k=0$

Hence, the coordinates of P are (7, 2) or (1, 0).

Example 55. Find the area of the triangle formed by the straight lines $7x-2y+10=0$, $7x+2y-10=0$ and $9x+y+2=0$ (without solving the vertices of the triangle).

Sol. The given lines are :

$$7x-2y+10=0$$
$$7x+2y-10=0$$
$$9x+y+2=0$$

$\therefore$ Area of triangle $\Delta=\frac{1}{2|C_1C_2C_3|}\begin{vmatrix}7&-2&10\\7&2&-10\\9&1&2\end{vmatrix}^2$ ...(i)

where, $C_1=\begin{vmatrix}7&2\\9&1\end{vmatrix}=7-18=-11,$

$C_2=\begin{vmatrix}9&1\\7&-2\end{vmatrix}=-18-7=-25$

and $C_3=\begin{vmatrix}7&-2\\7&2\end{vmatrix}=14+14=28,$

and $\begin{vmatrix}7&-2&10\\7&2&-10\\9&1&2\end{vmatrix}=10C_1-10C_2+2C_3$

$=10\times(-11)-10\times(-25)+2\times28=196$

$\therefore$ From Eq. (i), $\Delta=\frac{1}{2|-11\times(-25)\times28|}\times(196)^2$

$=\frac{196\times196}{2\times11\times25\times28}=\frac{686}{275}$ sq units

Example 56. If Δ_1 is the area of the triangle with vertices $(0,0),(a\tan\alpha,b\cot\alpha),(a\sin\alpha,b\cos\alpha)$; Δ_2 is the area of the triangle with vertices $(a,b),(a\sec^2\alpha,b\,\text{cosec}^2\alpha),(a+a\sin^2\alpha,b+b\cos^2\alpha)$ and Δ_3 is the area of the triangle with vertices $(0,0)$, $(a\tan\alpha,-b\cot\alpha),(a\sin\alpha,b\cos\alpha)$. Show that there is no value of α for which Δ_1,Δ_2 and Δ_3 are in GP.

Sol. We have, $\Delta_1 = \frac{1}{2}|(a\tan\alpha)(b\cos\alpha) - (a\sin\alpha)(b\cot\alpha)|$
($\because$ one vertex is (0,0))

$= \frac{1}{2}|ab||\sin\alpha - \cos\alpha|$ ... (i)

and $\Delta_2 = \frac{1}{2}\left|\begin{vmatrix} a-(a+a\sin^2\alpha) & a\sec^2\alpha-(a+a\sin^2\alpha) \\ b-(b+b\cos^2\alpha) & b\,\text{cosec}^2\,\alpha-(b+b\cos^2\alpha)\end{vmatrix}\right|$

(See remark 4)

$= \frac{1}{2}\left|\begin{vmatrix} -a\sin^2\alpha & a(\tan^2\alpha-\sin^2\alpha) \\ -b\cos^2\alpha & b(\cot^2\alpha-\cos^2\alpha)\end{vmatrix}\right|$

$= \frac{1}{2}|ab|\times\left|\begin{vmatrix} -\sin^2\alpha & \sin^2\alpha(\sec^2\alpha-1) \\ -\cos^2\alpha & \cos^2\alpha(\text{cosec}^2\alpha-1)\end{vmatrix}\right|$

$= \frac{1}{2}|ab|\times\left|\begin{vmatrix} -\sin^2\alpha & \sin^2\alpha\tan^2\alpha \\ -\cos^2\alpha & \cos^2\alpha\cot^2\alpha\end{vmatrix}\right|$

$= \frac{1}{2}|ab|\times|-\sin^2\alpha\cos^2\alpha\cot^2\alpha+\sin^2\alpha\cos^2\alpha\tan^2\alpha|$

$= \frac{1}{2}|ab|\times|-\cos^4\alpha+\sin^4\alpha|$

$= \frac{1}{2}|ab|\times|\sin^2\alpha+\cos^2\alpha|\times|\sin^2\alpha-\cos^2\alpha|$

$= \frac{1}{2}|ab|\times|1|\times|-\cos 2\alpha|$

$= \frac{1}{2}|ab|\times|\cos 2\alpha|$ ... (ii)

and $\Delta_3 = \frac{1}{2}|(a\tan\alpha)(b\cos\alpha)-(-b\cot\alpha)(a\sin\alpha)|$

$= \frac{1}{2}|ab||\sin\alpha+\cos\alpha|$ ... (iii)

Since, $\Delta_1, \Delta_2, \Delta_3$ are in GP, then $\Delta_1\Delta_3 = \Delta_2^2$

$\Rightarrow \frac{1}{2}|ab||\sin\alpha-\cos\alpha|\times\frac{1}{2}|ab||\sin\alpha+\cos\alpha|$

$= \frac{1}{4}|ab|^2|\cos 2\alpha|^2$ [from Eqs. (i), (ii) and (iii)]

$\Rightarrow |\sin^2\alpha-\cos^2\alpha| = |\cos 2\alpha|^2$

$\Rightarrow |-\cos 2\alpha| = |\cos 2\alpha|^2$

$\Rightarrow |\cos 2\alpha| = |\cos 2\alpha|^2$

$\Rightarrow |\cos 2\alpha|(1-|\cos 2\alpha|) = 0$

$\therefore 1-|\cos 2\alpha| = 0$ ($\because |\cos 2\alpha| \neq 0$)

$\Rightarrow |\cos 2\alpha| = 1$

or $\cos 2\alpha = \pm 1$ or $\cos 2\alpha = 1$

and $\cos 2\alpha = -1$

or $2\alpha = 2n\pi, 2\alpha = (2p+1)\pi$

or $\alpha = n\pi, \alpha = p\pi + \frac{\pi}{2}; n, p \in I$

For these values of α the vertices of the given triangles are not defined. Hence Δ_1, Δ_2 and Δ_3 cannot be in GP for any value of α.

Exercise for Session 3

1. The coordinates of the middle points of the sides of a triangle are (4, 2), (3, 3) and (2, 2), then coordinates of centroid are

(a) (3, 7 / 3) (b) (3, 3) (c) (4, 3) (d) (3, 4)

2. The incentre of the triangle whose vertices are $(-36, 7), (20, 7)$ and $(0, -8)$ is

(a) (0, – 1) (b) (–1, 0) (c) (1, 1) (d) $\left(\frac{1}{2}, 1\right)$

3. If the orthocentre and centroid of a triangle are $(-3, 5)$ and (3, 3) then its circumcentre is

(a) (6, 2) (b) (3, – 1) (c) (–3, 5) (d) (–3, 1)

4. An equilateral triangle has each side equal to a. If the coordinates of its vertices are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) then the square of the determinant $\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1\end{vmatrix}$ equals

(a) $3a^4$ (b) $\frac{3a^4}{2}$ (c) $\frac{3}{4}a^4$ (d) $\frac{3}{8}a^4$

5. The vertices of a triangle are $A(0,0), B(0,2)$ and $C(2,0)$. The distance between circumcentre and orthocentre is

(a) $\sqrt{2}$ (b) $\frac{1}{\sqrt{2}}$ (c) 2 (d) $\frac{1}{2}$

6. $A(a, b)$, $B(x_1, y_1)$ and $C(x_2, y_2)$ are the vertices of a triangle. If a, x_1, x_2 are in GP with common ratio r and b, y_1, y_2 are in GP with common ratio s, then area of ΔABC is

(a) $ab(r-1)(s-1)(s-r)$ (b) $\frac{1}{2}ab(r+1)(s+1)(s-r)$

(c) $\frac{1}{2}ab(r-1)(s-1)(s-r)$ (d) $ab(r+1)(s+1)(r-s)$

7. The points $(x+1, 2), (1, x+2), \left(\frac{1}{x+1}, \frac{2}{x+1}\right)$ are collinear, then x is equal to

(a) -4 (b) -8 (c) 4 (d) 8

8. The vertices of a triangle are $(6, 0), (0, 6)$ and $(6, 6)$. Then distance between its circumcentre and centroid, is

(a) $2\sqrt{2}$ (b) 2 (c) $\sqrt{2}$ (d) 1

9. The nine point centre of the triangle with vertices $(1, \sqrt{3}), (0, 0)$ and $(2, 0)$ is

(a) $\left(1, \frac{\sqrt{3}}{2}\right)$ (b) $\left(\frac{2}{3}, \frac{1}{\sqrt{3}}\right)$ (c) $\left(\frac{2}{3}, \frac{\sqrt{3}}{2}\right)$ (d) $\left(1, \frac{1}{\sqrt{3}}\right)$

10. The vertices of a triangle are $(0, 0), (1, 0)$ and $(0, 1)$. Then excentre opposite to $(0, 0)$ is

(a) $\left(1-\frac{1}{\sqrt{2}}, 1+\frac{1}{\sqrt{2}}\right)$ (b) $\left(1+\frac{1}{\sqrt{2}}, 1+\frac{1}{\sqrt{2}}\right)$ (c) $\left(1+\frac{1}{\sqrt{2}}, 1-\frac{1}{\sqrt{2}}\right)$ (d) $\left(1-\frac{1}{\sqrt{2}}, 1-\frac{1}{\sqrt{2}}\right)$

11. If α, β, γ are the real roots of the equation $x^3 - 3px^2 + 3qx - 1 = 0$, then find the centroid of the triangle whose vertices are $\left(\alpha, \frac{1}{\alpha}\right), \left(\beta, \frac{1}{\beta}\right)$ and $\left(\gamma, \frac{1}{\gamma}\right)$.

12. If centroid of a triangle be $(1,4)$ and the coordinates of its any two vertices are $(4, -8)$ and $(-9, 7)$, find the area of the triangle.

13. Find the centroid and incentre of the triangle whose vertices are $(1, 2), (2, 3)$ and $(3, 4)$.

14. Show that the area of the triangle with vertices $(\lambda, \lambda - 2), (\lambda + 3, \lambda)$ and $(\lambda + 2, \lambda + 2)$ is independent of λ.

15. Prove that the points $(a, b + c), (b, c + a)$ and $(c, a + b)$ are collinear.

16. Prove that the points $(a, b), (c, d)$ and $(a - c, b - d)$ are collinear, if $ad = bc$.

17. If the points $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) are collinear, show that $\sum\left(\frac{y_1 - y_2}{x_1 x_2}\right) = 0$, i.e.

$$\frac{y_1 - y_2}{x_1 x_2} + \frac{y_2 - y_3}{x_2 x_3} + \frac{y_3 - y_1}{x_3 x_1} = 0$$

18. The coordinates of points A, B, C and D are $(-3, 5), (4, -2), (x, 3x)$ and $(6, 3)$ respectively and $\frac{\Delta ABC}{\Delta BCD} = \frac{2}{3}$, find x.

19. Find the area of the hexagon whose vertices taken in order are $(5, 0), (4, 2), (1, 3), (-2, 2), (-3, -1)$ and $(0, -4)$.

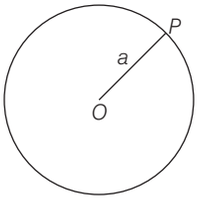
Session 4

Locus and Its Equation, Change of Axes the Transformation of Axes, Removal of the Term *xy* from $F(x, y) = ax^2 + 2hxy + by^2$ without Changing the Origin, Position of a Point which lies Inside a Triangle

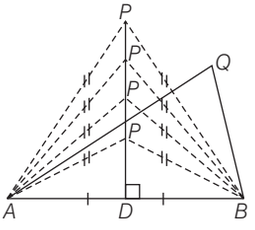
Locus and Its Equation

Locus : The locus of a moving point is the path traced out by that point under one or more given conditions.

For example 1. If a point P moves in a plane such that whose distance from a fixed point O (say) in the plane is always constant distance a. Thus the locus of the moving point P is clearly a circle with centre O and radius a.



For example 2. If a point P moves in a plane such that whose distance from two fixed points A and B (say) are always equal i.e. $PA = PB$



(The point P cannot be at Q because $AQ \neq BQ$)

Obviously all the positions of the moving point P lies on the right bisector of AB. Thus the locus of the moving point P is the right bisector of AB.

Equation of a Locus

A relation $f(x, y) = 0$ between x and y which is satisfied by each point on the locus and such that each point satisfying the equation is on the locus is called the ***equation of the locus***.

How to Find the Locus of a Point

Let (x_1, y_1) be the coordinates of the moving point say P. Now, apply the geometrical conditions on x_1, y_1 . This gives a relation between x_1 and y_1. Now replace x_1 by x and y_1 by y in the eliminant and resulting equation would be the equation of the locus.

***Corollary* 1 :** If x and y are not there in the question, the coordinates of P may also be taken as (x, y).

***Corollary* 2 :** If coordinates and equation are not given in the question, suitable choice of origin and axes may be made.

***Corollary* 3 :** To find the locus of the point of intersection of two straight lines, eliminate the parameter or parameters from the given lines. If more than one parameter, then additional condition or conditions will also be given.

Note

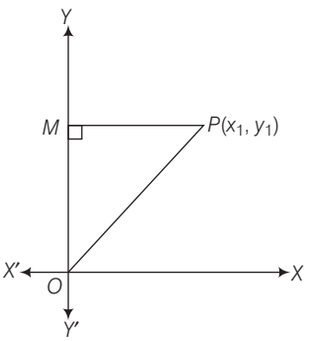
Simplify the equation by squaring both sides if square roots are there and taking LCM to remove the denominators.

Example 57. Find the locus of a point which moves such that its distance from the point (0, 0) is twice its distance from the *Y*-axis.

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required.

By hypothesis $|OP| = 2|PM|$ ($\because$ P lies in any quadrant)

$\Rightarrow \sqrt{(x_1^2 + y_1^2)} = 2|x_1|$



Squaring both sides, then

$$x_1^2 + y_1^2 = 4x_1^2$$

$$\Rightarrow \quad 3x_1^2 - y_1^2 = 0$$

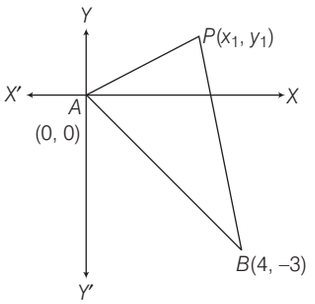
Changing (x_1, y_1) to (x, y), then

$$3x^2 - y^2 = 0$$

which is the required locus of P.

Example 58. Find the locus of the moving point P such that $2PA = 3PB$, where A is $(0, 0)$ and B is $(4, -3)$.

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required.



By hypothesis,

$$2PA = 3PB \text{ or } 4(PA)^2 = 9(PB)^2$$

$$\Rightarrow \quad 4\{x_1^2 + y_1^2\} = 9\{(x_1 - 4)^2 + (y_1 + 3)^2\}$$

$$\Rightarrow \quad 4(x_1^2 + y_1^2) = 9(x_1^2 + y_1^2 - 8x_1 + 6y_1 + 25)$$

or $\quad 5x_1^2 + 5y_1^2 - 72x_1 + 54y_1 + 225 = 0$

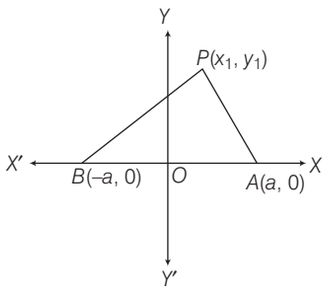
Changing (x_1, y_1) to (x, y), then

$$5x^2 + 5y^2 - 72x + 54y + 225 = 0$$

which is the required locus of P.

Example 59. A point moves so that the sum of the squares of its distances from two fixed points $A(a, 0)$ and $B(-a, 0)$ is constant and equal to $2c^2$, find the locus of the point.

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required.



By hypothesis, $\quad (PA)^2 + (PB)^2 = 2c^2$

$$\Rightarrow \quad (x_1 - a)^2 + (y_1 - 0)^2 + (x_1 + a)^2 + (y_1 - 0)^2 = 2c^2$$

$$\Rightarrow \quad 2x_1^2 + 2y_1^2 + 2a^2 = 2c^2$$

or $\quad x_1^2 + y_1^2 = c^2 - a^2$

Changing (x_1, y_1) to (x, y), then

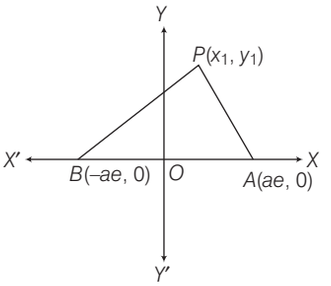
$$x^2 + y^2 = c^2 - a^2$$

which is the required locus of P.

Example 60. A point moves such that the sum of its distances from two fixed points $(ae, 0)$ and $(-ae, 0)$ is always $2a$. Prove that the equation of the locus is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad \textit{where} \quad b^2 = a^2(1 - e^2)$$

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required and $A(ae, 0)$ and $B(-ae, 0)$ be the given fixed points.



By hypothesis, $\quad |PA| + |PB| = 2a$

or $\quad \sqrt{(x_1 - ae)^2 + (y_1 - 0)^2} + \sqrt{(x_1 + ae)^2 + (y_1 - 0)^2} = 2a$

or $\quad \sqrt{(x_1^2 + y_1^2 - 2aex_1 + a^2e^2)} + \sqrt{(x_1^2 + y_1^2 + 2aex_1 + a^2e^2)}$

$$= 2a \qquad \text{...(i)}$$

Let $\quad l = x_1^2 + y_1^2 - 2aex_1 + a^2e^2$

and $\quad m = x_1^2 + y_1^2 + 2aex_1 + a^2e^2 \qquad (l - m \text{ method})$

then, Eq. (i) can be written as

$$\sqrt{l} + \sqrt{m} = 2a \qquad \text{...(ii)}$$

and $\quad l - m = -4aex_1$

or $\quad (\sqrt{l} + \sqrt{m})(\sqrt{l} - \sqrt{m}) = -4aex_1$

or $\quad 2a(\sqrt{l} - \sqrt{m}) = -4aex_1 \qquad [\text{from Eq. (ii)}]$

or $\quad \sqrt{l} - \sqrt{m} = -2ex_1 \qquad \text{...(iii)}$

Adding Eqs. (ii) and (iii), then

$$2\sqrt{l} = 2a - 2ex_1 \text{ or } \sqrt{l} = a - ex_1$$

Squaring both sides,

$$l = a^2 - 2aex_1 + e^2x_1^2$$

$$\Rightarrow \quad x_1^2 + y_1^2 - 2aex_1 + a^2e^2 = a^2 - 2aex_1 + e^2x_1^2$$

$$\Rightarrow \quad (1 - e^2)x_1^2 + y_1^2 = a^2(1 - e^2)$$

or $\quad \dfrac{x_1^2}{a^2} + \dfrac{y_1^2}{a^2(1 - e^2)} = 1$

or $\quad \dfrac{x_1^2}{a^2} + \dfrac{y_1^2}{b^2} = 1 \qquad [\because b^2 = a^2(1 - e^2)]$

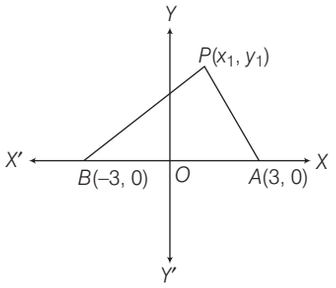
Changing (x_1, y_1) to (x, y), then

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

which is the required locus of P.

Example 61. Find the equation of the locus of a point which moves so that the difference of its distances from the points $(3, 0)$ and $(-3, 0)$ is 4 units.

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required and $A(3, 0)$ and $B(-3, 0)$ be the given fixed points.



By hypothesis

$$|PB| - |PA| = 4 \text{ (assume } |PB| > |PA|)$$

$$\Rightarrow \quad \sqrt{(x_1+3)^2 + (y_1-0)^2} - \sqrt{(x_1-3)^2 + (y_1-0)^2} = 4$$

$$\Rightarrow \quad \sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)} = 4 + \sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)}$$

Squaring both sides then,

$$x_1^2 + y_1^2 + 6x_1 + 9 = 16 + x_1^2 + y_1^2 - 6x_1 + 9 + 8\sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)}$$

or $$(12x_1 - 16) = 8\sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)}$$

or $$(3x_1 - 4) = 2\sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)}$$

Again, squaring both sides, then

$$9x_1^2 - 24x_1 + 16 = 4x_1^2 + 4y_1^2 - 24x_1 + 36$$

or $$5x_1^2 - 4y_1^2 = 20$$

$$\Rightarrow \quad \frac{x_1^2}{4} - \frac{y_1^2}{5} = 1$$

Changing (x_1, y_1) by (x, y), then

$$\frac{x^2}{4} - \frac{y^2}{5} = 1$$

which is the required locus of P.

Aliter ($l - m$ method) :

Since, $$|PB| - |PA| = 4$$

$$\Rightarrow \quad \sqrt{(x_1+3)^2 + (y_1-0)^2} - \sqrt{(x_1-3)^2 + (y_1-0)^2} = 4$$

$$\Rightarrow \quad \sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)} - \sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)} = 4 \quad \text{...(i)}$$

Let $$l = x_1^2 + y_1^2 + 6x_1 + 9$$

and $$m = x_1^2 + y_1^2 - 6x_1 + 9$$

then, Eq. (i) can be written as

$$\sqrt{l} - \sqrt{m} = 4 \quad \text{... (ii)}$$

and $$l - m = 12x_1$$

$$\Rightarrow \quad (\sqrt{l} + \sqrt{m})(\sqrt{l} - \sqrt{m}) = 12x_1$$

$$\Rightarrow \quad (\sqrt{l} + \sqrt{m})(4) = 12x_1 \quad \text{[from Eq. (ii)]}$$

$$\Rightarrow \quad \sqrt{l} + \sqrt{m} = 3x_1 \quad \text{...(iii)}$$

Adding Eqs. (ii) and (iii),

$$2\sqrt{l} = (3x_1 + 4)$$

Squaring both sides,

$$4l = 9x_1^2 + 24x_1 + 16$$

$$\Rightarrow \quad 4(x_1^2 + y_1^2 + 6x_1 + 9) = 9x_1^2 + 24x_1 + 16$$

$$\Rightarrow \quad 5x_1^2 - 4y_1^2 = 20 \quad \text{or} \quad \frac{x_1^2}{4} - \frac{y_1^2}{5} = 1$$

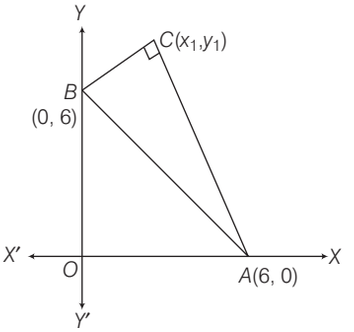
Changing (x_1, y_1) by (x, y), then

$$\frac{x^2}{4} - \frac{y^2}{5} = 1$$

which is the required locus of P.

Example 62. The ends of the hypotenuse of a right angled triangle are $(6, 0)$ and $(0, 6)$. Find the locus of the third vertex.

Sol. Let $C(x_1, y_1)$ be the moving point (third vertex) whose locus is required and $A(6, 0)$ and $B(0, 6)$ be the given vertices.



By hypothesis

$$(AC)^2 + (BC)^2 = (AB)^2 \qquad (\because \angle ACB = 90°)$$

$$\Rightarrow \quad (x_1-6)^2 + (y_1-0)^2 + (x_1-0)^2 + (y_1-6)^2 = 6^2 + 6^2$$

$$\Rightarrow \quad 2x_1^2 + 2y_1^2 - 12x_1 - 12y_1 = 0$$

or $$x_1^2 + y_1^2 - 6x_1 - 6y_1 = 0$$

Changing (x_1, y_1) by (x, y), then

$$x^2 + y^2 - 6x - 6y = 0$$

which is the required locus of third vertex C.

Aliter 1. Slope of $AC \times$ slope of $BC = -1$

$$\Rightarrow \quad \left(\frac{y_1 - 0}{x_1 - c}\right) \times \left(\frac{y_1 - r}{x_1 - 0}\right) = -1$$

or $$x_1^2 + y_1^2 - 6x_1 - 6y_1 = 0$$

Aliter 2. Mid-point of AB is $M \equiv (3, 3)$

$$\because \quad MA = MB = MC \Rightarrow (MA)^2 \equiv (MC)^2$$

$$(3-0)^2 + (3-6)^2 = (x_1-3)^2 (y_1-3)^2$$

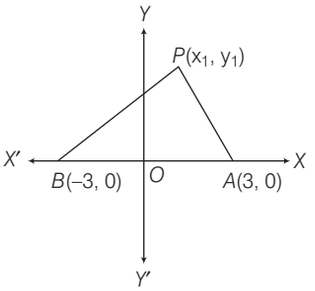
or $$x_1^2 + y_1^2 - 6x_1 - 6y_1 = 0$$

$\therefore$ Required locus is

$$x^2 + y^2 - 6x - 6y = 0$$

Example 63. Find the equation of the locus of a point which moves so that the sum of their distances from $(3, 0)$ and $(-3, 0)$ is less than 9.

Sol. Let $P(x_1, y_1)$ be the moving point whose locus is required and $A(3, 0)$ and $B(-3, 0)$ are the given points.



By hypothesis,

$$|PA| + |PB| < 9$$

$$\Rightarrow \quad \sqrt{\{(x_1-3)^2 + (y_1-0)^2\}} + \sqrt{\{(x_1+3)^2 + (y_1-0)^2\}} < 9$$

$$\Rightarrow \quad \sqrt{(x_1^2 + y_1^2 - 6x_1 + 9)} < 9 - \sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)}$$

On squaring, we get

$$(x_1^2 + y_1^2 - 6x_1 + 9) < (81 + x_1^2 + y_1^2 + 6x_1 + 9) - 18\sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)}$$

$$(\because a < b \Rightarrow a^2 < b^2 \text{ provided } a > 0)$$

$$\Rightarrow \quad -12x_1 - 81 < -18\sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)}$$

$$\Rightarrow \quad (4x_1 + 27) > 6\sqrt{(x_1^2 + y_1^2 + 6x_1 + 9)}$$

$$(\because \text{If } a > b, \text{ then } -a < -b)$$

On squaring, we get

$$16x_1^2 + 729 + 216x > 36x_1^2 + 36y_1^2 + 216x_1 + 324$$

$$\Rightarrow \quad 20x_1^2 + 36y_1^2 < 405$$

Changing (x_1, y_1) by (x, y), then

$$20x^2 + 36y^2 < 405$$

which is the required locus of P.

Example 64. Find the locus of a point whose coordinate are given by $x = t + t^2$, $y = 2t + 1$, *where t is variable.*

Sol. Given, $x = t + t^2$ ...(i)

and $y = 2t + 1$ ...(ii)

From Eq. (ii), $t = \left(\frac{y-1}{2}\right)$ ...(iii)

On eliminating t from Eqs. (i) and (iii), we get required locus as

$$x = \left(\frac{y-1}{2}\right) + \left(\frac{y-1}{2}\right)^2$$

$$\Rightarrow \quad x = \left(\frac{y-1}{2}\right)\left(1 + \frac{y-1}{2}\right)$$

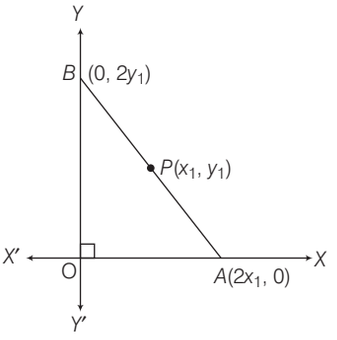
$$\Rightarrow \quad x = \left(\frac{y-1}{2}\right)\left(\frac{y+1}{2}\right)$$

or $4x = y^2 - 1$

or $y^2 = 4x + 1$

Example 65. A stick of length l rests against the floor and a wall of a room. If the stick begins to slide on the floor, find the locus of its middle point.

Sol. Let the cross section of the floor and wall be taken as the coordinate axes and AB be one of the position of the stick. Let the mid-point of AB be $P(x_1, y_1)$, then coordinates of A and B are $(2x_1, 0)$ and $(0, 2y_1)$ respectively.



But given, $|AB| = l$

$$\Rightarrow \quad (AB)^2 = l^2$$

$$\Rightarrow \quad (2x_1 - 0)^2 + (0 - 2y_1)^2 = l^2$$

$$\Rightarrow \quad 4x_1^2 + 4y_1^2 = l^2$$

Changing (x_1, y_1) by (x, y), then

$$4(x^2 + y^2) = l^2$$

which is the required locus of P.

Aliter :

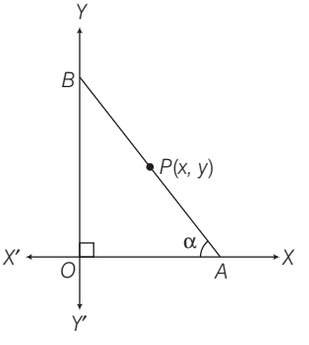
Since, $|AB| = l$

Let $\angle OAB = \alpha$

$\therefore$ $OA = l\cos\alpha$ and $OB = l\sin\alpha$

then, $A \equiv (l\cos\alpha, 0)$

and $B \equiv (0, l\sin\alpha)$



Let $P(x, y)$ be the mid-point of AB, then

$$2x = l\cos\alpha \quad ...(i)$$

$$2y = l\sin\alpha \quad ...(ii)$$

Squaring and adding Eqs. (i) and (ii), then

$$4(x^2 + y^2) = l^2$$

which is the required locus of P.

Example 66. Find the locus of the point of intersection of the lines $x\cos\alpha + y\sin\alpha = a$ and $x\sin\alpha - y\cos\alpha = b$, where α is variable.

Sol. Given equations are

$$x\cos\alpha + y\sin\alpha = a \quad ...(i)$$

and $$x\sin\alpha - y\cos\alpha = b \quad ...(ii)$$

Here, α is a variable, on eliminating α. Squaring and adding Eqs. (i) and (ii), we get required locus as

$$(x\cos\alpha + y\sin\alpha)^2 + (x\sin\alpha - y\cos\alpha)^2 = a^2 + b^2$$

or $$(x^2\cos^2\alpha + y^2\sin^2\alpha + 2xy\cos\alpha\sin\alpha) + (x^2\sin^2\alpha + y^2\cos^2\alpha - 2xy\sin\alpha\cos\alpha) = a^2 + b^2$$

$$\Rightarrow \quad x^2(\cos^2\alpha + \sin^2\alpha) + y^2(\sin^2\alpha + \cos^2\alpha) = a^2 + b^2$$

$$\Rightarrow \quad x^2 + y^2 = a^2 + b^2$$

Example 67. A variable line cuts X-axis at A, Y-axis at B, where $OA = a, OB = b$ (O as origin) such that $a^2 + b^2 = 1$.

Find the locus of

(i) centroid of ΔOAB

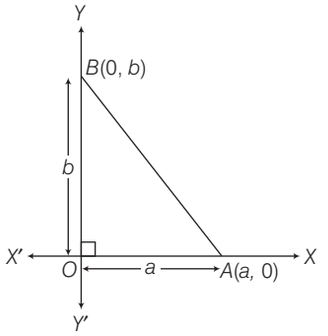
(ii) circumcentre of ΔOAB

Sol. (i) Coordinates of A and B are $(a, 0)$ and $(0, b)$ respectively.

If centroid of ΔOAB be $G(x, y)$

then $$x = \frac{0 + a + 0}{3} \quad \Rightarrow \quad a = 3x$$

and $$y = \frac{0 + 0 + b}{3} \quad \Rightarrow \quad b = 3y$$



On substituting in $a^2 + b^2 = 1$, we get

$$(3x)^2 + (3y)^2 = 1$$

or $$x^2 + y^2 = \frac{1}{9}$$

which is the required locus of G.

(ii) If the circumcentre be $C(x, y)$. Since in semicircle angle $90°$, then AB is the diameter of the circumcircle OAB.

$\therefore$ Circumcentre is the mid-point of AB.

Then $$x = \frac{a + 0}{2} \quad \Rightarrow \quad a = 2x$$

and $$y = \frac{0 + b}{2} \quad \Rightarrow \quad b = 2y$$

On substituting in $a^2 + b^2 = 1$, we get

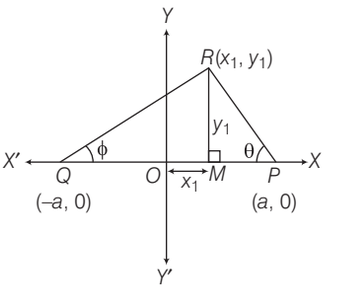
$$(2x)^2 + (2y)^2 = 1$$

or $$x^2 + y^2 = \frac{1}{4}$$

which is the required locus of C.

Example 68. Two points P and Q are given, R is a variable point on one side of the line PQ such that $\angle RPQ - \angle RQP$ is a positive constant 2α. Find the locus of the point R.

Sol. Let the X-axis along QP and the middle point of PQ is origin and let coordinates of moving point R be (x_1, y_1).



Let $$OP = OQ = a$$

then coordinates of P and Q are $(a, 0)$ and $(-a, 0)$ respectively.

Draw RM perpendicular on QP

$\therefore$ $$OM = x_1 \quad \text{and} \quad MR = y_1$$

and let $$\angle RPM = \theta \quad \text{and} \quad \angle RQM = \phi$$

Now, in ΔRMP,

$$\tan\theta = \frac{RM}{MP} = \frac{RM}{OP - OM} = \frac{y_1}{a - x_1} \quad ...(i)$$

and in ΔRMQ,

$$\tan\phi = \frac{RM}{QM} = \frac{RM}{OQ + OM} = \frac{y_1}{a + x_1} \quad ...(ii)$$

But given

$$\angle RPQ - \angle RQP = 2\alpha \quad \text{(constant)}$$

$$\Rightarrow \quad \theta - \phi = 2\alpha$$

$$\therefore \quad \tan(\theta - \phi) = \tan 2\alpha$$

$$\Rightarrow \quad \frac{\tan\theta - \tan\phi}{1 + \tan\theta\tan\phi} = \tan 2\alpha$$

$$\Rightarrow \quad \frac{\frac{y_1}{a-x_1}-\frac{y_1}{a+x_1}}{1+\left(\frac{y_1}{a-x_1}\right).\left(\frac{y_1}{a+x_1}\right)}=\tan 2\alpha$$

[from Eqs. (i) and (ii)]

$$\Rightarrow \quad \frac{2x_1y_1}{a^2-x_1^2+y_1^2}=\tan 2\alpha$$

or $\quad a^2-x_1^2+y_1^2=2x_1y_1\cot 2\alpha$

or $\quad x_1^2-y_1^2+2x_1y_1\cot 2\alpha=a^2$

Hence, locus of the point $R(x_1, y_1)$ is

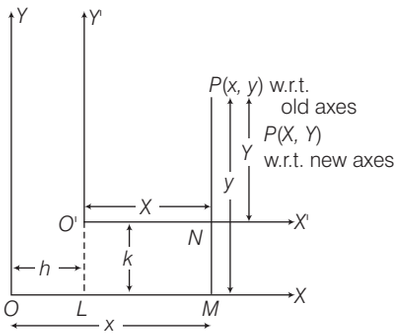
$$x^2-y^2+2xy\cot 2\alpha=a^2$$

Change of Axes OR the Transformations of Axes

In coordinate geometry we have discussed the coordinates of a point or the equation of a curve are always considered on taking a fixed point O as the origin and two perpendicular straight lines through O as the coordinates axes. For convenient the coordinates of the point or the equation of the curve changes when either the origin is changed or the direction of axes or both are suitably. These processes in coordinate geometry are known as the *transformations or change of axes.* This process of transformation of coordinates will be of great advantage to solve most of the problems very easily.

(i) Change of origin OR Shifting of origin (Translation of Axes)

To change the origin of coordinates to another point (h, k) *whereas the directions of axes remain unaltered.*



Let O be the origin of coordinates and OX, OY be the original coordinate axes. Let O' be the new origin and (h, k) its coordinates referred to the original axes. Draw two lines $O'X'$ and $O'Y'$ through O' and parallel to OX and OY respectively. Let $P(x, y)$ be any point referred to the original axes OX, OY. Again suppose that the coordinates of the same point P referred to the new axes $O'X', O'Y'$ are (X, Y).

From O' draw $O'L$ perpendicular to OX. from P draw PM perpendicular to OX to meet $O'X'$ in N. Then

$$OL=h, O'L=k, OM=x, PM=y, O'N=X$$

and $\quad PN=Y$

we have $\quad x=OM=OL+LM=OL+O'N=h+X$

i.e. $\quad \boldsymbol{x=X+h}$ ...(i)

and $\quad y=PM=PN+NM=PN+O'L=Y+k$

i.e. $\quad \boldsymbol{y=Y+k}$ ...(ii)

from Eqs. (i) and (ii),

$$\boldsymbol{X=x-h} \quad \text{and} \quad \boldsymbol{Y=y-k}$$

Thus, if origin is shifted to point (h, k) without rotation of axes, then new equation of curve can be obtained by putting $x+h$ in place of x and $y+k$ in place of y.

Remarks

1. In this case axes are shifted parallel to themselves, then it is also called **Transformation by parallel axes.**
2. **Inverse translation or shifting the origin back :** Some times it is required to shift the new origin back. Then putting $x-h$ in place of x and $y-k$ in place of y in any equation of curve referred to the new origin to get the corresponding equation referred to the old origin.
3. The above transformation is true whether the axes be rectangular or oblique.

Example 69. Find the equation of the curve $2x^2+y^2-3x+5y-8=0$ when the origin is transferred to the point $(-1, 2)$ without changing the direction of axes.

Sol. Here, we want to shift the origin to the point $(-1, 2)$ without changing the direction of axes. Then we replace x by $x-1$ and y by $y+2$ in the equation of given curve, then the transformed equation is

$$2(x-1)^2+(y+2)^2-3(x-1)+5(y+2)-8=0$$

$$\Rightarrow \quad 2x^2+y^2-7x+9y+11=0$$

Example 70. The equation of a curve referred to the new axes, axes retaining their direction and origin is $(4, 5)$ is $x^2+y^2=36$. Find the equation referred to the original axes.

Sol. Here we want to shift the $(4, 5)$ to the origin without changing the direction of axes. Then we replace x by $x-4$ and y by $y-5$ in the equation of given curve then the required equation is

$$(x-4)^2+(y-5)^2=36$$

$$\Rightarrow \quad x^2+y^2-8x-10y+5=0$$

Example 71. Shift the origin to a suitable point so that the equation $y^2 + 4y + 8x - 2 = 0$ will not contain term in y and the constant.

Sol. Let the origin be shifted to the point (h, k) without changing the direction of axes. Then we replace x by $x + h$ and y by $y + k$ in the equation of the given curve then the transformed equation is

$$(y + k)^2 + 4(y + k) + 8(x + h) - 2 = 0$$

$$\Rightarrow \quad y^2 + (2k + 4)y + 8x + (k^2 + 4k + 8h - 2) = 0$$

Since, this equation is required to be free from the term containing y and the constant, we have

$$2k + 4 = 0 \quad \text{and} \quad k^2 + 4k + 8h - 2 = 0$$

$$\therefore \quad k = -2 \quad \text{and} \quad h = \frac{3}{4}$$

Hence, the point to which the origin be shifted is $\left(\frac{3}{4}, -2\right)$.

Example 72. At what point the origin be shifted, if the coordinates of a point $(-1, 8)$ become $(-7, 3)$?

Sol. Let the origin be shifted to the point (h, k) without changing the direction of axes. Then we replace x by $x + h$ and y by $y + k$ and we get new co-ordinates. Here, given old coordinates and new coordinates are $(-1, 8)$ and $(-7, 3)$ respectively.

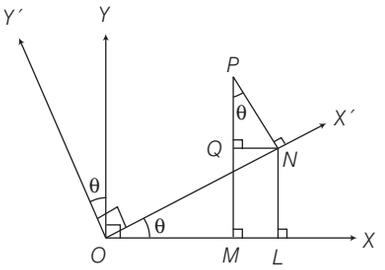
We have $\quad -1 + h = -7 \quad$ and $\quad 8 + k = 3$

$$\Rightarrow \quad h = -6 \quad \text{and} \quad k = -5$$

Hence, the origin must be shifted to $(-6, -5)$.

(ii) Rotation of Axes (Change of Directions of Axes)

To find the change in the coordinates of a point when the directions of axes are rotated through an angle θ the origin being fixed.



Let OX and OY be the original system of coordinate axes. Let OX' and OY' be the new axes obtained by rotating the original axes through an angle θ. Let P be a point in the plane whose coordinates are (x, y) and (X, Y) referred to old and new axes respectively. Draw PM and PN perpendiculars to OX and OX' and also NL and NQ perpendiculars to OX and PM. We have

$$OM = x, PM = y, ON = X, PN = Y$$

Now, $\quad x = OM = OL - ML$

$$\left(\because \text{Angle between any two lines = Angle between their perpendiculars i.e. } \angle XOX' = \angle NPM = \theta\right)$$

$$= OL - QN = ON\cos\theta - PN\sin\theta$$

$$= X\cos\theta - Y\sin\theta$$

i.e. $\quad \boldsymbol{x = X\cos\theta - Y\sin\theta}$ ...(i)

and $\quad y = PM = PQ + QM = PQ + NL$

$$= PN\cos\theta + ON\sin\theta$$

$$= Y\cos\theta + X\sin\theta$$

i.e. $\quad \boldsymbol{y = X\sin\theta + Y\cos\theta}$ ...(ii)

Now, multiplying Eqs. (i) by $\cos\theta$ and Eq. (ii) by $\sin\theta$ and adding we get

$$\boldsymbol{X = x\cos\theta + y\sin\theta} \quad \text{...(iii)}$$

Also, subtracting the product of Eq. (i) by $\sin\theta$ from the product of Eq. (ii) by $\cos\theta$, we get

$$\boldsymbol{Y = -x\sin\theta + y\cos\theta} \quad \text{...(iv)}$$

also $x^2 + y^2 = X^2 + Y^2 = OP^2$ are unchanged i.e. the distance of the point P from the origin O remains unaffected by the rotation of axes.

Rule : When the axes are rotated through θ, replace (x, y) by $(x\cos\theta - y\sin\theta, x\sin\theta + y\cos\theta)$.

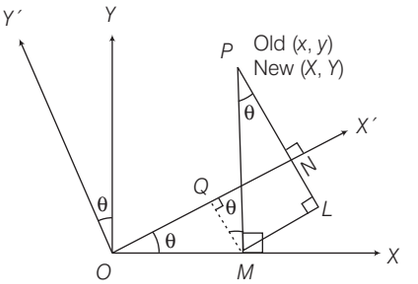
Shifting the coordinate axes back : Some times it is required to shift the new coordinates axes back. Then replace (x, y) by

$$(x\cos\theta + y\sin\theta, -x\sin\theta + y\cos\theta).$$

Independent Proof (Aliter)

The relations $X = x\cos\theta + y\sin\theta$ and $Y = -x\sin\theta + y\cos\theta$ can be obtained independently.

Proof : Draw PM and PN perpendiculars to OX and OX' and also ML and MQ perpendiculars to PN and OX' respectively.



We have, $\quad OM = x, PM = y, ON = X$

and $\quad PN = Y$

Also, angle between any two lines

= Angle between their perpendiculars lines

i.e. $\angle XOX' = \angle MPN = \angle PMQ = \theta$

$\therefore$ $X = ON = OQ + QN$

$= OQ + ML$

$= OM\cos\theta + PM\sin\theta$

$(\because OQ = OM\cos\theta$ and $ML = PM\sin\theta)$

$= x\cos\theta + y\sin\theta$

i.e. $\boldsymbol{X = x\cos\theta + y\sin\theta}$

and $Y = PN = PL - NL = PL - QM$

$= PM\cos\theta - OM\sin\theta$

$(\because PL = PM\cos\theta$ and $QM = OM\sin\theta)$

$= y\cos\theta - x\sin\theta$

i.e. $\boldsymbol{Y = -x\sin\theta + y\cos\theta}$

Remark :

The results Eqs. (i), (ii), (iii) and (iv) can be conveniently remembered by the following methods.

(i) Light heavy method : Let x, y be light and X, Y be heavy then heavy X, Y down and x, y up then

	x	y
X	$\cos\theta$	$\sin\theta$
Y	$-\sin\theta$	$\cos\theta$

third row is obtained by differentiating second row with respect to θ.

For remembrance C S (Civil Services)

$\downarrow$ $\downarrow$

$\cos\theta$ $\sin\theta$ $\left(\text{i.e. } \begin{matrix} C \to \cos\theta \\ S \to \sin\theta \end{matrix}\right)$

$\downarrow$ $\downarrow$

$-\sin\theta$ $\cos\theta$ $\left(\begin{matrix} (\cos\theta)' = -\sin\theta \\ (\sin\theta)' = \cos\theta \end{matrix}\right)$

(a) Finding x and y in terms of X and Y

x = Sum of the products of the elements in the left most column with the corresponding elements of the first column

i.e. $x = X\cos\theta - Y\sin\theta$

and y = Sum of the products of the elements in the left most column with the corresponding elements of the second column.

i.e. $y = X\sin\theta + Y\cos\theta$

Hence, $\left.\begin{matrix} x = X\cos\theta - Y\sin\theta \\ y = X\sin\theta + Y\cos\theta \end{matrix}\right\}$

(b) Finding X and Y in terms of x and y

X = Sum of the products of the elements of top-row with the corresponding elements of first row.

i.e. $X = x\cos\theta + y\sin\theta$

and Y = Sum of the products of the elements of top-row with the corresponding elements of second row.

i.e. $Y = -x\sin\theta + y\cos\theta$

Hence, $\left.\begin{matrix} X = x\cos\theta + y\sin\theta \\ Y = -x\sin\theta + y\cos\theta \end{matrix}\right\}$

(ii) Matrix method :

$$\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = A\begin{bmatrix} x \\ y \end{bmatrix} \text{ (say)}$$

and $$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} X \\ Y \end{bmatrix} = A'\begin{bmatrix} X \\ Y \end{bmatrix}$$

where, A' is the transpose matrix of A.

(iii) Complex number method :

Let $z = x + iy$

and $Z = X + iY$, where $i = \sqrt{-1}$

then $z = Ze^{i\theta}$ ...(i)

i.e. $(x + iy) = (X + iY)(\cos\theta + i\sin\theta)$

On comparing real and imaginary parts, we get

$\left.\begin{matrix} x = X\cos\theta - Y\sin\theta \\ y = X\sin\theta + Y\cos\theta \end{matrix}\right\}$

Again from Eq. (i), $Z = ze^{-i\theta}$

i.e. $(X + iY) = (x + iy)(\cos\theta - i\sin\theta)$

On comparing real and imaginary parts, we get

$\left.\begin{matrix} X = x\cos\theta + y\sin\theta \\ Y = -x\sin\theta + y\cos\theta \end{matrix}\right\}$

Example 73. If the axes are turned through 45°, find the transformed form of the equation $3x^2 + 3y^2 + 2xy = 2$.

Sol. Here, $\theta = 45°$ so $\sin\theta = \cos\theta = \frac{1}{\sqrt{2}}$

Replacing (x, y) by $(x\cos\theta - y\sin\theta, x\sin\theta + y\cos\theta)$

i.e. $\left(\frac{x-y}{\sqrt{2}}, \frac{x+y}{\sqrt{2}}\right)$

Then, $3x^2 + 3y^2 + 2xy = 2$ becomes

$$3\left(\frac{x-y}{\sqrt{2}}\right)^2 + 3\left(\frac{x+y}{\sqrt{2}}\right)^2 + 2\left(\frac{x-y}{\sqrt{2}}\right)\left(\frac{x+y}{\sqrt{2}}\right) = 2$$

$\Rightarrow \quad 3(2x^2 + 2y^2) + 2(x^2 - y^2) = 4$

$\Rightarrow \quad 8x^2 + 4y^2 = 4$

or $\quad 2x^2 + y^2 = 1$

which is free from the term containing xy.

Example 74. Prove that if the axes be turned through $\frac{\pi}{4}$ the equation $x^2 - y^2 = a^2$ is transformed to the form $xy = \lambda$. Find the value of λ.

Sol. Here, $\theta = \frac{\pi}{4}$ so $\sin\theta = \cos\theta = \frac{1}{\sqrt{2}}$

Replacing (x, y) by $(x\cos\theta - y\sin\theta, x\sin\theta + y\cos\theta)$

i.e. $\left(\frac{x-y}{\sqrt{2}}, \frac{x+y}{\sqrt{2}}\right)$

then, $x^2 - y^2 = a^2$ becomes

$$\left(\frac{x-y}{\sqrt{2}}\right)^2 - \left(\frac{x+y}{\sqrt{2}}\right)^2 = a^2$$

$$\Rightarrow \quad \left(\frac{x-y}{\sqrt{2}} + \frac{x+y}{\sqrt{2}}\right)\left(\frac{x-y}{\sqrt{2}} - \frac{x+y}{\sqrt{2}}\right) = a^2$$

$$\Rightarrow \quad \left(\frac{2x}{\sqrt{2}}\right)\left(\frac{-2y}{\sqrt{2}}\right) = a^2$$

or $\quad xy = -\frac{a^2}{2}$

Comparing it with $xy = \lambda$, then we get $\lambda = -\frac{a^2}{2}$.

Example 75. Through what angle should the axes be rotated so that the equation $9x^2 - 2\sqrt{3}\,xy + 7y^2 = 10$ may be changed to $3x^2 + 5y^2 = 5$?

Sol. Let angle be θ then replacing (x, y) by $(x\cos\theta - y\sin\theta, x\sin\theta + y\cos\theta)$

then, $\quad 9x^2 - 2\sqrt{3}xy + 7y^2 = 10$ becomes

$$9(x\cos\theta - y\sin\theta)^2 - 2\sqrt{3}$$
$$(x\cos\theta - y\sin\theta)(x\sin\theta + y\cos\theta)$$
$$+ 7(x\sin\theta + y\cos\theta)^2 = 10$$

$$\Rightarrow \quad x^2(9\cos^2\theta - 2\sqrt{3}\sin\theta\cos\theta + 7\sin^2\theta)$$
$$+ 2xy(-9\sin\theta\cos\theta - \sqrt{3}\cos 2\theta + 7\sin\theta\cos\theta)$$
$$+ y^2(9\cos^2\theta + 2\sqrt{3}\sin\theta\cos\theta + 7\cos^2\theta) = 10$$

On comparing with $3x^2 + 5y^2 = 5$ (coefficient of xy)

we get $-9\sin\theta\cos\theta - \sqrt{3}\cos 2\theta + 7\sin\theta\cos\theta = 0$

or $\quad \sin 2\theta = -\sqrt{3}\cos 2\theta$

or $\quad \tan 2\theta = -\sqrt{3} = \tan(180^\circ - 60^\circ)$

or $\quad 2\theta = 120^\circ$

$\therefore \quad \theta = 60^\circ$

Example 76. If (x, y) and (X, Y) be the coordinates of the same point referred to two sets of rectangular axes with the same origin and if $ux + vy$, when u and v are independent of X and Y become $VX + UY$, show that $u^2 + v^2 = U^2 + V^2$

Sol. Let the axes rotate an angle θ and if (x, y) be the point with respect to old axes and (X, Y) be the co-ordinates with respect to new axes, then

$$x + iy = (X + iY)e^{i\theta} = (X + iY)(\cos\theta + i\sin\theta)$$

On comparing real and imaginary parts, we get

$$\begin{cases} x = X\cos\theta - Y\sin\theta \\ y = X\sin\theta + Y\cos\theta \end{cases}$$

Then, $ux + vy = u(X\cos\theta - Y\sin\theta) + v(X\sin\theta + Y\cos\theta)$

$$= (u\cos\theta + v\sin\theta)X + (-u\sin\theta + v\cos\theta)Y$$

but given new curve $VX + UY$

then, $VX + UY = (u\cos\theta + v\sin\theta)$
$X + (-u\sin\theta + v\cos\theta)Y$

On comparing the coefficients of X and Y, we get

$$V = u\cos\theta + v\sin\theta \quad \text{...(i)}$$

and $\quad U = -u\sin\theta + v\cos\theta \quad \text{...(ii)}$

Squaring and adding Eqs. (i) and (ii), we get

$$V^2 + U^2 = (u\cos\theta + v\sin\theta)^2 + (-u\sin\theta + v\cos\theta)^2$$
$$= u^2 + v^2$$

Hence, $\quad u^2 + v^2 = U^2 + V^2$

Aliter 1 (By matrix method) :

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} X \\ Y \end{bmatrix} = \begin{bmatrix} X\cos\theta - Y\sin\theta \\ X\sin\theta + Y\cos\theta \end{bmatrix} \quad \text{...(i)}$$

$\because \quad ux + vy = [u \quad v]\begin{bmatrix} x \\ y \end{bmatrix} = [u\ v]\begin{bmatrix} X\cos\theta + Y\sin\theta \\ X\sin\theta + Y\cos\theta \end{bmatrix}$

[from (i)]

$$= uX\cos\theta - uY\sin\theta + vX\sin\theta + vY\cos\theta$$
$$= X(u\cos\theta + v\sin\theta) + Y(-u\sin\theta + v\cos\theta)$$

but given new curve $VX + UY$

Then, $VX + UY = X(u\cos\theta + v\sin\theta) + Y$
$(-u\sin\theta + v\cos\theta)$

On comparing the coefficients of X and Y, we get

$$V = u\cos\theta + v\sin\theta \quad \text{...(ii)}$$

$$U = -u\sin\theta + v\cos\theta \quad \text{...(iii)}$$

Squaring and adding Eqs. (ii) and (iii), we get

$$u^2 + v^2 = U^2 + V^2$$

Aliter 2 (Best approach) :

$$ux + vy = R_e((u - iv)(x + iy))$$
$$= R_e((u - iv)(X + iY)e^{i\theta}) \quad \text{...(i)}$$

and $\quad VX + UY = R_e((V - iU)(X + iY)) \quad \text{...(ii)}$

From Eqs. (i) and (ii), we get

$$V - iU = (u - iv)e^{i\theta}$$

Taking modulus both sides, then

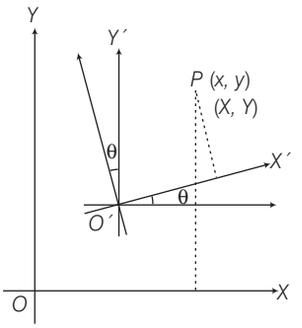
$$|V - iU| = |u - iv||e^{i\theta}|$$

$$\Rightarrow \quad \sqrt{(V^2 + U^2)} = \sqrt{u^2 + v^2} \cdot 1$$

or $$u^2 + v^2 = U^2 + V^2$$

(iii) Double Transformation (Origin Shifted and Axes Rotated)

If origin is shifted to the point. $O'(h, k)$ and at the same time the directions of axes are rotated through an angle θ in the anticlockwise sense such that new coordinates of $P(x, y)$ become (X, Y).



Then, we get $x = h + X\cos\theta - Y\sin\theta$ ...(i)

and $y = k + X\sin\theta + Y\cos\theta$ ...(ii)

In practice we have to replace x by $h + x\cos\theta - y\sin\theta$ and y by $k + x\sin\theta + y\cos\theta$.

Again, if we want to shift the coordinate axes back to their original positions, then we obtained X and Y by solving Eqs. (i) and (ii), then

$$X = (x - h)\cos\theta + (y - k)\sin\theta$$

and $$Y = -(x - h)\sin\theta + (y - k)\cos\theta$$

Example 77. What does the equation $2x^2 + 4xy - 5y^2 + 20x - 22y - 14 = 0$ becomes when referred to rectangular axes through the point $(-2, -3)$, the new axes being inclined at an angle of 45° *with the old ?*

Sol. Let $O'(-2, -3)$ be the new origin and axes are rotated about O' through an angle $45°$ in anticlockwise direction then replacing x and y by

$$-2 + x\cos 45° - y\sin 45°$$

and $$-3 + x\sin 45° + y\cos 45°$$

i.e. $-2 + \left(\frac{x - y}{\sqrt{2}}\right)$ and $-3 + \left(\frac{x + y}{\sqrt{2}}\right)$ respectively in the given curve, then the new equation of curve will be

$$2\left\{-2 + \left(\frac{x - y}{\sqrt{2}}\right)\right\}^2 + 4\left\{-2 + \left(\frac{x - y}{\sqrt{2}}\right)\right\}\left\{-3 + \left(\frac{x + y}{\sqrt{2}}\right)\right\}$$

$$-5\left\{-3 + \left(\frac{x + y}{\sqrt{2}}\right)\right\}^2 + 20\left\{-2 + \left(\frac{x - y}{\sqrt{2}}\right)\right\}$$

$$-22\left\{-3 + \left(\frac{x + y}{\sqrt{2}}\right)\right\} - 14 = 0$$

$$\Rightarrow \quad x^2 - 14xy - 7y^2 - 2 = 0$$

Removal of the Term xy from $f(x, y) = ax^2 + 2hxy + by^2$ without Changing the Origin

Clearly, $h \neq 0$

Rotating the axes through an angle θ, we have

$$x = X\cos\theta - Y\sin\theta$$

and $$y = X\sin\theta + Y\cos\theta$$

$\because$ $$f(x, y) = ax^2 + 2hxy + by^2$$

After rotation, new equation is

$$F(X, Y) = (a\cos^2\theta + 2h\cos\theta\sin\theta + b\sin^2\theta)X^2$$

$$+ 2\{(b - a)\cos\theta\sin\theta + h(\cos^2\theta - \sin^2\theta)\}XY$$

$$+ (a\sin^2\theta - 2h\cos\theta\sin\theta + b\cos^2\theta)Y^2$$

Now, coefficient of $XY = 0$

Then, we get $\cot 2\theta = \frac{a - b}{2h}$

Remark

Usually, we use the formula, $\tan 2\theta = \frac{2h}{a - b}$ for finding the angle of rotation, θ.

However, if $a = b$, we use $\cot 2\theta = \frac{a - b}{2h}$ as in this case $\tan 2\theta$ is not defined.

Example 78. Given the equation $4x^2 + 2\sqrt{3}xy + 2y^2 = 1$, through what angle should the axes be rotated so that the term in xy be wanting from the transformed equation.

Sol. Comparing the given equation with $ax^2 + 2hxy + by^2$, we get $a = 4$, $h = \sqrt{3}$ $b = 2$. If axes are to be rotated at θ, then

$$\tan 2\theta = \frac{2h}{a - b} = \frac{2\sqrt{3}}{2} = \sqrt{3} = \tan\frac{\pi}{3}$$

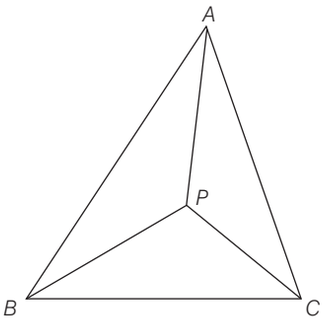
$$2\theta = \frac{\pi}{3}, \pi + \frac{\pi}{3} \Rightarrow 2\theta = \frac{\pi}{3}, \frac{4\pi}{3}$$

$\therefore$ $$\theta = \frac{\pi}{6}, \frac{2\pi}{3}$$

Position of a Point which Lies Inside a Triangle

If any point say (P) lies within the triangle ABC,

then $\Delta_1 + \Delta_2 + \Delta_3 = \Delta$



where, $\Delta =$ Area of triangle ABC,

$\Delta_1 =$ Area of ΔPBC,

$\Delta_2 =$ Area of ΔPCA,

$\Delta_3 =$ Area of ΔPAB

Also, $\Delta_1 \neq 0, \Delta_2 \neq 0, \Delta_3 \neq 0, \Delta \neq 0$

(Each individual area must be non-zero)

Example 79. Find λ if $(\lambda, \lambda+1)$ is an interior point of ΔABC where, $A \equiv (0,3); B \equiv (-2,0)$ and $C \equiv (6,1)$.

Sol. The point $P(\lambda, \lambda+1)$ will be inside the triangle ABC, then

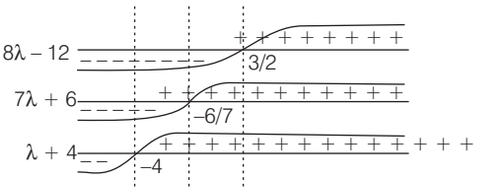
Area of ΔPBC + Area of ΔPCA + Area of ΔPAB = Area of ΔABC

$$\Rightarrow \frac{1}{2}\left|\begin{vmatrix} \lambda & \lambda+1 & 1 \\ -2 & 0 & 1 \\ 6 & 1 & 1 \end{vmatrix}\right| + \frac{1}{2}\left|\begin{vmatrix} \lambda & \lambda+1 & 1 \\ 6 & 1 & 1 \\ 0 & 3 & 1 \end{vmatrix}\right| + \frac{1}{2}\left|\begin{vmatrix} \lambda & \lambda+1 & 1 \\ 0 & 3 & 1 \\ -2 & 0 & 1 \end{vmatrix}\right|$$

$$= \frac{1}{2}\left|\begin{vmatrix} 0 & 3 & 1 \\ -2 & 0 & 1 \\ 6 & 1 & 1 \end{vmatrix}\right|$$

$$\Rightarrow \quad |7\lambda + 6| + |8\lambda - 12| + |\lambda + 4| = 22$$

For $\lambda < -4$:



Then, $-(7\lambda + 6) - (8\lambda - 12) - (\lambda + 4) = 22$

$\Rightarrow \quad -16\lambda = 20 \quad \therefore \quad \lambda = -\frac{5}{4}$

which is impossible.

For $-4 \leq \lambda < -\frac{6}{7}$:

Then, $-(7\lambda + 6) - (8\lambda - 12) + (\lambda + 4) = 22$

$\Rightarrow \quad -14\lambda = 12 \quad \therefore \quad = -\frac{6}{7}$

which is impossible.

For $-\frac{6}{7} \leq \lambda < \frac{3}{2}$:

Then, $(7\lambda + 6) - (8\lambda - 12) + \lambda + 4 = 22 \Rightarrow 22 = 22$

$\because$ at $\lambda = -\frac{6}{7}$, area of $\Delta PBC = 0$

$\therefore \quad \lambda \neq \frac{-6}{7}$

$\therefore \quad \lambda \in \left(-\frac{6}{7}, \frac{3}{2}\right)$

For $\lambda \geq \frac{3}{2}$:

Then, $7\lambda + 6 + 8\lambda - 12 + \lambda + 4 = 22 \Rightarrow 16\lambda = 24$

$\therefore \quad \lambda = \frac{3}{2}$

$\because$ at $\lambda = \frac{3}{2}$, area of $\Delta PCA = 0$

$\therefore \quad \lambda \neq \frac{3}{2}$

Hence, value of $\lambda \in \left(-\frac{6}{7}, \frac{3}{2}\right)$.

Exercise for Session 4

1. The equation of the locus of points equidistant from $(-1,-1)$ and $(4,2)$ is

(a) $3x-5y-7=0$ (b) $5x+3y-9=0$ (c) $4x+3y+2=0$ (d) $x-3y+5=0$

2. The equation of the locus of a point which moves so that its distance from the point $(ak,0)$ is k times its distance from the point $\left(\frac{a}{k},0\right)$, $(k\neq 1)$ is

(a) $x^2-y^2=a^2$ (b) $2x^2-y^2=2a^2$ (c) $xy=a^2$ (d) $x^2+y^2=a^2$

3. If the coordinates of a variable point P be $\left(t+\frac{1}{t},t-\frac{1}{t}\right)$, where t is the variable quantity, then the locus of P is

(a) $xy=8$ (b) $2x^2-y^2=8$ (c) $x^2-y^2=4$ (d) $2x^2+3y^2=5$

4. If the coordinates of a variable point P be $(\cos\theta+\sin\theta,\sin\theta-\cos\theta)$, where θ is the parameter, then the locus of P is

(a) $x^2-y^2=4$ (b) $x^2+y^2=2$ (c) $xy=3$ (d) $x^2+2y^2=3$

5. If a point moves such that twice its distance from the axis of x exceeds its distance from the axis of y by 2, then its locus is

(a) $x-2y=2$ (b) $x+2y=2$ (c) $2y-x=2$ (d) $2y-3x=5$

6. The equation $4xy-3x^2=a^2$ become when the axes are turned through an angle $\tan^{-1}2$ is

(a) $x^2+4y^2=a^2$ (b) $x^2-4y^2=a^2$ (c) $4x^2+y^2=a^2$ (d) $4x^2-y^2=a^2$

7. Transform the equation $x^2-3xy+11x-12y+36=0$ to parallel axes through the point $(-4,1)$ becomes $ax^2+bxy+1=0$ then $b^2-a=$

(a) $\frac{1}{4}$ (b) $\frac{1}{16}$ (c) $\frac{1}{64}$ (d) $\frac{1}{256}$

8. Find the equation of the locus of all points equidistant from the point $(2,4)$ and the Y-axis.

9. Find the equation of the locus of the points twice as far from $(-a,0)$ as from $(a,0)$.

10. OA and OB are two perpendicular straight lines. A straight line AB is drawn in such a manner that $OA+OB=8$. Find the locus of the mid point of AB.

11. The ends of a rod of length l move on two mutually perpendicular lines. Find the locus of the point on the rod which divides it in the ratio 1 : 2.

12. The coordinates of three points O, A, B are $(0,0)$, $(0,4)$ and $(6,0)$ respectively. A point P moves so that the area of ΔPOA is always twice the area of ΔPOB. Find the equation to both parts of the locus of P.

13. What does the equation $(a-b)(x^2+y^2)-2abx=0$ become, if the origin be moved to the point $\left(\frac{ab}{a-b},0\right)$?

14. The equation $x^2+2xy+4=0$ is transformed to the parallel axes through the point $(6,\lambda)$. For what value of λ its new form passes through the new origin ?

15. Show that if the axes be turned through $7\frac{1}{2}^\circ$; the equation $\sqrt{3}x^2+(\sqrt{3}-1)xy-y^2=0$ become free of xy in its new form.

16. Find the angle through which the axes may be turned so that the equation $Ax+By+C=0$ may reduce to the form $x=$ constant, and determine the value of this constant.

17. Transform $12x^2+7xy-12y^2-17x-31y-7=0$ to rectangular axes through the point $(1,-1)$ inclined at an angle $\tan^{-1}\left(\frac{4}{3}\right)$ to the original axes.

Shortcuts and Important Results to Remember

1 If D, E, F are the mid-points of the sides BC, CA, AB of ΔABC, the
$A = E + F - D$
$B = F + D - E$
and $C = D + E - F$

2 Orthocentre, nine point centre, centroid, circumcentre of a triangle are collinear. Centroid divides the line joining orthocentre and circumcentre in the ration 2 :1 (Internally) and nine point centre is the mid-point of orthocentre and circumcentre.

3 The circumcentre of a right angled triangle is the mid-point of the hypotenuse.

4 In an equilateral triangle orthocentre, nine point centre, centroid, circumcentre, incentre coincide.

5 The distance between the orthocentre and circumcentre in an equilateral triangle is zero.

6 The orthocentre of a triangle having vertices (α, β), (β, α) and (α, α) is (α, α).

7 Orthocentre of the triangle formed by the points $\left(\alpha, \frac{1}{\alpha}\right); \left(\beta, \frac{1}{\beta}\right); \left(\gamma, \frac{1}{\gamma}\right)$ is $\left(-\frac{1}{\alpha\beta\gamma}, -\alpha\beta\gamma\right)$

i.e. all points and orthocentre lie on $xy = 1$.

8 **Points in a triangle :** Centroid (G), Incentre (I), Excentres (I_1, I_2, I_3), Orthocentre (O), Circumcentre (C) are given by $\left(\frac{m_1x_1 + m_2x_2 + m_3x_3}{m_1 + m_2 + m_3}, \frac{m_1y_1 + m_2y_2 + m_3y_3}{m_1 + m_2 + m_3}\right)$, where

	m_1	m_2	m_3
G	1	1	1
I	$\sin A$	$\sin B$	$\sin C$
I_1	$-\sin A$	$\sin B$	$\sin C$
I_2	$\sin A$	$-\sin B$	$\sin C$
I_3	$\sin A$	$\sin B$	$-\sin C$
O	$\tan A$	$\tan B$	$\tan C$
C	$\sin 2A$	$\sin 2B$	$\sin 2B$

and vertices

$A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$, $C \equiv (x_3, y_3)$ and A, B, C are the angles of ΔABC.

9 If the circumcentre and centroid of a triangle are respectively (α, β), (γ, δ), then orthocentre will be $(3\gamma - 2\alpha, 3\delta - 2\beta)$.

10 If $ABCD$ is a parallelogram, then $D = A - B + C$.

11 If D, E, F are the mid-points of the sides BC, CA, AB of ΔABC, then the centroid of ΔABC = centroid of ΔDEF. If area of $\Delta ABC = \Delta$, then area of ΔAFE = area of ΔBDF = area of ΔCED = area of $\Delta DEF = \frac{\Delta}{4}$ and area of parallelogram $CEFD$ = area of parallelogram $BDEF$ = area of parallelogram $AEDF = \frac{\Delta}{2}$

12 Orthocentre of the right angle triangled ABC, right angled at A is A.

13 Circumcentre of the right angled triangle ABC, right angled at A is $\frac{B + C}{2}$.

14 X-axis divides the line segment joining (x_1, y_1), (x_2, y_2) in the ratio $-y_1 : y_2$ and Y-axis divides the same line segment in the ratio $-x_1 : x_2$.

15 Area of the triangle formed by $(x_1, y_{1)}, (x_2\ y_2), (x_3, y_3)$ is $\frac{1}{2}\left|\begin{vmatrix} x_1 - x_3 & x_2 - x_3 \\ y_1 - y_3 & y_2 - y_3 \end{vmatrix}\right|$.

16 The area of the triangle formed by $y = m_1x + c_1$, $y = m_2x + c_2$, $y = m_3\ x + c_3$ is $\frac{1}{2} \Sigma \frac{(c_1 - c_2)^2}{|m_1 - m_2|}$.

17 Area of the quadrilateral formed by $(x_1, y_1)(x_2, y_{2)}\ (x_3, y_3), (x_4, y_4)$ is
$$\frac{1}{2}\left|\begin{vmatrix} x_1 - x_3 & x_2 - x_4 \\ y_1 - y_3 & y_2 - y_4 \end{vmatrix}\right|$$

18 If $(x_1, y_1), (x_2, y_2)$ are the ends of the hypotenuse of a right angled isosceles triangle, then the third vertex is given by $\left(\frac{x_1 + x_2 \pm (y_1 - y_2)}{2}, \frac{y_1 + y_2 \mp (x_1 - x_2)}{2}\right)$

19 Given the two vertices (x_1, y_1) and (x_2, y_2) of an equilateral triangle, then its third vertex is given by $\left(\frac{x_1 + x_2 \pm \sqrt{3}(y_1 - y_2)}{2}, \frac{y_1 + y_2 \mp \sqrt{3}(x_1 - x_2)}{2}\right)$

20 Circumcentre of the triangle formed by the points $(x_1, y_1), (x_{2,}\ y_2)$ and (x_3, y_3) is same as that of triangle formed by the points $(0, 0)$, $(x_2 - x_1, y_2 - y_1), (x_3 - x_1, y_3 - y_1)$.

JEE Type Solved Examples :
Single Option Correct Type Questions

This section contains **5 multiple choice examples**. Each example has four choice (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

● ***Ex. 1.*** *Locus of centroid of the triangle whose vertices are* $(a\cos t, a\sin t), (b\sin t, -b\cos t)$ *and* $(1, 0)$*, where* t *is a parameter, is*

(a) $(3x-1)^2 + (3y)^2 = a^2 - b^2$

(b) $(3x-1)^2 + (3y)^2 = a^2 + b^2$

(c) $(3x+1)^2 + (3y)^2 = a^2 + b^2$

(d) $(3x+1)^2 + 3y^2 = a^2 - b^2$

Sol. (b) Let $A \equiv (a\cos t, a\sin t)$, $B \equiv (b\sin t, -b\cos t)$ and $C \equiv (1, 0)$

$$\therefore \text{Centroid} \equiv \left(\frac{a\cos t + b\sin t + 1}{3}, \frac{a\sin t - b\cos t}{3}\right)$$

Let $$x = \frac{a\cos t + b\sin t + 1}{3} \Rightarrow 3x - 1 = a\cos t + b\sin t \quad \ldots(i)$$

and $$y = \frac{a\sin t - b\cos t}{3} \Rightarrow 3y = a\sin t - b\cos t \quad \ldots(ii)$$

On squaring and adding Eqs. (i) and (ii), we get

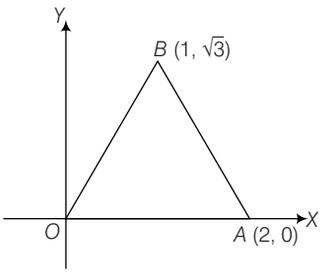
$$(3x-1)^2 + (3y)^2 = a^2 + b^2$$

which is locus of centroid.

● ***Ex. 2.*** *The incentre of triangle with vertices* $(1, \sqrt{3}), (0, 0)$ *and* $(2, 0)$ *is*

(a) $\left(1, \frac{\sqrt{3}}{2}\right)$ (b) $\left(\frac{2}{3}, \frac{1}{\sqrt{3}}\right)$ (c) $\left(\frac{2}{3}, \frac{\sqrt{3}}{2}\right)$ (d) $\left(1, \frac{1}{\sqrt{3}}\right)$

Sol. (d)



Let $O \equiv (0, 0)$, $A \equiv (2, 0)$

and $B \equiv (1, \sqrt{3})$

$\because$ $OA = 2 = OB = AB$

$\Rightarrow \Delta OAB$ is an equilateral.

$\therefore$ Incentre = Centroid

$$\equiv \left(\frac{0+2+1}{3}, \frac{0+0+\sqrt{3}}{3}\right)$$

$$\therefore \text{Incentre} \equiv \left(1, \frac{1}{\sqrt{3}}\right)$$

● ***Ex. 3.*** *Orthocentre of triangle with vertices* $(0, 0)$*, (3, 4) and (4, 0) is*

(a) $\left(3, \frac{5}{4}\right)$ (b) (3, 12)

(c) $\left(3, \frac{3}{4}\right)$ (d) (3, 9)

Sol. (c) Denote the points are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) from the matrix

$$P = \begin{bmatrix} x_1 - x_3 & y_1 - y_3 \\ x_2 - x_3 & y_2 - y_3 \end{bmatrix}$$

$$= \begin{bmatrix} -4 & 0 \\ -1 & 4 \end{bmatrix}$$

$$\therefore \quad \lambda = \frac{\vec{\mathbf{R}}_1 \cdot \vec{\mathbf{R}}_2}{|P|}$$

$$= \frac{(-4)(-1) + 0}{-16} = -\frac{1}{4}$$

$\therefore$ Circumcentre of the triangle

$$\equiv \left(\frac{x_1 + x_2 + \lambda(y_1 - y_2)}{2}, \frac{y_1 + y_2 - \lambda(x_1 - x_2)}{2}\right)$$

$$\equiv \left(\frac{3 - 4\lambda}{2}, \frac{4 + 3\lambda}{2}\right) \equiv \left(2, \frac{13}{8}\right)$$

i.e. $$C \equiv \left(2, \frac{13}{8}\right)$$

and centroid $G \equiv \left(\frac{7}{3}, \frac{4}{3}\right)$

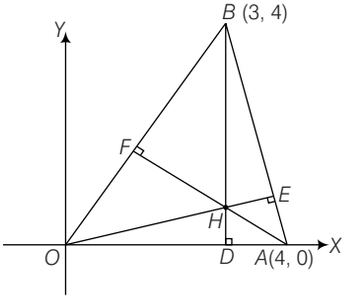
$\therefore$ Orthocentre

$$H \equiv \left(3 \times \frac{7}{3} - 2 \times 2, 3 \times \frac{4}{3} - 2 \times \frac{13}{8}\right)$$

$$\equiv \left(3, \frac{3}{4}\right)$$

Aliter : Let orthocentre

$$H \equiv (\alpha, \beta)$$



$\therefore$ Slope of $BH \times$ slope of $OA = -1$

$$\Rightarrow \quad \left(\frac{\beta - 4}{\alpha - 3}\right) \times \left(\frac{0}{4}\right) = -1$$

$\therefore \quad \alpha - 3 = 0$

$\Rightarrow \quad \alpha = 3$ ...(i)

and slope of $AH \times$ slope of $OB = -1$

$\Rightarrow \quad \left(\frac{\beta - 0}{\alpha - 4}\right) \times \left(\frac{4}{3}\right) = -1$

From Eq. (i), $\beta = \frac{3}{4}$

Hence, orthocentre is $\left(3, \frac{3}{4}\right)$.

● ***Ex. 4.*** *If x_1, x_2, x_3 as well as y_1, y_2, y_3 are in GP, with the same common ratio, then the points $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3)*

(a) lie on a straight line

(b) lie on an ellipse

(c) lie on a circle

(d) are vertices of a triangle

Sol. (a) Let common ratio of GP is r, then $x_2 = x_1 r$, $x_3 = x_1 r^2$, $y_2 = y_1 r$ and $y_3 = y_1 r^2$.

Let $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$

$\therefore$ Area of $\Delta ABC = \frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}\right|$

$= \frac{1}{2}\left|\begin{vmatrix} x_1 & y_1 & 1 \\ x_1 r & y_1 r & 1 \\ x_1 r^2 & y_1 r^2 & 1 \end{vmatrix}\right|$

$= \frac{1}{2}|x_1 y_1|\left|\begin{vmatrix} 1 & 1 & 1 \\ r & r & 1 \\ r^2 & r^2 & 1 \end{vmatrix}\right| = 0$ ($\because C_1$ and C_2 are identical)

$\Rightarrow$ Points A, B, C are collinear.

● ***Ex. 5.*** *Let A be the image of $(2, -1)$ with respect to Y-axis. Without transforming the origin, coordinate axis are turned at an angle 45° in the clockwise direction. Then, the coordiates of A in the new system are*

(a) $\left(-\frac{1}{\sqrt{2}}, -\frac{3}{\sqrt{2}}\right)$ (b) $\left(-\frac{3}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$

(c) $\left(\frac{1}{\sqrt{2}}, \frac{3}{\sqrt{2}}\right)$ (d) $\left(\frac{3}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$

Sol. (a) Since, the image of (h, k) w.r.t. Y-axis is $(-h, k)$.

$\therefore$ Coordinate of A are $(-2, -1)$.

If (X, Y) are the coordinates of A w.r.t. the new coordinate axes obtained by turning the axes through an angle 45° in the clockwise direction, then

$$X = -2\cos(-45°) - \sin(-45°) = -\frac{2}{\sqrt{2}} + \frac{1}{\sqrt{2}} = -\frac{1}{\sqrt{2}}$$

and $$Y = 2\sin(-45°) - \cos(-45°) = -\frac{2}{\sqrt{2}} - \frac{1}{\sqrt{2}} = -\frac{3}{\sqrt{2}}$$

$\therefore$ Required coordinates are $\left(-\frac{1}{\sqrt{2}}, -\frac{3}{\sqrt{2}}\right)$.

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **3 multiple choice examples**. Each example has four choices (a), (b), (c) and (d). Out of which **MORE THAN ONE** may be correct.

● ***Ex. 6.*** *Let $S_1, S_2, \ldots$, be squares such that for each $n \geq 1$, the length of a side of S_n equals the length of a diagonal of S_{n+1}. If the length of a side S_1 is 10 cm, then for which of the following value of n is the area of S_n less than 1 sq cm?*

(a) 7 (b) 8 (c) 9 (d) 10

Sol. (b,c,d)

If a be the side of the square, then diagonal $d = a\sqrt{2}$ by hypothesis

$$a_n = \sqrt{2}\, a_{n+1}$$

$\Rightarrow \quad a_{n+1} = \frac{a_n}{\sqrt{2}} = \frac{a_{n-1}}{(\sqrt{2})^2} = \frac{a_{n-2}}{(\sqrt{2})^3} = \ldots = \frac{a_1}{(\sqrt{2})^n}$

$\Rightarrow \quad a_n = \frac{a_1}{(\sqrt{2})^{n-1}} = \frac{10}{(2)^{(n-1)/2}}$

$\because$ Area of $S_n < 1 \Rightarrow a_n^2 < 1$

$\Rightarrow \quad \frac{100}{2^{n-1}} < 1$

$\Rightarrow \quad 2^{n-1} > 100 > 2^6$

$\Rightarrow \quad n - 1 > 6$

$\Rightarrow \quad n > 7$

$\therefore \quad n = 8, 9, 10, \ldots$

● ***Ex 7.*** *If each of the vertices of a triangle has integral coordinates, then the triangles may be*

(a) right angled (b) equilateral

(c) isosceles (d) scalene

Sol. (a,c,d) Let $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ be the vertices of triangle ABC. Given $x_1, y_1, x_2, y_2, x_3, y_3$ be all integers.

Now, area of $\Delta ABC = \frac{1}{2}|x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)|$

$=$ Rational ...(i)

If ΔABC is equilateral then,

$$\text{Area of } \Delta ABC = \frac{\sqrt{3}}{4}(\text{side})^2$$

$$= \frac{\sqrt{3}}{4}\{(x_1 - x_2)^2 + (y_1 - y_2)^2\}$$

$$= \text{Irrational} \quad \ldots(\text{ii})$$

It is clear from Eqs. (i) and (ii), ΔABC can not be equilateral.

● ***Ex. 8.*** *ABC is an isosceles triangle. If the coordinates of the base are $B(1, 3)$ and $C(-2, 7)$. The coordinates of vertex A can be*

(a) (1, 6) (b) $\left(-\frac{1}{2}, 5\right)$ (c) $\left(\frac{5}{6}, 6\right)$ (d) $\left(-7, \frac{1}{8}\right)$

Sol. (b,c,d) Let vertex of the ΔABC be $A(x, y)$

$$\therefore \quad AB = AC$$

$$\Rightarrow \quad (AB)^2 = (AC)^2$$

$$\Rightarrow \quad (x-1)^2 + (y-3)^2 = (x+2)^2 + (y-7)^2$$

$$\Rightarrow \quad 6x - 8y + 43 = 0 \quad \ldots(\text{i})$$

Here, use observe that the coordinates $\left(-\frac{1}{2}, 5\right)$, $\left(\frac{5}{6}, 6\right)$ and $\left(-7, \frac{1}{8}\right)$ satisfy the Eq. (i).

JEE Type Solved Examples : Paragraph Based Questions

■ This section contains **one solved paragraph** based **3 multiple choice questions**. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Paragraph

(Q. Nos. 9 to 11)

If $A\left(\alpha, \frac{1}{\alpha}\right)$, $B\left(\beta, \frac{1}{\beta}\right)$, $C\left(\gamma, \frac{1}{\gamma}\right)$ be the vertices of a ΔABC, where α, β are the roots of $x^2 - 6ax + 2 = 0$; β, γ are the roots of $x^2 - 6bx + 3 = 0$ and γ, α are the roots of $x^2 - 6cx + 6 = 0$; a, b, c being positive.

9. The value of $a + b + c$ is

(a) 1 (b) 2

(c) 3 (d) 5

10. The coordinates of centroid of ΔABC is

(a) $\left(1, \frac{11}{9}\right)$ (b) $\left(\frac{1}{3}, \frac{11}{18}\right)$

(c) $\left(2, \frac{11}{18}\right)$ (d) $\left(\frac{2}{3}, \frac{11}{19}\right)$

11. The coordinates of orthocentre of ΔABC is

(a) $\left(-\frac{1}{2}, -2\right)$ (b) $\left(-\frac{1}{3}, -3\right)$

(c) $\left(-\frac{1}{5}, -5\right)$ (d) $\left(-\frac{1}{6}, -6\right)$

Sol. $\because \alpha, \beta$ are the roots of $x^2 - 6ax + 2 = 0$

$$\therefore \quad \alpha + \beta = 6a \quad \ldots(\text{i})$$

$$\text{and} \quad \alpha\beta = 2 \quad \ldots(\text{ii})$$

Again, β, γ are the roots of $x^2 - 6bx + 3 = 0$

$$\therefore \quad \beta + \gamma = 6b \quad \ldots(\text{iii})$$

$$\text{and} \quad \beta\gamma = 3 \quad \ldots(\text{iv})$$

Again, γ, α are the roots of $x^2 - 6cx + 6 = 0$

$$\therefore \quad \gamma + \alpha = 6c \quad \ldots(\text{v})$$

$$\text{and} \quad \gamma\alpha = 6 \quad \ldots(\text{vi})$$

from Eqs. (ii), (iv) and (vi), we get

$$\alpha\beta \cdot \beta\gamma \cdot \gamma\alpha = 2 \cdot 3 \cdot 6$$

$$\Rightarrow \quad \alpha\beta\gamma = 6$$

$$\therefore \quad \alpha = 2, \beta = 1, \gamma = 3$$

9. (b) Adding Eqs. (i) , (iii) and (v), we get

$$2(\alpha + \beta + \gamma) = 6(a + b + c)$$

$$\text{or} \quad a + b + c = \frac{1}{3}(2 + 1 + 3) = 2$$

10. (c) Centroid of $\Delta ABC \equiv \left(\frac{\Sigma\alpha}{3}, \frac{\Sigma\alpha\beta}{3\alpha\beta\gamma}\right)$

$$\equiv \left(\frac{2+1+3}{3}, \frac{2\cdot 1 + 1\cdot 3 + 3\cdot 2}{3\cdot 2\cdot 1\cdot 3}\right)$$

$$\equiv \left(2, \frac{11}{18}\right)$$

11. (d) Orthocentre of $\Delta ABC \equiv \left(-\frac{1}{\alpha\beta\gamma}, -\alpha\beta\gamma\right)$

$$\equiv \left(-\frac{1}{6}, -6\right)$$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **one solved example**. The answer to this example is **a single digit integer** ranging from 0 to 9 (both inclusive).

● ***Ex.12.*** *If the points* $(-2, 0), \left(-1, \frac{1}{\sqrt{3}}\right)$ *and* $(\cos\theta, \sin\theta)$ *are collinear, then the number of values of* $\theta \in [0, 2\pi]$ *is*

Sol. (1) Since, the given points are collinear, then

$$\begin{vmatrix} -2 & 0 & 1 \\ -1 & \frac{1}{\sqrt{3}} & 1 \\ \cos\theta & \sin\theta & 1 \end{vmatrix} = 0$$

$$\Rightarrow \quad -2\left(\frac{1}{\sqrt{3}} - \sin\theta\right) - 0 + 1\left(-\sin\theta - \frac{\cos\theta}{\sqrt{3}}\right) = 0$$

$$\Rightarrow \quad \sqrt{3}\sin\theta - \cos\theta = 2$$

$$\Rightarrow \quad \frac{\sqrt{3}}{2}\sin\theta - \frac{1}{2}\cos\theta = 1$$

or $$\sin\left(\theta - \frac{\pi}{6}\right) = 1$$

or $$\theta - \frac{\pi}{6} = 2n\pi + \frac{\pi}{2}$$

for $n = 0$, $$\theta = \frac{\pi}{6} + \frac{\pi}{2} = \frac{2\pi}{3} \in [0, 2\pi]$$

Number of values θ is 1.

JEE Type Solved Examples :
Matching Type Questions

- This section contains **one solved example**. Which has four statements (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statements in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

● ***Ex. 13.*** *Match the following*

	Column I		Column II
A.	The points $(\lambda + 1, 1), (2\lambda + 1, 3)$ and $(2\lambda + 2, 2\lambda)$ are collinear then number of values of λ is	(p)	a prime number
B.	Area of ΔABC is 20 sq units, where A, B and C are (4, 6), (10, 14) and (x, y) respectively. AC is perpendicular to BC, then number of positions of C is	(q)	an odd number
C.	In a ΔABC coordinates of orthocentre, centroid and vertex A are respectively $(2, 2), (2, 1)$ and $(0, 2)$. The x-coordinate of vertex B is	(r)	a composite number
D.	A man starts from $P(-3, 4)$ and reaches the point $Q(0, 1)$ touching the X-axis at $R(\lambda, 0)$ such that $PR + RQ$ is minimum, then $10\lvert\lambda\rvert$ is	(s)	a perfect number

Sol. (A) $\rightarrow$ (p); (B) $\rightarrow$ (r); (C) $\rightarrow$ (p, q); (D) $\rightarrow$ (r, s)

(A) $\because$ Points are collinear

$$\therefore \quad \begin{vmatrix} \lambda + 1 & 1 & 1 \\ 2\lambda + 1 & 3 & 1 \\ 2\lambda + 2 & 2\lambda & 1 \end{vmatrix} = 0$$

$$\Rightarrow \quad (\lambda + 1)(3 - 2\lambda) - 1(2\lambda + 1 - 2\lambda - 2) + 1(4\lambda^2 + 2\lambda - 6\lambda - 6) = 0$$

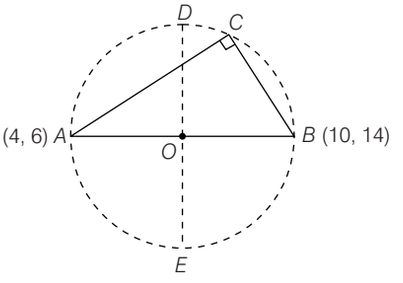
or $$2\lambda^2 - 3\lambda - 2 = 0$$

or $$(2\lambda + 1)(\lambda - 2) = 0$$

$$\therefore \quad \lambda = 2, -\frac{1}{2}$$

Number of values of λ is 2.

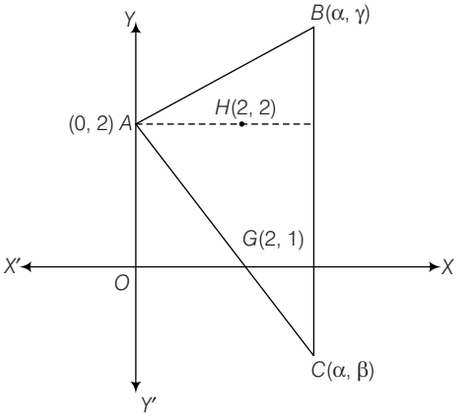
(B) $\because$ Area of triangles ABC is 20 sq units.



$\because$ C can not be at D and E

$\therefore$ Four positions are possible two above AB and two below AB.

(C)

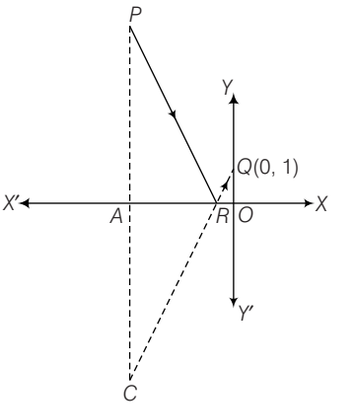


$\because \quad \frac{\alpha+\alpha+0}{3}=2$

$\therefore \quad \alpha=3$

$\Rightarrow$ x-coordinates of vertex $B=3$

(D) For $PR + RQ$ to be minimum, it should be the path of light



$\because \quad \angle PRA = \angle QRO$

From similar triangles PAR and QOR

$$\frac{AR}{RO}=\frac{PA}{QO} \quad \text{or} \quad \frac{\lambda+3}{0-\lambda}=\frac{4}{1}$$

or $\quad \lambda=-\frac{3}{5} \quad \therefore \quad 10|\lambda|=6.$

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** (Ex. Nos. 14 and 15) are Assertion-Reason type examples. Each of these examples contains two statements.

Statement I (Assertion) and **Statement II** (Reason)

Each of these examples also has four alternative choices, (a), (b), (c) and (d) only one out of which is the correct answer. You have to select the correct choice as given below :

(a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I

(b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I

(c) Statement I is true, Statement II is false

(d) Statement I is false, Statement II is true

● ***Ex. 14.*** **Statement I** *The area of the triangle formed by the points $A(100,102)$, $B(102,105)$, $C(104,107)$ is same as the area formed by $A'(0,0)$, $B'(2,3)$, $C'(4,5)$.*

Statement II *The area of the triangle is constant with respect to translation :*

Sol. (a) Area of triangle is unaltered by shifting origin to any point. If origin is shifted to (100, 102), then A, B, C becomes $A'(0,0)$, $B'(2,3)$, $C'(4,5)$ respectively. Hence, both statements are true and Statement II is correct explanation for Statement I.

● ***Ex. 15.*** **Statement I** *If centroid and circumcentre of a triangle are known its orthocentre can be found*

Statement II *Centroid, orthocentre and circumcentre of a triangle are collinear.*

Sol. (b) $\because$ Centroid divides orthocentre and circumcentre in the ratio 2 : 1 (internally).

$\therefore$ We can find easily orthocentre.

$\Rightarrow$ Statement I is true, and centroid, orthocentre and circumcentre are collinear Statement II is true but Statement II is not correct explanation for Statement I.

Subjective Type Examples

■ In this section, there are **7 subjective solved examples**.

● ***Ex. 16.*** *The four points $A(\alpha,0), B(\beta,0), C(\gamma,0)$ and $D(\delta,0)$ are such that α,β are the roots of equation $ax^2+2hx+b=0$ and γ,δ are those of equation $a'x^2+2h'x+b'=0$. Show that the sum of the ratios in which C and D divide AB is zero, if $ab'+a'b=2hh'$.*

Sol. Since, α,β are the roots of $ax^2+2hx+b=0$

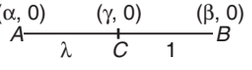
$$\therefore \quad \alpha+\beta=-\frac{2h}{a} \quad \text{and} \quad \alpha\beta=\frac{b}{a} \qquad \ldots(i)$$

and γ,δ are the roots of $a'x^2+2h'x+b'=0$

then, $$\gamma+\delta=-\frac{2h'}{a'} \quad \text{and} \quad \gamma\delta=\frac{b'}{a'} \qquad \ldots(ii)$$

Let C divides AB in the ratio $\lambda:1$

then

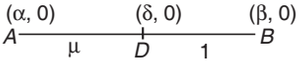


$$\gamma=\frac{\lambda\cdot\beta+1\cdot\alpha}{\lambda+1}$$

$$\therefore \quad \lambda=\frac{\gamma-\alpha}{\beta-\gamma}$$

and let D divides AB in the ratio $\mu:1$

then



$$\delta=\frac{\mu\cdot\beta+1\cdot\alpha}{\mu+1}$$

$$\therefore \quad \mu=\frac{\delta-\alpha}{\beta-\delta}$$

but given $\lambda+\mu=0$

$$\Rightarrow \quad \frac{\gamma-\alpha}{\beta-\gamma}+\frac{\delta-\alpha}{\beta-\delta}=0$$

$$\Rightarrow \quad (\alpha+\beta)(\gamma+\delta)-2\alpha\beta-2\gamma\delta=0$$

$$\Rightarrow \quad \left(-\frac{2h}{a}\right)\left(-\frac{2h'}{a'}\right)-\frac{2b}{a}-\frac{2b'}{a'}=0$$

[from Eqs. (i) and (ii)]

or $$ab'+a'b=2hh'$$

● ***Ex. 17.*** *If m_1 and m_2 are the roots of the equation $x^2+(\sqrt{3}+2)x+(\sqrt{3}-1)=0$ Show that the area of the triangle formed by the lines $y=m_1x, y=m_2x$ and $y=c$ is $\left(\frac{\sqrt{33}+\sqrt{11}}{4}\right)c^2$.*

Sol. Since, m_1 and m_2 are the roots of the equation

$$x^2+(\sqrt{3}+2)x+(\sqrt{3}-1)=0$$

then $$m_1+m_2=-(\sqrt{3}+2),\ m_1m_2=(\sqrt{3}-1)$$

$$\therefore \quad m_1-m_2=\sqrt{(m_1+m_2)^2-4m_1m_2}$$

$$=\sqrt{(3+4+4\sqrt{3}-4\sqrt{3}+4)}=\sqrt{11}$$

and coordinates of the vertices of the given triangle are $(0,0)$, $(c/m_1,c)$ and $(c/m_2,c)$.

Hence, the required area of triangle $=\frac{1}{2}\left|\frac{c}{m_1}\times c-\frac{c}{m_2}\times c\right|$

$$=\frac{1}{2}c^2\left|\left(\frac{1}{m_1}-\frac{1}{m_2}\right)\right|=\frac{1}{2}c^2\frac{|m_2-m_1|}{|m_1m_2|}$$

$$=\frac{1}{2}c^2\frac{\sqrt{11}}{(\sqrt{3}-1)}$$

$$=\frac{1}{2}c^2\cdot\frac{\sqrt{11}(\sqrt{3}+1)}{(\sqrt{3}-1)(\sqrt{3}+1)}$$

$$=\left(\frac{\sqrt{33}+\sqrt{11}}{4}\right)c^2$$

● ***Ex. 18.*** *If x coordinates of two points B and C are the roots of equation $x^2+4x+3=0$ and their y coordinates are the roots of equation $x^2-x-6=0$. If x coordinate of B is less than x coordinate of C and y coordinate of B is greater than the y coordinate of C and coordinates of a third point A be $(3,-5)$, find the length of the bisector of the interior angle at A.*

Sol. $\because \quad x^2+4x+3=0 \Rightarrow x=-1,-3$

and $\quad x^2-x-6=0 \Rightarrow x=-2,3$

Also, given that x and y coordinates of B are respectively less than and greater than the corresponding coordinates of C.

$$\therefore \quad B\equiv(-3,3) \quad \text{and} \quad C\equiv(-1,-2)$$

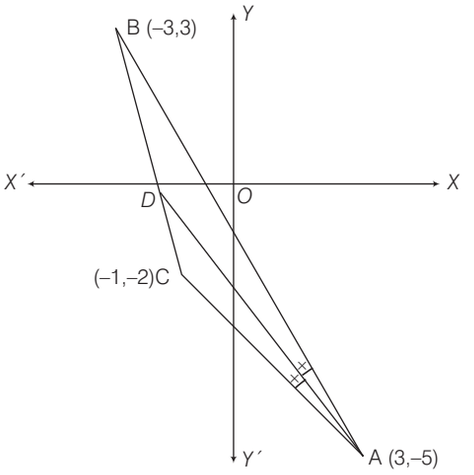
Now, $$AB=\sqrt{(3+3)^2+(-5-3)^2}=10$$

and $$AC=\sqrt{(3+1)^2+(-5+2)^2}=5$$

$$\therefore \quad \frac{AB}{AC}=\frac{2}{1}$$

Let AD be the bisector of $\angle BAC$, then

$$\frac{BD}{DC}=\frac{AB}{AC}=\frac{2}{1}$$



Thus, D divides BC internally in the ratio 2 : 1

$$\therefore \quad D \equiv \left(\frac{2(-1)+1(-3)}{2+1}, \frac{2(-2)+1(3)}{2+1} \right)$$

Thus, $$D \equiv \left(-\frac{5}{3}, -\frac{1}{3} \right)$$

Now, $$AD = \sqrt{\left(3+\frac{5}{3}\right)^2 + \left(-5+\frac{1}{3}\right)^2}$$

$$= \sqrt{\frac{196}{9}+\frac{196}{9}} = \frac{14\sqrt{2}}{3} \text{ units}$$

● ***Ex. 19.*** *The distance between two parallel lines is unity. A point P lies between the lines at a distance a from one of them. Find the length of a side of an equilateral triangle PQR, vertex Q of which lies on one of the parallel lines and vertex R lies on the other line.*

Sol. Let $PQ = QR = RP = r$

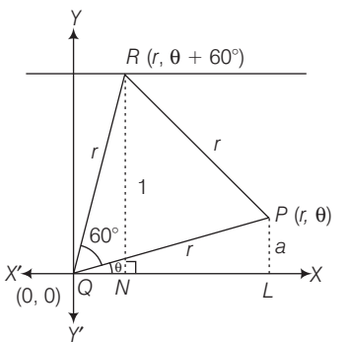
and $\angle PQL = \theta$

then, $\angle XQR = \theta + 60°$

Given, $PL = a$ and $RN = 1$ unit

In ΔPQL, $\sin\theta = \frac{PL}{QP} = \frac{a}{r}$

$$\therefore \quad a = r\sin\theta \qquad \ldots(i)$$



and in ΔQRN, $\sin(\theta+60°) = \frac{RN}{QR} = \frac{1}{r}$

$$\therefore \quad r\sin(\theta+60°) = 1$$

$$r\{\sin\theta\cos60° + \cos\theta\sin60°\} = 1$$

$$\Rightarrow \quad r\left\{\frac{1}{2}\sin\theta + \frac{\sqrt{3}}{2}\cos\theta\right\} = 1$$

$$\Rightarrow \quad r\left\{\frac{1}{2}\times\frac{a}{r} + \frac{\sqrt{3}}{2}\times\sqrt{1-\frac{a^2}{r^2}}\right\} = 1 \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow \quad \frac{a}{2} + \frac{\sqrt{3}}{2}\sqrt{(r^2-a^2)} = 1$$

$$\Rightarrow \quad \frac{\sqrt{3}}{2}\sqrt{(r^2-a^2)} = 1 - \frac{a}{2}$$

or $$\frac{3}{4}(r^2-a^2) = 1 + \frac{a^2}{4} - a$$

$$\Rightarrow \quad 3r^2 - 3a^2 = 4 + a^2 - 4a$$

$$\Rightarrow \quad 3r^2 = 4a^2 - 4a + 4$$

$$= 4(a^2 - a + 1)$$

$$\therefore \quad r = \frac{2}{\sqrt{3}}\sqrt{(a^2-a+1)}$$

Hence, length of side of an equilateral triangle

$$= \frac{2}{\sqrt{3}}\sqrt{(a^2-a+1)} \text{ units.}$$

● ***Ex. 20.*** *In a ΔABC, $A \equiv (\alpha, \beta)$, $B \equiv (1, 2)$, $C \equiv (2, 3)$ and point A lies on the line $y = 2x + 3$ where $\alpha, \beta \in I$. If the area of ΔABC be such that $[\Delta] = 2$, where $[.]$ denotes the greatest integer function, find all possible coordinates of A.*

Sol. $\because (\alpha, \beta)$ lies on $y = 2x + 3$

then $\beta = 2\alpha + 3$

Thus, the coordinates of A are $(\alpha, 2\alpha+3)$ ...(i)

$$\Delta = \frac{1}{2}\left|\left\{\begin{vmatrix}\alpha & 2\alpha+3\\ 1 & 2\end{vmatrix} + \begin{vmatrix}1 & 2\\ 2 & 3\end{vmatrix} + \begin{vmatrix}2 & 3\\ \alpha & 2\alpha+3\end{vmatrix}\right\}\right|$$

$$= \frac{1}{2}|2\alpha - (2\alpha+3) + 3 - 4 + 4\alpha + 6 - 3\alpha|$$

$$= \frac{1}{2}|\alpha + 2|$$

but $[\Delta] = 2$

$$\Rightarrow \quad \left[\frac{1}{2}|\alpha+2|\right] = 2$$

$$\Rightarrow \quad 2 \le \frac{|\alpha+2|}{2} < 3$$

$$\Rightarrow \quad 4 \le |\alpha+2| < 6$$

$$\Rightarrow \quad 4 \le \alpha + 2 < 6$$

and $$-6 < \alpha + 2 \le -4$$

$$\Rightarrow \quad 2 \le \alpha < 4 \quad \text{and} \quad -8 < \alpha \le -6$$

$$\because \quad \alpha \in I$$

$$\therefore \quad \alpha = 2, 3, -7, -6$$

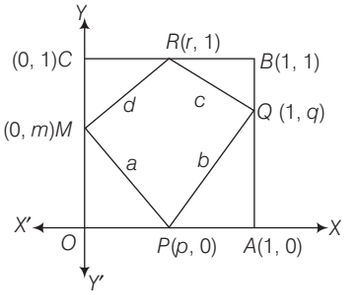
Hence, possible coordinates of A are $(2,7), (3,9), (-7,-11)$ and $(-6,-9)$.

● ***Ex. 21.*** *Let S be the square of unit area. Consider any quadrilateral which has one vertex on each side of S. If a,b,c and d denote the lengths of the sides of the quadrilateral, prove that* $2 \le a^2 + b^2 + c^2 + d^2 \le 4$.

Sol. Given S be the area of square with vertices
$O(0, 0), A(1, 0), B(1, 1), C(0, 1)$.

Let $PQRM$ be the quadrilateral with vertices
$P(p, 0), Q(1, q), R(r, 1)$ and $M(0, m)$

and sides $MP = a, PQ = b, QR = c, RM = d$



Then, $a^2 = p^2 + m^2$

$b^2 = (1-p)^2 + q^2$

$c^2 = (1-q)^2 + (1-r)^2$

$d^2 = r^2 + (1-m)^2$

$\therefore\ a^2 + b^2 + c^2 + d^2 = p^2 + (1-p)^2 + q^2 + (1-q)^2 + r^2 + (1-r)^2 + m^2 + (1-m)^2$

$= 2[p^2 + q^2 + r^2 + m^2 - p - q - r - m + 2]$

$= 2\left[\left(p - \frac{1}{2}\right)^2 + \left(q - \frac{1}{2}\right)^2 + \left(r - \frac{1}{2}\right)^2 + \left(m - \frac{1}{2}\right)^2 + 1\right] \ge 2$

$\Rightarrow\quad a^2 + b^2 + c^2 + d^2 \ge 2$ ...(i)

also, since $0 \le x \le 1$

$\therefore\quad x^2 \le 1$

$\therefore\quad a^2 \le 1, b^2 \le 1, c^2 \le 1, d^2 \le 1$

$\Rightarrow\quad a^2 + b^2 + c^2 + d^2 \le 4$ ...(ii)

From Eqs. (i) and (ii), we get

$2 \le a^2 + b^2 + c^2 + d^2 \le 4$

● ***Ex. 22.*** *The circumcentre of a triangle with vertices* $(a, a\tan\alpha), B(b, b\tan\beta)$ *and* $C(c, c\tan\gamma)$ *lies at the origin, where* $0 < \alpha, \beta, \gamma < \pi/2$ *and* $a + \beta + \gamma = \pi$. *Show that its orthocentre lies on the line*

$$4\cos\left(\frac{\alpha}{2}\right)\cos\left(\frac{\beta}{2}\right)\cos\left(\frac{\gamma}{2}\right)x - 4\sin\left(\frac{\alpha}{2}\right)\sin\left(\frac{\beta}{2}\right)\sin\left(\frac{\gamma}{2}\right)y = y$$

Sol. Since, the circumcentre of the triangle is at the origin O, we have $OA = OB = OC = R$, where R is the circumradius of the circumcircle.

$\therefore\quad (OA)^2 = R^2 \Rightarrow a^2 + a^2\tan^2\alpha = R^2 \Rightarrow a = R\cos\alpha$

Therefore, the coordinates of A are $(R\cos\alpha, R\sin\alpha)$.

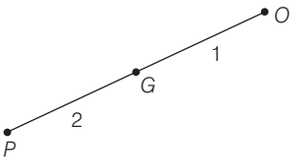
Similarly, the coordinates of B are $(R\cos\beta, R\sin\beta)$ and those of C are $(R\cos\gamma, R\sin\gamma)$.

Thus the coordinates of centroid G of ΔABC are

$$\left(\frac{R}{3}(\cos\alpha + \cos\beta + \cos\gamma), \frac{R}{3}(\sin\alpha + \sin\beta + \sin\gamma)\right)$$

Now, if $P(h, k)$ is the orthocentre of ΔABC, then

$$\frac{R}{3}(\cos\alpha + \cos\beta + \cos\gamma) = \frac{1\cdot h + 2\cdot 0}{1+2} \quad (\because PG : GO = 2:1)$$



$\Rightarrow\quad R(\cos\alpha + \cos\beta + \cos\gamma) = h$ ...(i)

and $\frac{R}{3}(\sin\alpha + \sin\beta + \sin\gamma) = \frac{1\cdot k + 2\cdot 0}{1+2}$

$\Rightarrow\quad R(\sin\alpha + \sin\beta + \sin\gamma) = k$ ...(ii)

Dividing (ii) by (i), then

$\Rightarrow\quad \frac{\sin\alpha + \sin\beta + \sin\gamma}{\cos\alpha + \cos\beta + \cos\gamma} = \frac{k}{h}$

$\Rightarrow\quad \frac{4\cos(\alpha/2)\cos(\beta/2)\cos(\gamma/2)}{1 + 4\sin(\alpha/2)\sin(\beta/2)\sin(\gamma/2)} = \frac{k}{h}$

(Because, $\alpha + \beta + y = \pi$ by identity)

Hence, the orthocentre $P(h, k)$ lies on the line

$$4\cos\left(\frac{\alpha}{2}\right)\cos\left(\frac{\beta}{2}\right)\cos\left(\frac{\gamma}{2}\right)x - 4\sin\left(\frac{\alpha}{2}\right)\sin\left(\frac{\beta}{2}\right)\sin\left(\frac{\gamma}{2}\right)y = y$$

Coordinate System and Coordinates Exercise 1 : Single Option Correct Type Questions

■ This section contains **15 multiple choice questions**. Each question has four choices (a), (b), (c), (d) out of which **ONLY ONE** is correct.

1. Vertices of a variable triangle are $(3, 4)$, $(5\cos\theta, 5\sin\theta)$ and $(5\sin\theta, -5\cos\theta)$, where $\theta \in R$. Locus of its orthocentre is
(a) $x^2 + y^2 + 6x + 8y - 25 = 0$
(b) $x^2 + y^2 - 6x + 8y - 25 = 0$
(c) $x^2 + y^2 + 6x - 8y - 25 = 0$
(d) $x^2 + y^2 - 6x - 8y - 25 = 0$

2. If a rod AB of length 2 units slides on coordinate axes in the first quadrant. An equilateral triangle ABC is completed with C on the side away from O. Then, locus of C is
(a) $x^2 + y^2 - xy + 1 = 0$
(b) $x^2 + y^2 - xy\sqrt{3} + 1 = 0$
(c) $x^2 + y^2 + xy\sqrt{3} - 1 = 0$
(d) $x^2 + y^2 - xy\sqrt{3} - 1 = 0$

3. The sides of a triangle are $3x + 4y$, $4x + 3y$ and $5x + 5y$ units, where $x > 0$, $y > 0$. The triangle is
(a) right angled (b) acute angled
(c) obtuse angled (d) isosceles

4. Let P and Q be the points on the line joining $A(-2, 5)$ and $B(3, 1)$ such that $AP = PQ = QB$. Then, the mid-point of PQ is
(a) $\left(\frac{1}{2}, 3\right)$ (b) $\left(-\frac{1}{4}, 4\right)$
(c) $(2, 3)$ (d) $(-1, 4)$

5. A triangle ABC right angled at A has points A and B as $(2, 3)$ and $(0, -1)$ respectively. If $BC = 5$ units, then the point C is
(a) $(4, 2)$ (b) $(-4, 2)$
(c) $(-4, 4)$ (d) $(4, -4)$

6. The locus of a point P which divides the line joining $(1, 0)$ and $(2\cos\theta, 2\sin\theta)$ internally in the ratio $2:3$ for all θ is
(a) a straight line (b) a circle
(c) a pair of straight lines (d) a parabola

7. The points with the coordinates $(2a, 3a)$, $(3b, 2b)$ and (c, c) are collinear
(a) for no value of a, b, c (b) for all values of a, b, c
(c) if $a, \frac{c}{5}, b$ are in HP (d) if $a, \frac{2c}{5}, b$ are in HP

8. The vertices of a triangle are $(0, 3)$, $(-3, 0)$ and $(3, 0)$. The coordinates of its orthocentre are
(a) $(0, -2)$ (b) $(0, 2)$
(c) $(0, 3)$ (d) $(0, -3)$

9. ABC is an equilateral triangle such that the vertices B and C lie on two parallel lines at a distance 6. If A lies between the parallel lines at a distance 4 from one of them, then the length of a side of the equilateral triangle is
(a) 8 (b) $\sqrt{\frac{88}{3}}$
(c) $\frac{4\sqrt{7}}{\sqrt{3}}$ (d) None of these

10. A, B, C are respectively the points $(1, 2)$, $(4, 2)$, $(4, 5)$. If T_1, T_2 are the points of trisection of the line segment AC and S_1, S_2 are the points of trisection of the line segment BC, the area of the quadrilateral $T_1S_1S_2T_2$ is
(a) 1 (b) $\frac{3}{2}$ (c) 2 (d) $\frac{5}{2}$

11. (i) The points $(-1, 0)$, $(4, -2)$ and $(\cos 2\theta, \sin 2\theta)$ are collinear
(ii) The points $(-1, 0)$, $(4, -2)$ and $\left(\frac{1-\tan^2\theta}{1+\tan^2\theta}, \frac{2\tan\theta}{1+\tan^2\theta}\right)$ are collinear
(a) both statements are equivalent
(b) statemetn (i) has more solution than statement (ii) for θ
(c) statement (ii) has more solution than statement (i) for θ
(d) None of the above

12. If $\alpha_1, \alpha_2, \alpha_3, \beta_1, \beta_2, \beta_3$ are the values of n for which $\sum_{r=0}^{n-1} x^{2r}$ is divisible by $\sum_{r=0}^{n-1} x^r$, then the triangle having vertices (α_1, β_1), (α_2, β_2) and (α_3, β_3) cannot be
(a) an isosceles triangle
(b) a right angled isosceles triangle
(c) a right angled triangle
(d) an equilateral triangle

13. A triangle ABC with vertices $A(-1, 0)$, $B\left(-2, \frac{3}{4}\right)$ and $C\left(-3, -\frac{7}{6}\right)$ has its orthocentre at H. Then, the orthocentre of triangle BCH will be
(a) $(-3, -2)$ (b) $(1, 3)$
(c) $(-1, 2)$ (d) None of these

14. If $\sum_{i=1}^{4}(x_i^2 + y_i^2) \le 2x_1x_3 + 2x_2x_4 + 2y_2y_3 + 2y_1y_4$, the points $(x_1, y_1), (x_2, y_2), (x_3, y_3), (x_4, y_4)$ are
(a) the vertices of a rectangle
(b) collinear
(c) the vertices of a trapezium
(d) None of the above

15. Without change of axes the origin is shifted to (h, k), then from the equation $x^2 + y^2 - 4x + 6y - 7 = 0$, then term containing linear powers are missing, then point (h, k) is
(a) (3, 2) (b) (−3, 2)
(c) (2, −3) (d) (−2, −3)

Coordinate System and Coordinates Exercise 2 : More than One Correct Option Type Questions

- This section contains **7 multiple choice questions**. Each questions has four choices (a), (b), (c), (d) out of which **MORE THAN ONE** may be correct.

16. If $(-6, -4), (3, 5), (-2, 1)$ are the vertices of a parallelogram, then remaining vertex can be
(a) $(0, -1)$ (b) $(-1, 0)$
(c) $(-11, -8)$ (d) $(7, 10)$

17. If the point $P(x, y)$ be equidistant from the points $A(a + b, a - b)$ and $B(a - b, a + b)$ then
(a) $ax = by$
(b) $bx = ay$
(c) $x^2 - y^2 = 2(ax + by)$
(d) P can be (a, b)

18. If the coordinates of the vertices of a triangle are rational numbers, then which of the following points of the triangle will always have rational coordinates
(a) centroid (b) incentre
(c) circumcentre (d) orthocentre

19. The points $A(-4, -1)$, $B(-2, -4)$, $C(4, 0)$ and $D(2, 3)$ are the vertices of a
(a) parallelogram (b) rectangle
(c) rhombus (d) square

20. The medians AD and BE of the triangle with vertices $A(0, b)$, $B(0, 0)$ and $C(a, 0)$ are mutually perpendicular if
(a) $b = a\sqrt{2}$ (b) $a = b\sqrt{2}$
(c) $b = -a\sqrt{2}$ (d) $a = -b\sqrt{2}$

21. The points $A(x, y)$, $B(y, z)$ and $C(z, x)$ represents the vertices of a right angled triangle, if
(a) $x = y$ (b) $y = z$
(c) $z = x$ (d) $x = y = z$

22. Let the base of a triangle lie along the line $x = a$ and be of length $2a$. The area of this triangles is a^2, if the vertex lies on the line
(a) $x = -a$ (b) $x = 0$
(c) $x = \frac{a}{2}$ (d) $x = 2a$

Coordinate System and Coordinates Exercise 3 : Paragraph Based Questions

- This section contains **2 solved paragraphs** based upon each of the paragraph, **3 multiple choice questions** have to be answered. Each of these question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Paragraph I

(Q. Nos. 23 to 25)

ABC is a triangle right angled at A, $AB = 2AC$. $A \equiv (1, 2)$, $B \equiv (-3, 1)$. ACD is an equilateral triangle. The vertices of two triangles are in anticlockwise sense. $BCEF$ is a square with vertices in clockwise sense.

23. If area of ΔACF is S, then the value of $8S$ is
(a) 42 (b) 51
(c) 62 (d) 102

24. Length of DE is
(a) $\sqrt{17}\sqrt{(4 - \sqrt{3})}$
(b) $\frac{\sqrt{17}}{2}\sqrt{(8 + \sqrt{3})}$
(c) $\frac{\sqrt{17}}{2}\sqrt{(4 + \sqrt{3})}$
(d) $\sqrt{15}\sqrt{(4 + \sqrt{3})}$

25. The y-coordinate of the centroid of the square $BCEF$ is
(a) $-\frac{1}{4}$ (b) $-\frac{3}{4}$
(c) $-\frac{5}{4}$ (d) $-\frac{7}{4}$

Paragraph II

(Q. Nos. 26 to 28)

Let $O(0,0)$, $A(2,0)$ *and* $B\left(1,\frac{1}{\sqrt{3}}\right)$ *be the vertices of a triangle.*

Let R be the region consisting of all those points P inside ΔOAB *satisfying.*

$d(P,OA) \le min\ \{d(P,OB), d(P,AB)\}$, *where, d denotes the distance from the point P to the corresponding line. Let M be the peak of region R.*

26. Length of perpendicular from M to OA is equal to

(a) $\sqrt{3}$ (b) $\frac{1}{\sqrt{3}}$ (c) 3 (d) $2-\sqrt{3}$

27. The perimeter of region R is equal to

(a) $4-\sqrt{3}$ (b) $4+\sqrt{3}$

(c) $4+3\sqrt{3}$ (d) $2+4\sqrt{(2-\sqrt{3})}$

28. The area of region R is equal to

(a) $2-\sqrt{3}$ (b) $2+\sqrt{3}$ (c) $2\sqrt{3}$ (d) $4+\sqrt{3}$

Coordinate System and Coordinates Exercise 4 : Single Integer Answer Type Questions

- This section contains **5 questions**. The answer to each example is **a single digit integer** ranging from 0 to 9 (both inclusive).

29. If the area of the triangle formed by the points $(2a, b), (a+b, 2b+a)$ and $(2b, 2a)$ be Δ_1 and the area of the triangle whose vertices are $(a+b, a-b), (3b-a, b+3a)$ and $(3a-b, 3b-a)$ be Δ_2, then the value of Δ_2/Δ_1 is

30. The diameter of the nine point circle of the triangle with vertices $(3, 4), (5\cos\theta, 5\sin\theta)$ and $(5\sin\theta, -5\cos\theta)$, where $\theta \in R$, is

31. The ends of the base of an isosceles triangle are $(2\sqrt{2}, 0)$ and $(0, \sqrt{2})$. One side is of length $2\sqrt{2}$. If Δ be the area of triangle, then the value of $[\Delta]$ is (where $[\cdot]$ denotes the greatest integer function)

32. If (x, y) is the incentre of the triangle formed by the points $(3, 4), (4, 3)$ and $(1, 2)$, then the value of x^2 is

33. Let P and Q be points on the line joining $A(-2, 5)$ and $B(3, 1)$ such that $AP = PQ = QB$. If mid-point of PQ is (a, b), then the value of $\frac{b}{a}$ is

Coordinate System and Coordinates Exercise 5 : Matching Type Questions

- The section contains **2 questions**. Each question has four statements (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

34. Consider the triangle with vertices $A(0, 0)$, $B(5, 12)$ and $C(16, 12)$.

	Column I	Column II	
A.	If (λ, μ) are the coordinates of centroid of triangle ABC, then $(\lambda+\mu)$ is divisible by	(p)	3
B.	If (λ, μ) are the coordinates of circumcentre of triangle ABC, then 2λ is divisible by	(q)	5
C.	If (λ, μ) are the coordinates of incentre of triangle ABC, then μ is divisible by	(r)	7
D.	If (λ, μ) are the coordinates of excentre opposite to vertex B, then $\lambda+\mu$ is divisible by	(s)	9

35. The vertices of a triangle are $A(-10, 8)$, $B(14, 8)$ and $C(-10, 26)$. Let G, I, H, O be the centroid, incentre, orthocentre, circumcentre respectively of ΔABC.

	Column I	Column II	
A.	The inradius r is	(p)	a prime number
B.	The circumradius R is	(q)	an even number
C.	The area of ΔIGH is	(r)	a composite number
D.	The area of ΔOGI is	(s)	a perfect number

Coordinate System and Coordinates Exercise 6 : Statement I and II Type Questions

■ **Directions** (Q. Nos. 36 to 39) are Assertion-Reason type questions. Each of these questions contains two statements :

Statement I (Assertion) and

Statement II (Reason)

Each of these question also has four alternative choices (a), (b), (c) and (d), only one out of which is the correct answer.

You have to select the correct choice as given below

(a) Statement I is true, statement II is true; statement II is a correct explanation for statement I

(b) Statement I is true, statement II is true; statement II is not a correct explanation for statement I

(c) Statement I is true, statement II is false

(d) Statement I is false, statement II is true

36. The vertices of a triangle an $A(1, 2)$, $B(-1, 3)$ and $C(3, 4)$. Let D, E, F divide BC, CA, AB respectively in the same ratio.

Statement I The centroid of triangle DEF is $(1, 3)$.

Statement II The triangle ABC and DEF have the same centroid.

37. **Statement I** Let the vertices of a ΔABC be $A(-5, -2)$, $B(7, 6)$ and $C(5, -4)$. Then, the coordinates of the circumcentre are $(1, 2)$.

Statement II In a right angled triangle, the mid point of the hypotenuse is the circumcentre of the triangle.

38. A line segment AB is divided internally and externally in the same ratio at P and Q respectively and M is the mid-point of AB.

Statement I MP, MB, MQ are in G.P

Statement II AP, AB and AQ are in H.P.

39. **Statement I** Transformation of the equation $x^2 - 3xy + 11x - 12y + 36 = 0$ to parallel axes through the point $(-4, 1)$ becomes $ax^2 + bxy + 1 = 0$, then $b^2 - a = \frac{1}{64}$.

Statement II If the axes turned through an angle θ, then the equation $f(x, y) = 0$ is transformed by replacing (x, y) by $((x\cos\theta - y\sin\theta), (x\sin\theta + y\cos\theta))$.

Coordinate System and Coordinates Exercise 7 : Subjective Type Questions

■ In this section, there are **7 subjective questions**.

40. If $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ are the vertices of a ΔABC and (x, y) be a point on the internal bisector of angle A, then prove that

$$b\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix} + c\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = 0$$

where, $AC = b$ and $AB = c$.

41. If a, b, c be the pth, qth and rth terms respectively of a HP, show that the points $(bc, p), (ca, q)$ and (ab, r) are collinear.

42. A line L intersects three sides BC, CA and AB of a triangle in P, Q, R respectively, show that

$$\frac{BP}{PC} \cdot \frac{CQ}{QA} \cdot \frac{AR}{RB} = -1$$

43. If the points, $\left(\frac{a^3}{a-1}, \frac{a^2-3}{a-1}\right), \left(\frac{b^3}{b-1}, \frac{b^2-3}{b-1}\right)$ and $\left(\frac{c^3}{c-1}\ \frac{c^2-3}{c-1}\right)$ are collinear for three distinct values a, b, c and $a \neq 1, b \neq 1$ and $c \neq 1$, then show that

$$abc - (bc + ca + ab) + 3(a + b + c) = 0$$

44. Show that the area of the triangle whose sides are $a_r x + b_r y + c_r = 0, r = 1, 2, 3$ is $\frac{\Delta^2}{2|C_1 C_2 C_3|}$, where C_1, C_2 and C_3 are the cofactors of c_1, c_2 and c_3 respectively in the determinant

$$\Delta = \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}$$

45. If $A_1, A_2, A_3, ..., A_n$ are n points in a plane whose coordinates are $(x_1, y_1), (x_2, y_2), (x_3, y_3), ..., (x_n, y_n)$ respectively. A_1A_2 is bisected in the point G_1; G_1A_3 is divided at G_2 in the ratio $1:2$; G_2A_4 is divided at G_3 in the ratio $1:3$; G_3A_5 at G_4 in the $1:4$ and so on until all the points are exhausted. Show that the coordinates of the final point so obtained are

$$\frac{x_1 + x_2 + ... + x_n}{n} \quad \text{and} \quad \frac{y_1 + y_2 + ... + y_n}{n}$$

46. If by change of axes without change of origin, the expression $ax^2 + 2hxy + by^2$ becomes $a_1x_1^2 + 2h_1x_1y_1 + b_1y_1^2$, prove that

(i) $a + b = a_1 + b_1$

(ii) $ab - h^2 = a_1b_1 - h_1^2$

(iii) $(a - b)^2 + 4h^2 = (a_1 - b_1)^2 + 4h_1^2$

Coordinate System and Coordinates Exercise 8 : Questions Asked in Previous 13 Year's Exams

- This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to **2017**.

47. If a vertex of a triangle is (1, 1) and the mid-points of two side through this vertex are $(-1, 2)$ and $(3, 2)$, then the centroid of the triangle is **[AIEEE 2005, 3M]**

(a) $\left(\frac{1}{3}, \frac{7}{3}\right)$ (b) $\left(1, \frac{7}{3}\right)$

(c) $\left(-\frac{1}{3}, \frac{7}{3}\right)$ (d) $\left(-1, \frac{7}{3}\right)$

48. Let $O(0, 0)$, $P(3, 4)$, $Q(6, 0)$ be the vertices of the triangle OPQ. The point R inside the triangle OPQ is such that the triangles OPR, PQR, OQR are of equal area. The coordinates of R are **[IIT-JEE 2007, 3M]**

(a) $\left(\frac{4}{3}, 3\right)$ (b) $\left(3, \frac{2}{3}\right)$

(c) $\left(3, \frac{4}{3}\right)$ (d) $\left(\frac{4}{3}, \frac{2}{3}\right)$

49. Let $A(h, k)$, $B(1, 1)$ and $C(2, 1)$ be the vertices of a right angled triangle with AC as its hypotenuse. If the area of the triangle is 1, then the set of values which 'k' can take is given by **[AIEEE 2007, 3M]**

(a) $\{1, 3\}$ (b) $\{0, 2\}$

(c) $(-1, 3\}$ (d) $\{-3, -2\}$

50. Three distinct points A, B and C are given in the 2-dimensional coordinates plane such that the ratio of the distance of any one of them from the point $(1, 0)$ to the distance from the point $(-1, 0)$ is equal to $\frac{1}{3}$. Then, the circumcentre of the triangle ABC is at the point **[AIEEE 2009, 4M]**

(a) $\left(\frac{5}{4}, 0\right)$ (b) $\left(\frac{5}{2}, 0\right)$

(c) $\left(\frac{5}{3}, 0\right)$ (d) $(0, 0)$

51. The x-coordinate of the incentre of the triangle that has the coordinates of mid-points of its sides are (0, 1), (1, 1) and (1, 0) is **[JEE Main 2013, 4M]**

(a) $2 + \sqrt{2}$ (b) $2 - \sqrt{2}$

(c) $1 + \sqrt{2}$ (d) $1 - \sqrt{2}$

52. The number of points, having both coordinates are integers, that lie in the interior of the triangle with vertices (0, 0), (0, 41) and (41, 0) is **[JEE Main 2015, 4M]**

(a) 820 (b) 780

(c) 901 (d) 861

53. Let k be an integer such that the triangle with vertices $(k, -3k)$, $(5, k)$ and $(-k, 2)$ has area 28 sq units. Then, the orthocentre of this triangle is at the point **[JEE Main 2017, 4M]**

(a) $\left(2, \frac{1}{2}\right)$ (b) $\left(2, -\frac{1}{2}\right)$

(c) $\left(1, \frac{3}{4}\right)$ (d) $\left(1, -\frac{3}{4}\right)$

Solutions

1. Since, the distance of all points from $O(0, 0) = 5$

$\therefore$ $O(0, 0)$ be the circumcentre.

Centroid of triangle (G)

$$\equiv \left(\frac{3 + 5\cos\theta + 5\sin\theta)}{3}, \frac{4 + 5\sin\theta - 5\cos\theta}{3}\right)$$

Let $H(\alpha, \beta)$ be the orthocentre of the triangle, then

$$\alpha = 3 + 5\cos\theta + 5\sin\theta$$

$\Rightarrow$ $(\alpha - 3) = 5\cos\theta + 5\sin\theta$ ...(i)

and $\beta = 4 + 5\sin\theta - 5\cos\theta$

$\Rightarrow$ $(\beta - 4) = 5\sin\theta - 5\cos\theta$ ...(ii)

On squaring and adding Eqs. (i) and (ii), we get

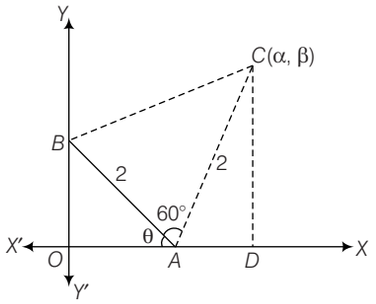
$$(\alpha - 3)^2 + (\beta - 4)^2 = 25 + 25$$

$\Rightarrow$ $\alpha^2 + \beta^2 - 6\alpha - 8\beta - 25 = 0$

Hence, the locus of $H(\alpha, \beta)$ is

$$x^2 + y^2 - 6x - 8y - 25 = 0$$

2.



Let $AB = AC = 2$

and $\angle BAO = \theta$

Let $C \equiv (\alpha, \beta)$

$\therefore$ $\alpha = 2\cos\theta + 2\cos(180° - (60° + \theta))$

$= 2\cos\theta - 2\cos(60° + \theta)$

$$= 2\cos\theta - 2\left\{\cos\theta \times \frac{1}{2} - \sin\theta \times \frac{\sqrt{3}}{2}\right\}$$

$= \cos\theta + \sqrt{3}\sin\theta$ ...(i)

and $\beta = 2\sin(180° - (60° + \theta))$

$= 2\sin(60° + \theta)$

$$= 2\left(\sin\theta \times \frac{1}{2} + \cos\theta \times \frac{\sqrt{3}}{2}\right)$$

$= \sin\theta + \sqrt{3}\cos\theta$ ...(ii)

Eliminating θ from Eqs. (i) and (ii), we get

$$\alpha^2 + \beta^2 - \alpha\beta\sqrt{3} - 1 = 0$$

Hence, the locus of $H(\alpha, \beta)$ is

$$x^2 + y^2 - xy\sqrt{3} - 1 = 0$$

3. Let $a = 3x + 4y$, $b = 4x + 3y$, $c = 5x + 5y$

$\therefore$ $$\cos C = \frac{a^2 + b^2 - c^2}{2ab}$$

$$= \frac{(3x + 4y)^2 + (4x + 3y)^2 - (5x + 5y)^2}{2(3x + 4y)(4x + 3y)}$$

$$= -\frac{xy}{(3x + 4y)(4x + 3y)} < 0$$

$\Rightarrow$ $C > 90°$

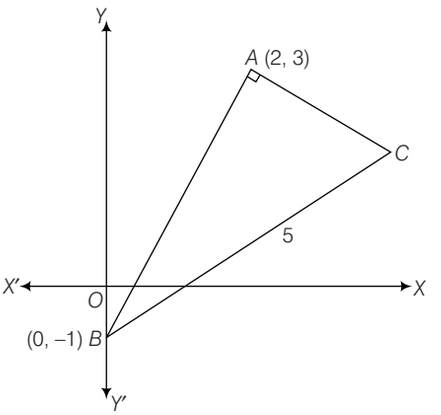
Hence, triangle is obtuse angled.

4.

$\because$ $AP = PQ = QB$

$\therefore$ mid-point of PQ = mid-point of $AB = \left(\frac{1}{2}, 3\right)$

5. $z_A = 2 + 3i$; $z_B = -i$ and $AB = \sqrt{(4 + 16)} = \sqrt{20} = 2\sqrt{5}$



$\therefore$ $(AC) = \sqrt{(BC)^2 - (AC)^2} = \sqrt{5}$

$\therefore$ $$\frac{z_C - z_A}{z_B - z_A} = \frac{AC}{AB}e^{i\pi/2} = \frac{i}{2}$$

$\Rightarrow$ $z_C - (2 + 3i) = \frac{i}{2}(-i - 2 - 3i)$

or $z_C = 2 + 3i - i + 2 = 4 + 2i$

$\therefore$ $C \equiv (4, 2)$

6. Let $P \equiv (h, k)$ and $A \equiv (1, 0)$, $B \equiv (2\cos\theta, 2\sin\theta)$

$\because$ $PA : PB = 2 : 3$

$\therefore$ $h = \frac{4\cos\theta + 3}{5} \Rightarrow 5h - 3 = 4\cos\theta$ ...(i)

and $k = \frac{4\sin\theta + 0}{5} \Rightarrow 5k = 4\sin\theta$ ...(ii)

OA squaring and adding Eqs. (i) and (ii), we get

$$(5h - 3)^2 + (5k)^2 = 16$$

$\therefore$ Locus of C is $(5x - 3)^2 + (5y)^2 = 16$

or $25(x^2 + y^2) - 30x - 7 = 0$

which is a circle.

7. $\frac{1}{2}\begin{vmatrix} 2a & 3a & 1 \\ 3b & 2b & 1 \\ c & c & 1 \end{vmatrix} = 0$

$\Rightarrow \quad 2a(2b-c) - 3a(3b-c) + 1(3bc - 2bc) = 0$

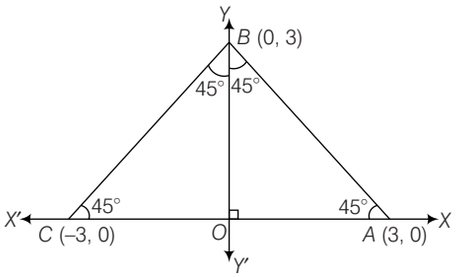
or $\quad -5ab + ac + bc = 0$

or $\quad c = \frac{5ab}{a+b}$

or $\quad \frac{2c}{5} = \frac{2ab}{a+b}$

Hence, $a, \frac{2c}{5}, b$ are in HP.

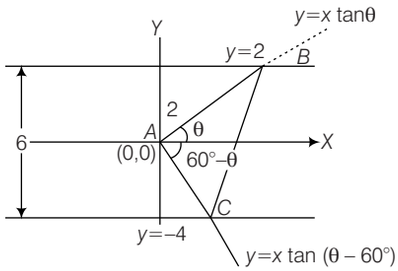
8.



It is clear from the figure orthocentre $\equiv (0, 3)$

9. Let, $A(0, 0)$

Coordinate of B are $(2\cot\theta, 2)$ and coordinate of C are $\{4\cot(60° - \theta), -4\}$



$\therefore \quad AB = AC$

$\Rightarrow \quad (AB)^2 = (AC)^2$

$4\cot^2\theta + 4 = 16\cot^2(60° - \theta) + 16$

$4\operatorname{cosec}^2\theta = 16\operatorname{cosec}^2(60° - \theta)$

$\Rightarrow \quad \sin(60° - \theta) = 2\sin\theta$

$\Rightarrow \quad \left(\frac{\sqrt{3}}{2}\cos\theta - \frac{1}{2}\sin\theta\right) = 2\sin\theta$

$\therefore \quad \tan\theta = \frac{\sqrt{3}}{5}$

$\therefore$ The required length

$= AB = \sqrt{(4\cot^2\theta + 4)}$

$= 2\sqrt{\frac{28}{3}} = \frac{4\sqrt{7}}{\sqrt{3}}$

10.

$\because \quad A \equiv (1, 2), B \equiv (4, 2), C \equiv (4, 5) \qquad (\because AT_1 = T_1T_2 = T_2C)$

T_1 divides AC in the ratio 1 : 2 internally, then

$$T_1 \equiv \left(\frac{1\times 4 + 2\times 1}{1+2}, \frac{1\times 5 + 2\times 2}{1+2}\right)$$

or $\quad T_1 \equiv (2, 3)$

and T_2 is the mid-point of T_1 and C, then

$$T_2 \equiv \left(\frac{2+4}{2}, \frac{3+5}{2}\right)$$

or $\quad T_2 \equiv (3, 4)$

S_1 divides BC in the ratio 1 : 2 (internally), then

$(\because BS_1 = S_1S_2 = S_2C)$

$$S_1 \equiv \left(\frac{1\times 4 + 2\times 4}{1+2}, \frac{1\times 5 + 2\times 2}{1+2}\right)$$

or $\quad S_1 \equiv (4, 3)$

and S_2 is the mid-point of S_1 and C, then

$$S_2 \equiv \left(\frac{4+4}{2}, \frac{3+5}{2}\right)$$

or $\quad S_2 = (4, 4)$

Area of quadrilateral $T_1S_1S_2T_2$

$$= \frac{1}{2}\begin{vmatrix} 2 & 3 \\ 4 & 3 \\ 4 & 4 \\ 3 & 4 \\ 2 & 3 \end{vmatrix}$$

$= \frac{1}{2}\left|(6 + 16 + 16 + 9) - (12 + 12 + 12 + 8)\right|$

$= \frac{3}{2}$ sq units.

11. **Statement (i)** :

$\because$ Points $(-1, 0), (4, -2)$ and $(\cos2\theta, \sin2\theta)$ are collinear.

$\therefore \quad \begin{vmatrix} -1-\cos2\theta & 0-\sin2\theta \\ 4-\cos2\theta & -2-\sin2\theta \end{vmatrix} = 0$

$\Rightarrow \quad 2 + \sin2\theta + 2\cos2\theta + \sin2\theta\cos2\theta + 4\sin2\theta - \sin2\theta\cos2\theta = 0$

$\Rightarrow \quad 5\sin2\theta + 2(1 + \cos2\theta) = 0$

or $\quad 10\sin\theta\cos\theta + 4\cos^2\theta = 0$

or $\quad 2\cos\theta(5\sin\theta + 2\cos\theta) = 0$

or $\quad \cos\theta = 0$ and $\tan\theta = -\frac{2}{5}$

or $\quad \theta = m\pi + \frac{\pi}{2}$

and $\quad \theta = n\pi + \tan^{-1}\left(\frac{-2}{5}\right); m, n \in I$

Statement (ii) :

$\because$ Points $(-1, 0), (4, -2)$ and $\left(\frac{1-\tan^2\theta}{1+\tan^2\theta}, \frac{2\tan\theta}{1+\tan^2\theta}\right)$ are collinear.

$$\therefore \quad \begin{vmatrix} -1-\frac{1-\tan^2\theta}{1+\tan^2\theta} & 0-\frac{2\tan\theta}{1+\tan^2\theta} \\ 4-\frac{1-\tan^2\theta}{1+\tan^2\theta} & -2-\frac{2\tan^2\theta}{1+\tan^2\theta} \end{vmatrix} = 0$$

$\Rightarrow \; 10\tan^3\theta + 4\tan^2\theta + 10\tan\theta + 4 = 0$

or $\quad (2\tan^2\theta + 2)(5\tan\theta + 2) = 0$

or $\quad \tan^2\theta \neq -1$

$\therefore \quad \tan\theta = -\frac{2}{5}$

$\Rightarrow \; \theta = p\pi + \tan^{-1}\left(\frac{-2}{5}\right), p \in I$

12. $\because \quad \frac{\sum_{r=0}^{n-1} x^{2r}}{\sum_{r=0}^{n-1} x^r} = \text{integer}$

$$\Rightarrow \quad \frac{\frac{1\cdot(1-x^{2n})}{(1-x^2)}}{\frac{1\cdot(1-x^n)}{(1-x)}} = \text{integer}$$

$$\Rightarrow \quad \frac{1+x^n}{1+x} = \text{integer}$$

n must be 1, 3, 5, 7, 9, 11, ...

$\therefore$ vertices are (1, 7), (3, 9), (5, 11)

Here, $(AB)^2 = 8, (BC)^2 = 8, (CA)^2 = 32$

$\therefore$ triangle cannot be an equilateral.

13. The orthocentre of ΔBCH is the vertex $A(-1, 0)$.

14. Given, $x_1^2 + y_1^2 + x_2^2 + y_2^2 + x_3^2 + y_3^2 + x_4^2 + y_4^2$

$\leq 2x_1x_3 + 2x_2x_4 + 2y_2y_3 + 2y_1y_4$

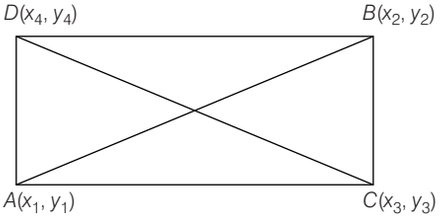
$\Rightarrow \; (x_1 - x_3)^2 + (x_2 - x_4)^2 + (y_2 - y_3)^2 + (y_1 - y_4)^2 \leq 0$

or $\quad (x_1 - x_3)^2 + (x_2 - x_4)^2 + (y_2 - y_3)^2 + (y_1 - y_4)^2 = 0$

or $\quad x_1 = x_3, x_2 = x_4, y_2 = y_3, y_1 = y_4$

or $\quad \frac{x_1 + x_2}{2} = \frac{x_3 + x_4}{2}$

and $\quad \frac{y_1 + y_2}{2} = \frac{y_3 + y_4}{2}$



Hence, AB and CD bisect each other

Therefore, $ACBD$ is a parallelogram. Also,

$(AB)^2 = (x_1 - x_2)^2 + (y_1 - y_2)^2 = (x_3 - x_4)^2 + (y_3 - y_4)^2 = (CD)^2$

Thus, $ACBD$ is a parallelogram and $AB = CD$.

Hence, it is a rectangle.

15. $(x + h)^2 + (y + k)^2 - 4(x + h) + 6(y + k) - 7 = 0$

$\Rightarrow \; x^2 + y^2 + 2x(h-2) + 2y(k+3) + (h^2 + k^2 - 4h + 6k - 7) = 0$

According to question

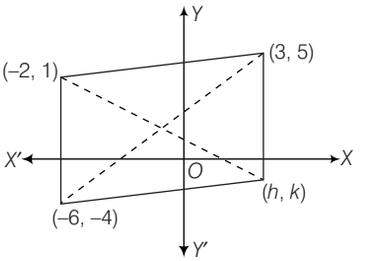
$$h - 2 = 0, k + 3 = 0$$

$\therefore \quad h = 2, k = -3$

hence, $\quad (h, k) \equiv (2, -3)$.

16. If the remaining vertex is (h, k), then

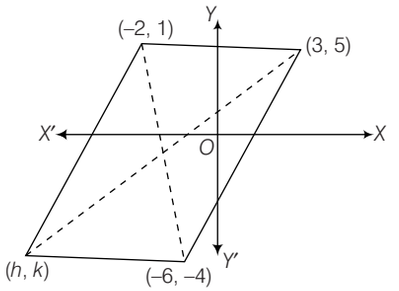
Case I



$h - 2 = 3 - 6, k + 1 = 5 - 4 \quad$ or $\quad h = -1, k = 0$

$\therefore$ Fourth vertex is $(-1, 0)$.

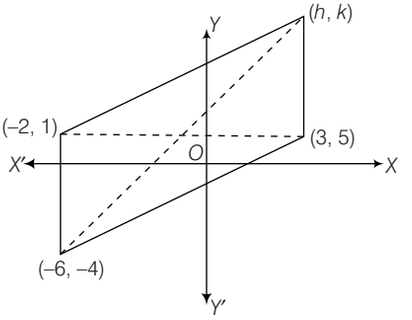
Case II



$h + 3 = -2 - 6, k + 5 = 1 - 4 \quad$ or $\quad h = -11, k = -8$

$\therefore$ Fourth vertex is $(-11, -8)$.

Case III



$$h - 6 = -2 + 3, k - 4 = 1 + 5$$

or $\quad h = 7, k = 10$

$\therefore$ Fourth vertex is (7, 10).

17. $(PA)^2 = (PB)^2$

$\Rightarrow \; (x - a - b)^2 + (y - a + b)^2 = (x - a + b)^2 + (y - a - b)^2$

$\Rightarrow \; (x - a + b)^2 - (x - a - b)^2 = (y - a + b)^2 - (y - a - b)^2$

$\Rightarrow \quad (2x - 2a)(2b) = (2y - 2a)(2b)$

or $\quad x = y$

and P is the mid-point of AB i.e., (a, a)

If P be (a, b), then $bx = ay \qquad (\because a = b)$

18. Let vertices of triangle ABC are

$$A \equiv (x_1, y_1),\ B \equiv (x_2, y_2) \text{ and } C \equiv (x_3, y_3)$$

where, $x_1, x_2, x_3, y_1, y_2, y_3 \in Q$

$\therefore$ $a = BC = \sqrt{(x_2 - x_3)^2 + (y_2 - y_3)^2}$

$=$ rational or irrational

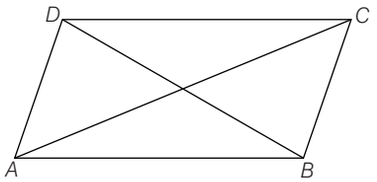
similarly, $b = CA,\ c = AB$

Then, incentre

$$\equiv \left(\frac{ax_1 + bx_2 + cx_3}{a + b + c}, \frac{ay_1 + by_2 + cy_3}{a + b + c} \right)$$

$\therefore$ Incentre has rational or irrational coordinates but centroid, circumcentre and orthocentre have always rational coordinates.

19. Since, $A \equiv (-4, -1),\ B \equiv (-2, -4),\ C \equiv (4, 0),\ D \equiv (2, 3)$



$\therefore$ $(AB)^2 = (-4 + 2)^2 + (-1 + 4)^2 = 13$

$(BC)^2 = (-2 - 4)^2 + (-4 - 0)^2 = 52$

$(CD)^2 = (4 - 2)^2 + (0 - 3)^2 = 13$

and $(DA)^2 = (2 + 4)^2 + (3 + 1)^2 = 52$

Clearly, $AB = CD$ and $BC = AD$

$\therefore$ $ABCD$ is a parallelogram.

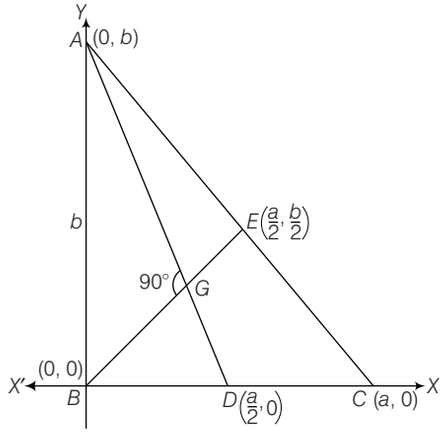
Again, $(AC)^2 = (-4 - 4)^2 + (-1 - 0)^2 = 65$

and $(BD)^2 = (-2 - 2)^2 + (-4 - 3)^2 = 65$

$\therefore$ $AC = BD$

Hence, $ABCD$ is a rectangle.

20.



$\because$ $BG = \frac{2}{3} BE = \frac{2}{3} \times \frac{\sqrt{(a^2 + b^2)}}{2}$

$\Rightarrow$ $(BG)^2 = \frac{1}{9}(a^2 + b^2)$ ...(i)

and $AG = \frac{2}{3} AD = \frac{2}{3} \times \sqrt{\left(\frac{a^2}{4} + b^2\right)}$

$\Rightarrow$ $(AG)^2 = \frac{1}{9}(a^2 + 4b^2)$ ...(ii)

Now, in right angled triangle ABG,

$(BA)^2 = (AG)^2 + (BG)^2$

$\Rightarrow$ $b^2 = \frac{1}{9}(a^2 + 4b^2) + \frac{1}{9}(a^2 + b^2)$ [from Eqs. (i) and (ii)]

$\Rightarrow$ $a^2 = 2b^2$

$\therefore$ $a = \pm b\sqrt{2}$

21. $\because$ $(AB)^2 = (x - y)^2 + (y - z)^2$

$(BC)^2 = (y - z)^2 + (z - x)^2$

and $(CA)^2 = (z - x)^2 + (x - y)^2$

Case I If $x = y$, then

$(AB)^2 + (CA)^2 = (BC)^2$

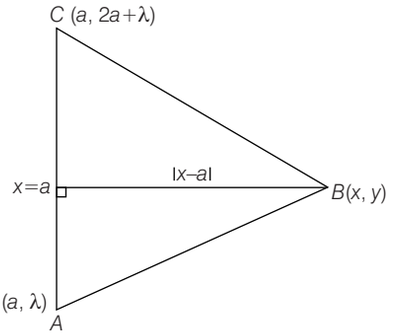
Case II If $y = z$, then

$(AB)^2 + (BC)^2 = (CA)^2$

Case III If $z = x$, then

$(BC)^2 + (CA)^2 = (AB)^2$

22.



Let $A \equiv (a, \lambda)$

then, $B \equiv (a, 2a + \lambda)$

and $C \equiv (x, y)$

Area of $\Delta ABC = a^2$ (given)

$\Rightarrow$ $\frac{1}{2} \times 2a \times |x - a| = a^2$

$\Rightarrow$ $|x - a| = a$

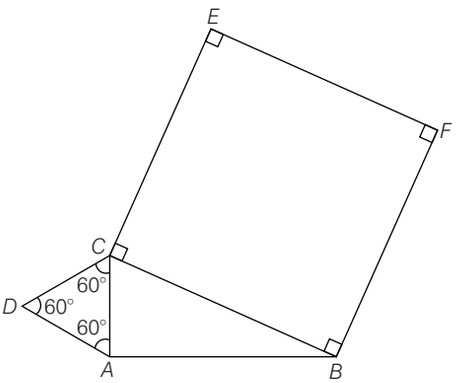
$\Rightarrow$ $x - a = \pm a$

$\Rightarrow$ $x = 0,\ x = 2a$

Sol. (Q. Nos. 23 to 25)

$$AB = \sqrt{(1 + 3)^2 + (2 - 1)^2} = \sqrt{17}$$

$$AC = \frac{1}{2} AB = \frac{1}{2}\sqrt{17}$$



For coordinates of C:

$$\frac{z_c - z_A}{z_B - z_A} = \frac{AC}{AB} e^{i\pi/2} = \frac{i}{2}$$

$$\Rightarrow\ z_c - (1 + 2i) = \frac{i}{2}(-3 + i - 1 - 2i)$$

$$= \frac{i}{2}(-4 - i) = -2i + \frac{1}{2}$$

or $$z_c = \frac{3}{2}$$

$$\therefore\quad C \equiv \left(\frac{3}{2}, 0\right)$$

For coordinates of D:

$$\frac{z_D - z_A}{z_C - z_A} = e^{i\pi/3}$$

$$\Rightarrow\ z_D - (1 + 2i) = \left(\frac{1}{2} + \frac{i\sqrt{3}}{2}\right)\left(\frac{1}{2} - 2i\right)$$

$$= \frac{1}{4} + \sqrt{3} - i + \frac{i\sqrt{3}}{4}$$

or $$z_D = \left(\frac{5}{4} + \sqrt{3}\right) + i\left(1 + \frac{\sqrt{3}}{4}\right)$$

$$\therefore\quad D \equiv \left(\frac{5}{4} + \sqrt{3}, 1 + \frac{\sqrt{3}}{4}\right)$$

For coordinates of F:

$$\frac{z_F - z_B}{z_C - z_B} = e^{-i\pi/2} = -i$$

$$\Rightarrow\ z_F - (-3 + i) = -i\left(\frac{9}{2} - i\right)$$

$$\Rightarrow\quad z_F = -4 - \frac{7}{2}i$$

$$\therefore\quad F \equiv \left(-4, -\frac{7}{2}\right), \text{ then}$$

$$E \equiv \left(\frac{1}{2}, -\frac{9}{2}\right)$$

23. $$S = \frac{1}{2}\left|\begin{vmatrix} 1 & 2 & 1 \\ \frac{3}{2} & 0 & 1 \\ -4 & -\frac{7}{2} & 1 \end{vmatrix}\right| = \frac{51}{8}$$

$$\therefore\quad 8S = 51$$

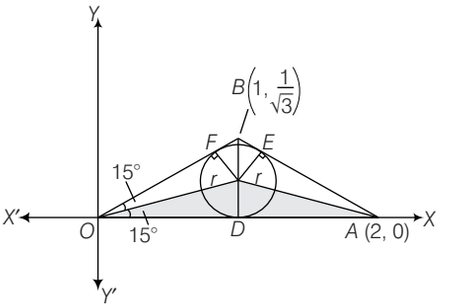
24. $$DE = \sqrt{\left(\frac{5}{4} + \sqrt{3} - \frac{1}{2}\right)^2 + \left(1 + \frac{\sqrt{3}}{4} + \frac{9}{2}\right)^2}$$

$$= \sqrt{\left(\frac{3}{4} + \sqrt{3}\right)^2 + \left(\frac{11}{2} + \frac{\sqrt{3}}{4}\right)^2} = \frac{\sqrt{17}}{2}\sqrt{(8 + \sqrt{3})}$$

25. y-coordinate of the centroid of the square

$$BCEF = \frac{0 - \frac{7}{2}}{2} = -\frac{7}{4}$$

■ ***Sol.*** (Q. Nos. 26 to 28)



Given, $O \equiv (0, 0)\ A \equiv (2, 0)$

and $$B \equiv \left(1, \frac{1}{\sqrt{3}}\right)$$

Let $P \equiv (x, y)$

If I be the incentre of ΔOAB.

If in radius = r, then

$ID = IE = IF = r$, *if* P at I,

then $d(P, OA) = d(P, OB) = d(P, AB) = r$,

But $d(P, OA) \le \min.\{d(P, OB), d(P, AB)\}$

which is possible only P lies in the ΔOIA

$\therefore$ M be the peak of region R.

$\therefore\quad M = I$

26. Length of perpendicular from M to $OA = ID = r = OD \tan 15°$

$$= 1 \times (2 - \sqrt{3})$$

$$= 2 - \sqrt{3}$$

27. Perimeter of region

$$R = IO + OA + AI$$

$$= r\,\text{cosec}\,15° + 2 + r\,\text{cosec}\,15°$$

$$= 2r\ \text{cosec}\,15° + 2$$

$$= 2(2 - \sqrt{3}) \cdot \frac{2\sqrt{2}}{(\sqrt{3} - 1)} + 2$$

$$= (\sqrt{3} - 1)^2 \cdot \frac{2\sqrt{2}}{(\sqrt{3} - 1)} + 2$$

$$= 2\sqrt{2}(\sqrt{3} - 1) + 2$$

$$\Rightarrow\quad = 2 + 4\sqrt{(2 - \sqrt{3})}$$

28. Area of region $R = \frac{1}{2} \times OA \times r$

$$= \frac{1}{2} \times 2 \times (2 - \sqrt{3}) = (2 - \sqrt{3})$$

29. We know that the area of the triangle formed by joining the mid-points of any triangle is one fourth of that triangle, then

$$\Delta_2 = 4\Delta_1$$

$$\therefore\quad \frac{\Delta_2}{\Delta_1} = 4$$

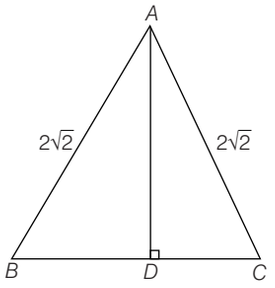
30. Since, the distance of all points from $O(0, 0) = 5$

$\therefore$Circumradius $(R) = 5$

Hence, diameter of nine point circle = $R = 5$

31. Let $B \equiv (2\sqrt{2}, 0), C \equiv (0, \sqrt{2})$

$\therefore \quad BC = \sqrt{(8+2)} = \sqrt{10}$



and $\quad AD = \sqrt{(AB)^2 - (BD)^2}$

$$= \sqrt{\left(8 - \frac{10}{4}\right)} = \sqrt{\frac{11}{2}}$$

$\therefore \quad \Delta = \frac{1}{2} \cdot BC \cdot AD$

$$= \frac{1}{2} \cdot \sqrt{10} \cdot \frac{\sqrt{11}}{\sqrt{2}} = \frac{\sqrt{55}}{2}$$

$\Rightarrow \quad [\Delta] = 3$

32. Let $A \equiv (3, 4), B \equiv (4, 3)$ and $C \equiv (1, 2)$

$\therefore \quad a = |BC| = \sqrt{(9+1)} = \sqrt{10}$

$b = |CA| = \sqrt{(4+4)} = 2\sqrt{2}$

$c = |AB| = \sqrt{(1+1)} = \sqrt{2}$

$$\Rightarrow \quad x = \frac{\sqrt{10} \times 3 + 2\sqrt{2} \times 4 + \sqrt{2} \times 1}{\sqrt{10} + 2\sqrt{2} + \sqrt{2}}$$

$$= \frac{3(\sqrt{10} + 3\sqrt{2})}{(\sqrt{10} + 3\sqrt{2})} = 3$$

$\therefore \quad x^2 = 9$

33.

$\because \quad AP = PQ = QB$

Let R is the mid-point of PQ such that $PR = RQ$.

Now, $\quad AR = AP + PR = QB + RQ = RB$

$\Rightarrow \quad AR = RB$

$\therefore$ R bisects the line segment AB, then

$$R \equiv \left(\frac{-2+3}{2}, \frac{5+1}{2}\right)$$

$$\equiv \left(\frac{1}{2}, 3\right) = (a, b) \qquad \text{(given)}$$

$\therefore \quad a = \frac{1}{2}, \; b = 3 \Rightarrow \frac{b}{a} = 6$

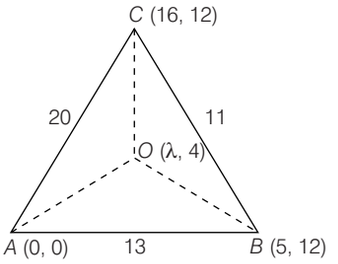
34. **(A)** Centroid of ΔABC is

$$\left(\frac{0+5+16}{3}, \frac{0+12+12}{3}\right) \equiv (7, 8)$$

Here, $\quad \lambda = 7, \mu = 8$

$\therefore \quad \lambda + \mu = 15$

(B)



$(OA)^2 = (OB)^2 = (OC)^2$

$\Rightarrow \quad \lambda^2 + \mu^2 = (\lambda - 5)^2 + (\mu - 12)^2 = (\lambda - 16)^2 + (\mu - 12)^2$

$\Rightarrow \quad (\lambda - 5)^2 + (\mu - 12)^2 = (\lambda - 16)^2 + (\mu - 12)^2$

or $\quad (\lambda - 5) = -(\lambda - 16)$

$\therefore \quad \lambda = \frac{21}{2} \Rightarrow 2\lambda = 21$

(C) Incentre of ΔABC is

$$\left(\frac{11 \times 0 + 13 \times 16 + 20 \times 5}{11 + 13 + 20}, \frac{11 \times 0 + 13 \times 12 + 20 \times 12}{11 + 13 + 20}\right)$$

$$\equiv (7, 9)$$

Here, $\quad \mu = 9$

(D) Excentre opposite to vertex B is

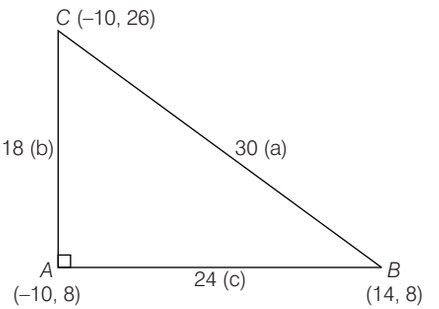
$$\left(\frac{11 \times 0 + 13 \times 16 - 20 \times 5}{11 + 13 - 20}, \frac{11 \times 0 + 13 \times 12 - 20 \times 12}{11 + 13 - 20}\right)$$

$$\equiv (27, -21)$$

Here, $\quad \lambda = 27, \mu = -21$

$\therefore \quad \lambda + \mu = 6$

35.



$$\Delta = \frac{1}{2}\left|\begin{vmatrix} -10 & 8 & 1 \\ 14 & 8 & 1 \\ -10 & 26 & 1 \end{vmatrix}\right| = 216$$

$$s = \frac{a+b+c}{2} = \frac{30+18+24}{2} = 36$$

$$G \equiv \left(\frac{-10+14-10}{3}, \frac{8+8+26}{3}\right)$$

$$\equiv (-2, 14)$$

$$I \equiv \left(\frac{30 \times -10 + 24 \times -10 + 18 \times 14}{30+24+18}, \frac{30 \times 8 + 24 \times 26 + 18 \times 8}{30+24+18}\right)$$

$$\equiv (-4, 14)$$

$H = A \equiv (-10, 8)$

$O =$ mid-point of $BC \equiv (2, 17)$

(A) $r = \dfrac{\Delta}{s} = \dfrac{216}{36} = 6$

(B) $R = \dfrac{BC}{2} = \dfrac{30}{2} = 15$

(C) Area of $\Delta IGH = \dfrac{1}{2}\left|\begin{vmatrix} -4 & 14 & 1 \\ -2 & 14 & 1 \\ -10 & 8 & 1 \end{vmatrix}\right| = 6$

(D) Area of $\Delta OGI = \dfrac{1}{2}\left|\begin{vmatrix} 2 & 17 & 1 \\ -2 & 14 & 1 \\ -4 & 14 & 1 \end{vmatrix}\right| = 3$

36. The centroid of triangle ABC is $G(1, 3)$. If D divided BC in the ratio $\lambda : 1$, then

$$D \equiv \left(\frac{3\lambda - 1}{\lambda + 1}, \frac{4\lambda + 3}{\lambda + 1}\right), E \equiv \left(\frac{\lambda + 3}{\lambda + 1}, \frac{3\lambda + 4}{\lambda + 1}\right)$$

and $$F \equiv \left(\frac{-\lambda + 1}{\lambda + 1}, \frac{3\lambda + 2}{\lambda + 1}\right)$$

$\therefore$ The centroid of triangle DEF is $(1, 3)$.

Both statements are true and statement II is correct explanation of statement I.

37. $\because$ $|AB| = \sqrt{(-5-7)^2 + (-2-6)^2} = 4\sqrt{13}$

$$|BC| = \sqrt{(7-5)^2 + (6+4)^2} = 2\sqrt{26}$$

and $$|CA| = \sqrt{(5+5)^2 + (-4+2)^2} = 2\sqrt{26}$$

$\because$ $(BC)^2 + (CA)^2 = (AB)^2$ and $|BC| = |CA|$

$\Rightarrow \Delta ABC$ is right angled isosceles triangle and right angle at C.

$\therefore$ Circumcentre is mid-point of A, $B \equiv (1, 2)$. Both statements are true and statement II is correct explanation of statement I.

38. Let $A \equiv (0, 0)$, $M \equiv (h, k)$, $B \equiv (2h, 2k)$ and let same ratio $\lambda : 1$

$$P \equiv \left(\frac{2h\lambda}{\lambda + 1}, \frac{2k\lambda}{\lambda + 1}\right), Q = \left(\frac{2h\lambda}{\lambda - 1}, \frac{2k\lambda}{\lambda - 1}\right)$$

$$AP = \frac{2\lambda}{(\lambda + 1)}\sqrt{(h^2 + k^2)},\ AB = 2\sqrt{(h^2 + k^2)},$$

$$AQ = \frac{2\lambda}{(\lambda - 1)}\sqrt{(h^2 + k^2)}$$

$\because$ $$\frac{AP - AB}{AB - AQ} = \frac{\lambda - 1}{\lambda + 1} = \frac{AP}{AQ}$$

$\therefore$ AP, AB and AQ are in HP.

$\Rightarrow$ $AM + MP$, $AM + MB$ and $AM + MQ$ are in HP

$\therefore$ MP, MB and MQ are in GP.

Both statements are true and statement II is correct explanation of statement I.

39. Replacing x by $(x - 4)$ and y by $y + 1$ is

$x^2 - 3xy + 11x - 12y + 36 = 0$, then

$(x-4)^2 - 3(x-4)(y+1) + 11(x-4) - 12(y+1) + 36 = 0$

$\Rightarrow$ $$x^2 - 3xy + 8 = 0$$

or $$\frac{x^2}{8} - \frac{3xy}{8} + 1 = 0$$

comparing with $ax^2 + bxy + 1 = 0$.

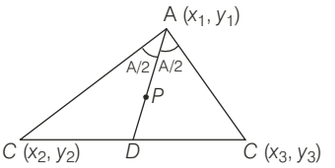
$\therefore$ $$a = \frac{1}{8}, b = -\frac{3}{8}$$

$\therefore$ $$b^2 - a = \frac{9}{64} - \frac{1}{8} = \frac{1}{64}$$

$\Rightarrow$ Statement I is true.

Hence, both statements are true and statement II is not correct explanation of statement I.

40. Let AD be the internal bisector of angle A.



Then, $$\frac{BD}{DC} = \frac{AB}{AC} = \frac{c}{b}$$

$\therefore$ $$D \equiv \left(\frac{cx_3 + bx_2}{c + b}, \frac{cy_3 + by_2}{c + b}\right)$$

Let $P \equiv (x, y)$. According to question, $P(x, y)$ lies on AD, therefore P, A, D are collinear

$\therefore$ $$\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ \dfrac{cx_3 + bx_2}{c + b} & \dfrac{cy_3 + by_2}{c + b} & 1 \end{vmatrix} = 0$$

or $$\frac{1}{(c+b)}\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ cx_3 + bx_2 & cy_3 + by_2 & c + b \end{vmatrix} = 0$$

or $$\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ cx_3 & cy_3 & c \end{vmatrix} + \begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ bx_2 & by_2 & b \end{vmatrix} = 0$$

(using the addition property of determinants)

or $$c\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} + b\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix} = 0$$

Hence, $$b\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix} + c\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = 0$$

41. Let first term and common difference of corresponding AP are A and D.

Since, pth term of HP $= a$

$\therefore$ pth term of AP $= \dfrac{1}{a}$

$\Rightarrow$ $$A + (p-1)D = \frac{1}{a} \quad \text{...(i)}$$

Similarly, $$A + (q-1)D = \frac{1}{b} \quad \text{...(ii)}$$

and $A + (r-1)\,D = \frac{1}{c}$ ...(iii)

Subtracting Eq. (ii) from Eq. (i),

$$(p-q)\,D = \frac{1}{a} - \frac{1}{b} \quad \text{...(iv)}$$

and subtracting Eq. (iii) from Eq. (ii),

$$(q-r)\,D = \frac{1}{b} - \frac{1}{c} \quad \text{...(v)}$$

Dividing Eq. (iv) by Eq. (v),

$$\frac{p-q}{q-r} = \frac{\frac{1}{a} - \frac{1}{b}}{\frac{1}{b} - \frac{1}{c}} = \frac{(b-a)}{ba} \times \frac{bc}{(c-b)}$$

$$\Rightarrow \quad \frac{p-q}{q-r} = \frac{bc-ac}{ac-ab} \quad \text{...(vi)}$$

Let $A\,(bc, p)$, $B\,(ca, q)$, $C\,(ab, r)$

$$\text{Slope of } AB = \frac{q-p}{ca-bc}$$

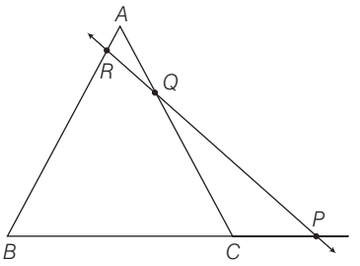
and $$\text{Slope of } BC = \frac{r-q}{ab-ca}$$

$$= \frac{q-p}{ca-bc} \quad \text{[from Eq. (vi)]}$$

Since, Slope of AB = slope of BC

Hence, A, B, C are collinear.

42. Suppose the equation of the line L is $ax + by + c = 0$. Let the coordinates of A, B, C be respectively $(x_1, y_1)\,; (x_2, y_2)\,; (x_3, y_3)$. Suppose P divides BC in the ratio $\lambda : 1$, then coordinates of P are $\left(\frac{\lambda x_3 + x_2}{\lambda + 1}, \frac{\lambda y_3 + y_2}{\lambda + 1}\right)$ since P lies on L.



$$\Rightarrow \quad a\left(\frac{\lambda x_3 + x_2}{\lambda + 1}\right) + b\left(\frac{\lambda y_3 + y_2}{\lambda + 1}\right) + c = 0$$

$$\Rightarrow \quad a(\lambda x_3 + x_2) + b(\lambda y_3 + y_2) + c(\lambda + 1) = 0$$

$$\Rightarrow \quad \lambda(ax_3 + by_3 + c) + (ax_2 + by_2 + c) = 0$$

$$\therefore \quad \frac{\lambda}{1} = \frac{BP}{CP} = -\frac{(ax_2 + by_2 + c)}{(ax_3 + by_3 + c)}$$

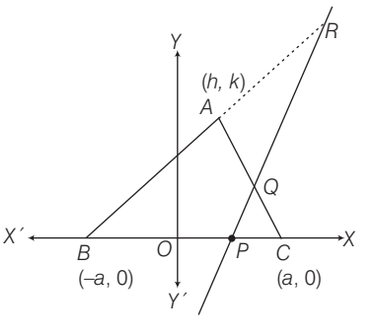
Similarly, $$\frac{CQ}{QA} = -\frac{(ax_3 + by_3 + c)}{(ax_1 + by_1 + c)}$$

and $$\frac{AR}{RB} = -\frac{(ax_1 + by_1 + c)}{(ax_2 + by_2 + c)}$$

Hence, $$\frac{BP}{PC} \cdot \frac{CQ}{QA} \cdot \frac{AR}{RB} = -1$$

Aliter :

Let middle point O of BC as the origin, BC as the X-axis and yy' as Y-axis.



Let $BC = 2a$

$\therefore \quad OB = OC = a$

Then, $B \equiv (-a, 0)$

and $C \equiv (a, 0)$

Let $A \equiv (h, k)$

Let P, Q, R divides BC, CA and AB in the ratio $\lambda : 1, \mu : 1$ and $\nu : 1$

i.e. $$\frac{BP}{PC} = \lambda, \frac{CQ}{QA} = \mu, \frac{AR}{RB} = \nu$$

Case I : Two sides divided internally and one side divided externally.

Hence, λ, μ are positive and ν is negative

Now, $$P \equiv \left(\frac{\lambda a - a}{\lambda + 1}, 0\right); Q \equiv \left(\frac{\mu h + a}{\mu + 1}, \frac{\mu k}{\mu + 1}\right)$$

and $$R \equiv \left(\frac{-a\nu + h}{\nu + 1}, \frac{k}{\nu + 1}\right)$$

Since, points P, Q, R are collinear.

$$\therefore \quad \frac{1}{2}\begin{vmatrix} \frac{\lambda a - a}{\lambda + 1} & 0 & 1 \\ \frac{\mu h + a}{\mu + 1} & \frac{\mu k}{\mu + 1} & 1 \\ \frac{-a\nu + h}{\nu + 1} & \frac{k}{\nu + 1} & 1 \end{vmatrix} = 0$$

or $$\begin{vmatrix} \lambda a - a & 0 & \lambda + 1 \\ \mu h + a & \mu k & \mu + 1 \\ -a\nu + h & k & \nu + 1 \end{vmatrix} = 0$$

or $$k\begin{vmatrix} \lambda a - a & 0 & \lambda + 1 \\ \mu h + a & \mu & \mu + 1 \\ -a\nu + h & 1 & \nu + 1 \end{vmatrix} = 0$$

Applying $R_2 \to R_2 - \mu R_3$, then

$$k\begin{vmatrix} \lambda a - a & 0 & \lambda + 1 \\ a + a\mu\nu & 0 & 1 - \mu\nu \\ -a\nu + h & 1 & \nu + 1 \end{vmatrix} = 0$$

or $$-k\begin{vmatrix} \lambda a - a & \lambda + 1 \\ a + a\mu\nu & 1 - \mu\nu \end{vmatrix} = 0$$

or $$-ka\begin{vmatrix}\lambda-1 & \lambda+1\\ 1+\mu\nu & 1-\mu\nu\end{vmatrix}=0$$

or $$-ka\{(\lambda-1)(1-\mu\nu)-(\lambda+1)(1+\mu\nu)\}=0$$

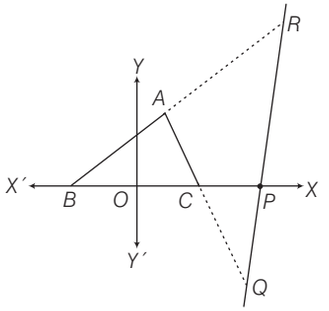
or $$-ka\{-2\lambda\mu\nu-2\}$$

$\Rightarrow$ $$2ka(\lambda\mu\nu+1)=0$$

or $$\lambda\mu\nu=-1 \qquad (\because\ ka\neq 0)$$

or $$\frac{BP}{PC}\cdot\frac{CQ}{QA}\cdot\frac{AR}{RB}=-1$$

Case II : All the three sides will be divided externally



Here, λ, μ and ν are negative.

Now, in case I formula for internal division will be used then we can show that

$$\lambda\mu\nu=-1$$

i.e. $$\frac{BP}{PC}\cdot\frac{CQ}{QA}\cdot\frac{AR}{RB}=-1$$

43. Since, given points are collinear, then

$$\frac{1}{2}\begin{vmatrix}\frac{a^3}{a-1} & \frac{a^2-3}{a-1} & 1\\ \frac{b^3}{b-1} & \frac{b^2-3}{b-1} & 1\\ \frac{c^3}{c-1} & \frac{c^2-3}{c-1} & 1\end{vmatrix}=0$$

$\Rightarrow$ $$\frac{1}{(a-1)(b-1)(c-1)}\begin{vmatrix}a^3 & a^2-3 & a-1\\ b^3 & b^2-3 & b-1\\ c^3 & c^2-3 & c-1\end{vmatrix}=0$$

or $$\begin{vmatrix}a^3 & a^2-3 & a-1\\ b^3 & b^2-3 & b-1\\ c^3 & c^2-3 & c-1\end{vmatrix}=0$$

$\Rightarrow$ $$\begin{vmatrix}a^3 & a^2 & a\\ b^3 & b^2 & b\\ c^3 & c^2 & c\end{vmatrix}+\begin{vmatrix}a^3 & a^2 & -1\\ b^3 & b^2 & -1\\ c^3 & c^2 & -1\end{vmatrix}+\begin{vmatrix}a^3 & -3 & a\\ b^3 & -3 & b\\ c^3 & -3 & c\end{vmatrix}+\begin{vmatrix}a^3 & -3 & -1\\ b^3 & -3 & -1\\ c^3 & -3 & -1\end{vmatrix}=0$$

or $$-abc\begin{vmatrix}1 & a & a^2\\ 1 & b & b^2\\ 1 & c & c^2\end{vmatrix}+\begin{vmatrix}1 & a^2 & a^3\\ 1 & b^2 & b^3\\ 1 & c^2 & c^3\end{vmatrix}-3\begin{vmatrix}1 & a & a^3\\ 1 & b & b^3\\ 1 & c & c^3\end{vmatrix}+0=0$$

or $$-abc(a-b)(b-c)(c-a)+(ab+bc+ca)(a-b)(b-c)(c-a)-3(a+b+c)(a-b)(b-c)(c-a)=0$$

$\Rightarrow$ $$-(a-b)(b-c)(c-a)\{abc-(ab+bc+ca)+3(a+b+c)\}=0$$

$\therefore$ $$abc-(ab+bc+ca)+3(a+b+c)=0$$

$$\left.\begin{array}{l}\because\ a,b,c \text{ are distinct}\\ \therefore a\neq b,\ b\neq c,\ c\neq a\\ \therefore(a-b)(b-c)(c-a)\neq 0\end{array}\right\}$$

a, b, c are distinct.

Aliter : Suppose the given points lie on the line $lx+my+n=0$

then, $$l\left(\frac{t^3}{t-1}\right)+m\left(\frac{t^2-3}{t-1}\right)+n=0$$

where, $t=a, b, c$

$\Rightarrow$ $$lt^3+mt^2+nt-(3m+n)=0 \qquad ...(i)$$

i.e. a, b, c are the roots of Eq. (i)

then, $$a+b+c=-\frac{m}{l}$$

$$ab+bc+ca=\frac{n}{l}$$

$$abc=\frac{(3m+n)}{l}$$

Now, $$abc-(bc+ca+ab)+3(a+b+c)$$

$$=\frac{(3m+n)}{l}-\frac{n}{l}-\frac{3m}{l}=0$$

Hence, $$abc-(bc+ca+ab)+3(a+b+c)=0$$

44. $\because\ \Delta^c=\Delta^2$

where, Δ^c be the determinant of cofactors of Δ.

Let, $$\Delta^c=\begin{vmatrix}A_1 & B_1 & C_1\\ A_2 & B_2 & C_2\\ A_3 & B_3 & C_3\end{vmatrix}$$

then, $$A_1=b_2c_3-b_3c_2,\ B_1=a_3c_2-a_2c_3,\ C_1=a_2b_3-a_3b_2$$

$$A_2=b_3c_1-b_1c_3,\ B_2=c_3a_1-c_1a_3,\ C_2=a_3b_1-a_1b_3$$

$$A_3=b_1c_2-b_2c_1,\ B_3=a_2c_1-a_1c_2,\ C_3=a_1b_2-a_2b_1$$

Given lines are

$$a_1x+b_1y+c_1=0 \qquad ...(i)$$

$$a_2x+b_2y+c_2=0 \qquad ...(ii)$$

$$a_3x+b_3y+c_3=0 \qquad ...(iii)$$

Let P be the point of intersection of Eqs. (ii) and (iii), then

$$\frac{x}{b_2c_3-b_3c_2}=\frac{y}{c_2a_3-c_3a_2}=\frac{1}{a_2b_3-a_3b_2}$$

i.e. $$\frac{x}{A_1}=\frac{y}{B_1}=\frac{1}{C_1}$$

$\therefore$ $$P\equiv\left(\frac{A_1}{C_1},\frac{B_1}{C_1}\right)$$

Similarly, if Q and R be the points of intersections of Eqs. (iii) and (i) and Eqs. (i) and (ii) respectively, then

$$Q\equiv\left(\frac{A_2}{C_2},\frac{B_2}{C_2}\right),\ R\equiv\left(\frac{A_3}{C_3},\frac{B_3}{C_3}\right)$$

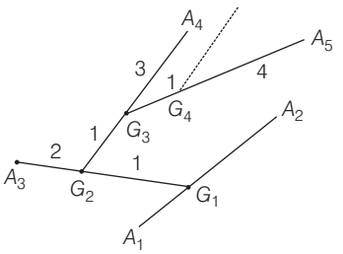
$$\therefore \text{ Area of } \Delta PQR = \frac{1}{2}\left|\begin{vmatrix} \frac{A_1}{C_1} & \frac{B_1}{C_1} & 1 \\ \frac{A_2}{C_2} & \frac{B_2}{C_2} & 1 \\ \frac{A_3}{C_3} & \frac{B_3}{C_3} & 1 \end{vmatrix}\right| = \frac{1}{2\,|\,C_1C_2C_3|}\begin{vmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{vmatrix}$$

$$= \frac{1}{2\,|\,C_1C_2C_3|}\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}^2 = \frac{\Delta^2}{2\,|\,C_1C_2C_3|}$$

45. Since, G_1 is the middle point of A_1A_2 where

$$A_1 \equiv (x_1, y_1) \quad \text{and} \quad A_2 \equiv (x_2, y_2)$$

$$\therefore \quad G_1 \equiv \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$$



Since, G_2 divided G_1A_3 internally in the ratio 1:2

$$\therefore \quad G_2 \equiv \left(\frac{2\cdot\left(\frac{x_1 + x_2}{2}\right) + 1.\,x_3}{2+1}, \frac{2\cdot\left(\frac{y_1 + y_2}{2}\right) + 1.y_3}{2+1}\right)$$

$$\text{i.e.} \quad G_2 \equiv \left(\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3}\right)$$

Again G_3 divides G_2A_4 internally in the ratio 1:3

$$\therefore \quad G_3 \equiv \left(\frac{3\cdot\left(\frac{x_1 + x_2 + x_3}{3}\right) + 1.x_4}{3+1}, \frac{3\cdot\left(\frac{y_1 + y_2 + y_3}{3}\right) + 1.y_4}{3+1}\right)$$

$$\text{i.e.} \quad G_3 \equiv \left(\frac{x_1 + x_2 + x_3 + x_4}{4}, \frac{y_1 + y_2 + y_3 + y_4}{4}\right)$$

Proceeding in this way, we can show that

$$G_{n-1} \equiv \left(\frac{x_1 + x_2 + \ldots + x_n}{n}, \frac{y_1 + y_2 + \ldots + y_n}{n}\right)$$

or we can say that the coordinates of the final point are

$$\frac{x_1 + x_2 + \ldots + x_n}{n} \text{ and } \frac{y_1 + y_2 + \ldots + y_n}{n}$$

46. Let the axes be rotated through an angle α, since (x, y) be the coordinates with respect to old axes and (x_1, y_1) be the coordinates with respect to new axes, then

$$x = x_1\cos\alpha - y_1\sin\alpha$$

and $$y = x_1\sin\alpha + y_1\cos\alpha$$

Now, the expression $ax^2 + 2hxy + by^2$ becomes

$$a(x_1\cos\alpha - y_1\sin\alpha)^2 + 2h(x_1\cos\alpha - y_1\sin\alpha)$$
$$(x_1\sin\alpha + y_1\cos\alpha) + b(x_1\sin\alpha + y_1\cos\alpha)^2$$

$$= x_1^2(a\cos^2\alpha + h\sin2\alpha + b\sin^2\alpha)$$
$$+ x_1y_1(2h\cos2\alpha - a\sin2\alpha + b\sin2\alpha)$$
$$+ y_1^2(a\sin^2\alpha - h\sin2\alpha + b\cos^2\alpha) \quad \ldots(i)$$

But, from question the expression $ax^2 + 2hxy + by^2$ transforms into

$$a_1x_1^2 + 2h_1x_1y_1 + b_1y_1^2 \quad \ldots(ii)$$

Therefore, the expressions (i) and (ii) are the same. Hence, equating the coefficients, we get

$$a_1 = a\cos^2\alpha + h\sin2\alpha + b\sin^2\alpha \quad \ldots(iii)$$

$$2h_1 = 2h\cos2\alpha - a\sin2\alpha + b\sin2\alpha \quad \ldots(iv)$$

$$b_1 = a\sin^2\alpha - h\sin2\alpha + b\cos^2\alpha \quad \ldots(v)$$

On adding Eqs. (iii) and (v), we get

$$a_1 + b_1 = a(\cos^2\alpha + \sin^2\alpha) + b(\sin^2\alpha + \cos^2\alpha)$$

or $$a_1 + b_1 = a + b \quad \ldots(vi)$$

Again, $$a_1 - b_1 = a(\cos^2\alpha - \sin^2\alpha) + 2h\sin2\alpha + b(\sin^2\alpha - \cos^2\alpha)$$

$$\Rightarrow \quad (a_1 - b_1) = (a - b)\cos2\alpha + 2h\sin2\alpha$$

$$(a_1 - b_1)^2 = (a - b)^2\cos^2 2\alpha + 4h^2\sin^2 2\alpha + 4h(a - b)\sin2\alpha\cos2\alpha \quad \ldots(vii)$$

Again, from Eq. (iv)

$$2h_1 = 2h\cos2\alpha - (a - b)\sin2\alpha$$

$$\therefore \quad 4h_1^2 = 4h^2\cos^2 2\alpha + (a - b)^2\sin^2 2\alpha - 4h(a - b)\sin2\alpha\cos2\alpha \quad \ldots(viii)$$

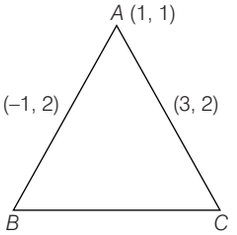
On adding Eqs. (vii) and (viii), we get

$$(a_1 - b_1)^2 + 4h_1^2 = (a - b)^2 + 4h^2$$

Again, $$4a_1b_1 - 4h_1^2 = (a_1 + b_1)^2 - (a_1 - b_1)^2 - 4h^2$$
$$= (a + b)^2 - (a - b)^2 - 4h^2 \quad [\text{from Eq. (vi)}]$$

Hence, $$a_1b_1 - h_1^2 = ab - h^2$$

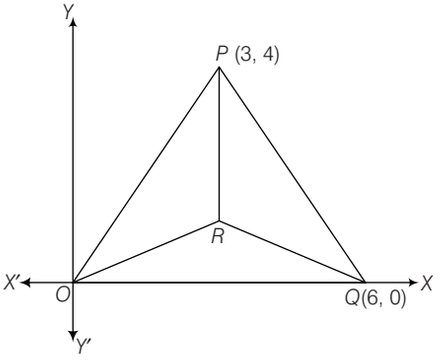
47. Vertex of triangle is (1, 1) and mid-point of sides through this vertex are (−1,2) and (3, 2)



$\Rightarrow$ Vertex B and C come out to be (−3, 3) and (5, 3)

$\therefore$ Centroid is $\frac{1-3+5}{3}, \frac{1+3+5}{3} \Rightarrow \left(1, \frac{7}{3}\right)$

48.

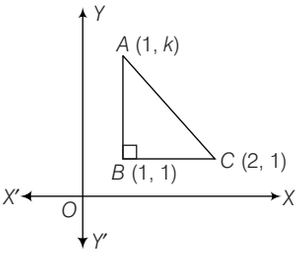


$\because$ Area of (ΔOPR) = Area of (ΔPQR) = Area of (ΔOQR)

$\therefore$ By geometry R should be the centroid of ΔOPQ

$$\therefore \quad R \equiv \left(\frac{0+3+6}{3}, \frac{0+4+0}{3}\right) \equiv \left(3, \frac{4}{3}\right)$$

49. Given, the vertices of a right angled triangle are $A(1, k)$, $B(1, 1)$ and $C(2, 1)$ and area of $\Delta ABC = 1$ sq unit



We know that, area of right angled triangle

$$= \frac{1}{2} \times BC \times AB = \frac{1}{2}(1)\left|(k-1)\right|$$

$$= \frac{1}{2}\left|k-1\right| \Rightarrow \pm(k-1) = 2$$

$$\Rightarrow \quad k = -1, 3$$

$$\therefore \quad K = \{-1, 3\}$$

50. Let $P \equiv (1, 0)$ and $Q \equiv (-1, 0)$

Given that, $\dfrac{AP}{AQ} = \dfrac{BP}{BQ} = \dfrac{CP}{CQ} = \dfrac{1}{3}$

$$\Rightarrow \quad 3AP = AQ \text{ or } 9(AP)^2 = (AQ)^2$$

Let $A \equiv (x, y)$, then

$$a((x-1)^2 + (y-0)^2) = (x+1)^2 + (y-0)^2$$

$$\Rightarrow \quad 8x^2 + 8y^2 - 20x + 8 = 0$$

$$\Rightarrow \quad x^2 + y^2 - \frac{5}{2}x + 1 = 0 \qquad \ldots(i)$$

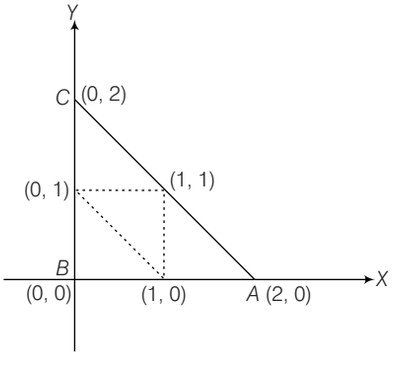
Circumcentre of ΔABC = Centre of circle Eq. (i)

$$= \left(\frac{5}{4}, 0\right)$$

51. From the figure, we have

$$a = 2, b = 2\sqrt{2}, c = 2$$

$$x_1 = 0, x_2 = 0, x_3 = 2 \quad (\because BC = a, CA = b, AB = c)$$



Now, x-coordinate of incentre is given as

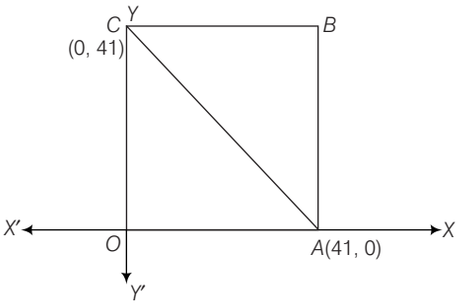
$$\frac{ax_1 + bx_2 + cx_3}{a+b+c}$$

$\Rightarrow$ x-coordinate of incentre

$$= \frac{2 \times 0 + 20\sqrt{2} \times 0 + 2 \times 2}{2 + 2 + 2\sqrt{2}}$$

$$= \frac{2}{2+\sqrt{2}} = 2 - \sqrt{2}$$

52.



Total number of integral points inside the square

$$OABC = 40 \times 40 = 1600.$$

Number of integral points on AC = Number of integral points on $OB = 40$ (namely (1, 1), (2, 2), (3, 3), ... , (40, 40)

Hence, number of integral points inside the

$$\Delta OAC = \frac{1600 - 40}{2} = 780$$

Aliter : $x > 0, y > 0$ $x + y < 41$ or $0 < x + y < 41$

$\therefore$ Number of integral points inside the $\Delta OAC = {}^{40}C_2 = 780$.

53. $\dfrac{1}{2}\left|\begin{vmatrix} k & -3k & 1 \\ 5 & k & 1 \\ -k & 2 & 1 \end{vmatrix}\right| = 28$

$$\Rightarrow \quad 5k^2 + 13k + 10 = \pm 56$$

$$\Rightarrow \quad 5k^2 + 13k - 46 = 0$$

or $\quad 5k^2 + 13k + 66 = 0$

$$\therefore \quad 5k^2 + 13k - 46 = 0$$

and $\quad 5k^2 + 13k + 66 \neq 0 \qquad (\because D < 0)$

$$\Rightarrow \quad k = 2, -\frac{23}{5}$$

$$\therefore \quad k = 2, k \neq -\frac{23}{5} \qquad (\because k \in I)$$

$\therefore$ Vertices an $A \equiv (2, -6)$, $B \equiv (5, 2)$, $C \equiv (-2, 2)$.

Denote the points are $(x_1, y_1), (x_2, y_2)$ and (x_3, y_3) from the matrix $P = \begin{bmatrix} x_1 - x_3 & y_1 - y_3 \\ x_2 - x_3 & y_2 - y_3 \end{bmatrix} = \begin{bmatrix} 4 & -8 \\ 7 & 0 \end{bmatrix}$

$$\therefore \quad \lambda = \frac{\vec{\mathbf{R}}_1 \cdot \vec{\mathbf{R}}_2}{|P|} = \frac{28}{56} = \frac{1}{2}$$

$\therefore$ Circumcentre of triangle is $\left(\dfrac{7 + \frac{1}{2} \times -8}{2}, \dfrac{-4 - \frac{1}{2} \times -3}{2}\right)$

or $\left(\dfrac{3}{2}, -\dfrac{5}{4}\right)$ and centroid is $\left(\dfrac{5}{3}, -\dfrac{2}{3}\right)$

then, orthocentre

$$= \left(\frac{5}{3} \times 3 - 2 \times \frac{3}{2}, -\frac{2}{3} \times 3 + 2 \times \frac{5}{4}\right) \text{ or } \left(2, \frac{1}{2}\right),$$

CHAPTER

02

The Straight Lines

Learning Part

Session 1

- Definition
- Slope or Gradient of a Line
- Lines Parallel to Coordinate Axes
- Different Forms of the Equation of a Straight Line
- The Distance Form or Symmetric Form or Parametric Form of a Line
- Angle of Inclination of a Line
- Angle Between Two Lines
- Intercepts of a Line on Axes
- Reduction of General Equation to Standard Form

Session 2

- Position of Two Points Relative to a Given Line
- Equations of Lines Parallel and Perpendicular to a Given Line
- Distance Between Two Parallel Lines
- Position of a Point which Lies Inside a Triangle
- Distance of a Point From a Line
- Area of Parallelogram

Session 3

- Points of Intersection of Two Lines
- Family of Lines
- Concurrent Lines
- How to Find Circumcentre and Orthocentre by Slopes

Session 4

- Equations of Straight Lines Passing Through a Given Point and Making a Given Angle with a Given Line
- Equation of the Bisectors
- Equation of that Bisector of the Angle Between Two Lines Which Contains a Given Point
- A Line Equally Inclined with Two Lines
- Bisector of the Angle Containing The Origin
- How to Distinguish the Acute (Internal) and Obtuse (External) Angle Bisectors

Session 5

- The Foot of Perpendicular Drawn from the Point (x_1, y_1) to the Line $ax + by + c = 0$
- Image or Reflection of a Point (x_1, y_1) in Different Cases
- Image or Reflection of a Point (x_1, y_1) about a Line Mirror
- Use of Image or Reflection

Session 6

- Reflection of Light
- Condition of Collineirty If Three Given Points are in Cyclic Order
- Refraction of Light

Practice Part

- JEE Type Examples
- Chapter Exercises

Arihant on Your Mobile !

Exercises with the symbol can be practised on your mobile. See inside cover page to activate for free.

Session 1

Definition, Angle of Inclination of a Line, Slope or Gradient of a Line, Angle Between Two Lines, Lines Parallel to Coordinate Axes, Intercepts of a Line on Axes, Different Forms of the Equation of A Straight Line, Reduction of General Equation to Standard Form, The Distance Form or Symmetric Form or Parametric Form of a Line

Definition

A straight line defined as the curve which is such that the line segment joining any two points on it lies wholly on it.

Theorem : Show that the general equation of the first degree in x, y represents a straight line.

Proof : The general equation of the first degree is

$$ax + by + c = 0 \quad \text{...(i)}$$

Let $P(x_1, y_1)$ and $Q(x_2, y_2)$ be the coordinates of any two points on the curve given by Eq. (i), then

$$ax_1 + by_1 + c = 0 \quad \text{...(ii)}$$

$$ax_2 + by_2 + c = 0 \quad \text{...(iii)}$$

Multiplying Eq. (iii) by λ and adding to Eq. (ii), we have

$$a(x_1 + \lambda x_2) + b(y_1 + \lambda y_2) + c(1 + \lambda) = 0$$

or $$a\left(\frac{x_1 + \lambda x_2}{1 + \lambda}\right) + b\left(\frac{y_1 + \lambda y_2}{1 + \lambda}\right) + c = 0 \quad (\lambda \neq -1)$$

This relation shows that the point

$$\left(\frac{x_1 + \lambda x_2}{1 + \lambda}, \frac{y_1 + \lambda y_2}{1 + \lambda}\right) \text{lies on Eq. (i).}$$

But from previous chapter we know that this point divides the join of $P(x_1, y_1)$ and $Q(x_2, y_2)$ is the ratio $\lambda : 1$.

Since, λ can have any value, so each point on the line PQ lies on Eq. (i) i.e. the line wholly lies on Eq. (i). Hence, by the definition of the straight line as given above we conclude that Eq. (i) represents a straight line.

Hence, the general equation of first degree in x, y *viz* $ax + by + c = 0$ represents a straight line.

Remarks

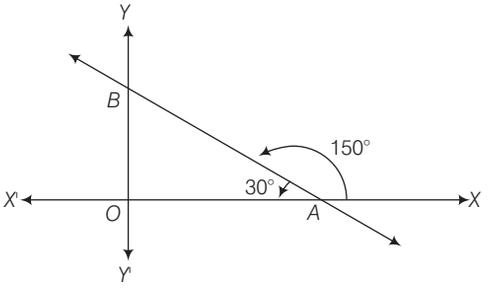
1. The number of **arbitrary constants** in the equation of a straight line is two (we observe three constants a, b and c in the equation $ax + by + c = 0$ of a straight line. The given equation of line can be rewritten as $\left(\frac{a}{c}\right)x + \left(\frac{b}{c}\right)y + 1 = 0$ or $px + qy + 1 = 0$ where $p = \frac{a}{c}$ and $q = \frac{b}{c}$.

   Thus, we have only two arbitrary constants p and q in the equation of a straight line.

   Hence, to completely determine the equation of a straight line, we require two conditions to determine the two unknowns in general.
2. A straight line is briefly written as a 'line.'
3. The equation of a straight line is the relation between x and y, which is satisfied by the coordinates of each and every point on the line.

Angle of Inclination of a Line

The angle of inclination of a line is the measure of the angle between the X-axis and the line measured in the anticlockwise direction.



Here, angle of inclination of line $AB = 150°$.

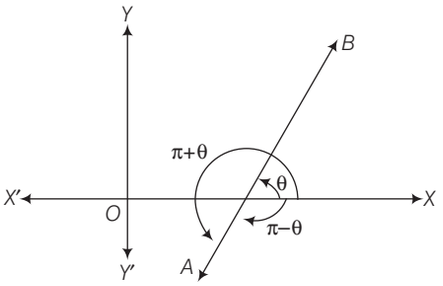
Remarks

1. When two lines are parallel, they have the same inclination.
2. The inclination of a line which is parallel to *X*-axis or coinciding with X-axis is 0°.
3. The angle of inclination of the line lies between 0° and 180° i.e. $0 < \theta \leq \pi$ and $\theta \neq \frac{\pi}{2}$.

Slope or Gradient of a Line

If inclination of a line is $(\theta \neq 90°)$, then $\tan\theta$ is called the slope or gradient of the line. It is usually denoted by *m*.

θ is positive or negative according as it is measured in anticlockwise or clockwise direction.



i.e. Slope of $AB = m$ of $AB = m(AB)$

$= \tan\theta$ or $\tan[-(\pi - \theta)]$

$= \tan(\pi + \theta)$

$=$ slope of $BA = m$ of BA

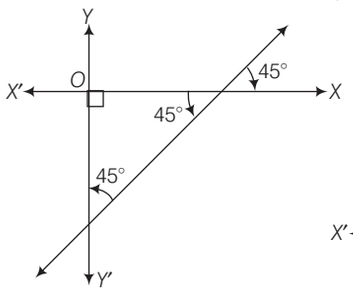
$= m(BA)$

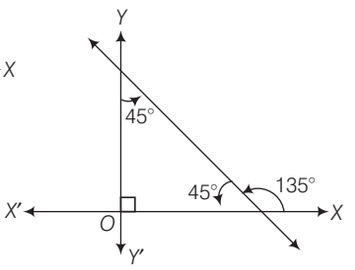
$\therefore \quad m(AB) = m(BA)$

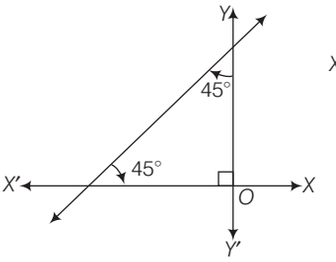
Hence, we do not take into consideration the direction of a line segment while talking of its slope.

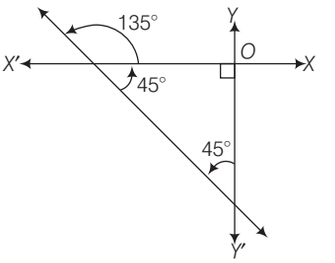
Remarks

1. Slope of a line is not the angle but is the tangent of the inclination of the line.
2. If a line is parallel to *X*-axis, then its slope = tan0° = 0.
3. Slope of a line parallel to *Y*-axis or perpendicular to *X*-axis is not defined. Whenever we say that the slope of a line is not defined.
4. If a line is equally inclined to the axes, then it will make an angle of 45° or 135° with the positive direction of *X*-axis. Slope in this case will be tan 45° or tan135°. i.e. ± 1





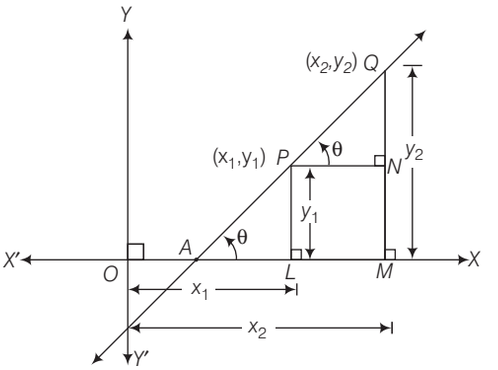




Theorem : If $P(x_1, y_1)$ and $Q(x_2, y_2)$ are two points on a line *l*, then the slope *m* of the line *l* is given by

$$m = \frac{y_2 - y_1}{x_2 - x_1}, x_1 \neq x_2$$

If $x_1 = x_2$, then *m* is not defined. In that case the line is perpendicular to *X*-axis.



Proof : Given $P(x_1, y_1)$ and $Q(x_2, y_2)$ are two points on a line *l*, let line *l* makes an angle θ with positive direction of *X*-axis. Draw *PL*, *QM* perpendiculars on *X*-axis and

$PN \perp QM$

Then, $PN = LM = OM - OL = x_2 - x_1$

and $QN = QM - NM = QM - PL$

$= y_2 - y_1$

Also, $\angle QAM = \angle QPN = \theta$

Now, in ΔQPN

$$\tan\theta = \frac{QN}{PN} = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\text{Difference of ordinates}}{\text{Difference of abscissaes}}$$

or $$m = \frac{y_2 - y_1}{x_2 - x_1}$$

If $x_1 = x_2$, then $\tan\theta = \infty$ or $\theta = \frac{\pi}{2}$ i.e. *m* is not defined or the line is perpendicular to *X*-axis.

Remarks

1. When the two lines are parallel, then their slopes are equal i.e. $m_1 = m_2$.
2. If three points *A*, *B*, *C* are collinear, then slope of *AB* = slope of *BC* = slope of *AC*.

Example 1. Find the inclination of the line whose slope is $-\frac{1}{\sqrt{3}}$.

Sol. Let α be the inclination of a line then its slope $= \tan\alpha$

$$\therefore \quad \tan\alpha = -\frac{1}{\sqrt{3}} = -\tan 30^\circ$$

$$= \tan(180^\circ - 30^\circ) = \tan 150^\circ$$

$$\Rightarrow \quad \alpha = 150^\circ$$

Example 2. Find the slope of the line through the points $(4,-6),(-2,-5)$.

Sol. Slope of the line $m = \frac{-5-(-6)}{-2-(4)} = -\frac{1}{6}$

Example 3. Determine λ, so that 2 is the slope of the line through $(2,5)$ and $(\lambda,3)$.

Sol. Slope of the line joining $(2,5)$ and $(\lambda,3)$

$$= \frac{3-5}{\lambda-2} = \frac{-2}{\lambda-2} = 2 \qquad \text{(given)}$$

$$\Rightarrow \quad -2 = 2\lambda - 4$$

$$\Rightarrow \quad 2\lambda = 2$$

$$\therefore \quad \lambda = 1$$

Example 4. Show that the line joining the points $(2,-3)$ and $(-5,1)$ is parallel to the line joining $(7,-1)$ and $(0,3)$.

Sol. Slope of the line joining the points $(2,-3)$ and $(-5,1)$ is

$$m_1 = \frac{1-(-3)}{-5-2} = -\frac{4}{7}$$

and slope of the line joining the points $(7,-1)$ and $(0,3)$ is

$$m_2 = \frac{3-(-1)}{0-7} = \frac{-4}{7}$$

Here, $\quad m_1 = m_2$

Hence, lines are parallel.

Example 5. ***Find whether the points*** $(-a,-b),[-(s+1)a,-(s+1)b]$ ***and*** $[(t-1)a,(t-1)b]$ ***are collinear ?***

Sol. Let $A \equiv (-a,-b)$, $B \equiv [-(s+1)a,-(s+1)b]$ and $C \equiv ((t-1)a,(t-1)b)$

Then, slope of $AB = \frac{-(s+1)b+b}{-(s+1)a+a} = \frac{b}{a}$

and slope of $BC = \frac{(t-1)b+(s+1)b}{(t-1)a+(s+1)a} = \frac{b}{a}$

Hence, given points are collinear.

Example 6. For what value of k the points $(k,2-2k),(-k+1,2k)$ and $(-4-k,6-2k)$ are collinear ?

Sol. Let $A \equiv (k,2-2k)$, $B \equiv (-k+1,2k)$ and $C \equiv (-4-k,6-2k)$ are collinear, then

Slope of AB = Slope of AC

$$\Rightarrow \quad \frac{2k-(2-2k)}{-k+1-k} = \frac{6-2k-(2-2k)}{-4-k-k}$$

$$\Rightarrow \quad \frac{4k-2}{-2k+1} = \frac{4}{-4-2k} \qquad \left(k \neq \frac{1}{2} (\because \text{Denominator} \neq 0)\right)$$

$$\Rightarrow \quad (4k-2)(-4-2k) = 4(-2k+1)$$

$$\Rightarrow \quad (2k-1)(-2-k) - (-2k+1) = 0$$

$$\Rightarrow \quad (2k-1)(-2-k+1) = 0$$

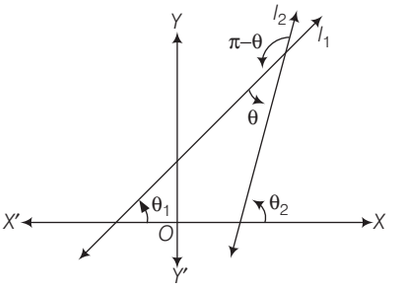
$$\therefore \quad k \neq \frac{1}{2}, \quad \therefore \quad k = -1$$

Angle Between Two Lines

Theorem : The acute angle θ between the lines having slopes m_1 and m_2 is given by

$$\theta = \tan^{-1}\left|\frac{m_1 - m_2}{1+m_1 m_2}\right|$$

Proof : Let l_1 and l_2 be two non-perpendicular lines, neither of which is parallel to the Y-axis.



Let m_1 and m_2 be the slopes of two given lines l_1 and l_2 respectively. Let θ_1 and θ_2 be the inclinations of these lines.

$$\therefore \quad m_1 = \tan\theta_1 \text{ and } m_2 = \tan\theta_2$$

Let θ and $\pi - \theta$ be the angles between the lines $\left(\theta \neq \frac{\pi}{2}\right)$.

Then, $\quad \theta_2 = \theta + \theta_1$ or $\theta = \theta_2 - \theta_1$

$$\Rightarrow \quad \tan\theta = \tan(\theta_2 - \theta_1)$$

$$\Rightarrow \quad \tan\theta = \left(\frac{\tan\theta_2 - \tan\theta_1}{1+\tan\theta_2\tan\theta_1}\right) = \left(\frac{m_2 - m_1}{1+m_1 m_2}\right) \quad \text{...(i)}$$

Also, $\quad \tan(\pi-\theta) = -\tan\theta = -\left(\frac{m_2 - m_1}{1+m_2 m_1}\right)$ ...(ii)

From Eqs. (i) and (ii) the angle between two lines of slopes m_1 and m_2 is given by

$$\tan\theta = \pm\left(\frac{m_1 - m_2}{1 + m_1 m_2}\right)$$

$$\Rightarrow \qquad \theta = \tan^{-1}\left[\pm\left(\frac{m_1 - m_2}{1 + m_1 m_2}\right)\right]$$

Hence, the acute angle between the lines l_1 and l_2 is given by

$$\theta = \tan^{-1}\left|\frac{m_1 - m_2}{1 + m_1 m_2}\right|.$$

***Corollary* 1 :** If two lines, whose slopes are m_1 and m_2 are parallel,

iff $\qquad \theta = 0^\circ \text{ (or } \pi) \Leftrightarrow \tan\theta = 0$

$$\Leftrightarrow \quad m_1 = m_2$$

Thus, when two lines are parallel, their slopes are equal.

***Corollary* 2 :** If two lines, whose slopes are m_1 and m_2 are perpendicular,

iff $\qquad \theta = \frac{\pi}{2}\left(\text{or} -\frac{\pi}{2}\right) \Leftrightarrow \cot\theta = 0$

$$\Leftrightarrow \quad m_1 m_2 = -1$$

Thus, when two lines are perpendicular, the product of their slopes is -1. The slope of each is the negative reciprocal of the slope of other i.e. if m is the slope of a line, then the slope of a line perpendicular to it is $-\frac{1}{m}$.

Example 7. Find the angle between the lines joining the points $(0, 0), (2, 3)$ and $(2, -2), (3, 5)$.

Sol. Let the given points be $A \equiv (0, 0)$, $B \equiv (2, 3)$, $C \equiv (2, -2)$ and $D \equiv (3, 5)$. Let m_1 and m_2 be the slopes of the lines AB and CD respectively.

$$\therefore \qquad m_1 = \frac{3-0}{2-0} = \frac{3}{2} \text{ and } m_2 = \frac{5-(-2)}{3-2} = 7$$

Let θ be the acute angle between the lines

$$\therefore \qquad \tan\theta = \left|\frac{m_1 - m_2}{1 + m_1 m_2}\right| = \left|\frac{\frac{3}{2} - 7}{1 + \left(\frac{3}{2}\right)\cdot 7}\right|$$

$$= \left|\frac{-11}{23}\right| = \frac{11}{23}$$

$$\therefore \qquad \theta = \tan^{-1}\left(\frac{11}{23}\right)$$

Example 8. The angle between two lines is $\frac{\pi}{4}$ and the slope of one of them is $\frac{1}{2}$. Find the slope of the other line.

Sol. If θ be the acute angle between the lines with slopes m_1 and m_2, then

$$\tan\theta = \left|\frac{m_1 - m_2}{1 + m_1 m_2}\right|$$

Let $\qquad \theta = \frac{\pi}{4}$ and $m_1 = \frac{1}{2}$

then $\qquad \tan\frac{\pi}{4} = \left|\frac{\frac{1}{2} - m_2}{1 + \frac{1}{2}\cdot m_2}\right|$

$$\Rightarrow \qquad 1 = \left|\frac{1 - 2m_2}{2 + m_2}\right|$$

$$\Rightarrow \qquad \frac{1 - 2m_2}{2 + m_2} = \pm 1$$

Taking positive sign then,

$$1 - 2m_2 = 2 + m_2$$

$$\therefore \qquad m_2 = -\frac{1}{3}$$

and taking negative sign then,

$$1 - 2m_2 = -2 - m_2$$

$$\therefore \qquad m_2 = 3$$

Hence, the slope of the other line is either $-\frac{1}{3}$ or 3.

Example 9. Without using pythagoras theorem, show that the points $A(-1, 3), B(0, 5)$ and $C(3, 1)$ are the vertices of a right angled triangle.

Sol. In ΔABC, we have

$$\text{Slope of side } AB = \frac{5-3}{0-(-1)} = 2 = m_1 \qquad \text{(say)}$$

$$\text{Slope of side } BC = \frac{1-5}{3-0} = -\frac{4}{3} = m_2 \qquad \text{(say)}$$

and $\qquad \text{Slope of side } CA = \frac{3-1}{-1-3} = -\frac{1}{2} = m_3 \qquad \text{(say)}$

Clearly, $\qquad m_1 m_3 = 2 \times \left(-\frac{1}{2}\right) = -1$

$\therefore$ AB and CA are perpendicular to each other i.e.

$$\angle BAC = 90^\circ$$

Hence, the given points are the vertices of a right angled triangle.

Example 10. ***A line passes through the points*** $A(2,-3)$ ***and*** $B(6,3)$ ***. Find the slopes of the lines which are***

(i) parallel to AB (ii) perpendicular to AB

Sol. Let m be the slope of AB. Then $m = \dfrac{3-(-3)}{6-2} = \dfrac{6}{4} = \dfrac{3}{2}$

(i) Let m_1 be the slope of a line parallel to AB, then

$$m_1 = m = \frac{3}{2}$$

(ii) The slope of a line perpendicular to AB is

$$-\frac{1}{m} = -\frac{1}{\frac{3}{2}} = -\frac{2}{3}$$

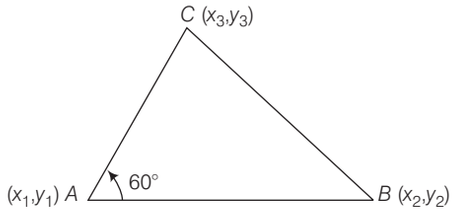
Example 11. Show that the triangle which has one of the angles as 60°, can not have all vertices with integral coordinates.

Sol. Let ABC be a triangle whose vertices are $A(x_1, y_1), B(x_2, y_2)$ and $C(x_3, y_3)$. Assume $x_1, x_2, x_3, y_1, y_2, y_3$ all are integers.

Let $\angle BAC = 60^\circ$

$$\text{Slope of } AC = \frac{y_3 - y_1}{x_3 - x_1} = m_1 \quad \text{(say)}$$

and $$\text{Slope of } AB = \frac{y_2 - y_1}{x_2 - x_1} = m_2 \quad \text{(say)}$$



Here, m_1 and m_2 are rational numbers
($\because x_1, x_2, x_3, y_1, y_2, y_3$ are integers)

$$\therefore \quad \tan(\angle BAC) = \frac{m_1 - m_2}{1 + m_1 m_2}$$

$$= \text{Rational} \quad (\because m_1 \text{ and } m_2 \text{ are rational})$$

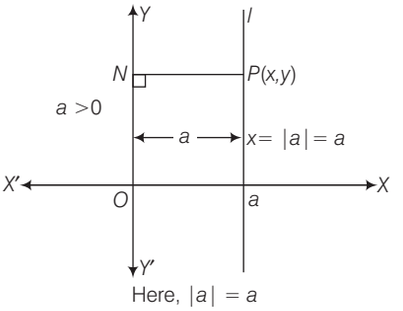
But $\tan(\angle BAC) = \tan 60^\circ = \sqrt{3} =$ Irrational

$\because$ Rational number $\neq$ Irrational number

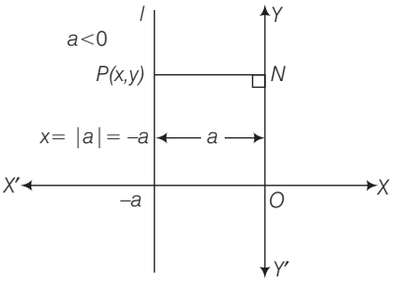
Which is contradiction so our assumption that the vertices are integers is wrong. Hence, the triangle having one angle of 60° can not have all vertices with integral coordinates.

Lines Parallel to Coordinate Axes

(i) **Equation of a line parallel to *Y*-axis :** Let l be a straight line parallel to Y-axis and at a distance a from it, a being the directed distance of the line from the Y-axis . Therefore, the line lies on the right of Y-axis if $a > 0$ and if $a < 0$, then the line would lies on the left of Y-axis.



Here, $|a| = a$



Here, $|a| = -a$

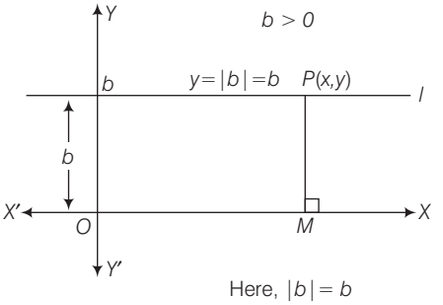
Let $P(x, y)$ be any point on the line l, then

$x = a$ is the required equation. (Here, $|a| = a$)

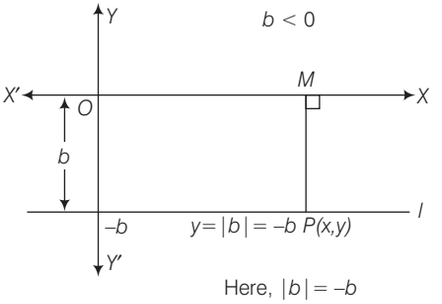
Remarks

1. In particular equation of Y-axis is $x = 0$ ($\because a = 0$)
2. A line is parallel to Y-axis, at a distance from it and is on the negative side of Y-axis, then its equation is $x = -a$.

(ii) **Equation of a line parallel to *X*-axis :** Let l be a straight line parallel to X-axis and at a distance b from it, b being the directed distance of the line from the X-axis. Therefore, the line lies above the X-axis, if $b > 0$ and if $b < 0$, then the line would lie below the X-axis.



Here, $|b| = b$



Here, $|b| = -b$

Let $P(x, y)$ be any point on the line l, then $y = b$ is the required equation (Here, $|b| = b$).

Remarks

1. In particular equation of X-axis is $y = 0$ $(\because b = 0)$
2. A line parallel to X-axis at a distance b from it and is on the negative side of X-axis, then its equation is $y = -b$.

Example 12. Find the equation of the straight line parallel to Y-axis and at a distance (i) 3 units to the right (ii) 2 units to the left.

Sol. (i) Equation of straight line parallel to Y-axis at a distance a units to the right is $x = a$.

$\therefore$ Required equation is $x = 3$

(ii) Equation of straight line parallel to Y-axis at a distance a units to the left is $x = -a$.

$\therefore$ Required equation is $x = -2$.

Example 13. ***Find the equation of the straight line parallel to X-axis and at a distance***

(i) 5 units above the X-axis

(ii) 9 *units below the X-axis.*

Sol. (i) Equation of a straight line parallel to X-axis at a distance b units above the X-axis is $y = b$.

$\therefore$ Required equation is $y = 5$

(ii) Equation of a straight line parallel to X-axis at a distance b units below the X-axis is $y = -b$.

$\therefore$ Required equation is $y = -9$

Example 14. Find the equation of the straight line which passes through the point $(2, -3)$ and is

(i) parallel to the X-axis

(ii) perpendicular to the X-axis

Sol. (i) Let equation of any line parallel to X-axis is

$$y = b \qquad \text{....(i)}$$

Since, it passes through the point $(2, -3)$.

Putting $y = -3$ in Eq. (i), then

$$b = -3$$

Hence, required equation of the line is $y = -3$.

Eq. (i) Let equation of any line perpendicular to X-axis = Equation of any line parallel to Y-axis is

$$x = a \qquad \text{...(ii)}$$

Since, it passes through the point $(2, -3)$ putting $x = 2$ in Eq. (ii)

Then, $2 = a \Rightarrow a = 2$

Hence, required equation of the line $x = 2$.

Example 15. Find the equation of a line which is equidistant from the lines $x = -\frac{7}{2}$ and $x = \frac{15}{2}$.

Sol. Since, the given (both) lines are parallel to Y-axis and the required line is equidistant from these lines, so it is also parallel to Y-axis. Let equation of any line parallel to Y-axis is

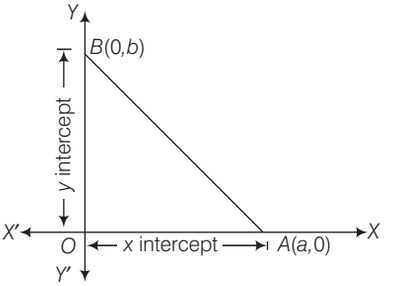
$$x = a$$

Here, $a = \dfrac{\left(-\frac{7}{2} + \frac{15}{2}\right)}{2} = \dfrac{8}{4} = 2$ units

Hence, its equation is $x = 2$.

Intercepts of a Line on Axes

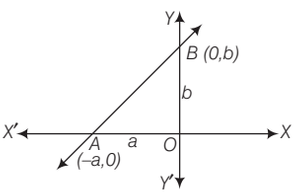
If a line cuts X-axis at $A(a, 0)$ and the Y-axis at $B(0, b)$ then OA and OB are known as the intercepts of the line on X-axis and Y-axis respectively. $|a|$ is called the length of intercept of the line on X-axis. Intercept of a line on X-axis may be positive or negative and $|b|$ is called the length of intercept of the line on Y-axis. Intercept of a line on Y-axis may be positive or negative.



Remark

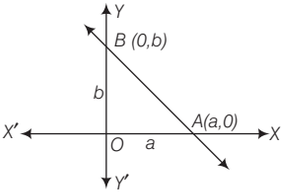
If a line parallel to Y-axis, then its intercept on Y-axis is not defined and if a line parallel to X-axis, then its intercept on X-axis is not defined.

Intercepts in II quadrant



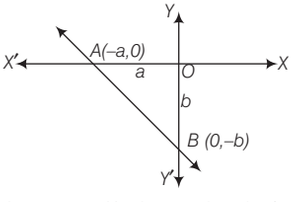
Intercept on X-axis $= -a$, length of intercept on X-axis $= |a|$
Intercept on Y-axis $= b$, length of intercept on Y-axis $= |b|$

Intercepts in I quadrant



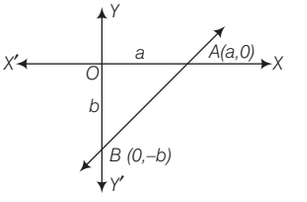
Intercept on X-axis $= a$, length of intercept on X-axis $= |a|$
Intercept on Y-axis $= b$, length of intercept on Y-axis $= |b|$

Intercepts in III quadrant



Intercept on X-axis $= -a$, length of intercept on X-axis $= |a|$
Intercept on Y-axis $= -b$, length of intercept on Y-axis $= |b|$

Intercepts in IV quadrant



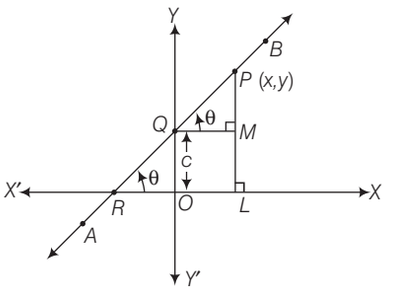
Intercept on X-axis $= a$, length of intercept on X-axis $= |a|$
Intercept on Y-axis $= -b$, length of intercept on Y-axis $= |b|$

Different Forms of the Equation of a Straight Line

(i) Slope-Intercept Form

Theorem : The equation of the straight line whose slope is m and which cuts an intercept c on the Y-axis is

$$y = mx + c$$



Proof : Let AB be a line whose slope is m and which cuts an intercept c on Y-axis. Let $P(x, y)$ be any point on the line. Draw $PL \perp$ to X-axis and $QM \perp$ to PL.

Then, from figure,

$$\angle PRL = \angle PQM = \theta, OQ = c$$

$$\therefore \quad PM = PL - ML = PL - OQ = y - c$$

and $$QM = OL = x$$

Now in ΔPQM, $$\tan\theta = \frac{PM}{QM}$$

$$\Rightarrow \quad m = \frac{y-c}{x} \Rightarrow y = mx + c$$

which is the required equation of the line.

Remarks

1. If the line passes through the origin, then $c = 0$ ($\because 0 = m.0 + c \Rightarrow c = 0$) and hence equation of the line will become $y = mx$.
2. Equation of any line may be taken as $y = mx + c$.
3. If the line is parallel to X-axis, then $\theta = 0°$
   i.e. $m = \tan 0° = 0$. Hence, equation of the line parallel to X-axis is $y = c$.

Example 16. If the straight line $y = mx + c$ passes through the points $(2, 4)$ and $(-3, 6)$, find the values of m and c.

Sol. Since, $(2, 4)$ lies on $y = mx + c$

$$\therefore \quad 4 = 2m + c \qquad ...(i)$$

Again, $(-3, 6)$ lies on $y = mx + c$

$$\therefore \quad 6 = -3m + c \qquad ...(ii)$$

On solving Eqs. (i) and (ii), we get $\quad m = -\frac{2}{5}, c = \frac{24}{5}$

Example 17. What are the inclination to the X-axis and intercept on Y-axis of the line

$$3y = \sqrt{3}x + 6 \ ?$$

Sol. The given equation can be written as

$$y = \frac{x}{\sqrt{3}} + 2 \qquad ...(i)$$

Now, comparing Eq. (i) with $y = mx + c$, then we get

$$m = \frac{1}{\sqrt{3}}$$

Let θ be the inclination to the X-axis, then

$$\tan\theta = \tan 30°$$

$$\therefore \quad \theta = 30° \quad \text{and} \quad c = 2.$$

Example 18. Find the equation of the straight line cutting off an intercept of 3 units on negative direction of Y-axis and inclined at an angle $\tan^{-1}\left(\frac{3}{5}\right)$ to the axis of x.

Sol. Here, $\quad c = -3$ and $\theta = \tan^{-1}\left(\frac{3}{5}\right)$

or $\quad \tan\theta = \frac{3}{5} = m$

Hence, the equation of the line

$$y = mx + c$$

i.e. $\quad y = \frac{3}{5}x - 3$

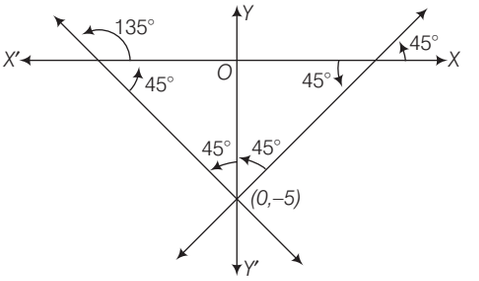
or $\quad 3x - 5y - 15 = 0$

Example 19. ***Find the equation to the straight line cutting off an intercept of 5 units on negative direction of Y-axis and being equally inclined to the axes.***

Sol. Here, $\quad c = -5$

$$m = \tan 45° \quad \text{or} \quad \tan 135°$$

i.e. $\quad m = \pm 1$



Hence, required equation is

$$y = (\pm 1)\, x - 5$$

or $\quad y = \pm x - 5$

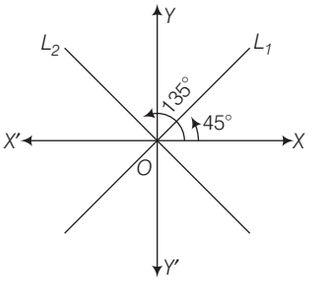
Example 20. Find the equations of the bisectors of the angle between the coordinate axes.

Sol. Let L_1 and L_2 be the straight lines bisecting the co-ordinate axes.

Both L_1 and L_2 pass through origin

$\therefore$ Equation of line through origin is $y = mx$

for L_1, $m = \tan 45° = 1$



$\therefore$ Equation of line L_1 is $y = x$

i.e. $x - y = 0$

For L_2, $m = \tan 135° = -1$

$\therefore$ Equation of line L_2 is $y = -x$

i.e. $x + y = 0$

Hence, equations of the bisectors of the angle between the coordinate axes are $x \pm y = 0$.

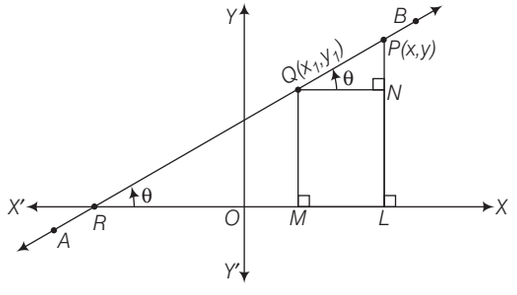
(ii) The Point-Slope Form of a Line

Theorem : The equation of the straight line which passes through the point (x_1, y_1) and has the slope 'm' is

$$y - y_1 = m(x - x_1)$$

Proof : Let AB be a straight line whose slope is m and which pass through the point $Q(x_1, y_1)$. Let the line AB cuts X-axis at R and $\angle BRX = \theta$, then

$$\tan\theta = m$$



Let $P(x, y)$ be any point on the line AB. Draws PL and QM perpendiculars from P and Q on X-axis respectively. Also draw QN perpendicular from Q on PL, then from figure

$$\angle PRL = \angle PQN = \theta,\ OL = x,\ OM = x_1,\ PL = y,\ QM = y_1$$

Then, $QN = ML = OL - OM = x - x_1$

and $PN = PL - NL = PL - QM = y - y_1$

Now, in triangle PQN,

$$\tan\theta = \frac{PN}{QN} = \frac{y - y_1}{x - x_1}$$

$$\therefore \quad m = \frac{y - y_1}{x - x_1}$$

or $$y - y_1 = m(x - x_1)$$

which is the required equation of the line.

Aliter : Let the equation of the required line be

$$y = mx + c \qquad \text{...(i)}$$

where, m is the slope of the line.

Since line Eq. (i) passes through the point (x_1, y_1), therefore

$$y_1 = mx_1 + c \qquad \text{...(ii)}$$

Subtracting (ii) form (i), we get

$$\boldsymbol{y - y_1 = m(x - x_1)}$$

which is the required equation of the line.

Corollary **:** If the line passes through the origin, then putting $x_1 = 0$ and $y_1 = 0$ in $y - y_1 = m(x - x_1)$.

It becomes $y = mx$, which is the equation of the line passing through the origin and having slope m.

Remark

The equation $y - y_1 = m(x - x_1)$ is called **point-slope** form or **one point** form of the equation.

Example 21. ***Find the equation of a line which makes an angle of 135° with the positive direction of X-axis and passes through the point*** $(3, 5)$ **.**

Sol. The slope of the line $= m = \tan 135° = -1$

Here $x_1 = 3, y_1 = 5$.

$\therefore$ The required equation of the line is

$$y - 5 = -1(x - 3)$$

or $$x + y - 8 = 0$$

Example 22. Find the equation of the straight line bisecting the segment joining the points $(5, 3)$ and $(4, 4)$ and making an angle of 45° with the positive direction of X-axis.

Sol. Here, m = slope of the line $= \tan 45° = 1$.

Let A be the mid-point of $(5, 3)$ and $(4, 4)$. Then, the coordinates of A are

$$\left(\frac{5+4}{2}, \frac{3+4}{2}\right) \quad \text{i.e.} \quad \left(\frac{9}{2}, \frac{7}{2}\right).$$

Hence, the required equation of the line is

$$y - \frac{7}{2} = 1\left(x - \frac{9}{2}\right)$$

or $$x - y - 1 = 0$$

Example 23. Find the equation of the right bisector of the line joining (1, 1) and (3, 5) .

Sol. Let m be the slope of the line joining (1, 1) and (3, 5).

Then, $m = \frac{5-1}{3-1} = \frac{4}{2} = 2$

$\therefore$ Slope (M) of right bisector of the join of (1, 1)

and $(3, 5) = -\frac{1}{m}$

$\therefore$ $M = -\frac{1}{2}$

Mid-point of the join of (1, 1) and (3, 5) is $\left(\frac{1+3}{2}, \frac{1+5}{2}\right)$

i.e. (2, 3) .

Hence, equation of the right bisector passing through (2, 3) and having slope $M = -\frac{1}{2}$ is

$$y - 3 = -\frac{1}{2}(x - 2)$$

or $x + 2y - 8 = 0$

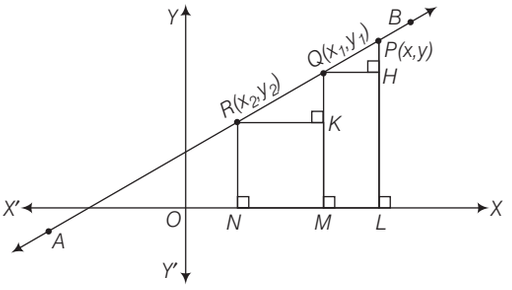
(iii) The Two-Point Form of a Line

Theorem : The equation of a line passing through two given points (x_1, y_1) and (x_2, y_2) is given by

$$y - y_1 = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)(x - x_1)$$

Proof :

Let AB be a line which passes through two points $Q(x_1, y_1)$ and $R(x_2, y_2)$. Let $P(x, y)$ be any point on the line AB.



Draws PL, QM and RN are perpendiculars from P, Q and R on X-axis respectively. Also draws QH and RK are perpendiculars on PL and QM respectively. Then from figure

$$ON = x_2, OM = x_1, OL = x, RN = y_2,$$
$$QM = y_1 \text{ and } PL = y$$

then, $RK = NM = OM - ON = x_1 - x_2$

$$QH = ML = OL - OM = x - x_1$$
$$QK = QM - KM = QM - RN = y_1 - y_2$$

and $PH = PL - HL = PL - QM = y - y_1$

Now, triangles PHQ and QKR are similar, then

$$\frac{PH}{QK} = \frac{QH}{RK}$$

$$\Rightarrow \quad \frac{y - y_1}{y_1 - y_2} = \frac{x - x_1}{x_1 - x_2}$$

or $$y - y_1 = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)(x - x_1)$$

which is the required equation of the line.

Aliter I : Let the equation of the required line be

$$y = mx + c \qquad \text{...(i)}$$

where m is the slope of the line.

Since, line Eq. (i) passes through the points (x_1, y_1) and (x_2, y_2) therefore

$$y_1 = mx_1 + c \qquad \text{...(ii)}$$

and $$y_2 = mx_2 + c \qquad \text{...(iii)}$$

Now, subtracting Eqs. (ii) from (i), we get

$$y - y_1 = m(x - x_1) \qquad \text{...(iv)}$$

and subtracting Eqs. (ii) from (iii), we get

$$y_2 - y_1 = m(x_2 - x_1) \qquad \text{...(v)}$$

Dividing Eqs. (iv) by (v) then, we get

$$\frac{y - y_1}{y_2 - y_1} = \frac{x - x_1}{x_2 - x_1}$$

or $$y - y_1 = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)(x - x_1)$$

which is the required equation of the line.

Aliter II : Since points, $P(x, y), Q(x_1, y_1)$ and $R(x_2, y_2)$ are collinear then area of $\Delta PQR = 0$

i.e. $$\frac{1}{2}\left|\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix}\right| = 0 \text{ or } \begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix} = 0$$

which is the required equation of the line.

Example 24. ***Find the equation to the straight line joining the points*** $\left(at_1, \frac{a}{t_1}\right)$ ***and*** $\left(at_2, \frac{a}{t_2}\right)$.

Sol. The equation of the line joining the points $\left(at_1, \frac{a}{t_1}\right)$ and $\left(at_2, \frac{a}{t_2}\right)$ is

$$y - \frac{a}{t_1} = \left(\frac{\frac{a}{t_2} - \frac{a}{t_1}}{at_2 - at_1}\right)(x - at_1)$$

$$\Rightarrow \quad y - \frac{a}{t_1} = -\frac{a(t_1 - t_2)}{at_1t_2(t_1 - t_2)}(x - at_1)$$

or $$y - \frac{a}{t_1} = -\frac{1}{t_1t_2}(x - at_1)$$

or $$t_1t_2y - at_2 = -x + at_1$$

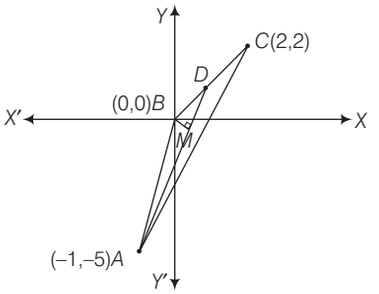
or $$x + t_1t_2y = a(t_1 + t_2)$$

which is the required equation of the line.

Example 25. Let ABC be a triangle with $A(-1,-5)$, $B(0,0)$ and $C(2,2)$ and let D be the middle point of BC. Find the equation of the perpendicular drawn from B to AD.

Sol. $\because$ D is the middle point of BC.

$\therefore$ Coordinates of D are $\left(\frac{0+2}{2}, \frac{0+2}{2}\right)$



i.e. $D(1, 1)$

Slope of median $AD = \frac{1+5}{1+1} = 3$

$\therefore$ Slope of BM which is perpendicular to $AD = -\frac{1}{3}$.

Hence, equation of the line BM is

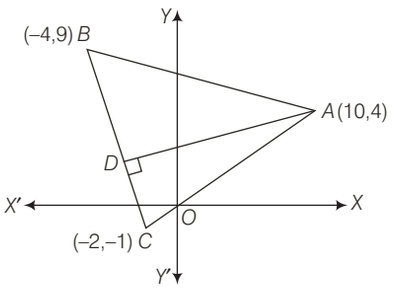
$$y - 0 = -\frac{1}{3}(x - 0) \Rightarrow x + 3y = 0$$

which is the required equation of the line.

Example 26. The vertices of a triangle are $A(10,4), B(-4,9)$ and $C(-2,-1)$. Find the equation of the altitude through A.

Sol. $\because$ Slope of $BC = \frac{-1-9}{-2+4} = \frac{-10}{2} = -5$

$\therefore$ Slope of altitude $AD = -\frac{1}{-5} = \frac{1}{5}$



Hence, equation of altitude AD which passes through $(0, 4)$ and having slope $\frac{1}{5}$ is

$$y - 4 = \frac{1}{5}(x - 10)$$

or $$x - 5y + 10 = 0$$

Example 27. ***Find the equations of the medians of a triangle, the coordinates of whose vertices are*** $(-1,6), (-3,-9)$ ***and*** $(5,-8)$**.**

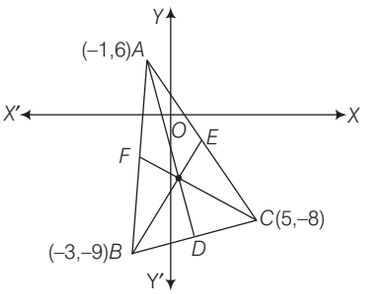
Sol. Let $A(-1, 6)$, $B(-3, -9)$ and $C(5, -8)$ be the vertices of ΔABC. Let D, E and F be the mid-points of the sides BC, CA and AB respectively.

Coordinates of $D \equiv \left(\frac{-3+5}{2}, \frac{-9-8}{2}\right)$

i.e. $\left(1, -\frac{17}{2}\right)$

Coordinates of $E \equiv \left(\frac{5-1}{2}, \frac{-8+6}{2}\right)$

i.e. $(2, -1)$



and coordinates of $F \equiv \left(\frac{-1-3}{2}, \frac{6-9}{2}\right)$

i.e. $(-2, -3/2)$

$\therefore$ Equation of the median AD = Equation of line through $(-1, 6)$ and $\left(1, -\frac{17}{2}\right)$ is

$$y - 6 = \frac{-\frac{17}{2} - 6}{1+1}(x + 1)$$

$$\Rightarrow \quad y - 6 = -\frac{29}{4}(x + 1) \quad \text{or} \quad 29x + 4y + 5 = 0$$

Equation of median BE is

$$y + 9 = \frac{-1+9}{2+3}(x + 3) \quad \text{or} \quad 8x - 5y - 21 = 0$$

and equation of median CF is

$$y + 8 = \frac{-\frac{3}{2} + 8}{-2-5}(x - 5)$$

or $$13x + 14y + 47 = 0$$

Example 28. Find the ratio in which the line segment joining the points (2, 3) and (4, 5) is divided by the line joining (6, 8) and (–3, –2) .

Sol. The equation of line passing through (6, 8) and (–3, – 2) is

$$y-8=\frac{-2-8}{-3-6}(x-6)$$

$\Rightarrow \quad 9y-72=10x-60$

or $\quad 10x-9y+12=0 \quad ...(i)$

Let the required ratio be $\lambda : 1$.

Now, the coordinates of the point P which divide the line segment joining the points (2, 3) and (4, 5) in the ratio $\lambda : 1$ is

$$P\left(\frac{2+4\lambda}{1+\lambda}, \frac{3+5\lambda}{1+\lambda}\right)$$

Clearly P lies on Eq. (i), then

$$10\left(\frac{2+4\lambda}{1+\lambda}\right)-9\left(\frac{3+5\lambda}{1+\lambda}\right)+12=0$$

or $\quad 20+40\lambda-27-45\lambda+12+12\lambda=0$

or $\quad 7\lambda+5=0 \quad \text{or} \quad \lambda=-\frac{5}{7}$

$\therefore$ The required ratio $=\lambda : 1=-\frac{5}{7}:1=-5:7$

Hence, the required ratio is 5 : 7 (externally).

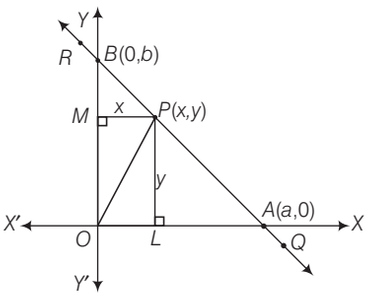
(iv) The Intercept Form of a Line :

Theorem : The equation of the straight line which cuts off intercepts of lengths of a and b on X-axis and Y-axis respectively, is

$$\frac{x}{a}+\frac{y}{b}=1$$

Proof : Let QR be a line which cuts off intercepts $OA = a$ and $OB = b$ on the X-axis and Y-axis respectively, where $a \neq 0$. The line is non vertical, because b is finite. Let $P(x, y)$ be a general point on the line.

Draws PL and PM perpendiculars on X-axis and Y-axis respectively. Then $PL = y$ and $OL = x$ also join OP. Clearly,



Area of ΔOAB = Area of ΔOAP + Area of ΔOPB

$\Rightarrow \quad \frac{1}{2}\cdot OA\cdot OB=\frac{1}{2}\cdot OA\cdot PL+\frac{1}{2}\cdot OB\cdot PM$

$\Rightarrow \quad \frac{1}{2}\cdot OA\cdot OB=\frac{1}{2}\cdot OA\cdot PL+\frac{1}{2}\cdot OB\cdot OL$

or $\quad \frac{1}{2}ab=\frac{1}{2}ay+\frac{1}{2}bx$

$\Rightarrow \quad ab=ay+bx$

or $\quad \frac{x}{a}+\frac{y}{b}=1$

which is the required equation of the line.

Aliter I : Equation of the line through $A(a, 0)$ and $B(0, b)$ is

$$y-0=\frac{b-0}{0-a}(x-a)$$

or $\quad -ay=bx-ab$

or $\quad bx+ay=ab$

or $\quad \frac{x}{a}+\frac{y}{b}=1$

which is the required equation of the line.

Aliter II : Points $A(a, 0)$, $P(x, y)$ and $B(0, b)$ are collinear, we have

slope of AB = slope of AP

$\Rightarrow \quad \frac{b-0}{0-a}=\frac{y-0}{x-a} \Rightarrow bx-ab=-ay$

$\Rightarrow \quad bx+ay=ab \Rightarrow \frac{x}{a}+\frac{y}{b}=1$

or

$$\begin{vmatrix} a & 0 & 1 \\ x & y & 1 \\ 0 & b & 1 \end{vmatrix}=0$$

$\Rightarrow \quad a(y-b)-0+1\cdot(bx)=0$

or $\quad bx+ay=ab$

or $\quad \frac{x}{a}+\frac{y}{b}=1$

which is the required equation of the line.

Example 29. Find the equation of the line through (2, 3) so that the segment of the line intercepted between the axes is bisected at this point.

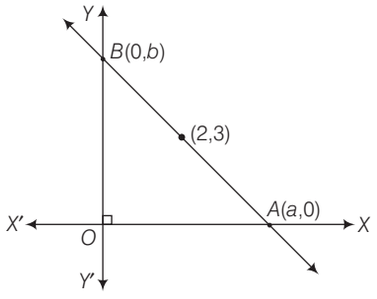
Sol. Let the required line segment be AB.

Let O be the origin and $OA = a$ and $OB = b$.

Then the coordinates of A and B are $(a, 0)$ and $(0, b)$ respectively.

$\therefore \quad \frac{a+0}{2} = 2 \Rightarrow a = 4$

and $\quad \frac{0+b}{2} = 3 \Rightarrow b = 6$



Hence, the equation of the required line is

$$\frac{x}{4} + \frac{y}{6} = 1$$

i.e. $\quad 3x + 2y = 12$

Example 30. Find the equation to the straight line which passes through the points $(3, 4)$ and have intercepts on the axes :

(a) equal in magnitude but opposite in sign

(b) such that their sum is 14

Sol. (a) Let intercepts on the axes be a and $-a$ respectively.

$\therefore$ The equation of the line in intercept form is

$$\frac{x}{a} + \frac{y}{-a} = 1 \quad \text{or} \quad x - y = a \qquad \text{...(i)}$$

Since, Eq. (i) passes through $(3, 4)$, then

$$3 - 4 = a$$

$\therefore \quad a = -1$

From Eq. (i), $\quad x - y + 1 = 0$

which is the required equation of the line.

(b) Let the equation of the line be $\frac{x}{a} + \frac{y}{b} = 1$

This passes through $(3, 4)$.

Therefore $\quad \frac{3}{a} + \frac{4}{b} = 1 \qquad \text{...(ii)}$

It is given that $a + b = 14$

$\therefore \quad b = 14 - a$

Putting $b = 14 - a$ in Eq. (ii), we get

$$\frac{3}{a} + \frac{4}{14-a} = 1$$

$\Rightarrow \quad 42 - 3a + 4a = 14a - a^2$

$\Rightarrow \quad a^2 - 13a + 42 = 0$

$\Rightarrow \quad (a-7)(a-6) = 0$

$\therefore \quad a = 6, 7$

Then, $\quad b = 8, 7 \qquad (\because b = 14 - a)$

Hence, the required equations are

$$\frac{x}{6} + \frac{y}{8} = 1 \quad \text{and} \quad \frac{x}{7} + \frac{y}{7} = 1$$

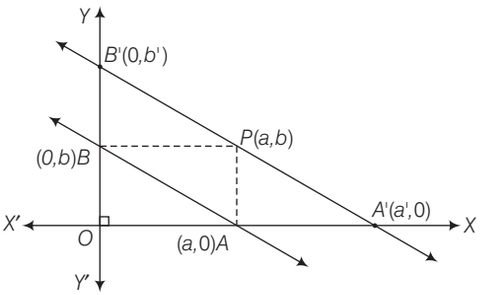
i.e. $\quad 4x + 3y = 24$ and $x + y = 7$

Example 31. Find the equation of the straight line through the point $P(a, b)$ parallel to the line $\frac{x}{a} + \frac{y}{b} = 1$. Also find the intercepts made by it on the axes.

Sol. Let the line $\frac{x}{a} + \frac{y}{b} = 1$

meets the axes in A and B respectively. So that

$$OA = a, OB = b$$



Let the required parallel line meet in A' and B' respectively, so that

$OA' = a'$ (say)

and $\quad OB' = b'$ (say)

$\therefore$ Equation of required line is

$$\frac{x}{a'} + \frac{y}{b'} = 1 \qquad \text{...(i)}$$

Since, $\Delta's$ OAB and $OA'B'$ are similar, then

$$\frac{OA'}{OA} = \frac{OB'}{OB}$$

i.e. $\quad \frac{a'}{a} = \frac{b'}{b} = \lambda$ (say)

$\Rightarrow \quad a' = a\lambda, b' = b\lambda$

Substituting these values in Eq. (i), then

$$\frac{x}{a\lambda} + \frac{y}{b\lambda} = 1 \qquad \text{...(ii)}$$

It passes through (a, b), then

$$\frac{a}{a\lambda} + \frac{b}{b\lambda} = 1$$

$\Rightarrow \quad \frac{2}{\lambda} = 1$ or $\lambda = 2$

From Eq. (ii) required equation is

$$\frac{x}{2a} + \frac{y}{2b} = 1$$

Evidently intercepts on the axes are $2a$ and $2b$.

(v) The Normal Form or Perpendicular Form of a Line

Theorem : The equation of the straight line upon which the length of perpendicular from the origin is p and this normal makes an angle α with the positive direction of X-axis is

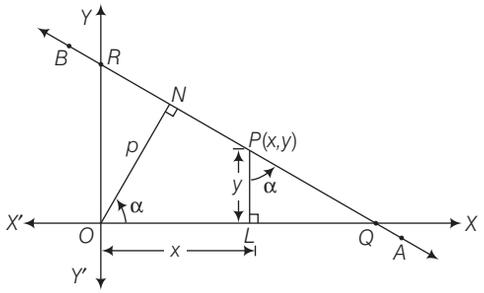
$$x\cos\alpha + y\sin\alpha = p.$$

Proof : Let AB be a line such that the length of perpendicular from O to the line be p

i.e. $ON = p$

and $\angle NOX = \alpha$

Let $P(x, y)$ be any point on the line. Draw PL perpendicular from P on X-axis.



Let line AB cuts X and Y-axes at Q and R respectively.

Now, $\angle NQO = 90° - \alpha$

$\therefore$ $\angle LPQ = 90° - (90° - \alpha) = \alpha$

In ΔPLQ, $\tan\alpha = \dfrac{LQ}{PL} = \dfrac{LQ}{y}$

$\therefore$ $LQ = y\tan\alpha$ ...(i)

Also, in ΔONQ, $\cos\alpha = \dfrac{ON}{OQ}$

$\Rightarrow$ $\cos\alpha = \dfrac{p}{OL + LQ}$

$\Rightarrow$ $OL\cos\alpha + LQ\cos\alpha = p$

$\Rightarrow$ $x\cos\alpha + y\tan\alpha\cos\alpha = p$

$(\because OL = x \text{ and } LQ = y\tan\alpha)$

$\therefore$ $\boldsymbol{x\cos\alpha + y\sin\alpha = p}$

which is the required equation of the line AB.

Aliter I : $\because \angle NOQ = \alpha$

then $\angle NOR = 90° - \alpha$

Now, in ΔONQ, $\sec\alpha = \dfrac{OQ}{ON} = \dfrac{OQ}{p}$

or $OQ = p\sec\alpha$

Also in ΔONR, $\sec(90° - \alpha) = \dfrac{OR}{ON}$

$\Rightarrow$ $\operatorname{cosec}\alpha = \dfrac{OR}{p}$

or $OR = p\operatorname{cosec}\alpha$

Thus, AB makes intercepts $p\sec\alpha$ and $p\operatorname{cosec}\alpha$ on X-axis and Y-axis respectively.

$\therefore$ Equation of AB is $\dfrac{x}{p\sec\alpha} + \dfrac{y}{p\operatorname{cosec}\alpha} = 1$

or $\boldsymbol{x\cos\alpha + y\sin\alpha = p}$

which is the required equation of the line AB.

Aliter II : The points $Q(p\sec\alpha, 0)$, $P(x, y)$ and $R(0, p\operatorname{cosec}\alpha)$ are collinear, then

$$\begin{vmatrix} p\sec\alpha & 0 & 1 \\ x & y & 1 \\ 0 & p\operatorname{cosec}\alpha & 1 \end{vmatrix} = 0$$

or $p\sec\alpha(y - p\operatorname{cosec}\alpha) - 0 + 1(px\operatorname{cosec}\alpha) = 0$

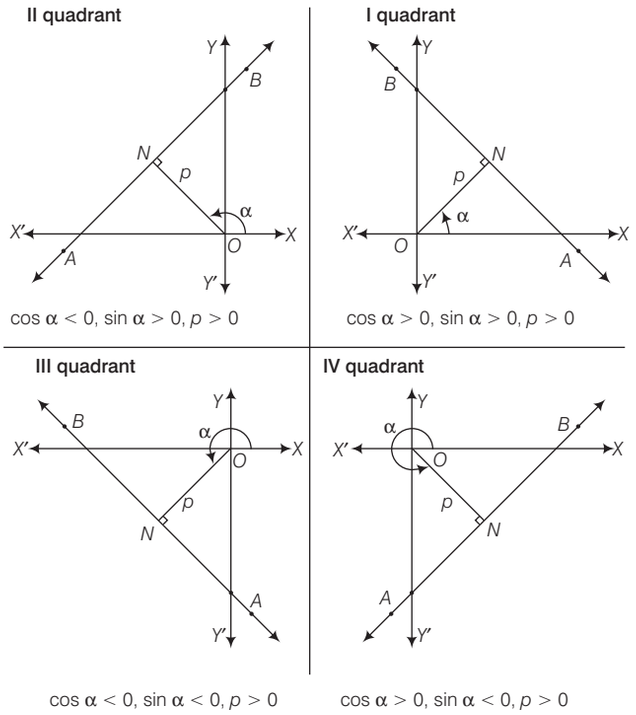
or $p(y\sin\alpha - p) + px\cos\alpha = 0$

or $\boldsymbol{x\cos\alpha + y\sin\alpha = p}$

which is the required equation of the line AB.

Remarks

1. Here, p is always taken as positive and α is measured from positive direction of X-axis in anticlockwise direction between 0 and 2π (i.e. $0 \le \alpha < 2\pi$).
2. (Coefficient of $x)^2$+ (Coefficient of $y)^2 = \cos^2\alpha + \sin^2\alpha = 1$
3. $\cos\alpha$ and $\cos(90° - \alpha)$ are the direction cosines of ON.
4.



***Corollary* 1 :** If $\alpha = 0°$, then equation $x\cos\alpha + y\sin\alpha = p$ becomes $x\cos 0° + y\sin 0° = p$

i.e. $x = p$ (Equation of line parallel to Y-axis)

***Corollary* 2 :** If $\alpha = \frac{\pi}{2}$, then equation $x\cos\alpha + y\sin\alpha = p$ becomes $x\cos\left(\frac{\pi}{2}\right) + y\sin\left(\frac{\pi}{2}\right) = p$

i.e. $y = p$ (Equation of line parallel to X-axis).

***Corollary* 3 :** If $\alpha = 0°$, $p = 0$ then equation $x\cos\alpha + y\sin\alpha = p$ becomes $x\cos 0° + y\sin 0° = 0$

i.e. $x = 0$ (Equation of Y-axis)

***Corollary* 4 :** If $\alpha = \frac{\pi}{2}$, $p = 0$ then equation $x\cos\alpha + y\sin\alpha = p$ becomes $x\cos\left(\frac{\pi}{2}\right) + y\sin\left(\frac{\pi}{2}\right) = 0$

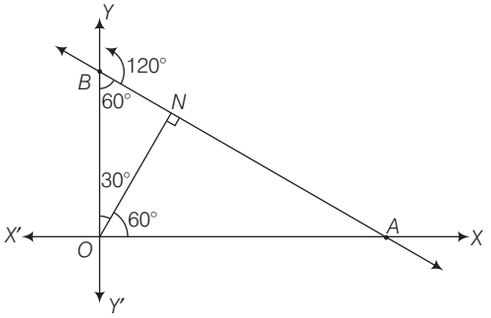
i.e. $y = 0$ (Eq. (i) of X-axis).

Example 32. The length of perpendicular from the origin to a line is 9 and the line makes an angle of 120° with the positive direction of Y-axis. Find the equation of the line.

Sol. Here, $\alpha = 60°$ and $p = 9$.

$\therefore$ Equation of the required line is

$x\cos 60° + y\sin 60° = 9$



$\Rightarrow \quad x\left(\frac{1}{2}\right) + y\left(\frac{\sqrt{3}}{2}\right) = 9$

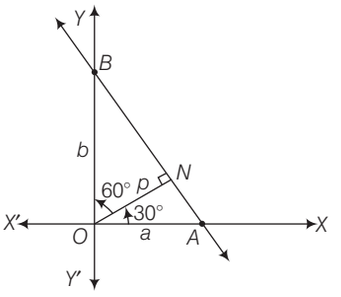
or $\quad x + y\sqrt{3} = 18$

Example 33. Find the equation of the straight line on which the perpendicular from origin makes an angle of 30° with X-axis and which forms a triangle of area $\left(\frac{50}{\sqrt{3}}\right)$ sq units with the coordinates axes.

Sol. Let $\angle NOA = 30°$

Let $ON = p > 0, OA = a, OB = b$

In ΔONA, $\quad \cos 30° = \frac{ON}{OA} = \frac{p}{a}$



$\Rightarrow \quad \frac{\sqrt{3}}{2} = \frac{p}{a}$ or $a = \frac{2p}{\sqrt{3}}$

and in ΔONB, $\cos 60° = \frac{ON}{OB} = \frac{p}{b}$

$\Rightarrow \quad \frac{1}{2} = \frac{p}{b}$ or $b = 2p$

$\because \quad$ Area of $\Delta OAB = \frac{1}{2}ab = \frac{1}{2}\left(\frac{2p}{\sqrt{3}}\right)$

$(2p) = \frac{2p^2}{\sqrt{3}}$

$\therefore \quad \frac{2p^2}{\sqrt{3}} = \frac{50}{\sqrt{3}}$ (given)

$\Rightarrow \quad p^2 = 25$

or $\quad p = 5 \quad (\because p > 0)$

$\therefore$ Using $x\cos\alpha + y\sin\alpha = p$, the equation of the line AB is

$x\cos 30° + y\sin 30° = 5$

or $\quad x\sqrt{3} + y = 10$

Reduction of General Equation to Standard Form

Let $Ax + By + C = 0$ be the general equation of a straight line where A and B are not both zero.

(i) Reduction of 'Slope-Intercept' Form

Given equation is $Ax + By + C = 0$

$\Rightarrow \quad By = -Ax - C$

$\Rightarrow \quad y = \left(-\frac{A}{B}\right)x + \left(-\frac{C}{B}\right)$ (Assuming $B \neq 0$)

Comparing it with $y = mx + c$

we get $\quad$ slope $(m) = -\frac{A}{B} = -\frac{\text{coefficient of } x}{\text{coefficient of } y}$

and $\quad y$ intercept $(c) = -\frac{C}{B} = -\frac{\text{constant term}}{\text{coefficient of } y}$

***Corollary* 1 :** Find angle between the lines $A_1x + B_1y + C_1 = 0$ and $A_2x + B_2y + C_2 = 0$.

Slope of the line

$$A_1x + B_1y + C_1 = 0 \text{ is } -\frac{A_1}{B_1} = m_1 \qquad \text{(say)}$$

and slope of the line

$$A_2x + B_2y + C_2 = 0 \text{ is } -\frac{A_2}{B_2} = m_2 \qquad \text{(say)}$$

If θ is the angle between the two lines, then

$$\tan\theta = \left|\frac{m_1 - m_2}{1 + m_1m_2}\right| = \left|\frac{\left(-\frac{A_1}{B_1}\right) - \left(-\frac{A_2}{B_2}\right)}{1 + \left(-\frac{A_1}{B_1}\right)\left(-\frac{A_2}{B_2}\right)}\right|$$

$$= \left|\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right|$$

$$\therefore \qquad \theta = \tan^{-1}\left|\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right|$$

***Corollary* 2 :** Find the condition of (i) parallelism (ii) perpendicularity of the lines

$$A_1x + B_1y + C_1 = 0$$

and $\qquad A_2x + B_2y + C_2 = 0$

(i) If the two lines are parallel, $\theta = 0°$

$$\therefore \qquad \tan\theta = \tan 0° = 0$$

$$\Rightarrow \qquad \left|\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right| = 0$$

$$\Rightarrow \qquad A_1B_2 - A_2B_1 = 0$$

or $\qquad \frac{A_1}{A_2} = \frac{B_1}{B_2}$ **(Remember)**

which is required condition of parallelism.

(ii) If the two lines are perpendicular, $\theta = 90°$

$$\therefore \qquad \tan\theta = \tan 90° = \infty$$

$$\Rightarrow \qquad \left|\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right| = \infty$$

$$\Rightarrow \qquad A_1A_2 + B_1B_2 = 0 \qquad \textbf{(Remember)}$$

which is required condition of perpendicularity.

Remark

If two lines are coincident, then

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} = \frac{C_1}{C_2} \qquad \textbf{(Remember)}$$

(ii) Reduction to 'Intercept' Form

Given equation is $Ax + By + C = 0$

$$\Rightarrow \qquad Ax + By = -C$$

$$\Rightarrow \qquad \frac{A}{-C}x + \frac{B}{-C}y = 1 \qquad \text{(Assuming } C \neq 0\text{)}$$

$$\Rightarrow \qquad \frac{x}{(-C/A)} + \frac{y}{(-C/B)} = 1 \quad \text{(Assuming } A \neq 0, B \neq 0\text{)}$$

Comparing with $\frac{x}{a} + \frac{y}{b} = 1$

we get, $\quad x\text{-intercept } (a) = -\frac{C}{A} = -\frac{\text{constant term}}{\text{coefficient of } x}$

and $\quad y\text{-intercept } (b) = -\frac{C}{B} = -\frac{\text{constant term}}{\text{coefficient of } y}$

(iii) Reduction to 'Normal' Form

Given equation is $Ax + By + C = 0$. Let its **normal form** be $x\cos\alpha + y\sin\alpha = p$.

Clearly, equations $Ax + By + C = 0$ and $x\cos\alpha + y\sin\alpha = p$ represent the same line.

Therefore, $\qquad \frac{A}{\cos\alpha} = \frac{B}{\sin\alpha} = \frac{C}{-p}$

$$\Rightarrow \qquad \cos\alpha = -\frac{Ap}{C}$$

and $\qquad \sin\alpha = -\frac{Bp}{C}$ ...(i)

$$\cos^2\alpha + \sin^2\alpha = 1$$

$$\left(-\frac{Ap}{C}\right)^2 + \left(-\frac{Bp}{C}\right)^2 = 1$$

or $\qquad p^2 = \frac{C^2}{A^2 + B^2}$

$$\Rightarrow \qquad p = \frac{|C|}{\sqrt{(A^2 + B^2)}}$$

From Eq. (i), $\cos\alpha = -\frac{|C|}{C} \cdot \frac{A}{\sqrt{(A^2 + B^2)}}$,

$$\sin\alpha = -\frac{|C|}{C} \cdot \frac{B}{\sqrt{(A^2 + B^2)}}.$$

Putting the values of $\cos\alpha, \sin\alpha$ and p in $x\cos\alpha + y\sin\alpha = p$, we get

$$x\left(\frac{-|C|}{C}\cdot\frac{A}{\sqrt{(A^2+B^2)}}\right)x+y\left(\frac{-|C|}{C}\cdot\frac{B}{\sqrt{(A^2+B^2)}}\right)$$
$$=\frac{|C|}{\sqrt{(A^2+B^2)}}$$

$$\Rightarrow\quad\left(-\frac{A}{\sqrt{(A^2+B^2)}}\right)x+\left(-\frac{B}{\sqrt{(A^2+B^2)}}\right)y=\frac{C}{\sqrt{(A^2+B^2)}}$$

This is the normal form of the line $Ax+By+C=0$.

Rule : First shift the constant term on the RHS and make it positive, if it is not so by multiplying the whole equation by '-1' and then divide both sides by

$$\sqrt{(\text{coefficient of } x)^2+(\text{coefficient of } y)^2}$$

Example 34. Reduce $x+\sqrt{3}y+4=0$ to the :

(i) Slope-intercept form and find its slope and y-intercept

(ii) Intercept form and find its intercepts on the axes

(iii) Normal form and find the values of p and α

Sol. (i) Given equation is $x+\sqrt{3}\,y+4=0$

$\Rightarrow\quad \sqrt{3}y=-x-4$

$\Rightarrow\quad y=\left(-\frac{1}{\sqrt{3}}\right)x+\left(-\frac{4}{\sqrt{3}}\right)$

which is in the slope-intercept form $y=mx+c$

Where slope $(m)=-\frac{1}{\sqrt{3}}$ and y-intercept $(c)=-\frac{4}{\sqrt{3}}$

(ii) Given equation is

$x+\sqrt{3}y+4=0$

$\Rightarrow\quad x+\sqrt{3}y=-4$

$\Rightarrow\quad \frac{x}{-4}+\frac{\sqrt{3}y}{-4}=1$

$\Rightarrow\quad \frac{x}{-4}+\frac{y}{-4/\sqrt{3}}=1$

which is in the intercept form $\frac{x}{a}+\frac{y}{b}=1$

where x-intercept $(a)=-4$ and y-intercept $(b)=-\frac{4}{\sqrt{3}}$

(iii) Given equation is $x+\sqrt{3}y+4=0$

$\Rightarrow\quad x+\sqrt{3}y=-4$

$\Rightarrow\quad -x-\sqrt{3}y=4$ (RHS made positive)

Dividing both sides by $\sqrt{(-1)^2+(-\sqrt{3})^2}=2$, we get

$$\left(-\frac{1}{2}\right)x+\left(-\frac{\sqrt{3}}{2}\right)y=2$$

Which is the normal form $x\cos\alpha+y\sin\alpha=p$.

where, $\cos\alpha=-\frac{1}{2}=-\cos 60^\circ=\cos(180^\circ-60^\circ)$

or $\cos(180^\circ+60^\circ)$

$\therefore\quad \alpha=120^\circ$ or 240°

and $\sin\alpha=-\frac{\sqrt{3}}{2}=-\sin 60^\circ=\sin(180^\circ+60^\circ)$

or $\sin(360^\circ-60^\circ)$

$\therefore\quad \alpha=240^\circ$ or 300°

Hence, $\alpha=240^\circ,\ p=2$

$\therefore$ Required normal form is

$$x\cos 240^\circ+y\sin 240^\circ=2$$

Example 35. Find the measure of the angle of intersection of the lines whose equations are $3x+4y+7=0$ and $4x-3y+5=0$.

Sol. Given lines are $3x+4y+7=0,\ 4x-3y+5=0$. Comparing the given lines with $A_1x+B_1y+C_1=0,\ A_2x+B_2y+C_2=0$ respectively, we get

$A_1=3,\ B_1=4$ and $A_2=4,\ B_2=-3$

$\because\quad A_1A_2+B_1B_2=3\times 4+4(-3)=0$

Hence, the given lines are perpendicular.

Example 36. Find the angle between the lines

$(a^2-ab)\,y=(ab+b^2)\,x+b^3$

and $(ab+a^2)\,y=(ab-b^2)\,x+a^3$

where $a>b>0$.

Sol. The given equations of lines can be written as

$$(ab+b^2)\,x-(a^2-ab)\,y+b^3=0 \quad ...(i)$$

and $$(ab-b^2)\,x-(ab+a^2)\,y+a^3=0 \quad ...(ii)$$

Comparing the given lines (i) and (ii) with the lines

$A_1x+B_1y+C_1=0$ and $A_2x+B_2y+C_2=0$

respectively, we get

$A_1=ab+b^2,\ B_1=-(a^2-ab)$

and $A_2=ab-b^2,\ B_2=-(ab+a^2)$

Let θ be the acute angle between the lines, then

$$\tan\theta=\left|\frac{A_1B_2-A_2B_1}{A_1A_2+B_1B_2}\right|$$

$$\tan\theta=\left|\frac{(ab+b^2)\times(-(ab+a^2))-(ab-b^2)\times(-(a^2-ab))}{(ab+b^2)(ab-b^2)+(a^2-ab)(ab+a^2)}\right|$$

$$=\left|\frac{-\{a^2b^2+a^3b+ab^3+a^2b^2-a^3b+a^2b^2+a^2b^2-b^3a\}}{(a^2b^2-b^4+a^4-a^2b^2)}\right|$$

$$=\left|\frac{-4a^2b^2}{a^4-b^4}\right|=\frac{4a^2b^2}{a^4-b^4}$$

$$\therefore\ \theta=\tan^{-1}\left(\frac{4a^2b^2}{a^4-b^4}\right)$$

Example 37. Two equal sides of an isosceles triangle are given by the equations $7x - y + 3 = 0$ and $x + y - 3 = 0$ and its third side passes through the point $(1, -10)$. Determine the equation of the third side.

Sol. Given equations

$$7x - y + 3 = 0 \quad \text{...(i)}$$

and $$x + y - 3 = 0 \quad \text{...(ii)}$$

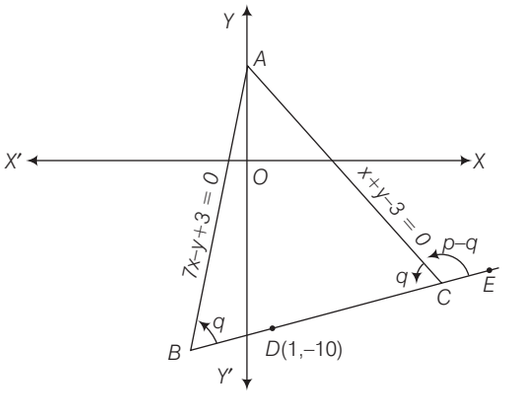
represents two equal sides AB and AC of an isosceles triangle ABC. Since its third side passes through $D(1, -10)$ then its equation is

$$y + 10 = m(x - 1) \quad \text{...(iii)}$$

$\because$ $AB = AC$

Let $\angle ABC = \angle ACB = \theta$

then $\angle ACE = \pi - \theta$



From Eqs. (i) and (ii), slopes of AB and AC are

$$m_1 = 7 \quad \text{and} \quad m_2 = -1$$

respectively.

$$\therefore \quad \tan\theta = \frac{7 - m}{1 + 7m}$$

and $$\tan(\pi - \theta) = \frac{-1 - m}{1 + (-1)\, m} = -\left(\frac{1 + m}{1 - m}\right)$$

$$\Rightarrow \quad -\tan\theta = -\left(\frac{1 + m}{1 - m}\right) \Rightarrow \tan\theta = \left(\frac{1 + m}{1 - m}\right)$$

$$\therefore \quad \frac{7 - m}{1 + 7m} = \frac{1 + m}{1 - m}$$

$$\Rightarrow \quad (7 - m)(1 - m) = (1 + 7m)(1 + m)$$

$$\Rightarrow \quad 6m^2 + 16m - 6 = 0$$

or $$3m^2 + 8m - 3 = 0 \text{ or } (3m - 1)(m + 3) = 0$$

$$\Rightarrow \quad m = \frac{1}{3}, -3$$

Hence from Eq. (iii), the third side BC has two equations

$$y + 10 = \frac{1}{3}(x - 1) \text{ and } y + 10 = -3(x - 1)$$

or $$x - 3y - 31 = 0 \quad \text{and} \quad 3x + y + 7 = 0$$

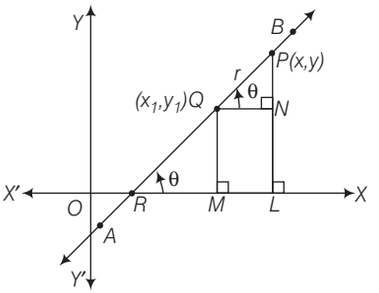
The Distance form or Symmetric form or Parametric form of a line

Theorem : The equation of the straight line passing through (x_1, y_1) and making an angle θ with the positive direction of X-axis is

$$\frac{x - x_1}{\cos\theta} = \frac{y - y_1}{\sin\theta} = r$$

where, r is the directed distance between the points (x, y) and (x_1, y_1).

Proof : Let AB be a line which passes through the point $Q(x_1, y_1)$ and meet X-axis at R and makes an angle θ with the positive direction of X-axis.



Let $P(x, y)$ be any point on the line at a distance r from Q. Draws PL and QM are perpendiculars from P and Q on X-axis respectively and draw QN perpendicular on PL. Then,

$$QN = ML = OL - OM = x - x_1$$

and $$PN = PL - NL = PL - QM = y - y_1$$

from ΔPQN,

$$\cos\theta = \frac{QN}{PQ} = \frac{x - x_1}{r} \text{ or } \frac{x - x_1}{\cos\theta} = r \quad \text{...(i)}$$

and $$\sin\theta = \frac{PN}{PQ} = \frac{y - y_1}{r} \text{ or } \frac{y - y_1}{\sin\theta} = r \quad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$\frac{x - x_1}{\cos\theta} = \frac{y - y_1}{\sin\theta} = r$$

***Corollary* 1 :** $\because$ $\dfrac{x - x_1}{\cos\theta} = \dfrac{y - y_1}{\sin\theta} = r$, then

$$\left.\begin{aligned} x &= x_1 + r\cos\theta \\ y &= y_1 + r\sin\theta \end{aligned}\right\}$$

parametric equations of straight line AB.

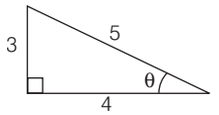
***Corollary* 2 :** If P point above Q then r is positive then coordinates of P are $(x_1 + r\cos\theta, y_1 + r\sin\theta)$ and if P below Q then r is negative then coordinates of P are $(x_1 - r\cos\theta, y_1 - r\sin\theta)$.

Example 38. ***The slope of a straight line through*** $A(3,2)$ ***is*** $\frac{3}{4}$***. Find the coordinates of the points on the line that are 5 units away from*** A***.***

Sol. Let straight line makes an angle θ with positive direction of X-axis,

then $\tan\theta = \frac{3}{4}$

$\therefore$ $\sin\theta = \frac{3}{5}$ and $\cos\theta = \frac{4}{5}$



$\therefore$ Equation of the straight line through $A(3,2)$ in parametric form is

$$\frac{x-3}{\cos\theta} = \frac{y-2}{\sin\theta} = \pm 5$$

$\therefore$ $x = 3 \pm 5\cos\theta = 3 \pm 5 \times \frac{4}{5} = 3 \pm 4 = 7 \text{ or } -1$

and $y = 2 \pm 5\sin\theta = 2 \pm 5 \times \frac{3}{5} = 2 \pm 3 = 5 \text{ or } -1$

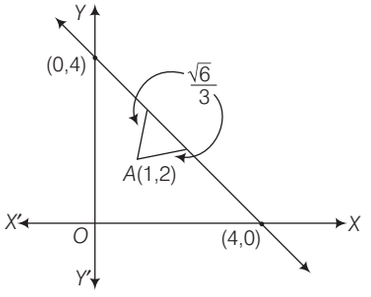
Hence, the coordinates of the points are $(7,5)$ and $(-1,-1)$.

Example 39. ***Find the direction in which a straight line must be drawn through the point*** $(1,2)$ ***so that its point of intersection with the line*** $x+y=4$ ***may be at a distance*** $\frac{1}{3}\sqrt{6}$ ***from this point.***

Sol. Let the straight line makes an angle θ with the positive direction of X-axis.

$\therefore$ Equation of the line through $(1,2)$ in parametric form is

$$\frac{x-1}{\cos\theta} = \frac{y-2}{\sin\theta} = \frac{1}{3}\sqrt{6}$$



or $x = 1 + \frac{\sqrt{6}}{3}\cos\theta$ and $y = 2 + \frac{\sqrt{6}}{3}\sin\theta$

Since, the point $\left(1 + \frac{\sqrt{6}}{3}\cos\theta, 2 + \frac{\sqrt{6}}{3}\sin\theta\right)$ lies on the line

$x + y = 4$

$\therefore$ $1 + \frac{\sqrt{6}}{3}\cos\theta + 2 + \frac{\sqrt{6}}{3}\sin\theta = 4$

$\Rightarrow$ $\frac{\sqrt{6}}{3}(\cos\theta + \sin\theta) = 1$

$\Rightarrow$ $\cos\theta + \sin\theta = \frac{3}{\sqrt{6}} = \frac{\sqrt{3}}{\sqrt{2}}$

$\Rightarrow$ $\frac{1}{\sqrt{2}}\cos\theta + \frac{1}{\sqrt{2}}\sin\theta = \frac{\sqrt{3}}{2}$

$\Rightarrow$ $\cos\left(\theta - \frac{\pi}{4}\right) = \cos\left(\frac{\pi}{6}\right)$

$\theta - \frac{\pi}{4} = 2n\pi \pm \frac{\pi}{6}; n \in I$

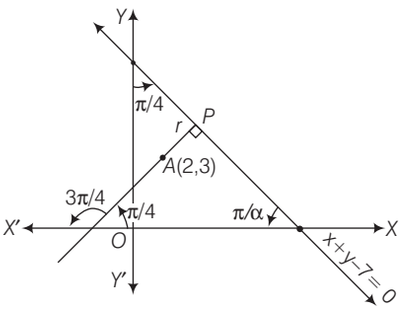
for $n = 0$, $\theta = \pm\frac{\pi}{6} + \frac{\pi}{4}$ $(\because 0 \le \theta < \pi)$

$= 15°, 75°$

Example 40. A line through $(2,3)$ makes an angle $\frac{3\pi}{4}$ with the negative direction of X-axis. Find the length of the line segment cut off between $(2,3)$ and the line $x+y-7=0$.

Sol. $\because$ Line makes an angle $\frac{3\pi}{4}$ with the negative direction of X-axis.

$\therefore$ Line makes an angle $\frac{\pi}{4}$ with the positive direction of X-axis.



$\therefore$ The equation of the line through $(1,2)$ in parametric form is

$$\frac{x-2}{\cos\left(\frac{\pi}{4}\right)} = \frac{y-3}{\sin\left(\frac{\pi}{4}\right)} = r$$

i.e. $\frac{x-2}{\frac{1}{\sqrt{2}}} = \frac{y-3}{\frac{1}{\sqrt{2}}} = r$ ...(i)

$\therefore$ $x = 2 + \frac{r}{\sqrt{2}}$ and $y = 3 + \frac{r}{\sqrt{2}}$

Let the line (i) meet the line $x + y - 7 = 0$ in P

$\therefore$ Coordinates of $P\left(2 + \frac{r}{\sqrt{2}}, 3 + \frac{r}{\sqrt{2}}\right)$ lies on $x + y - 7 = 0$

then $2 + \frac{r}{\sqrt{2}} + 3 + \frac{r}{\sqrt{2}} - 7 = 0$

or $\frac{2r}{\sqrt{2}} = 2$ or $r = \sqrt{2}$

$\therefore$ $AP = \sqrt{2}$

Example 41. Find the distance of the point $(2, 3)$ from the line $2x - 3y + 9 = 0$ measured along the line $2x - 2y + 5 = 0$.

Sol. Since, slope of the line $2x - 2y + 5 = 0$ is 1, its makes an angle $\frac{\pi}{4}$ with positive direction of X-axis.

The equation of the line through $(2, 3)$ and making an angle $\frac{\pi}{4}$ in parametric form

$$\frac{x-2}{\cos\left(\frac{\pi}{4}\right)} = \frac{y-3}{\sin\left(\frac{\pi}{4}\right)} = r \text{ or } \frac{x-2}{\frac{1}{\sqrt{2}}} = \frac{y-3}{\frac{1}{\sqrt{2}}} = r$$

Coordinates of any point on this line are $\left(2 + \frac{r}{\sqrt{2}}, 3 + \frac{r}{\sqrt{2}}\right)$.

This point lies on the line $2x - 3y + 9 = 0$

$$\Rightarrow \quad 2\left(2 + \frac{r}{\sqrt{2}}\right) - 3\left(3 + \frac{r}{\sqrt{2}}\right) + 9 = 0$$

$$\Rightarrow \quad -\frac{r}{\sqrt{2}} + 4 = 0$$

$$\therefore \quad r = 4\sqrt{2}$$

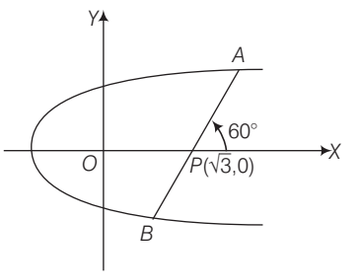
Example 42. If the line $y - \sqrt{3}x + 3 = 0$ cuts the parabola $y^2 = x + 2$ at A and B, then find the value of $PA.\ PB$ {where $P \equiv (\sqrt{3}, 0)$}.

Sol. Slope of line $y - \sqrt{3}x + 3 = 0$ is $\sqrt{3}$

If line makes an angle θ with X-axis, then $\tan\theta = \sqrt{3}$

$$\therefore \quad \theta = 60°$$

$$\frac{x - \sqrt{3}}{\cos 60°} = \frac{y - 0}{\sin 60°} = r$$



$$\Rightarrow \left(\sqrt{3} + \frac{r}{2}, \frac{r\sqrt{3}}{2}\right) \text{ be a point on the parabola } y^2 = x + 2$$

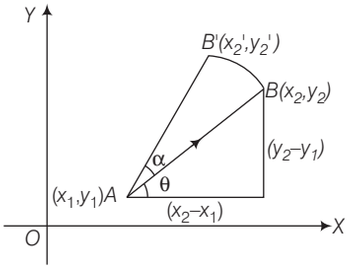
then, $\frac{3}{4}r^2 = \sqrt{3} + \frac{r}{2} + 2 \Rightarrow 3r^2 - 2r - 4(2 + \sqrt{3}) = 0$

$$\therefore \quad PA \cdot PB = r_1 r_2 = \left|\frac{-4(2+\sqrt{3})}{3}\right| = \frac{4(2+\sqrt{3})}{3}$$

Special Corollaries

(i) **Angle made by AB with positive X-axis (where A and B are given points)** :be two points and let AB makes an angle θ with the positive direction of X-axis and let d be the distance between A and B. Then Let $A(x_1, y_1)$ and $B(x_2, y_2)$

$$\cos\theta = \frac{x_2 - x_1}{d}, \sin\theta = \frac{y_2 - y_1}{d}$$



where, $d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} = AB$

and $x_2 = x_1 + d\cos\theta, y_2 = y_1 + d\sin\theta$

If AB rotates an angle α about A, then new coordinates of B are

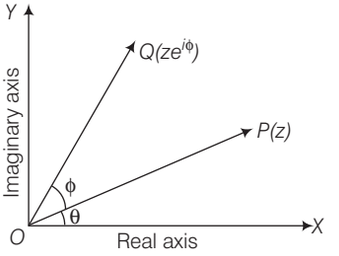
$$x_2' = x_1 + d\cos(\theta + \alpha),$$
$$y'_2 = y_1 + d\sin(\theta + \alpha)$$

and here, $AB = AB' = d$.

(ii) **Complex number as a rotating arrow in Argand plane** :

Let $z = r(\cos\theta + i\sin\theta) = re^{i\theta}$, where $i = \sqrt{-1}$ ... (i)

be a complex number representing a point P in the Argand plane.



Then, $OP = |z| = r$ and $\angle POX = \theta$

Now, consider complex number $z_1 = ze^{i\phi}$

or $z_1 = re^{i\theta} \cdot e^{i\phi} = r \cdot e^{i(\theta+\phi)}$ [from Eq. (i)]

Clearly the complex number z_1 represents a point Q in the Argand plane, when

$$OQ = r \quad \text{and} \quad \angle QOX = \theta + \phi$$

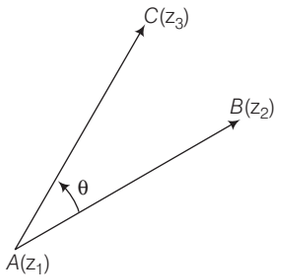
Clearly multiplication of z with $e^{i\phi}$ rotates the vector $\vec{OP}$ through angle ϕ in anti-clockwise sense. Similarly multiplication of z with $e^{-i\phi}$ will rotate the vector $\vec{OP}$ in clockwise sense.

Remark

If z_1, z_2 and z_3 are the affixes of the three points A, B and C such that $AC = AB$ and $\angle CAB = \theta$. Therefore

$$\vec{AB} = z_2 - z_1, \vec{AC} = z_3 - z_1$$

Then $\vec{AC}$ will be obtained by rotating $\vec{AB}$ through an angle θ in anticlockwise sense and therefore



$$\vec{AC} = \vec{AB}e^{i\theta}$$

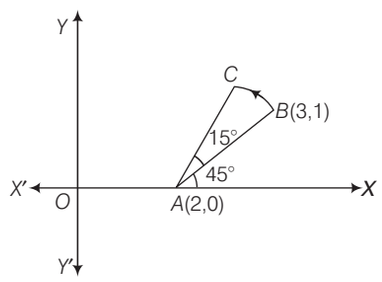
or $$(z_3 - z_1) = (z_2 - z_1)\, e^{i\theta} \text{ or } \left(\frac{z_3 - z_1}{z_2 - z_1}\right) = e^{i\theta}$$

Example 43. The line joining the points $A(2, 0)$ and $B(3, 1)$ is rotated about A in the anticlockwise direction through an angle of 15°. Find the equation of the line in the new position. If B goes to C in the new position, what will be the coordinates of C ?

Sol. By special corollary (i)

Here $$AB = \sqrt{(2-3)^2 + (0-1)^2} = \sqrt{2}$$

and slope of $$AB = \frac{1-0}{3-2} = 1 = \tan 45°$$



$$\therefore \quad \angle BAX = 45°$$

Now line AB is rotated through an angle of 15°

$$\Rightarrow \quad \angle CAX = 45° + 15° = 60°$$

and $$AB = AC = \sqrt{2}$$

Equation of line AC in parametric form is

$$\left.\begin{aligned} x &= 2 + r\cos 60° \\ y &= 0 + r\sin 60° \end{aligned}\right\} \quad \text{...(i)}$$

Since, $AC = r = \sqrt{2}$

Put $r = \sqrt{2}$ in Eq. (i), then

$$x = 2 + \sqrt{2}\cdot\frac{1}{2} = \frac{4+\sqrt{2}}{2}$$

and $$y = \sqrt{2}\,.\,\frac{\sqrt{3}}{2} = \frac{\sqrt{6}}{2}$$

Equation of the line AC is

$$\frac{x-2}{y} = \cot 60° = \frac{1}{\sqrt{3}}$$

or $$x\sqrt{3} - y - 2\sqrt{3} = 0$$

and coordinates of C are $\left(\frac{4+\sqrt{2}}{2}, \frac{\sqrt{6}}{2}\right)$.

Aliter (By special corollary (ii))

$\because$ $A \equiv (2, 0)$, $B \equiv (3, 1)$, let $C \equiv (x, y)$

$\therefore$ $z_A = 2, z_B = 3 + i,\ z_C = x + iy$, where $i = \sqrt{-1}$

$$\frac{z_C - z_A}{z_B - z_A} = e^{i\frac{5\pi}{12}} \qquad \left(\because 15° = \frac{5\pi}{12}\right)$$

$$\Rightarrow \quad z_C - 2 = (1+i)(\cos 15° + i\sin 15°)$$

or $$z_C = 2 + (1+i)\left(\frac{\sqrt{3}+1}{2\sqrt{2}} + i\left(\frac{\sqrt{3}-1}{2\sqrt{2}}\right)\right)$$

$$= \left(2 + \frac{\sqrt{3}+1}{2\sqrt{2}} - \frac{\sqrt{3}-1}{2\sqrt{2}}\right) + i\left(\frac{\sqrt{3}+1}{2\sqrt{2}} + \frac{\sqrt{3}-1}{2\sqrt{2}}\right)$$

$$= \left(2 + \frac{1}{\sqrt{2}}\right) + i\left(\frac{\sqrt{3}}{\sqrt{2}}\right) = \frac{4+\sqrt{2}}{2} + i\left(\frac{\sqrt{6}}{2}\right)$$

$$\therefore \quad C \equiv \left(\frac{4+\sqrt{2}}{2}, \frac{\sqrt{6}}{2}\right)$$

and equation of AC

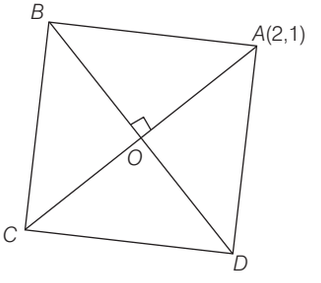
$$y - 0 = \tan 60°\,(x - 2) \Rightarrow x\sqrt{3} - y - 2\sqrt{3} = 0$$

Example 44. The centre of a square is at the origin and one vertex is $A(2, 1)$. Find the coordinates of other vertices of the square.

Sol. [By special corollary (ii)]

$\because$ $A \equiv (2, 1)$

$\therefore$ $z_A = 2 + i$, where $i = \sqrt{-1}$



Now, in triangle AOB,

$$OA = OB, \angle AOB = 90° = \frac{\pi}{2}$$

$\therefore$ $z_B = z_A e^{i\frac{\pi}{2}} = iz_A = 2i - 1$

$\therefore$ $B \equiv (-1, 2)$

$\because$ O is the mid-point of AC and BD

$\therefore$ $C \equiv (-2, -1)$ and $D \equiv (1, -2)$.

Example 45. The extremities of the diagonal of a square are $(1,1)$, $(-2,-1)$. Obtain the other two vertices and the equation of the other diagonal.

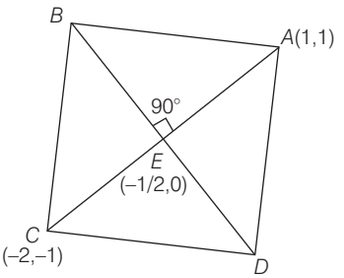
Sol. **(By special corollary (ii))**

$\because$ $A \equiv (1, 1)$

$\therefore$ $z_A = 1 + i$, where $i = \sqrt{-1}$

and $C \equiv (-2, -1)$

$\therefore$ $z_C = -2 - i$



then centre of square $E \equiv \left(-\frac{1}{2}, 0\right)$

$\therefore$ $z_E = -\frac{1}{2}$

Now, in ΔAEB, $(EA = EB)$

$$\frac{z_B - z_E}{z_A - z_E} = e^{i\frac{\pi}{2}} = i$$

$\Rightarrow$ $z_B + \frac{1}{2} = i\left(1 + i + \frac{1}{2}\right)$

$\therefore$ $z_B = -\frac{3}{2} + \frac{3}{2}i$

$B \equiv \left(-\frac{3}{2}, \frac{3}{2}\right)$

then $D \equiv \left(-1 + \frac{3}{2}, -\frac{3}{2}\right)$

or $D \equiv \left(\frac{1}{2}, -\frac{3}{2}\right)$

Hence, equation of other diagonal BD is

$$y - 0 = \frac{\frac{3}{2} - 0}{-\frac{3}{2} + \frac{1}{2}}\left(x + \frac{1}{2}\right)$$

$\Rightarrow$ $6x + 4y + 3 = 0$

Exercise for Session 1

1. The distance of the point (3, 5) from the line $2x + 3y - 14 = 0$ measured parallel to the line $x - 2y = 1$ is

(a) $\frac{7}{\sqrt{5}}$ (b) $\frac{7}{\sqrt{13}}$ (c) $\sqrt{5}$ (d) $\sqrt{13}$

2. The lines $x\cos\alpha + y\sin\alpha = p_1$ and $x\cos\beta + y\sin\beta = p_2$ will be perpendicular, if

(a) $\alpha = \beta$ (b) $|\alpha - \beta| = \pi/2$

(c) $\alpha = \pi/2$ (d) $\alpha \pm \beta = \pi/2$

3. If each of the points $(x_1, 4)$, $(-2, y_1)$ lies on the line joining the points $(2, -1)$, $(5, -3)$, then the point $P(x_1, y_1)$ lies on the line

(a) $6(x + y) - 25 = 0$ (d) $2x + 6y + 1 = 0$

(c) $2x + 3y - 6 = 0$ (d) $6(x + y) + 25 = 0$

4. The equation of the straight line passing through the point (4, 3) and making intercepts on the coordinate axes whose sum is –1 is

(a) $\frac{x}{2} + \frac{y}{3} = -1$ and $\frac{x}{-2} + \frac{y}{1} = -1$ (b) $\frac{x}{2} - \frac{y}{3} = -1$ and $\frac{x}{-2} + \frac{y}{1} = -1$

(c) $\frac{x}{2} + \frac{y}{3} = 1$ and $\frac{x}{-2} + \frac{y}{1} = 1$ (d) $\frac{x}{2} - \frac{y}{3} = 1$ and $\frac{x}{-2} + \frac{y}{1} = 1$

5. If the straight lines $ax + by + c = 0$ and $x\cos\alpha + y\sin\alpha = c$ enclose an angle $\pi/4$ between them and meet the straight line $x\sin\alpha - y\cos\alpha = 0$ in the same point, then

(a) $a^2 + b^2 = c^2$ (b) $a^2 + b^2 = 2$ (c) $a^2 + b^2 = 2c^2$ (d) $a^2 + b^2 = 4$

6. The angle between the lines $2x - y + 3 = 0$ and $x + 2y + 3 = 0$ is

(a) 30° (b) 45° (c) 60° (d) 90°

7. The inclination of the straight line passing through the point (–3, 6) and the mid-point of the line joining the points (4, –5) and (–2, 9) is

(a) $\pi/4$ (b) $\pi/2$ (c) $3\pi/4$ (d) π

8. A square of side a lies above the *X*-axis and has one vertex at the origin. The side passing through the origin makes an angle $\pi/6$ with the positive direction of *X*-axis. The equation of its diagonal not passing through the origin is

(a) $y(\sqrt{3} - 1) - x(1 - \sqrt{3}) = 2a$ (b) $y(\sqrt{3} + 1) + x(1 - \sqrt{3}) = 2a$

(c) $y(\sqrt{3} + 1) + x(1 + \sqrt{3}) = 2a$ (d) $y(\sqrt{3} + 1) + x(\sqrt{3} - 1) = 2a$

9. $A(1,3)$ and $C(7,5)$ are two opposite vertices of a square. The equation of side through *A* is

(a) $x + 2y - 7 = 0$ (b) $x - 2y + 5 = 0$

(c) $2x + y - 5 = 0$ (d) $2x - y + 1 = 0$

10. The equation of a straight line passing through the point $(-5, 4)$ and which cuts off an intercept of $\sqrt{2}$ units between the lines $x + y + 1 = 0$ and $x + y - 1 = 0$ is

(a) $x - 2y + 13 = 0$ (b) $2x - y + 14 = 0$

(c) $x - y + 9 = 0$ (d) $x - y + 10 = 0$

11. Equation to the straight line cutting off an intercept 2 from negative direction of the axis of *y* and inclined at 30° to the positive direction of axis of *x* is

(a) $y + x - \sqrt{3} = 0$ (b) $y - x + 2 = 0$

(c) $y - x\sqrt{3} - 2 = 0$ (d) $y\sqrt{3} - x + 2\sqrt{3} = 0$

12. What is the value of *y* so that the line through $(3, y)$ and (2, 7) is parallel to the line through (–1, 4) and (0, 6) ?

13. A straight line is drawn through the point $P(2,2)$ and is inclined at an angle of 30° with the *X*-axis. Find the coordinates of two points on it at a distance 4 from *P* on either side of *P*.

14. If the straight line through the point $P(3,4)$ makes an angle $\frac{\pi}{6}$ with *X*-axis and meets the line $12x + 5y + 10 = 0$ at *Q*, find the length of *PQ*.

15. Find the distance of the point (2, 3) from the line $2x - 3y + 9 = 0$ measured along the line $x - y + 1 = 0$.

16. A line is such that its segment between the straight line $5x - y - 4 = 0$ and $3x + 4y - 4 = 0$ is bisected at the point $(1,5)$. Obtain the equation.

17. The side *AB* and *AC* of a ΔABC are respectively $2x + 3y = 29$ and $x + 2y = 16$. If the mid-point of *BC* is (5, 6), then find the equation of *BC*.

18. A straight line through $A(-15, -10)$ meets the lines $x - y - 1 = 0$, $x + 2y = 5$ and $x + 3y = 7$ respectively at *A*, *B* and *C*. If $\frac{12}{AB} + \frac{40}{AC} = \frac{52}{AD}$, prove that the line passes through the origin.

Session 2

Position of Two Points Relative to a Given Line, Position of a Point Which Lies Inside a Triangle, Equations of Lines Parallel and Perpendicular to a Given Line, Distance of a Point From a Line, Distance Between Two Parallel Lines, Area of Parallelogram,

Position of Two Points Relative to a Given Line

Theorem : The points $P(x_1, y_1)$ and $Q(x_2, y_2)$ lie on the same or opposite sides of the line $ax + by + c = 0$ according as

$$\frac{ax_1 + by_1 + c}{ax_2 + by_2 + c} > 0 \text{ or } < 0 .$$

Proof : Let the line PQ be divided by the line $ax + by + c = 0$ in the ratio $\lambda : 1$ (internally) at the point R.

$\therefore$ The coordinates of R are $\left(\frac{x_1 + \lambda x_2}{1+\lambda}, \frac{y_1 + \lambda y_2}{1+\lambda}\right)$.

The point of R lies on the line $ax + by + c = 0$

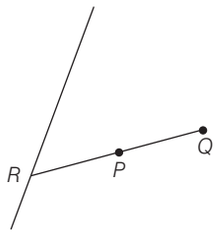
then $\quad a\left(\frac{x_1 + \lambda x_2}{1+\lambda}\right) + b\left(\frac{y_1 + \lambda y_2}{1+\lambda}\right) + c = 0$

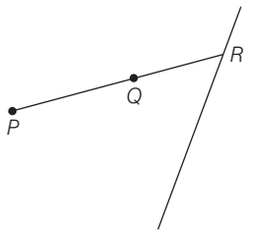
$\Rightarrow \quad \lambda(ax_2 + by_2 + c) + (ax_1 + by_1 + c) = 0$

$\Rightarrow \quad \lambda = -\left(\frac{ax_1 + by_1 + c}{ax_2 + by_2 + c}\right) \qquad (\because ax_2 + by_2 + c \neq 0)$

Case I : Let P and Q are on same side of the line $ax + by + c = 0$.

$\therefore$ R divides PQ externally.





$\therefore$ λ is negative

$\Rightarrow \quad -\left(\frac{ax_1 + by_1 + c}{ax_2 + by_2 + c}\right) < 0$

$\Rightarrow \quad \left(\frac{ax_1 + by_1 + c}{a x_2 + by_2 + c}\right) > 0$

or $\quad \frac{f(x_1, y_1)}{f(x_2, y_2)} > 0$

where, $f(x, y) \equiv ax + by + c$.

Case II : Let P and Q are on opposite sides of the line $ax + by + c = 0$

$\therefore$ R divides PQ internally.

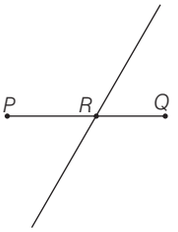
$\therefore$ λ is positive

$\Rightarrow \quad -\left(\frac{ax_1 + by_1 + c}{ax_2 + by_2 + c}\right) > 0$

$\Rightarrow \quad \left(\frac{ax_1 + by_1 + c}{ax_2 + by_2 + c}\right) < 0$

or $\quad \frac{f(x_1, y_1)}{f(x_2, y_2)} < 0$

where, $f(x, y) = ax + by + c$



Remarks

1. The side of the line where origin lies is known as origin side.
2. A point (α, β) will lie on origin side of the line $ax + by + c = 0$, if $a\alpha + b\beta + c$ and c have same sign.
3. A point (α, β) will lie on non-origin side of the line $ax + by + c = 0$, if $a\alpha + b\beta + c$ and c have opposite sign.

Example 46. Are the points $(2,1)$ and $(-3,5)$ on the same or opposite side of the line $3x-2y+1=0$?

Sol. Let $f(x,y)\equiv 3x-2y+1$

$$\therefore \quad \frac{f(2,1)}{f(-3,5)}=\frac{3(2)-2(1)+1}{3(-3)-2(5)+1}=-\frac{5}{18}<0$$

Therefore, the two points are on the opposite sides of the given line.

Example 47. Is the point $(2,-7)$ lies on origin side of the line $2x+y+2=0$?

Sol. Let $f(x,y)\equiv 2x+y+2$

$$\therefore \quad f(2,-7)=2(2)-7+2=-1$$

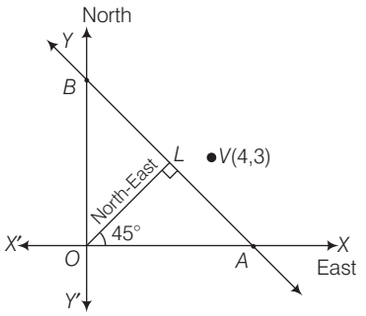
$f(2,-7)<0$ and constant $2>0$

Hence, the point $(2,-7)$ lies on non-origin side.

Example 48. A straight canal is at a distance of $4\frac{1}{2}$ km from a city and the nearest path from the city to the canal is in the north-east direction. Find whether a village which is at 3 km north and 4 km east from the city lies on the canal or not. If not, then on which side of the canal is the village situated ?

Sol. Let $O(0,0)$ be the given city and AB be the straight canal.

Given, $OL=\frac{9}{2}$ km



$\therefore$ Equation of AB

i.e. Equation of canal is

$$x\cos 45^\circ + y\sin 45^\circ = \frac{9}{2}$$

or
$$x+y=\frac{9}{\sqrt{2}} \qquad \text{...(i)}$$

Let V be the given village, then $V\equiv(4,3)$

Putting $x=4$ and $y=3$ in Eq. (i),

then $4+3=\frac{9}{\sqrt{2}}$, i.e. $7=\frac{9}{\sqrt{2}}$ which is impossible.

Hence, the given village V does not lie on the canal.

Also if $f(x,y)\equiv x+y-\frac{9}{\sqrt{2}}$

$$\therefore \quad \frac{f(4,3)}{f(0,0)}=\left(\frac{4+3-\frac{9}{\sqrt{2}}}{0+0-\frac{9}{\sqrt{2}}}\right)=-\left(\frac{7\sqrt{2}-9}{9}\right)<0$$

Hence, the village is on that side of the canal on which origin or the city lies.

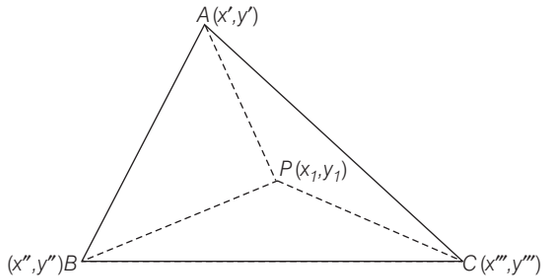
Position of a Point Which Lies Inside a Triangle

Let $P(x_1,y_1)$ be the point and equations of the sides of a triangle are

$$BC: a_1x+b_1y+c_1=0$$

$$CA: a_2x+b_2y+c_2=0$$

and
$$AB: a_3x+b_3y+c_3=0$$



First find the coordinates of A, B and C say,

$$A\equiv(x',y');\ B\equiv(x'',y'') \text{ and } C\equiv(x''',y''')$$

and if coordinates of A, B, C are given, then find equations of BC, CA and AB.

If $P(x_1,y_1)$ lies inside the triangle, then P and A must be on the same side of BC, P and B must be on the same side of AC, P and C must be on the same side of AB , then

$$\frac{a_1x_1+b_1y_1+c_1}{a_1x'+b_1y'+c_1}>0 \qquad \text{...(i)}$$

$$\frac{a_2x_1+b_2y_1+c_2}{a_2x''+b_2y''+c_2}>0 \qquad \text{...(ii)}$$

and
$$\frac{a_3x_1+b_3y_1+c_3}{a_3x'''+b_3y'''+c_3}>0 \qquad \text{...(iii)}$$

The required values of $P(x_1,y_1)$ must be intersection of these inequalities Eqs. (i), (ii) and (iii).

Aliter (Best Method) : First draw the exact diagram of the problem. If the point $P(x_1, y_1)$ move on the line $y = ax + b$ for all x_1, then

$$P \equiv (x_1, ax_1 + b)$$

and the portion DE of the line $y = ax + b$ (Excluding D and E) lies within the triangle. Now line $y = ax + b$ cuts any two sides out of three sides, then find coordinates of D and E.

$$D \equiv (\alpha, \beta)$$

and $E \equiv (\gamma, \delta)$ (say)

then $\alpha < x_1 < \gamma$

and $\beta < ax_1 + b < \delta$

Example 49. For what values of the parameter t does the point $P(t, t+1)$ lies inside the triangle ABC where $A \equiv (0, 3), B \equiv (-2, 0)$ and $C \equiv (6, 1)$.

Sol. Equations of sides

$$BC : x - 8y + 2 = 0$$

$$CA : x + 3y - 9 = 0$$

and $AB : 3x - 2y + 6 = 0$

Since, $P(t, t+1)$ lies inside the triangle ABC, then P and A must be on the same side of BC

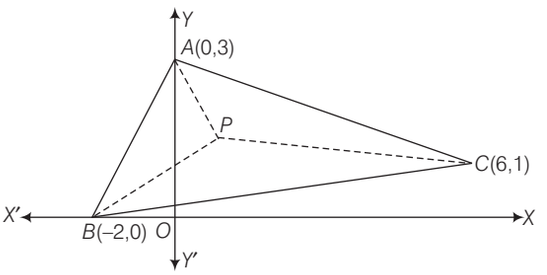
$$\therefore \quad \frac{\text{value of } (x - 8y + 2) \text{ at } P(t, t+1)}{\text{value of } (x - 8y + 2) \text{ at } A(0, 3)} > 0$$

i.e. $$\frac{t - 8(t+1) + 2}{0 - 24 + 2} > 0$$

or $$\frac{-7t - 6}{-22} > 0$$

or $$7t + 6 > 0$$

$$\therefore \quad t > -\frac{6}{7} \qquad \text{...(i)}$$



and P, B must be on the same side of CA

$$\therefore \quad \frac{\text{value of } (x + 3y - 9) \text{ at } P(t, t+1)}{\text{value of } (x + 3y - 9) \text{ at } B(-2, 0)} > 0$$

i.e. $$\frac{t + 3(t+1) - 9}{-2 + 0 - 9} > 0$$

or $$\frac{4t - 6}{-11} > 0$$

or $$4t - 6 < 0$$

$$\therefore \quad t < \frac{3}{2} \qquad \text{...(ii)}$$

and P, C must be on the same side of AB

$$\therefore \quad \frac{\text{value of } (3x - 2y + 6) \text{ at } P(t, t+1)}{\text{value of } (3x - 2y + 6) \text{ at } C(6, 1)} > 0$$

i.e. $$\frac{3t - 2(t+1) + 6}{18 - 2 + 6} > 0$$

or $$\frac{t + 4}{22} > 0$$

or $$t + 4 > 0$$

$$\therefore \quad t > -4 \qquad \text{...(iii)}$$

From Eqs. (i), (ii) and (iii), we get

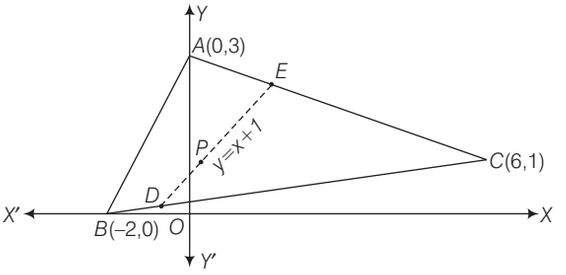
$$-\frac{6}{7} < t < \frac{3}{2}$$

i.e. $$t \in \left(-\frac{6}{7}, \frac{3}{2}\right)$$

Aliter : First draw the exact diagram of ΔABC, the point $P(t, t+1)$ move on the line

$$y = x + 1$$

for all t.



Now, D and E are the intersection of

$$y = x + 1, x - 8y + 2 = 0$$

and $y = x + 1, \quad x + 3y - 9 = 0$

respectively.

$$\therefore \quad D \equiv \left(-\frac{6}{7}, \frac{1}{7}\right)$$

and $$E \equiv \left(\frac{3}{2}, \frac{5}{2}\right)$$

Thus, the points on the line $y = x + 1$ whose x-coordinates lies between $-\frac{6}{7}$ and $\frac{3}{2}$ lie within the triangle ABC.

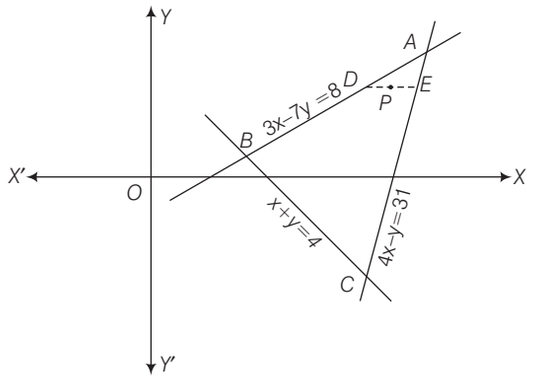
Hence, $$-\frac{6}{7} < t < \frac{3}{2}$$

i.e. $$t \in \left(-\frac{6}{7}, \frac{3}{2}\right)$$

Example 50. Find λ if $(\lambda, 2)$ is an interior point of ΔABC formed by $x + y = 4$, $3x - 7y = 8$ and $4x - y = 31$.

Sol. Let $P \equiv (\lambda, 2)$

First draw the exact diagram of ΔABC, the point $P(\lambda, 2)$ move on the line $y = 2$ for all λ.



Now, D and E are the intersection of

$$3x - 7y = 8, y = 2$$

and $4x - y = 31, y = 2$ respectively.

$$\therefore \quad D \equiv \left(\frac{22}{3}, 2\right) \text{ and } E \equiv \left(\frac{33}{4}, 2\right)$$

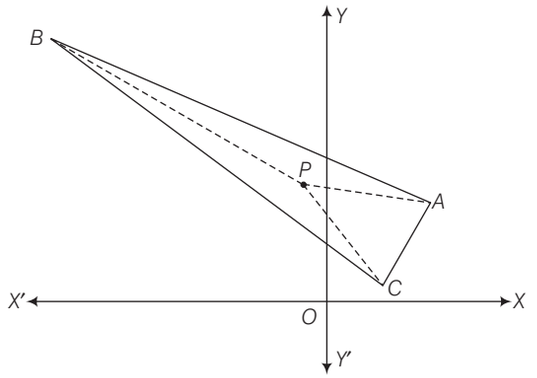
Thus, the points on the line $y = 2$ whose x-coordinates lies between $\frac{22}{3}$ and $\frac{33}{4}$ lie within the ΔABC.

Hence, $$\frac{22}{3} < \lambda < \frac{33}{4}$$

i.e. $$\lambda \in \left(\frac{22}{3}, \frac{33}{4}\right)$$

Example 51. Determine all values of α for which the point (α, α^2) lies inside the triangle formed by the lines $2x + 3y - 1 = 0$, $x + 2y - 3 = 0$ and $5x - 6y - 1 = 0$.

Sol. The coordinates of the vertices are



$$A\left(\frac{5}{4}, \frac{7}{8}\right), B(-7, 5) \text{ and } C\left(\frac{1}{3}, \frac{1}{9}\right)$$

$\because P(\alpha, \alpha^2)$ lies inside the ΔABC, then

(i) A and P must lie on the same side of BC

(ii) B and P must lie on the same side of CA

(iii) C and P must lie on the same side of AB, then

$$\frac{\frac{5}{2} + \frac{21}{8} - 1}{2\alpha + 3\alpha^2 - 1} > 0$$

$$\Rightarrow \quad \frac{33}{2\alpha + 3\alpha^2 - 1} > 0$$

or $$3\alpha^2 + 2\alpha - 1 > 0$$

$$\Rightarrow \quad (\alpha + 1)\left(\alpha - \frac{1}{3}\right) > 0$$

$$\Rightarrow \quad \alpha \in (-\infty, -1) \cup \left(\frac{1}{3}, \infty\right) \quad \text{...(i)}$$

and $$\frac{-35 - 30 - 1}{5\alpha - 6\alpha^2 - 1} > 0$$

$$\Rightarrow \quad 5\alpha - 6\alpha^2 - 1 < 0$$

$$\Rightarrow \quad \left(\alpha - \frac{1}{3}\right)\left(\alpha - \frac{1}{2}\right) > 0$$

$$\therefore \quad \alpha \in (-\infty, 1/3) \cup (1/2, \infty) \quad \text{..(ii)}$$

and $$\frac{\frac{1}{3} + \frac{2}{9} - 3}{\alpha + 2\alpha^2 - 3} > 0$$

$$\Rightarrow \quad \alpha + 2\alpha^2 - 3 < 0$$

$$\Rightarrow \quad (2\alpha + 3)(\alpha - 1) < 0$$

$$\therefore \quad \alpha \in (-3/2, 1) \quad \text{...(iii)}$$

From Eq. (i), Eq. (ii) and Eq. (iii), we get

$$\alpha \in (-3/2, -1) \cup (1/2, 1).$$

Aliter : Let $P(\alpha, \alpha^2)$ first draw the exact diagram of ΔABC.

The point $P(\alpha, \alpha^2)$ move on the curve $y = x^2$ for all α.

Now, intersection of $y = x^2$

and $$2x + 3y - 1 = 0$$

or $$2x + 3x^2 - 1 = 0$$

$$\therefore \quad x = -1, x = \frac{1}{3}$$

Let intersection points

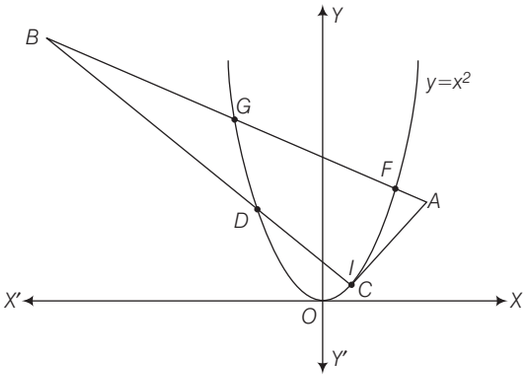
$$D \equiv (-1, 1) \text{ and } E \equiv \left(\frac{1}{3}, \frac{1}{9}\right)$$

intersection of $y = x^2$

and $$x + 2y - 3 = 0$$

or $$x + 2x^2 - 3 = 0$$

$$\therefore \quad x = 1, x = -3/2$$



Let intersection points

$$F \equiv (1, 1) \text{ and } G \equiv \left(-\frac{3}{2}, \frac{9}{4}\right)$$

and intersection of $y = x^2$ and $5x - 6y - 1 = 0$

or $\quad 5x - 6x^2 - 1 = 0$

$\therefore \quad x = \frac{1}{3}, x = \frac{1}{2}$

Let intersection points

$$H \equiv \left(\frac{1}{3}, \frac{1}{9}\right) \text{ and } I \equiv \left(\frac{1}{2}, \frac{1}{4}\right).$$

Thus the points on the curve $y = x^2$ whose x-coordinate lies between $-3/2$ & -1 and $\frac{1}{2}$ & 1 lies within the triangle ABC.

Hence, $\quad -\frac{3}{2} < \alpha < -1 \text{ or } \frac{1}{2} < \alpha < 1$

i.e. $\quad \alpha \in \left(-\frac{3}{2}, -1\right) \cup \left(\frac{1}{2}, 1\right)$

Equations of Lines Parallel and Perpendicular to a Given Line

Theorem 1: The equation of line parallel to $ax + by + c = 0$ is $ax + by + \lambda = 0$, where λ is some constant.

Proof : Let the equation of any line parallel to

$$ax + by + c = 0 \quad \text{...(i)}$$

be $\quad a_1 x + b_1 y + c_1 = 0 \quad \text{...(ii)}$

then $\quad \frac{a_1}{a} = \frac{b_1}{b} = k \quad \text{(say)}$

$\therefore \quad a_1 = ak, b_1 = bk$

Then from Eq. (ii),

$$akx + bky + c = 0$$

Dividing it by k, then

$$ax + by + \frac{c}{k} = 0$$

or $\quad ax + by + \lambda = 0 \quad \left(\text{writing } \lambda \text{ for } \frac{c}{k}\right)$

Hence, any line parallel to $ax + by + c = 0$ is

$$ax + by + \lambda = 0$$

where λ is some constant.

Aliter : The given line is

$$ax + by + c = 0 \quad \text{...(i)}$$

Its slope $= -\frac{a}{b}$

Thus, any line parallel to Eq. (i) is given by

$$y = \left(-\frac{a}{b}\right)x + \lambda_1$$

$\Rightarrow \quad ax + by - b\lambda_1 = 0$

$\Rightarrow \quad ax + by + \lambda = 0 \quad (\text{writing } \lambda \text{ for } -b\lambda_1)$

where, λ is some constant.

Corollary **:** The equation of the line parallel to $ax + by + c = 0$ and passing through (x_1, y_1) is

$$a(x - x_1) + b(y - y_1) = 0$$

Working Rule :

(i) Keep the terms containing x and y unaltered.

(ii) Change the constant.

(iii) The constant λ is determined from an additional condition given in the problem.

Theorem 2 : The equation of the line perpendicular to the line $ax + by + c = 0$ is

$bx - ay + \lambda = 0$, where λ is some constant.

Proof : Let the equation of any line perpendicular to

$$ax + by + c = 0 \quad \text{... (i)}$$

be $\quad a_1 x + b_1 y + c_1 = 0 \quad \text{...(ii)}$

then $\quad aa_1 + bb_1 = 0$

or $\quad aa_1 = -bb_1$

$\Rightarrow \quad \frac{a_1}{b} = \frac{b_1}{-a} = k \quad \text{(say)}$

$\therefore \quad a_1 = bk, b_1 = -ak$

Then, from Eq. (ii), $bkx - aky + c_1 = 0$ dividing it by k, then

$$bx - ay + \frac{c_1}{k} = 0$$

or $bx - ay + \lambda = 0$ $\left(\text{writing } \lambda \text{ for } \frac{c_1}{k}\right)$

Hence, any line perpendicular to $ax + by + c = 0$ is

$$bx - ay + \lambda = 0$$

where, λ is some constant.

Aliter : The given line is

$$ax + by + c = 0 \quad ...(i)$$

$$\text{Its slope} = -\frac{a}{b}$$

Slope of perpendicular line of Eq. (i) is $\frac{b}{a}$.

Thus any line perpendicular to Eq. (i) is given by

$$y = \left(\frac{b}{a}\right)x + \lambda_1$$

$\Rightarrow$ $bx - ay + a\lambda_1 = 0$

or $bx - ay + \lambda = 0$ (writing λ for $a\lambda_1$)

where, λ is some constant.

***Corollary* 1 :** The equation of the line through (x_1, y_1) and perpendicular to $ax + by + c = 0$ is

$$b(x - x_1) - a(y - y_1) = 0$$

***Corollary* 2 :** Also equation of the line perpendicular to $ax + by + c = 0$ is written as

$$\frac{x}{a} - \frac{y}{b} + k = 0, \text{ where } k \text{ is some constant.}$$

Working Rule :

(i) Interchange the coefficients of x and y and changing sign of one of these coefficients.

(ii) Changing the constant term.

(iii) The value of λ can be determined from an additional condition given in the problem.

Example 52. Find the general equation of the line which is parallel to $3x - 4y + 5 = 0$. Also find such line through the point $(-1, 2)$.

Sol. Equation of any parallel to $3x - 4y + 5 = 0$ is

$$3x - 4y + \lambda = 0 \quad ...(i)$$

which is general equation of the line.

Also Eq. (i) passes through $(-1, 2)$, then

$$3(-1) - 4(2) + \lambda = 0$$

$\therefore$ $\lambda = 11$

Then from Eq. (i) required line is

$$3x - 4y + 11 = 0$$

Example 53. Find the general equation of the line which is perpendicular to $x + y + 4 = 0$. Also find such line through the point $(1, 2)$.

Sol. Equation of any line perpendicular to $x + y + 4 = 0$ is

$$x - y + \lambda = 0 \quad ...(i)$$

which is general equation of the line.

Also Eq. (i) passes through $(1, 2)$, then

$$1 - 2 + \lambda = 0$$

$\therefore$ $\lambda = 1$

Then from Eq. (i), required line is

$$x - y + 1 = 0$$

Example 54. Show that the equation of the line passing through the point $(a\cos^3\theta, a\sin^3\theta)$ and perpendicular to the line

$x \sec\theta + y \operatorname{cosec}\theta = a$ is

$x\cos\theta - y\sin\theta = a\cos 2\theta$

Sol. The given equation $x \sec\theta + y \operatorname{cosec}\theta = a$ can be written as

$$x\sin\theta + y\cos\theta = a\sin\theta\cos\theta \quad ...(i)$$

$\therefore$ equation of perpendicular line of Eq. (i) is

$$x\cos\theta - y\sin\theta = \lambda \quad ...(ii)$$

Also it is pass through $(a\cos^3\theta, a\sin^3\theta)$

$\therefore$ $a\cos^3\theta\cdot\cos\theta - a\sin^3\theta\cdot\sin\theta = \lambda$

$\Rightarrow$ $\lambda = a(\cos^4\theta - \sin^4\theta)$

$= a(\cos^2\theta + \sin^2\theta)(\cos^2\theta - \sin^2\theta)$

$= a\cdot 1\cdot\cos 2\theta = a\cos 2\theta$

From Eq. (ii), the required equation of the line is

$$x\cos\theta - y\sin\theta = a\cos 2\theta$$

Aliter : (From corollary (2) of Theorem (2)

Equation of any line perpendicular to the line

$x\sec\theta + y\operatorname{cosec}\theta = a$, is

$$\frac{x}{\sec\theta} - \frac{y}{\operatorname{cosec}\theta} = k$$

or $x\cos\theta - y\sin\theta = k \quad ...(iii)$

Also, it pass through $(a\cos^3\theta, a\sin^3\theta)$

$\therefore$ $a\cos^3\theta\cdot\cos\theta - a\sin^3\theta\cdot\sin\theta = k$

or $k = a(\cos^4\theta - \sin^4\theta)$

$= a(\cos^2\theta + \sin^2\theta)(\cos^2\theta - \sin^2\theta)$

$= a\cdot 1\cdot\cos 2\theta$

$= a\cos 2\theta$

From Eq. (iii), the required equation of the line is

$$x\cos\theta - y\sin\theta = a\cos 2\theta$$

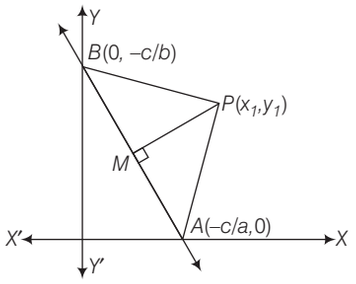
Distance of a Point From a Line

Theorem : The length of perpendicular from a point (x_1, y_1) to the line $ax + by + c = 0$ is

$$\frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

Proof : Given line is $ax + by + c = 0$

$$\Rightarrow \quad \frac{x}{\left(-\frac{c}{a}\right)} + \frac{y}{\left(-\frac{c}{b}\right)} = 1$$



Let the given line intersects the X-axis and Y-axis at A and B respectively, then coordinates of A and B are $\left(-\frac{c}{a}, 0\right)$ and $\left(0, -\frac{c}{b}\right)$ respectively.

Draw PM perpendicular to AB.

Now, Area of ΔPAB

$$= \frac{1}{2}\left| x_1\left(0 + \frac{c}{b}\right) - \frac{c}{a}\left(-\frac{c}{b} - y_1\right) + 0\,(y_1 - 0)\right|$$

$$= \frac{1}{2}\left|\frac{c}{ab}\right| |ax_1 + by_1 + c| \qquad \ldots(i)$$

Let $PM = p$

Also, area of ΔPAB

$$= \frac{1}{2} \cdot AB \cdot PM = \frac{1}{2}\sqrt{\left\{\left(-\frac{c}{a} - 0\right)^2 + \left(0 + \frac{c}{b}\right)^2\right\}} \cdot p$$

$$= \frac{1}{2}\left|\frac{c}{ab}\right| \sqrt{(a^2 + b^2)} \cdot p \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we have

$$\frac{1}{2}\left|\frac{c}{ab}\right| \sqrt{(a^2 + b^2)} \cdot p = \frac{1}{2}\left|\frac{c}{ab}\right| |ax_1 + by_1 + c|$$

or $$p = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

Aliter I : Let PM makes an angle θ with positive direction of X-axis.

Then, equation of PM in distance form will be

$$\frac{x - x_1}{\cos\theta} = \frac{y - y_1}{\sin\theta} = p \qquad (\because PM = p)$$

Therefore coordinates of M will be

$$(x_1 + p\cos\theta, y_1 + p\sin\theta)$$

Since, M lies on $ax + by + c = 0$, then

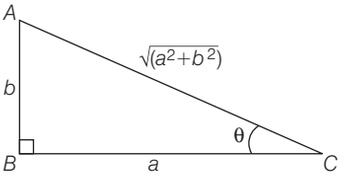
$$a\,(x_1 + p\cos\theta) + b\,(y_1 + p\sin\theta) + c = 0$$

or $$p\,(a\cos\theta + b\sin\theta) = -(ax_1 + by_1 + c) \qquad \ldots(iii)$$

Since, slope of $AB = -\frac{a}{b}$

$\therefore$ Slope of $PM = \frac{b}{a}$

$\therefore$ $\tan\theta = \frac{b}{a}$ ($\because$ PM makes an angle θ with positive direction of X-axis)



then $$\sin\theta = \frac{b}{\sqrt{(a^2 + b^2)}}$$

and $$\cos\theta = \frac{a}{\sqrt{(a^2 + b^2)}}$$

Now, from Eq. (iii),

$$p\left(\frac{a^2}{\sqrt{(a^2 + b^2)}} + \frac{b^2}{\sqrt{(a^2 + b^2)}}\right) = -(ax_1 + by_1 + c)$$

or $$p = -\frac{(ax_1 + by_1 + c)}{\sqrt{(a^2 + b^2)}}$$

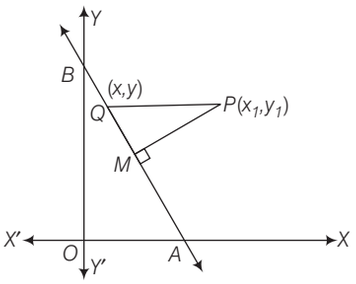
Since, p is positive

$\therefore$ $$p = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

Aliter II : Let $Q\,(x, y)$ be any point on the line

$$ax + by + c = 0$$

Hence, the length of perpendicular from P on AB will be least value of PQ.



Let $z = (PQ)^2$

$= (x - x_1)^2 + (y - y_1)^2$ ...(iv)

$= (x - x_1)^2 + \left(-\frac{c}{b} - \frac{ax}{b} - y_1\right)^2$

$\left(\because ax + by + c = 0 \;\; \therefore y = -\frac{c}{b} - \frac{ax}{b}\right)$

$\therefore \quad \frac{dz}{dx} = 2(x - x_1) + 2\left(-\frac{c}{b} - \frac{ax}{b} - y_1\right)\left(-\frac{a}{b}\right)$

and $\frac{d^2z}{dx^2} = 2 + 2\left(-\frac{a}{b}\right)\left(-\frac{a}{b}\right) = 2\left(1 + \frac{a^2}{b^2}\right) = \text{positive}$

$\because$ z is minimum

$\therefore$ PQ is also minimum.

For maximum or minimum, $\frac{dz}{dx} = 0$

$2(x - x_1) + 2\left(-\frac{c}{b} - \frac{ax}{b} - y_1\right)\left(-\frac{a}{b}\right) = 0$

or $2(x - x_1) + 2(y - y_1)\left(-\frac{a}{b}\right) = 0 \quad \left(\because y = -\frac{c}{b} - \frac{ax}{b}\right)$

or $\frac{(x - x_1)}{a} = \frac{(y - y_1)}{b} = \frac{a(x - x_1) + b(y - y_1)}{a \cdot a + b \cdot b}$

$= \frac{(ax + by + c) - (ax_1 + by_1 + c)}{(a^2 + b^2)}$

(by law of proportion)

$= \frac{0 - (ax_1 + by_1 + c)}{(a^2 + b^2)} \quad (\because ax + by + c = 0)$

$\Rightarrow \quad (x - x_1) = -\frac{a(ax_1 + by_1 + c)}{(a^2 + b^2)}$

and $(y - y_1) = -\frac{b(ax_1 + by_1 + c)}{(a^2 + b^2)}$

$\therefore$ From Eq. (iv),

$PQ = \sqrt{(ax_1 + by_1 + c)^2 \frac{(a^2 + b^2)}{(a^2 + b^2)^2}} = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$

$\because$ Least value of PQ is PM

$\therefore \quad p = PM = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$

Aliter III : Let $M \equiv (h, k)$

Since, $M(h, k)$ lies on AB,

$ah + bk + c = 0$ ..(v)

Now, AB and PM are perpendicular to each other, then

(slope of PM) $\times$ (slope of AB) $= -1$

$\Rightarrow \quad \frac{y_1 - k}{x_1 - h} \times \left(-\frac{a}{b}\right) = -1$

$\Rightarrow \quad \frac{x_1 - h}{a} = \frac{y_1 - k}{b} = \frac{a(x_1 - h) + b(y_1 - k)}{a \cdot a + b \cdot b}$

(by law of proportion)

$= \frac{(ax_1 + by_1 + c) - (ah + bk + c)}{a^2 + b^2}$

$= \frac{ax_1 + by_1 + c}{a^2 + b^2}$ [from Eq. (v)]

$\therefore \quad (PM)^2 = (x - x_1)^2 + (y - y_1)^2$

$= \left(\frac{ax_1 + by_1 + c}{a^2 + b^2}\right)^2 (a^2 + b^2)$

$\therefore$ Length of perpendicular

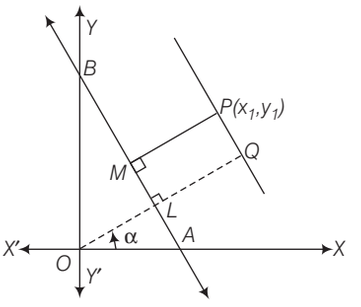
$PM = \pm \frac{(ax_1 + by_1 + c)}{\sqrt{(a^2 + b^2)}}$

Hence, $PM = p = \frac{|ax_1 + by_1 + c)}{\sqrt{(a^2 + b^2)}}$

Aliter IV : Equation of AB in normal form is

$\frac{a}{\sqrt{(a^2 + b^2)}} x + \frac{b}{\sqrt{(a^2 + b^2)}} y = \frac{-c}{\sqrt{(a^2 + b^2)}}$

$\Rightarrow \quad OL = -\frac{c}{\sqrt{(a^2 + b^2)}}$



Equation of line parallel to AB and passes through (x_1, y_1) is

$$a(x - x_1) + b(y - y_1) = 0$$

or $$ax + by = ax_1 + by_1$$

Normal form is

$$\frac{a}{\sqrt{(a^2 + b^2)}} x + \frac{b}{\sqrt{(a^2 + b^2)}} y = \frac{ax_1 + by_1}{\sqrt{(a^2 + b^2)}}$$

$$\Rightarrow \quad OQ = \frac{ax_1 + by_1}{\sqrt{(a^2 + b^2)}}$$

$$\therefore \quad PM = QL = OQ - OL = \frac{ax_1 + by_1 + c}{\sqrt{(a^2 + b^2)}}$$

Hence, required perpendicular distance

$$p = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

Aliter V : The equation of line through $P(x_1, y_1)$ and perpendicular to $ax + by + c = 0$ is

$$b(x - x_1) - a(y - y_1) = 0 \qquad ...(vi)$$

If this perpendicular meet the line $ax + by + c = 0$ in $M(x_2, y_2)$ then (x_2, y_2) lie on both the lines $ax + by + c = 0$ and Eq. (vi), then

$b(x_2 - x_1) - a(y_2 - y_1) = 0, ax_2 + by_2 + c = 0$

$ax_2 + by_2 + c = a(x_2 - x_1) + b(y_2 - y_1) + ax_1 + by_1 + c = 0$

or $$b(x_2 - x_1) - a(y_2 - y_1) = 0 \qquad ...(vii)$$

and $$a(x_2 - x_1) + b(y_2 - y_1) = -(ax_1 + by_1 + c) \qquad ...(viii)$$

On squaring and adding Eqs. (vii) and (viii), we get

$$(a^2 + b^2)((x_2 - x_1)^2 + (y_2 - y_1)^2) = (ax_1 + by_1 + c)^2$$

or $$PM = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

$$= \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

Hence, length of perpendicular

$$PM = p = \frac{|ax_1 + by_1 + c|}{\sqrt{(a^2 + b^2)}}$$

***Corollary* 1 :** The length of perpendicular from the origin to the line $ax + by + c = 0$ is

$$\frac{|a \cdot 0 + b \cdot 0 + c|}{\sqrt{(a^2 + b^2)}} \quad \text{i.e.} \quad \frac{|c|}{\sqrt{(a^2 + b^2)}}$$

***Corollary* 2 :** The length of perpendicular from (x_1, y_1) to the line $x \cos\alpha + y \sin\alpha = p$ is

$$\frac{|x_1 \cos\alpha + y_1 \sin\alpha - p|}{\sqrt{(\cos^2\alpha + \sin^2\alpha)}} = |x_1 \cos\alpha + y_1 \sin\alpha - p|$$

Working Rule :

(i) Put the point (x_1, y_1) for (x, y) on the LHS while the RHS is zero.

(ii) Divide LHS after Eq. (i) by $\sqrt{(a^2 + b^2)}$, where a and b are the coefficients of x and y respectively.

Example 55. Find the sum of the abscissas of all the points on the line $x + y = 4$ that lie at a unit distance from the line $4x + 3y - 10 = 0$.

Sol. Any point on the line $x + y = 4$ can be taken as $(x_1, 4 - x_1)$. As it is at a unit distance from the line $4x + 3y - 10 = 0$, we get

$$\frac{|4x_1 + 3(4 - x_1) - 10|}{\sqrt{(4^2 + 3^2)}} = 1$$

$$\Rightarrow \quad |x_1 + 2| = 5 \Rightarrow x_1 + 2 = \pm 5$$

$$\Rightarrow \quad x_1 = 3 \quad \text{or} \quad -7$$

$\therefore$ Required sum $= 3 - 7 = -4$.

Example 56. If p and p' are the length of the perpendiculars from the origin to the straight lines whose equations are $x \sec\theta + y \operatorname{cosec}\theta = a$ and $x \cos\theta - y \sin\theta = a \cos 2\theta$, then find the value of $4p^2 + p'^2$.

Sol. We have, $p = \frac{|-a|}{\sqrt{(\sec^2\theta + \operatorname{cosec}^2\theta)}}$

$$\therefore \quad p^2 = \frac{a^2}{\sec^2\theta + \operatorname{cosec}^2\theta} = \frac{a^2 \sin^2\theta \cos^2\theta}{1}$$

$$\Rightarrow \quad 4p^2 = a^2 \sin^2 2\theta \qquad ...(i)$$

and $$p' = \frac{|-a \cos 2\theta|}{\sqrt{(\cos^2\theta + \sin^2\theta)}} = |-a \cos 2\theta|$$

$$\therefore \quad (p')^2 = a^2 \cos^2 2\theta \qquad ...(ii)$$

$\therefore$ Adding Eqs. (i) and (ii), we get

$$4p^2 + p'^2 = a^2$$

Example 57. ***If p is the length of the perpendicular from the origin to the line $\frac{x}{a} + \frac{y}{b} = 1$, then prove that $\frac{1}{a^2} + \frac{1}{b^2} = \frac{1}{p^2}$.***

Sol. p = length of perpendicular from origin to

$$\frac{x}{a} + \frac{y}{b} = 1$$

$$= \frac{|0 + 0 - 1|}{\sqrt{\left(\frac{1}{a}\right)^2 + \left(\frac{1}{b}\right)^2}} = \frac{1}{\sqrt{\left(\frac{1}{a^2} + \frac{1}{b^2}\right)}}$$

or $$\frac{1}{p^2} = \frac{1}{a^2} + \frac{1}{b^2} \quad \text{or} \quad \frac{1}{a^2} + \frac{1}{b^2} = \frac{1}{p^2}$$

Example 58. Prove that no line can be drawn through the point $(4, -5)$ so that its distance from $(-2, 3)$ will be equal to 12.

Sol. Suppose, if possible.

Equation of line through $(4, -5)$ with slope of m is

$$y + 5 = m(x - 4)$$

$$\Rightarrow \quad mx - y - 4m - 5 = 0$$

Then, $$\frac{|m(-2) - 3 - 4m - 5|}{\sqrt{m^2 + 1}} = 12$$

$$\Rightarrow \quad |-6m - 8| = 12\sqrt{(m^2 + 1)}$$

On squaring, $$(6m + 8)^2 = 144(m^2 + 1)$$

$$\Rightarrow \quad 4(3m + 4)^2 = 144(m^2 + 1)$$

$$\Rightarrow \quad (3m + 4)^2 = 36(m^2 + 1)$$

$$\Rightarrow \quad 27m^2 - 24m + 20 = 0 \qquad \text{...(i)}$$

Since, the discriminant of Eq. (i) is $(-24)^2 - 4 \cdot 27 \cdot 20 = -1584$ which is negative, there is no real value of m. Hence no such line is possible.

Distance between Two Parallel Lines

Let the two parallel lines be

$$ax + by + c = 0 \quad \text{and} \quad ax + by + c_1 = 0$$

The distance between the parallel lines is the perpendicular distance of any point on one line from the other line.

Let (x_1, y_1) be any point on $ax + by + c = 0$

$$\therefore \quad ax_1 + by_1 + c = 0 \qquad \text{...(i)}$$

Now, perpendicular distance of the point (x_1, y_1) from the line $ax + by + c_1 = 0$ is

$$\frac{|ax_1 + by_1 + c_1|}{\sqrt{(a^2 + b^2)}} = \frac{|c_1 - c|}{\sqrt{(a^2 + b^2)}} \quad \text{[from Eq. (i)]}$$

This is required distance between the given parallel lines.

Aliter I : The distance between the lines is

$$d = \frac{\lambda}{\sqrt{(a^2 + b^2)}}$$

(i) $\lambda = |c_1 - c|$, if both the lines are on the same side of the origin.

(ii) $\lambda = |c_1| + |c|$, if the lines are on the opposite side of the origin.

Aliter II : Find the coordinates of any point on one of the given lines, preferably putting $x = 0$ or $y = 0$. Then the perpendicular distance of this point from the other line is the required distance between the lines.

Example 59. Find the distance between the lines $5x - 12y + 2 = 0$ and $5x - 12y - 3 = 0$.

Sol. The distance between the lines

$5x - 12y + 2 = 0$ and $5x - 12y - 3 = 0$ is

$$\frac{|2 - (-3)|}{\sqrt{(5)^2 + (-12)^2}} = \frac{5}{13}$$

Aliter I : The constant term in both equations are 2 and -3 which are of opposite sign. Hence origin lies between them.

$\therefore$ Distance between lines is $\dfrac{|2| + |-3|}{\sqrt{(5)^2 + (-12)^2}} = \dfrac{5}{13}$

Aliter II : Putting $y = 0$ in $5x - 12y - 3 = 0$ then $x = \dfrac{3}{5}$

$\therefore \quad \left(\dfrac{3}{5}, 0\right)$ lie on $5x - 12y - 3 = 0$

Hence, distance between the lines

$5x - 12y + 2 = 0$ and $(5x - 12y - 3 = 0)$

= Distance from $\left(\dfrac{3}{5}, 0\right)$ to the line $5x - 12y + 2 = 0$

$$= \frac{\left|5 \times \frac{3}{5} - 0 + 2\right|}{\sqrt{5^2 + (-12)^2}} = \frac{5}{13}$$

Example 60. Find the equations of the line parallel to $5x - 12y + 26 = 0$ and at a distance of 4 units from it.

Sol. Equation of any line parallel to $5x - 12y + 26 = 0$ is

$$5x - 12y + \lambda = 0 \qquad \text{...(i)}$$

Since, the distance between the parallel lines is 4 units, then

$$\frac{|\lambda - 26|}{\sqrt{(5)^2 + (-12)^2}} = 4$$

or $\quad |\lambda - 26| = 52 \quad$ or $\quad \lambda - 26 = \pm 52$

or $\quad \lambda = 26 \pm 52 \quad \therefore \quad \lambda = -26$ or 78

Substituting the values of λ in Eq. (i), we get

$$5x - 12y - 26 = 0$$

and $\quad 5x - 12y + 78 = 0$

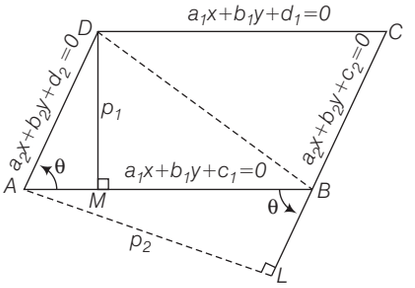
Area of Parallelogram

Theorem : Area of parallelogram $ABCD$ whose sides AB, BC, CD and DA are represented by $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + c_2 = 0$, $a_1x + b_1y + d_1 = 0$ and $a_2x + b_2y + d_2 = 0$ is

$$\frac{p_1 p_2}{\sin\theta} \quad \text{or} \quad \frac{|c_1 - d_1||c_2 - d_2|}{\left|\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}\right|}$$

where, p_1 and p_2 are the distances between parallel sides and θ is the angle between two adjacent sides.

Proof : Since, p_1 and p_1 are the distances between the pairs of parallel sides of the parallelogram and θ is the angle between two adjacent sides, then



Area of parallelogram $ABCD$

$$= 2 \times \text{Area of } \Delta ABD$$

$$= 2 \times \frac{1}{2} \times AB \times p_1$$

$$= AB \times p_1$$

$$= \frac{p_2}{\sin\theta} \times p_1 \qquad \left(\because \text{in } \Delta ABL, \sin\theta = \frac{p_2}{AB} \right)$$

$$= \frac{p_1 p_2}{\sin\theta} \qquad \ldots(i)$$

Now, p_1 = Distance between parallel sides AB and DC

$$= \frac{|c_1 - d_1|}{\sqrt{(a_1^2 + b_1^2)}}$$

and p_2 = Distance between parallel sides AD and BC

$$= \frac{|c_2 - d_2|}{\sqrt{(a_2^2 + b_2^2)}}$$

Also, $\tan\theta = \left| \frac{m_1 - m_2}{1 + m_1 m_2} \right| = \left| \frac{-\frac{a_1}{b_1} - \left(-\frac{a_2}{b_2}\right)}{1 + \left(-\frac{a_1}{b_1}\right)\left(-\frac{a_2}{b_2}\right)} \right|$

$$\left(\because \; m_1 = \text{slope of } AB = -\frac{a_1}{b_1} \right.$$

$$\left. \text{and } m_2 = \text{slope of } AD = -\frac{a_2}{b_2} \right)$$

$$= \left| \frac{a_1 b_2 - a_2 b_1}{a_1 a_2 + b_1 b_2} \right|$$

$$\therefore \qquad \sin\theta = \frac{|a_1 b_2 - a_2 b_1|}{\sqrt{(a_1^2 + b_1^2)(a_2^2 + b_2^2)}}$$

Now, substitute the values of p_1, p_2 and $\sin\theta$ in Eq. (i)

$$\therefore \text{ Area of parallelogram } ABCD = \frac{|c_1 - d_1||c_2 - d_2|}{|a_1 b_2 - a_2 b_1|} = \frac{|c_1 - d_1||c_2 - d_2|}{\left| \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \right|}$$

Corollaries :

1. If $p_1 = p_2$, then $ABCD$ becomes a rhombus

$$\therefore \text{ Area of rhombus } ABCD = \frac{p_1^2}{\sin\theta} = \frac{(c_1 - d_1)^2}{|a_1 b_2 - a_2 b_1| \sqrt{\left(\frac{a_1^2 + b_1^2}{a_2^2 + b_2^2} \right)}}$$

2. If d_1 and d_2 are the lengths of two perpendicular diagonals of a rhombus, then

$$\text{Area of rhombus} = \frac{1}{2} d_1 d_2$$

3. Area of the parallelogram whose sides are $y = mx + a$, $y = mx + b$, $y = nx + c$ and $y = nx + d$ is $\frac{|a - b||c - d|}{|m - n|}$.

Example 61. Show that the area of the parallelogram formed by the lines $x + 3y - a = 0$, $3x - 2y + 3a = 0$, $x + 3y + 4a = 0$ and $3x - 2y + 7a = 0$ is $\frac{20}{11} a^2$ sq units.

Sol. Required area of the parallelogram

$$= \frac{|-a - 4a||3a - 7a|}{\left| \begin{vmatrix} 1 & 3 \\ 3 & -2 \end{vmatrix} \right|} = \frac{20}{11} a^2 \text{ sq units}$$

Example 62. Show that the area of the parallelogram formed by the lines

$$x\cos\alpha + y\sin\alpha = p,\ x\cos\alpha + y\sin\alpha = q,$$

$$x\cos\beta + y\sin\beta = r,\ x\cos\beta + y\sin\beta = s \text{ is}$$

$$|(p - q)(r - s)\,\text{cosec}\,(\alpha - \beta)|.$$

Sol. The equation of sides of the parallelogram are

$$x\cos\alpha + y\sin\alpha - p = 0,$$

$$x\cos\alpha + y\sin\alpha - q = 0,$$

$$x\cos\beta + y\sin\beta - r = 0,$$

and $$x\cos\beta + y\sin\beta - s = 0$$

$\therefore$ Required area of the parallelogram

$$= \frac{|-p-(-q)|\,|-r-(-s)|}{\left|\begin{vmatrix}\cos\alpha & \sin\alpha\\ \cos\beta & \sin\beta\end{vmatrix}\right|} = \frac{|p-q|\,|r-s|}{|\sin(\beta-\alpha)|}$$

$$= |(p-q)(r-s)\operatorname{cosec}(\alpha-\beta)|$$

Example 63. Prove that the diagonals of the parallelogram formed by the lines

$$\frac{x}{a}+\frac{y}{b}=1,\ \frac{x}{b}+\frac{y}{a}=1,\ \frac{x}{a}+\frac{y}{b}=2 \text{ and } \frac{x}{b}+\frac{y}{a}=2$$

are at right angles. Also find its area ($a \neq b$).

Sol. The distance between the parallel sides

$$\frac{x}{a}+\frac{y}{b}=1 \quad \text{and} \quad \frac{x}{a}+\frac{y}{b}=2$$

is $$\frac{|2-1|}{\sqrt{\left(\frac{1}{a^2}+\frac{1}{b^2}\right)}} = \frac{1}{\sqrt{\left(\frac{1}{a^2}+\frac{1}{b^2}\right)}} = p_1 \quad \text{(say)}$$

and the distance between the parallel sides

$$\frac{x}{b}+\frac{y}{a}=1 \quad \text{and} \quad \frac{x}{b}+\frac{y}{a}=2$$

is $$\frac{|2-1|}{\sqrt{\left(\frac{1}{b^2}+\frac{1}{a^2}\right)}} = \frac{1}{\sqrt{\left(\frac{1}{a^2}+\frac{1}{b^2}\right)}} = p_2 \quad \text{(say)}$$

Here, $p_1 = p_2$.

$\therefore$ Parallelogram is a rhombus.

But we know that diagonals of rhombus are perpendicular to each other.

$\therefore$ Area of the rhombus $= \dfrac{|(-1+2)(-1+2)|}{\left|\begin{vmatrix}\frac{1}{a} & \frac{1}{b}\\ \frac{1}{b} & \frac{1}{a}\end{vmatrix}\right|}$

$$= \frac{a^2b^2}{|b^2-a^2|}(a \neq b)$$

Example 64. Show that the four lines $ax \pm by \pm c = 0$ enclose a rhombus whose area is $\dfrac{2c^2}{|ab|}$.

Sol. The given lines are

$$ax+by+c=0 \quad \text{...(i)}$$

$$ax+by-c=0 \quad \text{...(ii)}$$

$$ax-by+c=0 \quad \text{...(iii)}$$

and $$ax-by-c=0 \quad \text{...(iv)}$$

Distance between the parallel lines Eqs. (i) and (ii) is $\dfrac{2c}{\sqrt{(a^2+b^2)}} = p_1$ (say) and distance between the parallel lines Eqs. (iii) and (iv) is

$$\frac{2c}{\sqrt{(a^2+b^2)}} = p_2 \quad \text{(say)}$$

Here, $p_1 = p_2$

$\therefore$ it is a rhombus.

$\therefore$ Area of rhombus $= \dfrac{|(c+c)(c+c)|}{\left|\begin{vmatrix}a & b\\ a & -b\end{vmatrix}\right|} = \dfrac{4c^2}{|-2ab|} = \dfrac{2c^2}{|ab|}$

Exercise for Session 2

1. The number of lines that are parallel to $2x+6y-7=0$ and have an intercept 10 between the coordinate axes is

(a) 1 (b) 2 (c) 4 (d) infinitely many

2. The distance between the lines $4x+3y=11$ and $8x+6y=15$ is

(a) $\frac{7}{2}$ (b) $\frac{7}{5}$ (c) $\frac{7}{10}$ (d) $\frac{9}{10}$

3. If the algebraic sum of the perpendicular distances from the points (2, 0), (0, 2) and (1, 1) to a variable straight line is zero, then the line passes through the point

(a) (1, 1) (b) (–1, 1) (c) (–1, –1) (d) (1, –1)

4. If the quadrilateral formed by the lines $ax+by+c=0$, $a'x+b'y+c'=0$, $ax+by+c'=0$ and $a'x+b'y+c'=0$ have perpendicular diagonals, then

(a) $b^2+c^2=b'^2+c'^2$ (b) $c^2+a^2=c'^2+a'^2$ (c) $a^2+b^2=a'^2+b'^2$ (d) None of these

5. The area of the parallelogram formed by the lines $3x-4y+1=0$, $3x-4y+3=0$, $4x-3y-1=0$ and $4x-3y-2=0$, is

(a) $\frac{1}{7}$ sq units (b) $\frac{2}{7}$ sq units (c) $\frac{3}{7}$ sq units (d) $\frac{4}{7}$ sq units

6. Area of the parallelogram formed by the lines $y = mx$, $y = mx + 1$, $y = nx$ and $y = nx + 1$ equals

(a) $\frac{|m+n|}{(m-n)^2}$ (b) $\frac{2}{|m+n|}$ (c) $\frac{1}{|m+n|}$ (d) $\frac{1}{|m-n|}$

7. The coordinates of a point on the line $y = x$ where perpendicular distance from the line $3x + 4y = 12$ is 4 units, are

(a) $\left(\frac{3}{7}, \frac{5}{7}\right)$ (b) $\left(\frac{3}{2}, \frac{3}{2}\right)$ (c) $\left(-\frac{8}{7}, -\frac{8}{7}\right)$ (d) $\left(\frac{32}{7}, -\frac{32}{7}\right)$

8. A line passes through the point $(2, 2)$ and is perpendicular to the line $3x + y = 3$, then its y-intercept is

(a) $-\frac{2}{3}$ (b) $\frac{2}{3}$ (c) $-\frac{4}{3}$ (d) $\frac{4}{3}$

9. If the points (1, 2) and (3, 4) were to be on the opposite side of the line $3x - 5y + a = 0$, then

(a) $7 < a < 11$ (b) $a = 7$ (c) $a = 11$ (d) $a < 7$ or $a > 11$

10. The lines $y = mx$, $y + 2x = 0$, $y = 2x + k$ and $y + mx = k$ form a rhombus if m equals

(a) –1 (b) $\frac{1}{2}$ (c) 1 (d) 2

11. The points on the axis of x, whose perpendicular distance from the straight line $\frac{x}{a} + \frac{y}{b} = 1$ is a

(a) $\frac{b}{a}(a \pm \sqrt{(a^2 + b^2)}, 0)$ (b) $\frac{a}{b}(b \pm \sqrt{(a^2 + b^2)}, 0)$

(c) $\frac{b}{a}(a + b, 0)$ (d) $\frac{a}{b}(a \pm \sqrt{(a^2 + b^2)}, 0)$

12. The three sides of a triangle are given by $(x^2 - y^2)(2x + 3y - 6) = 0$. If the point $(-2, a)$ lies inside and $(b, 1)$ lies outside the triangle, then

(a) $a \in \left(2, \frac{10}{3}\right); b \in (-1, 1)$ (b) $a \in \left(-2, \frac{10}{3}\right); b \in \left(-1, \frac{9}{2}\right)$

(c) $a \in \left(1, \frac{10}{3}\right); b \in (-3, 5)$ (d) None of these

13. Are the points (3, 4) and (2, –6) on the same or opposite sides of the line $3x - 4y = 8$?

14. If the points (4, 7) and $(\cos\theta, \sin\theta)$, where $0 < \theta < \pi$, lie on the same side of the line $x + y - 1 = 0$, then prove that θ lies in the first quadrant.

15. Find the equations of lines parallel to $3x - 4y - 5 = 0$ at a unit distance from it.

16. Show that the area of the parallelogram formed by the lines $2x - 3y + a = 0, 3x - 2y - a = 0, 2x - 3y + 3a = 0$ and $3x - 2y - 2a = 0$ is $\frac{2a^2}{5}$ sq units.

17. A line 'L' is drawn from $P(4, 3)$ to meet the lines $L_1 : 3x + 4y + 5 = 0$ and $L_2 : 3x + 4y + 15 = 0$ at point A and B respectively. From 'A' a line, perpendicular to L is drawn meeting the line L_2 at A_1. Similarly from point 'B' a line, perpendicular to L is drawn meeting the line L_1 at B_1. Thus a parallelogram AA_1BB_1 is formed. Find the equation (s) of 'L' so that the area of the parallelogram AA_1BB_1 is least.

18. The vertices of a ΔOBC are $O(0, 0)$, $B(-3, -1)$, $C(-1, -3)$. Find the equation of the line parallel to BC and intersecting the sides OB and OC and whose perpendicular distance from the origin is $\frac{1}{2}$.

Session 3

Point of Intersection of Two Lines, Concurrent Lines Family of Lines, How to Find Circumcentre and Orthocentre by Slopes

Points of Intersection of Two Lines

Let $a_1x + b_1y + c_1 = 0$ and $a_2x + b_2y + c_2 = 0$ be two non-parallel lines. If (x_1, y_1) be the coordinates of their point of intersection,

then $a_1x_1 + b_1y_1 + c_1 = 0$ and $a_2x_1 + b_2y_1 + c_2 = 0$

Solving these two by cross multiplication, then

$$\frac{x_1}{b_1c_2 - b_2c_1} = \frac{y_1}{c_1a_2 - c_2a_1} = \frac{1}{a_1b_2 - a_2b_1}$$

we get $$(x_1, y_1) \equiv \left(\frac{b_1c_2 - b_2c_1}{a_1b_2 - a_2b_1}, \frac{c_1a_2 - c_2a_1}{a_1b_2 - a_2b_1}\right)$$

$$\equiv \left(\frac{\begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix}}{\begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix}}, \frac{\begin{vmatrix} c_1 & c_2 \\ a_1 & a_2 \end{vmatrix}}{\begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix}}\right)$$

Remarks

1. Here lines are not parallel, they have unequal slopes, then, $a_1b_2 - a_2b_1 \neq 0$
2. In solving numerical questions, we should not be remember the coordinates (x_1, y_1) given above, but we solve the equations directly.

Concurrent Lines

The three given lines are concurrent, if they meet in a point. Hence to prove that three given lines are concurrent, we proceed as follows :

I Method : Find the point of intersection of any two lines by solving them simultaneously. If this point satisfies the third equation also, then the given lines are concurrent.

II Method : The three lines $a_ix + b_iy + c_i = 0, i = 1, 2, 3$ are concurrent if

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0$$

III Method : The condition for the lines $P = 0, Q = 0$ and $R = 0$ to be concurrent is that three constants l, m, n (not all zeros at the same time) can be obtained such that

$$lP + mQ + nR = 0$$

Remarks

1. The reader is advised to follow method I in numerical problems.
2. For finding unknown quantity applying method II.

Example 65. Show that the lines

$2x + 3y - 8 = 0$, $x - 5y + 9 = 0$ and $3x + 4y - 11 = 0$

are concurrent.

Sol. **I Method :** Solving the first two equations, we see that their point of intersection is $(1, 2)$ which also satisfies the third equation

$$3 \times 1 + 4 \times 2 - 11 = 0$$

Hence the given lines are concurrent.

II Method : We have $\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} 2 & 3 & 8 \\ 1 & -5 & 9 \\ 3 & 4 & -11 \end{vmatrix}$

Applying $C_3 \to C_3 + C_1 + 2C_2$

$$= \begin{vmatrix} 2 & 3 & 0 \\ 1 & -5 & 0 \\ 3 & 4 & 0 \end{vmatrix} = 0$$

Hence the given lines are concurrent.

III Method : Suppose

$$l(2x + 3y - 8) + m(x - 5y + 9) + n(3x + 4y - 11) = 0$$

$$\Rightarrow \quad x(2l + m + 3n) + y(3l - 5m + 4n) + (-8l + 9m - 11n) = 0$$

$$= 0 \cdot x + 0 \cdot y + 0$$

On comparing,

$$2l + m + 3n = 0, 3l - 5m + 4n = 0, -8l + 9m - 11n = 0$$

After solving, we get $l = 19, m = 1, n = -13$

Hence, $19(2x + 3y - 8) + (x - 5y + 9) - 13(3x + 4y - 11) = 0$

Hence the given lines are concurrent.

Example 66. If the lines $ax+y+1=0$, $x+by+1=0$ and $x+y+c=0$ (a,b and c being distinct and different from 1) are concurrent, then find the value of $\frac{1}{1-a}+\frac{1}{1-b}+\frac{1}{1-c}$.

Sol. The given lines are concurrent, then

$$\begin{vmatrix} a & 1 & 1 \\ 1 & b & 1 \\ 1 & 1 & c \end{vmatrix}=0 \Rightarrow \begin{vmatrix} a & 1-a & 1-a \\ 1 & b-1 & 0 \\ 1 & 0 & c-1 \end{vmatrix}=0$$

(applying $C_2 \to C_2 - C_1$ and $C_3 \to C_3 - C_1$)

Expanding along first row

$\Rightarrow \quad a(b-1)(c-1)-(1-a)(c-1)-(1-a)(b-1)=0$

$\Rightarrow \quad a(1-b)(1-c)+(1-a)(1-c)+(1-a)(1-b)=0$

Dividing by $(1-a)(1-b)(1-c)$, then

$$\frac{a}{1-a}+\frac{1}{1-b}+\frac{1}{1-c}=0$$

$$\Rightarrow \quad -1+\frac{1}{1-a}+\frac{1}{1-b}+\frac{1}{1-c}=0$$

Hence, $$\frac{1}{1-a}+\frac{1}{1-b}+\frac{1}{1-c}=1$$

Example 67. Show that the three straight lines $2x-3y+5=0$, $3x+4y-7=0$ and $9x-5y+8=0$ meet in a point.

Sol. If we multiply these three equations by 3, 1 and -1, we have

$$3(2x-3y+5)+(3x+4y-7)-(9x-5y+8)=0$$

which is an identity.

Hence, three lines meet in a point.

Family of Lines

Theorem : Any line through the point of intersection of the lines $a_1x+b_1y+c_1=0$ and $a_2x+b_2y+c_2=0$ can be represented by the equation

$$(a_1x+b_1y+c_1)+\lambda(a_2x+b_2y+c_2)=0$$

where λ is a parameter which depends on the other property of line.

Proof : The equations of the lines are

$$a_1x+b_1y+c_1=0 \quad \text{...(i)}$$

and $$a_2x+b_2y+c_2=0 \quad \text{...(ii)}$$

Multiplying μ and ν in Eqs. (i) and (ii) and adding, we get

$$\mu(a_1x+b_1y+c_1)+\nu(a_2x+b_2y+c_2)=0$$

where μ, ν are any constants not both zero.

Dividing both sides by μ, then

$$(a_1x+b_1y+c_1)+\frac{\nu}{\mu}(a_2x+b_2y+c_2)=0$$

$$\Rightarrow (a_1x+b_1y+c_1)+\lambda(a_2x+b_2y+c_2)=0 \left(\text{where, } \lambda=\frac{\nu}{\mu}\right)$$

It is a first degree equation in x and y. So it represents family of lines through the point of intersection of Eqs. (i) and (ii).

Thus, the family of straight lines through the intersection of lines

$$L_1 \equiv a_1x+b_1y+c_1=0$$

and $$L_2 \equiv a_2x+b_2y+c_2=0 \text{ is}$$

$$(a_1x+b_1y+c_1)+\lambda(a_2x+b_2y+c_2)=0$$

i.e. $$L_1+\lambda L_2=0$$

Corollaries **:**

1. The equation $L_1+\lambda L_2=0$ or $\mu L_1+\nu L_2=0$ represent a line passing through the intersection of the lines $L_1=0$ and $L_2=0$ which is a fixed point, where λ, μ, ν are constants.
2. For finding fixed point, the number of constants in family of lines are one or two. If number of constants more than two, then convert in two or one constant form.

Example 68. Find the equation of the straight line passing through the point $(2,1)$ and through the point of intersection of the lines $x+2y=3$ and $2x-3y=4$.

Sol. Equation of any straight line passing through the intersection of the lines $x+2y=3$ and $2x-3y=4$ is

$$\lambda(x+2y-3)+(2x-3y-4)=0 \quad \text{...(i)}$$

Since, it passes through the point $(2, 1)$

$\therefore \quad \lambda(2+2-3)+(4-3-4)=0$

$\Rightarrow \quad \lambda-3=0$

$\therefore \quad \lambda=3$

Now, substituting this value of λ in (i), we get

$$3(x+2y-3)+(2x-3y-4)=0$$

i.e. $$5x+3y-13=0$$

which is the equation of required line.

Example 69. The family of lines $x(a+2b)+y(a+3b)=a+b$ passes through the point for all values of a and b. Find the point.

Sol. The given equation can be written as

$$a(x+y-1)+b(2x+3y-1)=0$$

which is equation of a line passing through the point of intersection of the lines $x+y-1=0$ and $2x+3y-1=0$. The point of intersection of these lines is $(2,-1)$. Hence the given family of lines passes through the point $(2,-1)$ for all values of a and b.

Example 70. If $3a+2b+6c=0$ the family of straight lines $ax+by+c=0$ passes through a fixed point. Find the coordinates of fixed point.

Sol. Given, $3a+2b+6c=0$

or $$\frac{a}{2}+\frac{b}{3}+c=0 \quad \text{...(i)}$$

and family of straight lines is

$$ax+by+c=0 \quad \text{...(ii)}$$

Subtracting Eqs. (i) from (ii), then

$$a\left(x-\frac{1}{2}\right)+b\left(y-\frac{1}{3}\right)=0$$

which is equation of a line passing through the point of intersection of the lines

$$x-\frac{1}{2}=0 \quad \text{and} \quad y-\frac{1}{3}=0$$

$\therefore$ The coordinates of fixed point are $\left(\frac{1}{2},\frac{1}{3}\right)$.

Example 71. If $4a^2+9b^2-c^2+12ab=0$, then the family of straight lines $ax+by+c=0$ is either concurrent at ... or at ....

Sol. Given, $4a^2+9b^2-c^2+12ab=0$

or $$(2a+3b)^2-c^2=0$$

or $$c=\pm(2a+3b) \quad \text{...(i)}$$

and family of straight lines is

$$ax+by+c=0 \quad \text{...(ii)}$$

Substituting the value of c from Eqs. (i) in (ii), then

$$ax+by\pm(2a+3b)=0$$

$\Rightarrow$ $$a(x\pm 2)+b(y\pm 3)=0$$

Taking '+' sign : $a(x+2)+b(y+3)=0$

which is equation of a line passing through the point of intersection of the lines $x+2=0$ and $y+3=0$

$\therefore$ coordinates of fixed point are $(-2,-3)$.

Taking '–' sign : $a(x-2)+b(y-3)=0$

which is equation of a line passing through the point of intersection of the lines

$$x-2=0 \quad \text{and} \quad y-3=0$$

$\therefore$ coordinates of fixed point are $(2,3)$

Hence, the family of straight lines $ax+by+c=0$ is either concurrent at $(-2,-3)$ or *at* $(2,3)$.

Example 72. Find the equation of the line passing through the point of intersection of the lines $x+5y+7=0, 3x+2y-5=0$

and (a) parallel to the line $7x+2y-5=0$

(b) perpendicular to the line $7x+2y-5=0$

Sol. Any line passing through the point of intersection of the given lines is

$$(x+5y+7)+\lambda(3x+2y-5)=0$$

$\Rightarrow$ $$x(1+3\lambda)+y(5+2\lambda)+(7-5\lambda)=0 \quad \text{...(i)}$$

Its slope $=-\dfrac{(1+3\lambda)}{(5+2\lambda)}$

(a) Line Eq. (i) is to be parallel to $7x+2y-5=0$

then $$-\frac{(1+3\lambda)}{(5+2\lambda)}=-\frac{7}{2}$$

$\Rightarrow$ $$2+6\lambda=35+14\lambda$$

$\Rightarrow$ $$8\lambda=-33$$

$\Rightarrow$ $$\lambda=-\frac{33}{8}$$

Substituting this value of λ in Eq. (i), we get the required equation as $7x+2y-17=0$

(b) Line, (i) is to be perpendicular to $7x+2y-5=0$

$\therefore$ $$-\frac{(1+3\lambda)}{(5+2\lambda)}\times-\left(\frac{7}{2}\right)=-1$$

or $$7+21\lambda=-10-4\lambda$$

$\therefore$ $$\lambda=-\frac{17}{25}$$

Substituting this value of λ is Eq. (i), we get the required equation as

$$2x-7y-20=0.$$

Aliter :

The point of intersection of the given lines

$x+5y-7=0$ and $3x+2y-5=0$ is $(3,-2)$.

$\therefore$ Equation of line through $(3,-2)$ is

$$y+2=m(x-3) \quad \text{...(ii)}$$

(a) Line (ii) is parallel to $7x+2y-5=0$

$\therefore$ $$m=-\frac{7}{2}$$

Hence, the equation of the required line is

$$y+2=-\frac{7}{2}(x-3)$$

or $$7x+2y-17=0$$

(b) Line (ii) is perpendicular to $7x+2y-5=0$

then $$m\times\left(-\frac{7}{2}\right)=-1$$

or $$m=\frac{2}{7}$$

Hence, the equation of the required line is

$$y+2=\frac{2}{7}(x-3)$$

or $$2x-7y-20=0$$

Example 73. Find the equation of straight line which passes through the intersection of the straight lines

$$3x - 4y + 1 = 0 \quad \textit{and} \quad 5x + y - 1 = 0$$

and cuts off equal intercepts from the axes.

Solution : Equation of any line passing through the intersection of the given lines is

$$(3x - 4y + 1) + \lambda (5x + y - 1) = 0$$

$$\Rightarrow \quad x(3 + 5\lambda) + y(-4 + \lambda) + (1 - \lambda) = 0 \qquad ...(i)$$

$$\Rightarrow \quad \frac{x}{\left(\frac{\lambda - 1}{3 + 5\lambda}\right)} + \frac{y}{\left(\frac{\lambda - 1}{\lambda - 4}\right)} = 1$$

but given x-intercept = y-intercept

i.e. $$\left(\frac{\lambda - 1}{3 + 5\lambda}\right) = \left(\frac{\lambda - 1}{\lambda - 4}\right)$$

$$\Rightarrow \quad \frac{1}{3 + 5\lambda} = \frac{1}{\lambda - 4}$$

$(\lambda \neq 1 \because$ if $\lambda = 1$ then line (i) pass through origin)

$$\therefore \quad \lambda - 4 = 3 + 5\lambda$$

or $$4\lambda = -7$$

$$\therefore \quad \lambda = -\frac{7}{4}$$

Substituting the value of λ in Eq. (i), we get required equation is $23x + 23y = 11$.

Example 74. If t_1 and t_2 are roots of the equation $t^2 + \lambda t + 1 = 0$, where λ is an arbitrary constant. Then prove that the line joining the points $(at_1^2, 2at_1)$ and $(at_2^2, 2at_2)$ always passes through a fixed point. Also find that point.

Sol. $\because t_1$ and t_2 are the roots of the equation $t^2 + \lambda t + 1 = 0$

$$\therefore \quad t_1 + t_2 = -\lambda \quad \text{and} \quad t_1 t_2 = 1 \qquad ...(i)$$

Equation of the line joining the points $(at_1^2, 2at_1)$ and $(at_2^2, 2at_2)$ is

$$y - 2at_1 = \frac{2at_2 - 2at_1}{at_2^2 - at_1^2}(x - at_1^2)$$

$$\Rightarrow \quad y - 2at_1 = \frac{2}{(t_2 + t_1)}(x - at_1^2)$$

$$\Rightarrow \quad y(t_1 + t_2) - 2at_1 t_2 - 2at_1^2 = 2x - 2at_1^2$$

$$\Rightarrow \quad y(t_1 + t_2) - 2at_1 t_2 = 2x$$

$$\Rightarrow \quad y(-\lambda) - 2a = 2x \qquad \text{[from Eq. (i)]}$$

or $$(x + a) + \lambda\left(\frac{y}{2}\right) = 0$$

which is equation of a line passing through the point of intersection of the lines $x + a = 0$ and $\frac{y}{2} = 0$.

$\therefore$ coordinates of fixed point are $(-a, 0)$.

Example 75. A variable straight line through the point of intersection of the lines $\frac{x}{a} + \frac{y}{b} = 1$ and $\frac{x}{b} + \frac{y}{a} = 1$ meets the coordinate axes in A and B. Show that the locus of the mid-point of AB is the curve $2xy(a + b) = ab(x + y)$.

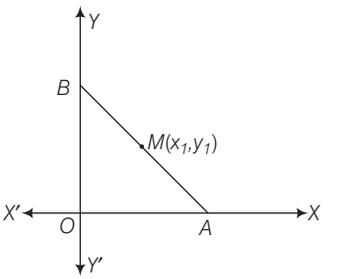
Sol. Any line through the point of intersection of given lines is

$$\left(\frac{x}{a} + \frac{y}{b} - 1\right) + \lambda\left(\frac{x}{b} + \frac{y}{a} - 1\right) = 0$$

$$x\left(\frac{1}{a} + \frac{\lambda}{b}\right) + y\left(\frac{1}{b} + \frac{\lambda}{a}\right) = (1 + \lambda)$$

$$\Rightarrow \quad x\left(\frac{b + a\lambda}{ab}\right) + y\left(\frac{a + b\lambda}{ab}\right) = (1 + \lambda)$$

$$\Rightarrow \quad \frac{x}{\left\{\frac{ab(1 + \lambda)}{b + a\lambda}\right\}} + \frac{y}{\left\{\frac{ab(1 + \lambda)}{a + b\lambda}\right\}} = 1$$



This meets the X-axis at

$$A \equiv \left(\frac{ab(1 + \lambda)}{b + a\lambda}, 0\right)$$

and meets the Y-axis at

$$B \equiv \left(0, \frac{ab(1 + \lambda)}{a + b\lambda}\right)$$

Let the mid-point of AB is $M(x_1, y_1)$, then

$$x_1 = \frac{ab(1 + \lambda)}{2(b + a\lambda)} \quad \text{and} \quad y_1 = \frac{ab(1 + \lambda)}{2(a + b\lambda)}$$

$$\therefore \quad \frac{1}{x_1} + \frac{1}{y_1} = \frac{2(b + a\lambda)}{ab(1 + \lambda)} + \frac{2(a + b\lambda)}{ab(1 + \lambda)}$$

$$= \frac{2}{ab(1 + \lambda)}(b + a\lambda + a + b\lambda)$$

$$= \frac{2}{ab(1 + \lambda)}(a + b)(1 + \lambda)$$

$$\Rightarrow \quad \frac{(x_1 + y_1)}{x_1 y_1} = \frac{2(a + b)}{ab}$$

$$\Rightarrow \quad 2x_1 y_1 (a + b) = ab(x_1 + y_1)$$

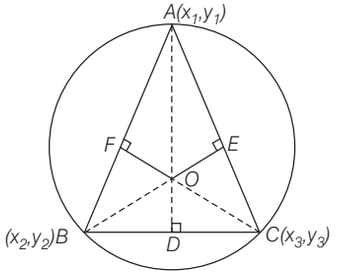
Hence, the locus of mid point of AB is

$$2xy(a + b) = ab(x + y).$$

How to Find Circumcentre and Orthocentre by Slopes

(i) Circumcentre

The circumcentre of a triangle is the point of intersection of the perpendicular bisectors of the sides of a triangle. It is the centre of the circle which passes through the vertices of the triangle and so its distance from the vertices of the triangle is the same and this distance is known as the **circumradius** of the triangle.



Let $O(x, y)$ be the circumcentre.

If D, E and F are the mid points of BC, CA and AB respectively and $OD \perp BC, OE \perp CA$ and $OF \perp AB$

$\therefore$ slope of $OD \times$ slope of $BC = -1$

and slope of $OE \times$ slope of $CA = -1$

and slope of $OF \times$ slope of $AB = -1$

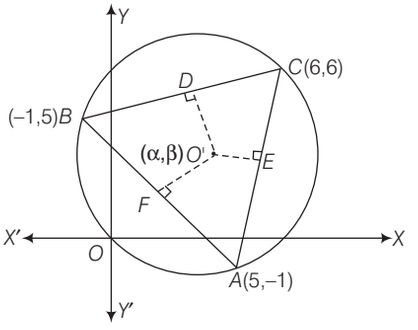
Solving any two, we get (x, y).

Example 76. Find the coordinates of the circumcentre of the triangle whose vertices are $A(5, -1), B(-1, 5)$ and $C(6, 6)$. Find its radius also.

Sol. Let circumcentre be $O'(\alpha, \beta)$ and mid points of sides BC, CA and AB are $D\left(\frac{5}{2}, \frac{11}{2}\right)$, $E\left(\frac{11}{2}, \frac{5}{2}\right)$ and $F(2, 2)$ respectively. Since $O'D \perp BC$.

$\therefore$ Slope of $O'D \times$ slope of $BC = -1$

$$\Rightarrow \quad \frac{\beta - \frac{11}{2}}{\alpha - \frac{5}{2}} \times \frac{6-5}{6+1} = -1$$



$$\Rightarrow \quad \frac{2\beta - 11}{7(2\alpha - 5)} = -1$$

$$\Rightarrow \quad 2\beta - 11 = -14\alpha + 35$$

$$\Rightarrow \quad 14\alpha + 2\beta = 46$$

$$\therefore \quad 7\alpha + \beta = 23 \qquad \ldots(i)$$

and $O'E \perp CA$

$\therefore$ Slope of $O'E \times$ Slope of $CA = -1$

$$\Rightarrow \quad \frac{\beta - \frac{5}{2}}{\alpha - \frac{11}{2}} \times \frac{-1-6}{5-6} = -1$$

$$\Rightarrow \quad \frac{2\beta - 5}{2\alpha - 11} \times \frac{7}{1} = -1$$

$$\Rightarrow \quad 14\beta - 35 = -2\alpha + 11$$

$$\therefore \quad 2\alpha + 14\beta = 46$$

$$\therefore \quad \alpha + 7\beta = 23 \qquad \ldots(ii)$$

Solving Eqs. (i) and (ii), we get

$$\alpha = \beta = \frac{23}{8}$$

$\therefore$ Circumcentre $= \left(\frac{23}{8}, \frac{23}{8}\right)$

$\therefore$ Circumradius $= O'A = O'B = O'C$

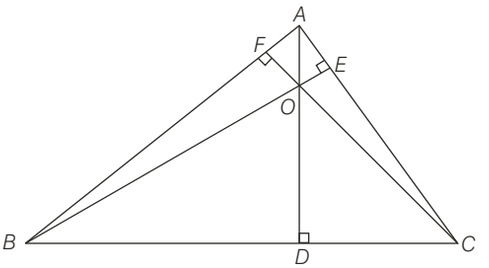
$$= O'C = \sqrt{(\alpha - 6)^2 + (\beta - 6)^2}$$

$$= \sqrt{\left(\frac{23}{8} - 6\right)^2 + \left(\frac{23}{8} - 6\right)^2}$$

$$= \sqrt{\left(\frac{25}{8}\right)^2 + \left(\frac{25}{8}\right)^2} = \frac{25\sqrt{2}}{8} \text{ units.}$$

(ii) Orthocentre

The orthocentre of a triangle is the point of intersection of altitudes.



Here O is the orthocentre since $AD \perp BC, BE \perp CA$ and $CF \perp AB$, then $OA \perp BC, OB \perp CA$, and $OC \perp AB$

Solving any two we can get coordinates of O.

Remarks

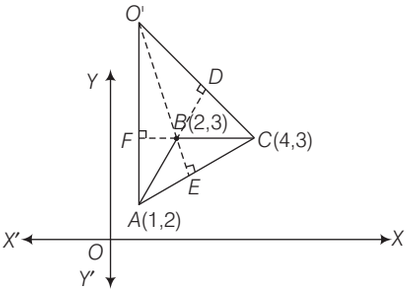
1. If any two lines out of three lines i.e. AB, BC and CA are perpendicular, then orthocentre is the point of intersection of two perpendicular lines.
2. Firstly find the slope of lines BC, CA and AB.

Example 77. Find the orthocentre of the triangle formed by the lines $xy = 0$ and $x + y = 1$.

Sol. Three sides of the triangle are $x = 0$, $y = 0$ and $x + y = 1$. The coordinates of the vertices are $O(0, 0)$, $A(1, 0)$ and $B(0, 1)$. The triangle OAB is a right angled triangle having right angle at O. Therefore $O(0, 0)$ is the orthocentre. Since we know that the point of intersection of two perpendicular lines is the orthocentre of the triangle OAB.

Example 78. Find the orthocentre of the triangle ABC whose angular points are $A(1, 2)$, $B(2, 3)$ and $C(4, 3)$..

Sol. Now, Slope of $BC = \dfrac{3-3}{4-2} = 0$



Slope of $CA = \dfrac{2-3}{1-4} = \dfrac{1}{3}$

and Slope of $AB = \dfrac{3-2}{2-1} = 1$

Let orthocentre be $O'(\alpha, \beta)$ then

Slope of $O'A \times$ slope of $BC = -1$

$$\frac{2-\beta}{1-\alpha} \times 0 = -1$$

$$\Rightarrow \quad \frac{0}{1-\alpha} = -1$$

$$\Rightarrow \quad 1 - \alpha = 0$$

$$\therefore \quad \alpha = 1$$

and Slope of $OB \times$ slope of $CA = -1$

$$\Rightarrow \quad \frac{3-\beta}{2-\alpha} \times \frac{1}{3} = -1$$

$$\Rightarrow \quad 3 - \beta = 3\alpha - 6$$

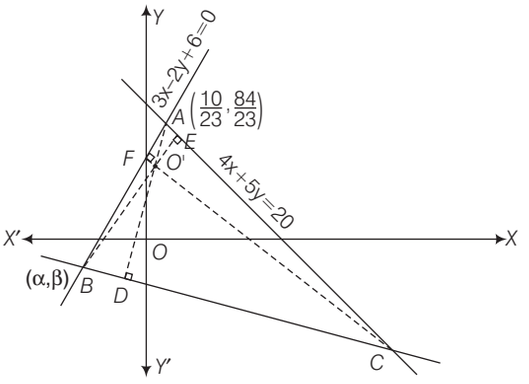
$$\Rightarrow \quad 3\alpha + \beta = 9$$

$$\therefore \quad \beta = 6 \qquad (\because \alpha = 1)$$

Hence, orthocentre of the given triangle is $(1, 6)$.

Example 79. The equations of two sides of a triangle are $3x - 2y + 6 = 0$ and $4x + 5y = 20$ and the orthocentre is $(1, 1)$. Find the equation of the third side.

Sol. Let $3x - 2y + 6 = 0$ and $4x + 5y = 20$ are the equations of the sides AB and AC. The point of intersection of AB and AC is $\left(\dfrac{10}{23}, \dfrac{84}{23}\right)$. Let slope of BC is m. Since $O'A \perp BC$



$\therefore$ Slope of $O'A \times$ Slope of $BC = -1$

$$\Rightarrow \quad \frac{\frac{84}{23} - 1}{\frac{10}{23} - 1} \times m = -1$$

$$\Rightarrow \quad \frac{61}{-13} m = -1$$

$$\therefore \quad m = \frac{13}{61}$$

Let the vertex B is (α, β).

(α, β) lies on $3x - 2y + 6 = 0$

$$\therefore \quad 3\alpha - 2\beta + 6 = 0 \qquad \text{...(i)}$$

and $O'B \perp AC$

$\therefore$ Slope of $O'B \times$ slope of $AC = -1$

$$\frac{\beta - 1}{\alpha - 1} \times \left(-\frac{4}{5}\right) = -1$$

$$\Rightarrow \quad 4\beta - 4 = 5\alpha - 5$$

$$\Rightarrow \quad 5\alpha - 4\beta - 1 = 0 \qquad \text{...(ii)}$$

Solving Eqs. (i) and (ii), we get

$$\alpha = -13 \quad \text{and} \quad \beta = -\frac{33}{2}$$

Since, third side passes through $\left(-13, -\dfrac{33}{2}\right)$ with slope $\dfrac{13}{61}$, therefore its equation is

$$y + \frac{33}{2} = \frac{13}{61}(x + 13)$$

$$\Rightarrow \quad 122y + 33 \times 61 = 26x + 2 \times 169$$

$$\Rightarrow \quad 26x - 122y - 1675 = 0$$

Aliter : The equation of line through A. i.e. point of intersection of AB and AC is

$$(3x - 2y + 6) + \lambda\,(4x + 5y - 20) = 0 \qquad \text{...(i)}$$

it passes through $(1, 1)$, then

$$(3 - 2 + 6) + \lambda\,(4 + 5 - 20) = 0$$

$$\Rightarrow \quad 7 - 11\lambda = 0$$

$$\therefore \quad \lambda = \frac{7}{11}$$

From Eq. (i), $(3x-2y+6)+\frac{7}{11}(4x+5y-20)=0$

$\Rightarrow \quad 61x+13y-74=0$

$\therefore \quad$ Slope of $AD=-\frac{61}{13}$

$\Rightarrow \quad$ Slope of $BC=\frac{13}{61}$

If coordinates of $B(\alpha,\beta)$, B lies on AB

$\therefore \quad 3\alpha-2\beta+6=0 \quad ...(ii)$

and $O'B\perp CA$

then $\frac{\beta-1}{\alpha-1}\times\left(-\frac{4}{5}\right)=-1$

$\Rightarrow \quad 5\alpha-4\beta-1=0 \quad ...(iii)$

Solving Eqs. (ii) and (iii), we get

$$\alpha=-13 \quad \text{and} \quad \beta=-\frac{33}{2}$$

$\therefore$ Equation of third side i.e. BC is

$$y+\frac{33}{2}=\frac{13}{61}(x+13)$$

$\therefore \quad 26x-122y-1675=0$

Example 80. If the orthocentre of the triangle formed by the lines $2x+3y-1=0$, $x+2y-1=0$, $ax+by-1=0$ is at origin, then find (a,b).

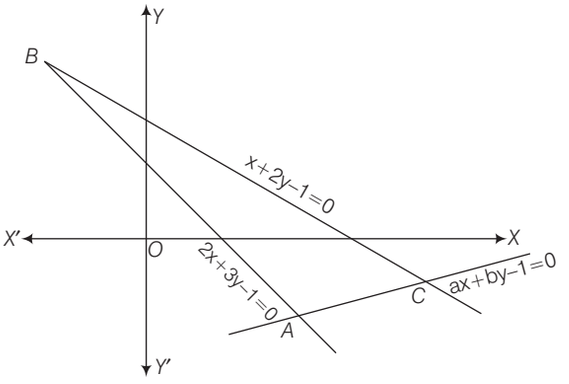
Sol. The equation of a line through A i.e. the point of intersection of AB and AC, is

$$(2x+3y-1)+\lambda(ax+by-1)=0 \quad ...(i)$$

It passes through $O(0,0)$, then

$$-1-\lambda=0$$

$\therefore \quad \lambda=-1$



From Eq. (i),

$$2x+3y-1-ax-by+1=0$$

$\Rightarrow \quad (2-a)x+(3-b)y=0$

Since, $AD\perp BC$

$\therefore \quad -\frac{(2-a)}{(3-b)}\times\left(-\frac{1}{2}\right)=-1$

$\Rightarrow \quad 2-a=-6+2b$

$\Rightarrow \quad a+2b=8 \quad ...(ii)$

Similarly, $BE\perp AC$, we get

$$a+b=0 \quad ...(iii)$$

Solving Eqs. (ii) and (iii), we get

$$b=8 \quad \text{and} \quad a=-8$$

$\therefore \quad (a,b)$ is $(-8,8)$.

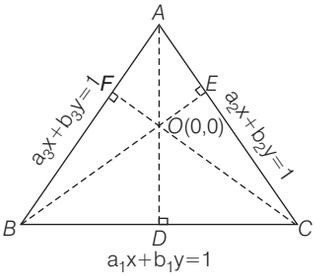
Example 81. If the equations of the sides of a triangle are $a_r x+b_r y=1; r=1,2,3$ and the orthocentre is the origin, then prove that

$$a_1a_2+b_1b_2=a_2a_3+b_2b_3=a_3a_1+b_3b_1.$$

Sol. The equation of the line through A, i.e. the point of intersection of AB and AC is

$$(a_2x+b_2y-1)+\lambda(a_3x+b_3y-1)=0 \quad ...(i)$$

It passes through $(0,0)$, then



$$-1-\lambda=0$$

$\therefore \quad \lambda=-1$

From Eq. (i), $a_2x+b_2y-1-a_3x-b_3y+1=0$

$\therefore \quad (a_2-a_3)x+(b_2-b_3)y=0$

Since, $AD\perp BC$

$\therefore$ Slope of $AD\times$ slope of $BC=-1$

$$-\frac{(a_2-a_3)}{(b_2-b_3)}\times\left(-\frac{a_1}{b_1}\right)=-1$$

$\Rightarrow \quad a_1a_2-a_3a_1=-b_1b_2+b_1b_3$

$\Rightarrow \quad a_1a_2+b_1b_2=a_3a_1+b_3b_1 \quad ...(ii)$

Similarly, $BE\perp CA$, then we get

$$a_1a_2+b_1b_2=a_2a_3+b_2b_3 \quad ...(iii)$$

From Eqs. (ii) and (iii), we get

$$a_1a_2+b_1b_2=a_2a_3+b_2b_3=a_3a_1+b_3b_1$$

Exercise for Session 3

1. The locus of the point of intersection of lines $x\cos\alpha + y\sin\alpha = a$ and $x\sin\alpha - y\cos\alpha = b$ (α is a parameter) is

(a) $2(x^2 + y^2) = a^2 + b^2$ (b) $x^2 - y^2 = a^2 - b^2$

(c) $x^2 + y^2 = a^2 + b^2$ (d) $x^2 - y^2 = a^2 + b^2$

2. If a, b, c are in AP then $ax + by + c = 0$ represents

(a) a straight line (b) a family of concurrent lines

(c) a family of parallel lines (d) None of these

3. If the lines $x + 2ay + a = 0$, $x + 3by + b = 0$ and $x + 4cy + c = 0$ are concurrent, then a, b, c are in

(a) AP (b) GP

(c) HP (d) AGP

4. The set of lines $ax + by + c = 0$, where $3a + 2b + 4c = 0$ is concurrent at the point

(a) $\left(\frac{3}{4}, \frac{1}{2}\right)$ (b) $\left(\frac{1}{2}, \frac{3}{4}\right)$

(c) $\left(-\frac{3}{4}, -\frac{1}{2}\right)$ (d) $\left(-\frac{1}{2}, -\frac{3}{4}\right)$

5. If the lines $ax + y + 1 = 0$, $x + by + 1 = 0$ and $x + y + c = 0$, (a, b and c being distinct and different from 1) are concurrent, then the value of $\frac{a}{a-1} + \frac{b}{b-1} + \frac{c}{c-1}$ is

(a) –2 (b) –1

(c) 1 (d) 2

6. If $u \equiv a_1x + b_1y + c_1 = 0$ and $v \equiv a_2x + b_2y + c_2 = 0$ and $\frac{a_1}{a_2} = \frac{b_1}{b_2} = \frac{c_1}{c_2}$, then $u + kv = 0$ represents

(a) $u = 0$ (b) a family of concurrent lines

(c) a family of parallel lines (d) None of these

7. The straight lines $x + 2y - 9 = 0$, $3x + 5y - 5 = 0$ and $ax + by - 1 = 0$ are concurrent, if the straight line $35x - 22y + 1 = 0$ passes through the point

(a) (a, b) (b) (b, a)

(c) $(a, -b)$ (d) $(-a, b)$

8. If the straight lines $x + y - 2 = 0$, $2x - y + 1 = 0$ and $ax + by - c = 0$ are concurrent, then the family of lines $2ax + 3by + c = 0$ (a, b, c are non-zero) is concurrent at

(a) (2, 3) (b) $\left(\frac{1}{2}, \frac{1}{3}\right)$

(c) $\left(-\frac{1}{6}, -\frac{5}{9}\right)$ (d) $\left(\frac{2}{3}, -\frac{7}{5}\right)$

9. The straight line through the point of intersection of $ax + by + c = 0$ and $a'x + b'y + c' = 0$ are parallel to Y-axis has the equation

(a) $x(ab' - a'b) + (cb' - c'b) = 0$ (b) $x(ab' + a'b) + (cb' + c'b) = 0$

(c) $y(ab' - a'b) + (c'a - ca') = 0$ (d) $y(ab' + a'b) + (c'a + ca') = 0$

10. If the equations of three sides of a triangle are $x + y = 1, 3x + 5y = 2$ and $x - y = 0$, then the orthocentre of the triangle lies on the line/lines

(a) $5x - 3y = 1$ (b) $5y - 3x = 1$

(c) $2x - 3y = 1$ (d) $5x - 3y = 2$

11. Find the equation of the line through the intersection of $2x - 3y + 4 = 0$ and $3x + 4y - 5 = 0$ and perpendicular to $6x - 7y + c = 0$

(a) $199y + 120x = 125$ (b) $199y - 120x = 125$

(c) $119x + 102y = 125$ (d) $119x - 102y = 125$

12. The locus of the point of intersection of the lines $\frac{x}{a} - \frac{y}{b} = m, \frac{x}{a} + \frac{y}{b} = \frac{1}{m}$ is

(a) a circle (b) an ellipse

(c) a hyperbola (d) a parabola

13. Find the condition on a and b, such that the portion of the line $ax + by - 1 = 0$, intercepted between the lines $ax + y + 1 = 0$ and $x + by = 0$ subtends a right angled at the origin.

14. If the lines $(a - b - c)x + 2ay + 2a = 0, 2bx + (b - c - a)y + 2b = 0$ and $(2c + 1)x + 2cy + c - a - b = 0$ are concurrent, then prove that either $a + b + c = 0$ or $(a + b + c)^2 + 2a = 0$.

15. Prove that the lines $ax + by + c = 0, bx + cy + a = 0$ and $cx + ay + b = 0$ are concurrent if $a + b + c = 0$ or $a + b\omega + c\omega^2 = 0$ or $a + b\omega^2 + c\omega = 0$, where ω is a complex cube root of unity.

16. Find the equation of the straight line which passes through the intersection of the lines $x - y - 1 = 0$ and $2x - 3y + 1 = 0$ and is parallel to (i) X-axis (ii) Y-axis (iii) $3x + 4y = 14$.

17. Let a, b, c be parameters. Then, the equation $ax + by + c = 0$ will represent a family of straight lines passing through a fixed-point, if there exists a linear relation between a, b and c.

18. Prove that the family of lines represented by $x(1 + \lambda) + y(2 - \lambda) + 5 = 0, \lambda$ being arbitrary, pass through a fixed point. Also find the fixed point.

19. Prove that $\left(-a, -\frac{a}{2}\right)$ is the orthocentre of the triangle formed by the lines $y = m_i x + \frac{a}{m_i}, i = 1, 2, 3; m_1, m_2, m_3$ being the roots of the equation $x^3 - 3x^2 + 2 = 0$.

Session 4

Equations of Straight Lines Passing Through a Given Point and Making a Given Angle with a Given Line, A Line Equally Inclined With Two Lines, Equation of the Bisectors, Bisector of the Angle Containing the Origin, Equation of that Bisector of the Angle Between Two Lines which Contains a Given Point, How to Distinguish the Acute (Internal) and Obtuse (External) Angle Bisectors

Equations of Straight Lines Passing Through a Given Point and Making a Given Angle with a Given Line

Theorem : Prove that the equations of the straight lines which pass through a given point (x_1, y_1) and make a given angle α with the given straight line $y = mx + c$ are

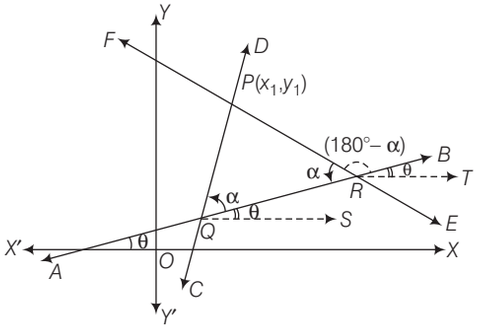
$$y - y_1 = \tan(\theta \pm \alpha)(x - x_1)$$

where, $m = \tan\theta$.

Proof : Let AB be the given line which makes an angle θ with X-axis.

$\therefore$ $m = \tan\theta$

Let CD and EF are two required lines which make angle α with the given line. Let these lines meet the given line AB at Q and R respectively



$\therefore$ $\angle DQS = \angle PQR + \angle RQS = (\alpha + \theta)$

$\therefore$ Equation of line CD is

$$y - y_1 = \tan(\theta + \alpha)(x - x_1) \quad \ldots(i)$$

and $\angle FRT = \angle FRB + \angle BRT$

$$= 180° - \alpha + \theta$$

$$= 180° + (\theta - \alpha)$$

$\therefore$ Equation of line EF is

$$y - y_1 = \tan(180° + \theta - \alpha)(x - x_1)$$

or $$y - y_1 = \tan(\theta - \alpha)(x - x_1) \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$y - y_1 = \tan(\theta \pm \alpha)(x - x_1)$$

These are the equations of the two required lines.

Example 82. Find the equations of the straight lines passing through the point $(2, 3)$ and inclined at $\pi/4$ radians to the line $2x + 3y = 5$.

Sol. Let the line $2x + 3y = 5$ make an angle θ with positive X-axis.

Then $$\tan\theta = -\frac{2}{3}$$

Now $$\tan\theta \cdot \tan\frac{\pi}{4} = -\frac{2}{3} \times 1$$

$$= -\frac{2}{3} \neq \pm 1$$

Slopes of required lines are

$$\tan\left(\theta + \frac{\pi}{4}\right) \text{ and } \tan\left(\theta - \frac{\pi}{4}\right)$$

$$\therefore \quad \tan\left(\theta+\frac{\pi}{4}\right)=\frac{\tan\theta+\tan\left(\frac{\pi}{4}\right)}{1-\tan\theta\tan\left(\frac{\pi}{4}\right)}=\frac{\left(-\frac{2}{3}\right)+1}{1-\left(-\frac{2}{3}\right)(1)}=\frac{1}{5}$$

and $$\tan\left(\theta-\frac{\pi}{4}\right)=\frac{\tan\theta-\tan\left(\frac{\pi}{4}\right)}{1+\tan\theta\tan\left(\frac{\pi}{4}\right)}$$

$$=\frac{\left(-\frac{2}{3}\right)-1}{1+\left(-\frac{2}{3}\right)(1)}=-5$$

$\therefore$ Equations of required lines are

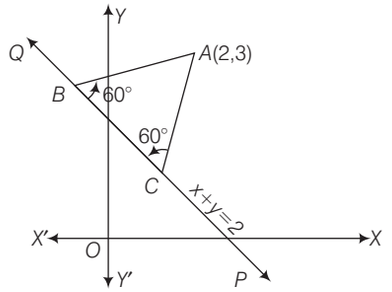
$$y-3=\frac{1}{5}(x-2) \text{ and } y-3=-5(x-2)$$

i.e. $x-5y+13=0$ and $5x+y-13=0$

Example 83. A vertex of an equilateral triangle is $(2, 3)$ and the opposite side is $x+y=2$. Find the equations of the other sides.

Sol. Let $A(2,3)$ be one vertex and $x+y=2$ be the opposite side of an equilateral triangle. Clearly remaining two sides pass through the point $A(2,3)$ and make an angle $60°$ with $x+y=2$

$\because$ Slope of $x+y=2$ is -1



Let $\tan\theta=-1$

$\therefore \quad \theta=135°$

$\therefore$ Equations of the other two sides are

$$y-3=\tan(135°\pm60°)(x-2)$$

i.e. sides are

$y-3=\tan(195°)(x-2)$ (taking '+' sign)

$\Rightarrow \quad y-3=\tan(180°+15°)(x-2)$

$\Rightarrow \quad y-3=\tan 15°(x-2)$

$\Rightarrow \quad y-3=(2-\sqrt{3})(x-2)$

$\Rightarrow \quad (2-\sqrt{3})x-y=1-2\sqrt{3}$

and $y-3=\tan(75°)(x-2)$ (taking '–' sign)

$\Rightarrow \quad y-3=\cot 15°(x-2)$

$\Rightarrow \quad y-3=(2+\sqrt{3})(x-2)$

$\Rightarrow \quad (2+\sqrt{3})x-y=1+2\sqrt{3}$

Hence, equations of other sides are

$$(2-\sqrt{3})x-y=1-2\sqrt{3}$$

and $$(2+\sqrt{3})x-y=1+2\sqrt{3}$$

Example 84. The straight lines $3x+4y=5$ and $4x-3y=15$ intersect at a point A. On these lines, the points B and C are chosen so that $AB=AC$. Find the possible equations of the line BC passing through the point $(1,2)$.

Sol. Clearly $\angle BAC=90°$

$\because \quad AB=AC$

$\therefore \quad \angle ABC=\angle BCA=45°$

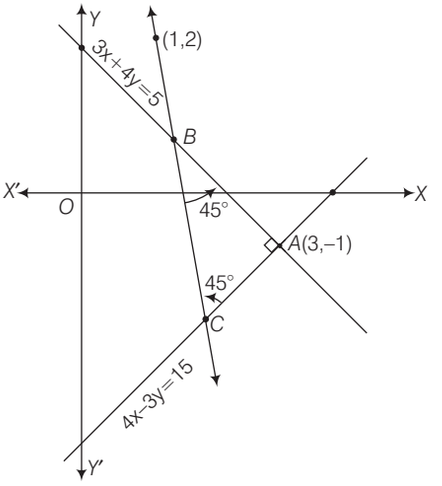
$\alpha=45°$

$\because$ Slope of $3x+4y=5$ is $-\frac{3}{4}$

Let $\tan\theta=-\frac{3}{4}$

So, possible equations of BC are given by

$$y-2=\tan(\theta\pm\alpha)(x-1)$$



$$\Rightarrow \quad y-2=\left(\frac{\tan\theta\pm\tan\alpha}{1\mp\tan\theta\tan\alpha}\right)(x-1)$$

$$\Rightarrow \quad y-2=\left(\frac{-\frac{3}{4}\pm1}{1\mp\left(-\frac{3}{4}\right)(1)}\right)(x-1)$$

$$\Rightarrow \quad y-2=\left(\frac{-3\pm4}{4\mp(-3)}\right)(x-1)$$

$$\Rightarrow \quad y-2=\frac{1}{4-(-3)}(x-1) \quad \text{(taking upper sign)}$$

or $\quad x-7y+13=0$

and $y-2=\dfrac{(-3-4)}{(4+(-3))}(x-1)$ (taking below sign)

or $7x+y-9=0$

Hence, possible equation of the line BC are $x-7y+13=0$ and $7x+y-9=0$

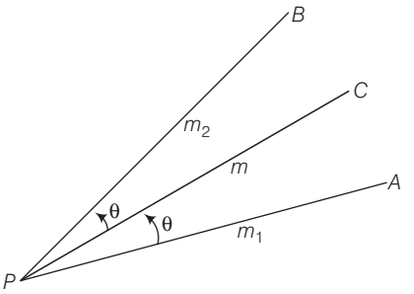
A Line Equally Inclined with Two Lines

Theorem : If two lines with slopes m_1 and m_2 be equally inclined to a line with slope m, then

$$\left(\frac{m_1-m}{1+mm_1}\right)=-\left(\frac{m_2-m}{1+mm_2}\right)$$

Proof : Let be two lines of slopes m_1 and m_2 intersecting at a point P.

Let $\angle CPA=\angle BPC=\theta$



$\therefore$ $\tan(\angle CPA)=\left(\dfrac{m-m_1}{1+mm_1}\right)$

or $\tan\theta=\left(\dfrac{m-m_1}{1+mm_1}\right)$ $(\because m>m_1)$ ...(i)

and $\tan(\angle BPC)=\left(\dfrac{m_2-m}{1+m_2m}\right)$

or $\tan\theta=\left(\dfrac{m_2-m}{1+m_2m}\right)$ $(\because m_2>m)$ ... (ii)

From Eqs. (i) and (ii), we get

$$\left(\frac{m-m_1}{1+mm_1}\right)=\left(\frac{m_2-m}{1+m_2m}\right) \text{ or } \left(\frac{m_1-m}{1+mm_1}\right)=-\left(\frac{m_2-m}{1+mm_2}\right)$$

Remarks

1. The above equation gives two values of m which are the slopes of the lines parallel to the bisectors of the angles between the two given lines.
2. Sign of m in both brackets is same.

Example 85. Find the equations to the straight lines passing through the point $(2, 3)$ and equally inclined to the lines $3x-4y-7=0$ and $12x-5y+6=0$.

Sol. Let m be the slope of the required line. Then its equation is

$$y-3=m(x-2) \quad \text{...(i)}$$

It is given that line (i) is equally inclined to the lines $3x-4y-7=0$ and $12x-5y+6=0$ then

$$\Rightarrow \left(\frac{\frac{3}{4}-m}{1+\frac{3}{4}m}\right)=-\left(\frac{\frac{12}{5}-m}{1+\frac{12}{5}m}\right)$$

$$\left(\begin{array}{c}\text{slope of } 3x-4y-7=0 \text{ is } \dfrac{3}{4}\\ \text{and slope of } 12x-5y+6=0 \text{ is } \dfrac{12}{5}\end{array}\right)$$

$$\Rightarrow \left(\frac{3-4m}{4+3m}\right)=-\left(\frac{12-5m}{5+12m}\right)$$

$$\Rightarrow (3-4m)(5+12m)+(4+3m)(12-5m)=0$$

$$\Rightarrow 63m^2-32m-63=0$$

$$\Rightarrow (7m-9)(9m+7)=0$$

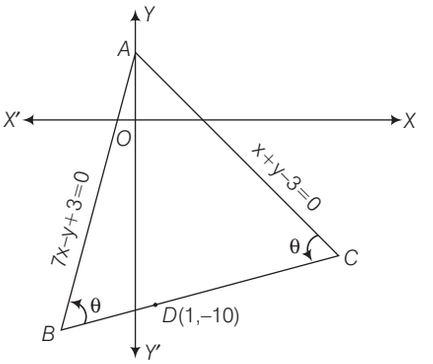
$$\therefore \quad m=\frac{9}{7},-\frac{7}{9}$$

Putting these values of m in Eq. (i) we obtain the equations of required lines as $9x-7y+3=0$ and $x+9y-41=0$.

Example 86. Two equal sides of an isosceles triangle are given by the equations $7x-y+3=0$ and $x+y-3=0$ and its third side passes through the point $(1,-10)$. Determine the equation of the third side.

Sol. Let m be the slope of BC. Since $AB=AC$.

Therefore BC makes equal angles with AB and AC.



Then $\left(\dfrac{7-m}{1+7m}\right)=-\left(\dfrac{-1-m}{1+(-1)m}\right)$

$$\Rightarrow (7-m)(1-m)-(1+7m)(1+m)=0$$

$$\Rightarrow 6m^2+16m-6=0$$

$$\Rightarrow 3m^2+8m-3=0$$

$\Rightarrow \quad (3m-1)(m+3)=0$

$\Rightarrow \quad m=\frac{1}{3}, -3$

Equation of third side BC is $y+10=m(x-1)$

i.e. $y+10=\frac{1}{3}(x-1)$ and $y+10=-3(x-1)$

or $x-3y-31=0$ and $3x+y+7=0$

Equation of the Bisectors

Theorem : Prove that the equation of the bisectors of the angles between the lines

$$a_1x+b_1y+c_1=0 \quad \text{and} \quad a_2x+b_2y+c_2=0$$

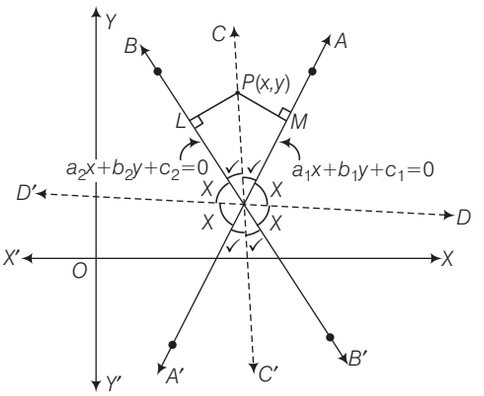
are given by $\dfrac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\pm\dfrac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$

Proof : Let the given lines be AA' and BB' whose equations are

$$a_1x+b_1y+c_1=0 \qquad ...(i)$$

and $$a_2x+b_2y+c_2=0 \qquad ...(ii)$$

Since bisectors of the angles between the two lines are the locus of a point which moves in a plane such that whose distance from two lines are equal.



Let CC' and DD' be the two bisectors of the angle between the lines AA' and BB'. Let $P(x, y)$ be any point on CC', then

Length of the perpendicular from P on AA'

= length of the perpendicular from P on BB'

$$\therefore \quad \frac{|a_1x+b_1y+c_1|}{\sqrt{(a_1^2+b_1^2)}}=\frac{|a_2x+b_2y+c_2|}{\sqrt{(a_2^2+b_2^2)}}$$

or $$\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\pm\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$$

These are the required equations of the bisectors.

Note

The two bisectors are perpendicular to each other.

Example 87. Find the equations of the bisectors of the angles between the straight lines $3x-4y+7=0$ and $12x+5y-2=0$.

Sol. The equations of the bisectors of the angles between $3x-4y+7=0$ and $12x+5y-2=0$ are

$$\frac{(3x-4y+7)}{\sqrt{(3)^2+(-4)^2}}=\pm\frac{(12x+5y-2)}{\sqrt{(12)^2+(5)^2}}$$

or $$\frac{(3x-4y+7)}{5}=\pm\frac{(12x+5y-2)}{13}$$

or $$(39x-52y+91)=\pm(60x+25y-10)$$

Taking the positive sign, we get

$$21x+77y-101=0$$

as one bisector.

Taking the negative sign, we get $99x-77y+81=0$ as the second bisector.

Bisector of the Angle Containing the Origin

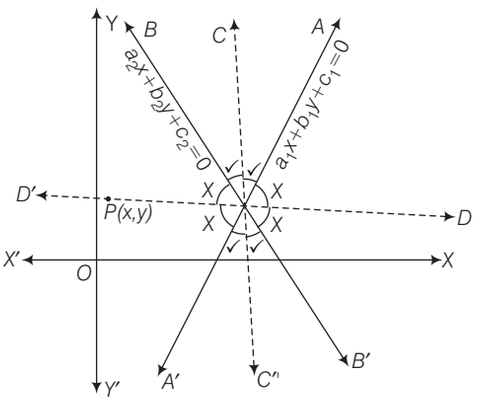
Let equations of lines be

$$a_1x+b_1y+c_1=0 \qquad ...(i)$$

$$a_2x+b_2y+c_2=0 \qquad ...(ii)$$

where c_1 and c_2 are positive.

Let $P(x, y)$ be taken on the bisector of the angle which contains the origin.



(i) Let $P(x, y)$ lies on DD', then either $O(0,0)$ and $P(x, y)$ will lie on the same side of the two lines Eqs. (i) and (ii), then

$$\frac{a_1x+b_1y+c_1}{0+0+c_1}>0$$

and $$\frac{a_2x+b_2y+c_2}{0+0+c_2}>0$$

or $$a_1x+b_1y+c_1>0$$

and $$a_2x+b_2y+c_2>0 \qquad (\because c_1, c_2>0)$$

If the origin $O(0,0)$ and $P(x,y)$ lie on the opposite side of the two lines Eqs. (i) and (ii), then

$$\frac{a_1x+b_1y+c_1}{0+0+c_1}<0 \quad \text{and} \quad \frac{a_2x+b_2y+c_2}{0+0+c_2}<0$$

or $\quad a_1x+b_1y+c_1<0 \quad \text{and} \quad a_2x+b_2y+c_2<0$

$(\because c_1, c_2 > 0)$

Then equation of bisectors will be

$$\frac{|a_1x+b_1y+c_1|}{\sqrt{(a_1^2+b_1^2)}}=\frac{|a_2x+b_2y+c_2|}{\sqrt{(a_2^2+b_2^2)}}$$

Case I : If $a_1x+b_1y+c_1>0$ and $a_2x+b_2y+c_2>0$

then $\quad \frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$

Case II : If $a_1x+b_1y+c_1<0$ and $a_2x+b_2y+c_2<0$

then $\quad -\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=-\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$

i.e. $\quad \frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$

Thus is both cases equation of the bisector containing the origin, when c_1 and c_2 are positive is

$$\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$$

and equation of the bisector of the angle between the lines

$$a_1x+b_1y+c_1=0 \quad \text{and} \quad a_2x+b_2y+c_2=0$$

which does not contain the origin when c_1 and c_2 are positive is

$$\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=-\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$$

Working Rule :

(i) First re-write the equations of the two lines so that their constant terms are positive.

(ii) The bisector of the angle containing the origin and does not containing the origin, then taking +ve and − ve sign in

$$\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\pm\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$$ respectively.

Example 88. Find the equations of angular bisector bisecting the angle containing the origin and not containing the origin of the lines $4x+3y-6=0$ and $5x+12y+9=0$.

Sol. Firstly make the constant terms (c_1, c_2) positive, then

$$-4x-3y+6=0 \text{ and } 5x+12y+9=0$$

$\therefore$ The equation of the bisector bisecting the angle containing origin is

$$\frac{(-4x-3y+6)}{\sqrt{(-4^2)+(-3)^2}}=\frac{(5x+12y+9)}{\sqrt{(5)^2+(12)^2}}$$

$$\Rightarrow \quad \left(\frac{-4x-3y+6}{5}\right)=\left(\frac{5x+12y+9}{13}\right)$$

$$\Rightarrow \quad -52x-39y+78=25x+60y+45$$

$$\Rightarrow \quad 77x+99y-33=0 \text{ or } 7x+9y-3=0$$

and the equation of the bisector bisecting the angle not containing origin is

$$\frac{(-4x-3y+6)}{\sqrt{(-4)^2+(-3)^2)}}=-\frac{(5x+12y+9)}{\sqrt{(5^2)+(12)^2}}$$

$$\Rightarrow \quad \left(\frac{-4x-3y+6}{5}\right)=-\left(\frac{5x+12y+9}{13}\right)$$

$$\Rightarrow \quad -52x-39y+78=-25x-60y-45$$

$$\Rightarrow \quad 27x-21y-123=0 \text{ or } 9x-7y-41=0$$

Equation of that Bisector of the Angle between Two Lines which Contains a Given Point

Let the equations of the two lines be

$$a_1x+b_1y+c_1=0 \quad \text{...(i)}$$

and $\quad a_2x+b_2y+c_2=0 \quad \text{...(ii)}$

The equation of the bisector of the angle between the two lines containing the points (h,k) will be

$$\frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$$

or $\quad \frac{(a_1x+b_1y+c_1)}{\sqrt{(a_1^2+b_1^2)}}=-\frac{(a_2x+b_2y+c_2)}{\sqrt{(a_2^2+b_2^2)}}$

according as $a_1h+b_1k+c_1$ and $a_2h+b_2k+c_2$ are of the same sign or opposite sign.

Example 89. Find the bisector of the angle between the lines $2x+y-6=0$ and $2x-4y+7=0$ which contains the point (1, 2).

Sol. Value of $2x+y-6$ at (1, 2) is − 2 (negative)

and value of $2x-4y+7$ at (1, 2) is 1 (positive)

i.e. opposite sign.

$\therefore$ Equation of bisector containing the point (1, 2) is

$$\frac{(2x+y-6)}{\sqrt{(2^2+1^2)}}=-\frac{(2x-4y+7)}{\sqrt{(2)^2+(-4)^2}}$$

$$\Rightarrow \quad 2(2x+y-6)+(2x-4y+7)=0$$

or $\quad 6x-2y-5=0$

How to Distinguish the Acute (Internal) and Obtuse (External) Angle Bisectors?

Let the equations of the two lines be

$$a_1x + b_1y + c_1 = 0 \quad ...(i)$$

and $$a_2x + b_2y + c_2 = 0 \quad ...(ii)$$

where, $c_1 > 0, c_2 > 0$.

$\because$ Equations of bisectors are

$$\frac{(a_1x + b_1y + c_1)}{\sqrt{(a_1^2 + b_1^2)}} = \pm \frac{(a_2x + b_2y + c_2)}{\sqrt{(a_2^2 + b_2^2)}} \quad ...(iii)$$

when Eq. (iii) be simplified, let the bisectors be

$$p_1x + q_1y + r_1 = 0 \quad ...(iv)$$

and $$p_2x + q_2y + r_2 = 0 \quad ...(v)$$

Since the two bisectors are at right angles, the angle α between the acute (internal) bisector and any one of the given lines must lie between 0 and 45° i.e. $0 < \alpha < 45°$.

$\therefore$ $$0 < \tan\alpha < 1$$

If m_1 and m_2 are the slopes of Eqs. (i) and (iii) respectively.

Then, $$m_1 = -\frac{a_1}{b_1} \quad \text{and} \quad m_2 = -\frac{p_1}{q_1}$$

$\therefore$ $$\tan\alpha = \left|\frac{m_1 - m_2}{1 + m_1\, m_2}\right|$$

$$= \left|\frac{\left(-\frac{a_1}{b_1}\right) - \left(-\frac{p_1}{q_1}\right)}{1 + \left(-\frac{a_1}{b_1}\right)\left(-\frac{p_1}{q_1}\right)}\right| = \left|\frac{a_1q_1 - b_1p_1}{b_1q_1 + a_1p_1}\right|$$

Hence, if $0 < \tan\alpha < 1$, $p_1x + q_1y + r_1 = 0$ is the acute (internal) bisector and if $\tan\alpha > 1$, $p_2x + q_2y + r_2 = 0$ is the obtuse (external) bisector.

Shortcut Method for finding Acute (Internal) and Obtuse (External) Angle Bisectors

Let the equations of the two lines be

$$a_1x + b_1y + c_1 = 0$$

$$a_2x + b_2y + c_2 = 0$$

Taking $$c_1 > 0, c_2 > 0 \text{ and } a_1b_2 \neq a_2b_1$$

Then equations of the bisectors are

$$\frac{(a_1x + b_1y + c_1)}{\sqrt{(a_1^2 + b_1^2)}} = \pm \frac{(a_2\ x + b_2\ y + c_2)}{\sqrt{(a_2^2 + b_2^2)}}$$

Conditions	Acute angle bisector	Obtuse angle bisector
$a_1a_2 + b_1b_2 > 0$	−	+
$a_1a_2 + b_1b_2 < 0$	+	−

Remarks

1. Bisectors are perpendiculars to each other.
2. `+' sign gives the bisector of the angle containing origin.
3. If $a_1a_2 + b_1b_2 > 0$ then the origin lies in obtuse angle and if $a_1a_2 + b_1b_2 < 0$, then the origin lies in acute angle.

Explanation : Equations of given lines in normal form will be respectively

$$-\frac{a_1x}{\sqrt{(a_1^2 + b_1^2)}} - \frac{b_1y}{\sqrt{(a_1^2 + b_1^2\ )}} = \frac{c_1}{\sqrt{(a_1^2 + b_1^2)}} \ (\because c_1 > 0)$$

and $$-\frac{a_2x}{\sqrt{(a_2^2 + b_2^2)}} - \frac{b_2y}{\sqrt{(a_2^2 + b_2^2)}} = \frac{c_2}{\sqrt{(a_2^2 + b_2^2)}} \ (\because c_2 > 0)$$

If $$\cos\alpha = -\frac{a_1}{\sqrt{(a_1^2 + b_1^2)}} \quad \text{then} \quad \sin\alpha = -\frac{b_1}{\sqrt{(a_1^2 + b_1^2)}}$$

and $$\cos\beta = -\frac{a_2}{\sqrt{(a_2^2 + b_2^2)}} \quad \text{then} \quad \sin\beta = -\frac{b_2}{\sqrt{(a_2^2 + b_2^2)}}$$

Now, $$\cos(\alpha - \beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$$

$$= \frac{(a_1a_2 + b_1b_2)}{\sqrt{(a_1^2 + b_1^2)}\sqrt{(a_2^2 + b_2^2)}}$$

$$\cos(\alpha - \beta) > 0 \quad \text{or} \quad < 0$$

according as $(\alpha - \beta)$ is acute or obtuse.

i.e. $$a_1a_2 + b_1b_2 > 0 \quad \text{or} \quad < 0$$

Hence, bisector of the angle between the lines will be the bisector of the acute or obtuse angle according as origin lies in the acute or obtuse angle according as $a_1a_2 + b_1b_2 < 0$ or >0.

Example 90. Find the equation of the bisector of the obtuse angle between the lines $3x - 4y + 7 = 0$ and $12x + 5y - 2 = 0$.

Sol. Firstly make the constant terms (c_1, c_2) positive

$$3x - 4y + 7 = 0 \quad \text{and} \quad -12x - 5y + 2 = 0$$

$\because$ $a_1a_2 + b_1b_2 = (3)(-12) + (-4)(-5) = -36 + 20 = -16$

$\therefore$ $a_1a_2 + b_1b_2 < 0$

Hence "–" sign gives the obtuse bisector.

$\therefore$ Obtuse bisector is

$$\frac{(3x - 4y + 7)}{\sqrt{(3)^2 + (-4)^2}} = -\frac{(-12x - 5y + 2)}{\sqrt{(-12)^2 + (-5)^2}}$$

$\Rightarrow$ $13(3x - 4y + 7) = -5(-12x - 5y + 2)$

$\Rightarrow$ $21x + 77y - 101 = 0$ is the obtuse angle bisector.

Example 91. Find the bisector of acute angle between the lines $x + y - 3 = 0$ and $7x - y + 5 = 0$.

Sol. Firstly, make the constant terms (c_1, c_2) positive then

$-x - y + 3 = 0$ and $7x - y + 5 = 0$

$\because \quad a_1a_2 + b_1b_2 = (-1)(7) + (-1)(-1) = -7 + 1 = -6$

i.e. $a_1a_2 + b_1b_2 < 0$

Hence "+" sign gives the acute bisector.

$\therefore$ Acute bisector is $\dfrac{-x - y + 3}{\sqrt{(-1)^2 + (-1)^2}} = + \dfrac{7x - y + 5}{\sqrt{(7)^2 + (-1)^2}}$

$\Rightarrow \quad \dfrac{-x - y + 3}{\sqrt{2}} = \dfrac{7x - y + 5}{5\sqrt{2}}$

$\Rightarrow \quad -5x - 5y + 15 = 7x - y + 5$

$\therefore \quad 12x + 4y - 10 = 0 \quad$ or $\quad 6x + 2y - 5 = 0$

is the acute angle bisector.

Example 92. Find the coordinates of incentre of the triangle. The equation of whose sides are

$AB : x + y - 1 = 0, BC : 7x - y - 15 = 0$

and $CA : x - y - 1 = 0$.

Sol. Firstly, make the constant terms $(c_1, c_2,$ and $c_3)$ positive

i.e. $AB : -x - y + 1 = 0$ ...(i)

$BC : -7x + y + 15 = 0$ ...(ii)

$CA : -x + y + 1 = 0$ ...(iii)

$\because$ The incentre of triangle is the point of intersection of internal or acute angle bisectors.

Internal bisector of *AB* and *BC* :

$-x - y + 1 = 0$

$-7x + y + 15 = 0$

$\because \quad a_1a_2 + b_1b_2 = (-1)(-7) + (-1)(1) = 6 > 0$

$\therefore$ Acute or internal bisector is

$$\frac{(-x - y + 1)}{\sqrt{(-1)^2 + (-1)^2}} = -\frac{(-7x + y + 15)}{\sqrt{(-7)^2 + (1)^2}}$$

$$\Rightarrow \quad \frac{(-x - y + 1)}{\sqrt{2}} = -\frac{(-7x + y + 15)}{5\sqrt{2}}$$

$\Rightarrow \quad -5x - 5y + 5 = 7x - y - 15$

or $\quad 12x + 4y - 20 = 0$

or $\quad 3x + y - 5 = 0$ ...(iv)

Internal bisector of BC and CA :

$-7x + y + 15 = 0$

$-x + y + 1 = 0$

$\because \quad a_1a_2 + b_1b_2 = (-7)(-1) + (1)(1) = 8 > 0$

$\because$ Acute or internal bisector is

$$\frac{(-7x + y + 15)}{\sqrt{(-7)^2 + (1)^2}} = -\frac{(-x + y + 1)}{\sqrt{(-1)^2 + (1)^2}}$$

$$\Rightarrow \quad \frac{-7x + y + 15}{5\sqrt{2}} = \frac{(x - y - 1)}{\sqrt{2}}$$

$\Rightarrow \quad -7x + y + 15 = 5x - 5y - 5$

or $\quad 12x - 6y - 20 = 0$

or $\quad 6x - 3y - 10 = 0$ ...(v)

Finally, solve Eqs. (iv) and (v), we get

$$x = \frac{5}{3} \text{ and } y = 0$$

Hence coordinates of incentre are $\left(\frac{5}{3}, 0\right)$.

Exercise for Session 4

1. The straight lines $2x + 11y - 5 = 0, 24x + 7y - 20 = 0$ and $4x - 3y - 2 = 0$

(a) form a triangle

(b) are only concurrent

(c) are concurrent with one line bisecting the angle between the other two

(d) None of the above

2. The line $x + 3y - 2 = 0$ bisects the angle between a pair of straight lines of which one has the equation $x - 7y + 5 = 0$. The equation of other line is

(a) $3x + 3y - 1 = 0$ (b) $x - 3y + 2 = 0$ (c) $5x + 5y + 3 = 0$ (d) $5x + 5y - 3 = 0$

3. P is a point on either of the two lines $y - \sqrt{3}\,|x| = 2$ at a distance of 5 units from their point of intersection. The coordinates of the foot of the perpendicular from P on the bisector of the angle between them are

(a) $\left(0, \dfrac{4 + 5\sqrt{3}}{2}\right)$ or $\left(0, \dfrac{4 - 5\sqrt{3}}{2}\right)$ depending on which the point P is taken

(b) $\left(0, \dfrac{4 + 5\sqrt{3}}{2}\right)$ (c) $\left(0, \dfrac{4 - 5\sqrt{3}}{2}\right)$ (d) $\left(\dfrac{5}{2}, \dfrac{5\sqrt{3}}{2}\right)$

4. In a triangle ABC, the bisectors of angles B and C lie along the lines $x = y$ and $y = 0$. If A is (1, 2), then the equation of line BC is

(a) $2x + y = 1$ (b) $3x - y = 5$ (c) $x - 2y = 3$ (d) $x + 3y = 1$

5. In ΔABC, the coordinates of the vertex A are (4, –1) and lines $x - y - 1 = 0$ and $2x - y = 3$ are the internal bisecters of angles B and C. Then, the radius of the incircle of triangle ABC is

(a) $\frac{5}{\sqrt{5}}$ (b) $\frac{3}{\sqrt{5}}$ (c) $\frac{6}{\sqrt{5}}$ (d) $\frac{7}{\sqrt{5}}$

6. The equation of the straight line which bisects the intercepts made by the axes on the lines $x + y = 2$ and $2x + 3y = 6$ is

(a) $2x = 3$ (b) $y = 1$ (c) $2y = 3$ (d) $x = 1$

7. The equation of the bisector of the acute angle between the lines $2x - y + 4 = 0$ and $x - 2y = 1$ is

(a) $x + y + 5 = 0$ (b) $x - y + 1 = 0$ (c) $x - y = 5$ (d) $x - y + 5 = 0$

8. The equation of the bisector of that angle between the lines $x + y = 3$ and $2x - y = 2$ which contains the point (1, 1) is

(a) $(\sqrt{5} - 2\sqrt{2})x + (\sqrt{5} + \sqrt{2})y = 3\sqrt{5} - 2\sqrt{2}$ (b) $(\sqrt{5} + 2\sqrt{2})x + (\sqrt{5} - \sqrt{2})y = 3\sqrt{5} + 2\sqrt{2}$

(c) $3x = 10$ (d) $3x - 5y + 2 = 0$

9. Find the equations of the two straight lines through (7, 9) and making an angle of 60° with the line $x - \sqrt{3}y - 2\sqrt{3} = 0$.

10. Equation of the base of an equilateral triangle is $3x + 4y = 9$ and its vertex is at the point (1, 2). Find the equations of the other sides and the length of each side of the triangle.

11. Find the coordinates of those points on the line $3x + 2y = 5$ which are equidistant from the lines $4x + 3y - 7 = 0$ and $2y - 5 = 0$.

12. Two sides of rhombus $ABCD$ are parallel to the lines $y = x + 2$ and $y = 7x + 3$. If the diagonal of the rhombus intersect at the point (1, 2) and the vertex A lies on Y-axis, find the possible coordinates of A.

13. The bisector of two lines L_1 and L_2 are given by $3x^2 - 8xy - 3y^2 + 10x + 20y - 25 = 0$. If the line L_1 passes through origin, find the equation of line L_2.

14. Find the equation of the bisector of the angle between the lines $x + 2y - 11 = 0$ and $3x - 6y - 5 = 0$ which contains the point (1, –3).

15. Find the equation of the bisector of the angle between the lines $2x - 3y - 5 = 0$ and $6x - 4y + 7 = 0$ which is the supplement of the angle containing the point (2, –1).

Session 5

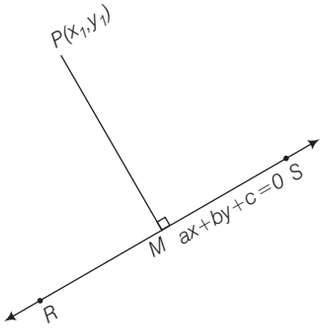
The Foot of Perpendicular Drawn from the Point (x_1, y_1) to the Line $ax + by + c = 0$, Image or Reflection of a Point (x_1, y_1) about a Line Mirror, Image or Reflection of a Point In Different Cases, Use of Image or Reflection

The Foot of Perpendicular Drawn from the Point (x_1, y_1) to the Line $ax + by + c = 0$

Let $P \equiv (x_1, y_1)$ and let M be the foot of perpendicular drawn from P on $ax + by + c = 0$.

In order to find the coordinates of M, find the equation of the line PM which is perpendicular to RS and passes through $P(x_1, y_1)$, i.e. $bx - ay = bx_1 - ay_1$

or $b(x - x_1) - a(y - y_1) = 0$ and solving it with $ax + by + c = 0$, then we get coordinates of M.



Aliter I : Let the coordinates of M are (x_2, y_2) then $M(x_2, y_2)$ lies on $ax + by + c = 0$

$$\Rightarrow \quad ax_2 + by_2 + c = 0 \qquad ...(i)$$

and $\because PM \perp RS$

then (Slope of PM) (Slope of RS) $= -1$

$$\Rightarrow \quad \left(\frac{y_2 - y_1}{x_2 - x_1}\right) \times \left(-\frac{a}{b}\right) = -1$$

or $$bx_2 - ay_2 = bx_1 - ay_1 \qquad ...(ii)$$

Solving Eqs. (i) and (ii), we get (x_2, y_2).

Aliter II : Let the coordinates of M are (x_2, y_2)

$\because \quad PM \perp RS$

and M lies on $\quad ax + by + c = 0$

i.e. $$ax_2 + by_2 + c = 0 \qquad ...(iii)$$

and $$\left(\frac{y_2 - y_1}{x_2 - x_1}\right) \times \left(-\frac{a}{b}\right) = -1 \qquad (\because PM \perp RS)$$

or $$\frac{x_2 - x_1}{a} = \frac{y_2 - y_1}{b}$$

or $$\frac{x_2 - x_1}{a} = \frac{y_2 - y_1}{b} = \frac{a(x_2 - x_1) + b(y_2 - y_1)}{(a^2 + b^2)}$$

(By ratio proportion method)

$$= \frac{(ax_2 + by_2) - (ax_1 + by_1)}{a^2 + b^2}$$

$$= \frac{-c - (ax_1 + by_1)}{a^2 + b^2} \qquad \text{[from Eq. (iii)]}$$

or $$\frac{x_2 - x_1}{a} = \frac{y_2 - y_1}{b} = -\frac{(ax_1 + by_1 + c)}{(a^2 + b^2)}$$

Example 93. Find the coordinates of the foot of the perpendicular drawn from the point (2, 3) to the line $y = 3x + 4$.

Sol. Given line is

$$3x - y + 4 = 0 \qquad ...(i)$$

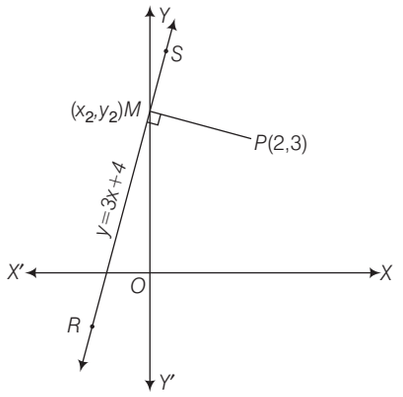
Let Eq. $P \equiv (2, 3)$.

Let, M be the foot of perpendicular drawn from P on RS.

Then equation of PM passes through $P(2, 3)$ and perpendicular to RS is

$$x + 3y - (2 + 3 \times 3) = 0$$

i.e. $$x + 3y - 11 = 0 \qquad ...(ii)$$



Solving Eqs. (i) and (ii), we get

$$x = -\frac{1}{10}, y = \frac{37}{10}$$

$$\therefore \quad M \equiv \left(-\frac{1}{10}, \frac{37}{10}\right)$$

Aliter I : Let the coordinates of M be (x_2, y_2) then $M(x_2, y_2)$ lies on $3x - y + 4 = 0$

$$\Rightarrow \quad 3x_2 - y_2 + 4 = 0 \qquad \ldots(iii)$$

and $\because PM \perp RS$

$\therefore$ (Slope of PM) $\times$ (Slope of RS) $= -1$

$$\Rightarrow \quad \left(\frac{y_2 - 3}{x_2 - 2}\right) \times (3) = -1$$

$$\text{or} \quad x_2 + 3y_2 - 11 = 0 \qquad \ldots(iv)$$

Solving Eqs. (iii) and (iv), we get

$$x_2 = -\frac{1}{10}, y_2 = \frac{37}{10}$$

$$\therefore \quad M \equiv \left(-\frac{1}{10}, \frac{37}{10}\right)$$

Aliter II : By Ratio Proportion Method :

$$\frac{x_2 - 2}{3} = \frac{y_2 - 3}{-1} = \frac{-(3 \times 2 - 3 + 4)}{3^2 + (-1)^2}$$

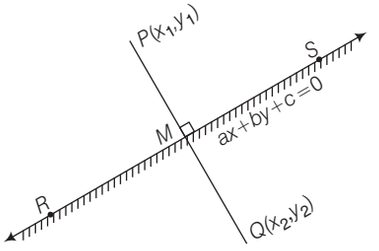
$$\Rightarrow \quad \frac{x_2 - 2}{3} = \frac{y_2 - 3}{-1} = -\frac{7}{10}$$

$$x_2 = -\frac{1}{10} \text{ and } y_2 = \frac{37}{10}$$

$$\therefore \quad M \equiv \left(-\frac{1}{10}, \frac{37}{10}\right)$$

Image or Reflection of a Point (x_1, y_1) About a Line Mirror

Let $Q \equiv (x_2, y_2)$ be the image of $P \equiv (x_1, y_1)$ then find coordinates of the foot of perpendicular M drawn from the point $P(x_1, y_1)$ on RS and use fact that M is the mid- point P and Q.



$$\text{i.e.} \quad M \equiv \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$$

Aliter I : Ratio Proportion Method :

$$\because \quad PQ \perp RS$$

$$\therefore \quad (\text{ Slope of } PQ) \times (\text{ Slope of } RS) = -1$$

$$\text{or} \quad \left(\frac{y_2 - y_1}{x_2 - x_1}\right) \times \left(-\frac{a}{b}\right) = -1$$

$$\text{or} \quad \frac{(x_2 - x_1)}{a} = \frac{(y_2 - y_1)}{b}$$

$$\text{or} \quad \frac{x_2 - x_1}{a} = \frac{y_2 - y_1}{b} = \frac{a(x_2 - x_1) + b(y_2 - y_1)}{a^2 + b^2}$$

$$= \frac{a(2x - x_1 - x_1) + b(2y - y_1 - y_1)}{a^2 + b^2}$$

$$\left(\because \begin{array}{l} M(x, y) \text{ is mid-point of } P \text{ and } Q \\ \therefore\ x_2 = 2x - x_1 \text{ and } y_2 = 2y - y_1 \end{array}\right)$$

$$= \frac{-2ax_1 - 2by_1 + 2(ax + by)}{a^2 + b^2}$$

$$= \frac{-2ax_1 - 2by_1 + 2(-c)}{a^2 + b^2} \quad (\because ax + by = -c)$$

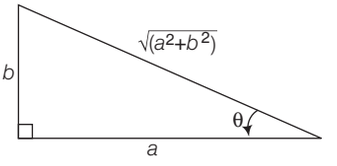
$$= \frac{-2(ax_1 + by_1 + c)}{(a^2 + b^2)}$$

$$\text{i.e.} \quad \frac{x_2 - x_1}{a} = \frac{y_2 - y_1}{b} = -\frac{2(ax_1 + by_1 + c)}{(a^2 + b^2)}$$

Aliter II : By Distance form or Symmetric form or parametric form :

$$\because \quad \text{Slope of } RS = -\frac{a}{b}$$

$$\therefore \quad \text{Slope of } PQ = \frac{b}{a}$$



Let $\tan\theta = \frac{b}{a}$

$\therefore \quad \sin\theta = \frac{b}{\sqrt{(a^2+b^2)}}$

and $\cos\theta = \frac{a}{\sqrt{(a^2+b^2)}}$

Put the equation of the mirror line such that the coefficient of y becomes negative.

Suppose if $b > 0$

then $ax + by + c = 0$

becomes $-ax - by - c = 0$

and $p = PM =$ Directed distance from $P(x_1, y_1)$ on $-ax - by - c = 0$ (i.e. p +ve or −ve)

$$= \left(\frac{-ax_1 - by_1 - c}{\sqrt{(a^2+b^2)}}\right)$$

$\therefore \quad PQ = 2PM = 2p = 2\left(\frac{-ax_1 - by_1 - c}{\sqrt{(a^2+b^2)}}\right) = r$

$\Rightarrow$ Required image has the coordinates $(x_1 + r\cos\theta, y_1 + r\sin\theta)$.

Example 94. Find the image of the point $(4, -13)$ with respect to the line mirror $5x + y + 6 = 0$.

Sol. Let, $P \equiv (4, -13)$ and Let, $Q \equiv (x_2, y_2)$ be mirror image P with respect to line mirror $5x + y + 6 = 0$.

Let, $M(\alpha, \beta)$ be the foot of perpendicular from $P(4, -13)$ on the line mirror $5x + y + 6 = 0$, then

$$\frac{\alpha - 4}{5} = \frac{\beta + 13}{1} = \frac{-(5\times 4 - 13 + 6)}{5^2 + 1^2}$$

or $\frac{\alpha - 4}{5} = \frac{\beta + 13}{1} = -\frac{1}{2}$

$\therefore \quad M \equiv \left(\frac{3}{2}, -\frac{27}{2}\right)$

$\because$ M is the mid-point of P and Q, then

$$Q \equiv (x_2, y_2) \equiv \left(2\times\frac{3}{2} - 4, 2\times\left(-\frac{27}{2}\right) + 13\right)$$

i.e. $Q \equiv (-1, -14)$

Aliter I :

By Ratio Proportion Method : Let, $Q(x_2, y_2)$ the image of $P(4, -13)$ with respect to line mirror $5x + y + 6 = 0$, then

$$\frac{x_2 - 4}{5} = \frac{y_2 + 13}{1} = -\frac{2(5\times 4 - 13 + 6)}{5^2 + 1^2} = -1$$

or $x_2 - 4 = -5$ and $y_2 + 13 = -1$

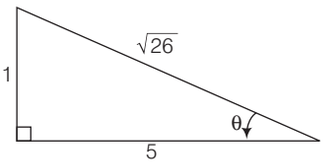
$\therefore \quad x_2 = -1$ and $y_2 = -14$

Hence $Q \equiv (-1, -14)$.

Aliter II :

By distance form or Symmetric form or Parametric form : Let, $P \equiv (4, -13)$ and Q be the image of P with respect to line mirror $(RS)\ 5x + y + 6 = 0$

$\because$ Slope of $RS = -5$



$\therefore$ Slope of $PQ = \frac{1}{5} = \tan\theta$

$\therefore \quad \sin\theta = \frac{1}{\sqrt{26}}$ and $\cos\theta = \frac{5}{\sqrt{26}}$

Now, put the equation of the mirror line such that the coefficient of y becomes negative.

Then, $5x + y + 6 = 0$ becomes $-5x - y - 6 = 0$ and

$p = \perp$ Directed distance from $P(4, -13)$ on $(-5x - y - 6 = 0)$

$$= \frac{-5\times 4 + 13 - 6}{\sqrt{(-5)^2 + (-1)^2}} = -\frac{13}{\sqrt{26}}$$

$\therefore \quad PQ = r = 2p = -\frac{26}{\sqrt{26}} = -\sqrt{26}$

Hence, required image has the coordinates

$$Q \equiv (4 - \sqrt{26}\cos\theta, -13 - \sqrt{26}\sin\theta)$$

i.e. $\left(4 - \sqrt{26}\times\frac{5}{\sqrt{26}}, -13 - \sqrt{26}\times\frac{1}{\sqrt{26}}\right)$

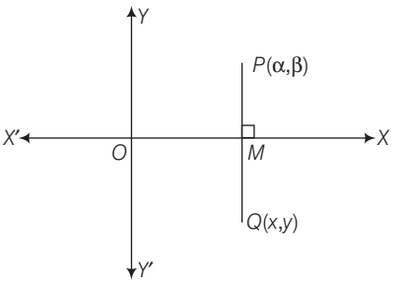
i.e. $(4 - 5, -13 - 1)$

Hence, $Q \equiv (-1, -14)$

Image or Reflection of a Point in Different Cases

(i) The image or reflection of a point with respect to *X*-axis

Let $P(\alpha, \beta)$ be any point and $Q(x, y)$ be its image about X-axis, then (M is the mid-point of P and Q)



$x = \alpha$ and $y = -\beta$

$\therefore$ $Q \equiv (\alpha, -\beta)$

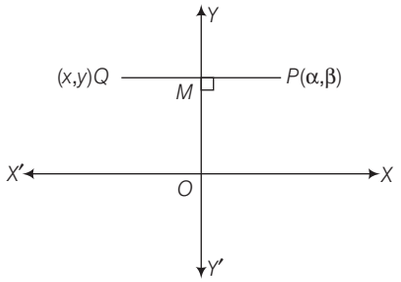
i.e. sign change of ordinate.

Remark

The image of the line $ax + by + c = 0$ about X-axis is $ax - by + c = 0$

(ii) The image or reflection of a point with respect to Y-axis

Let $P(\alpha, \beta)$ be any point and $Q(x, y)$ be its image about Y-axis, then (M is the mid-point of PQ)



$x = -\alpha$ and $y = \beta$

$\therefore$ $Q \equiv (-\alpha, \beta)$

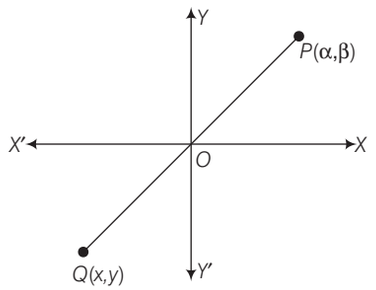
i.e. sign change of abscissae.

Remark

The image of the line $ax + by + c = 0$ about Y-axis is $-ax + by + c = 0$

(iii) The image or reflection of a point with respect to origin

Let $P(\alpha, \beta)$ be any point and $Q(x, y)$ be its image about the origin (O is the mid point of PQ), then



$x = -\alpha$ and $y = -\beta$

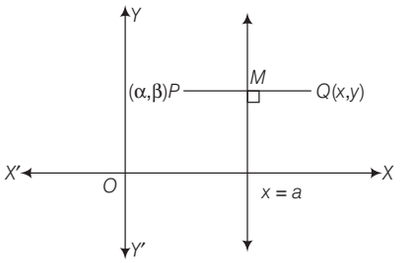
$\therefore$ $Q \equiv (-\alpha, -\beta)$

i.e. sign change of abscissae and ordinate.

Remark

The image of the line $ax + by + c = 0$ about origin is $-ax - by + c = 0$.

(iv) The image or reflection of a point with respect to the line $x = a$



Let $P(\alpha, \beta)$ be any point and $Q(x, y)$ be its image about the line $x = a$, then $y = \beta$

$\therefore$ Coordinates of M are (a, β)

$\because$ M is the mid-point of PQ

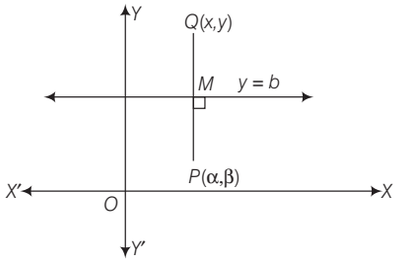
$\therefore$ $Q \equiv (2a - \alpha, \beta)$

Remark

The image of the line $ax + by + c = 0$ about the line $x = \lambda$ is $a(2\lambda - x) + by + c = 0$

(v) The image or reflection of a point with respect to the line $y = b$

Let $P(\alpha, \beta)$ be any point and $Q(x, y)$ be its image about the line y =b, then $x = \alpha$



$\therefore$ Co-ordinates of M are (α, b)

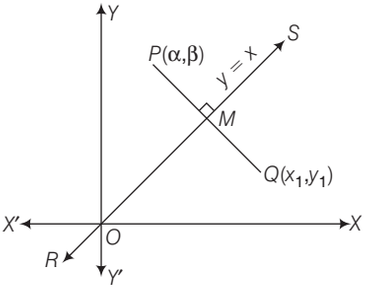
$\because$ M is the mid-point of PQ $\therefore$ $Q \equiv (\alpha, 2b - \beta)$

Remark

The image of the line $ax + by + c = 0$ about the line $y = \mu$ is $ax + b(2\mu - y) + c = 0$.

(vi) The image or reflection of a point with respect to the line y = x

Let $P(\alpha, \beta)$ be any point and $Q(x_1, y_1)$ be its image about the line $y = x$ (RS), then $PQ \perp RS$



$\therefore$ (Slope of PQ) $\times$ (Slope of RS) $=-1$

or $$\frac{y_1-\beta}{x_1-\alpha}\times 1=-1$$

or $$x_1-\alpha=\beta-y_1 \quad ...(i)$$

and mid--point of PQ lie on $y=x$

i.e. $$\left(\frac{y_1+\beta}{2}\right)=\left(\frac{x_1+\alpha}{2}\right)$$

or $$x_1+\alpha=\beta+y_1 \quad ...(ii)$$

Solving Eqs. (i) and (ii), we get $x_1=\beta$ and $y_1=\alpha$

$\therefore$ $Q\equiv(\beta,\alpha)$ i.e. interchange of x and y.

Remark

The image of the line $ax + by + c = 0$ about the line $y = x$ is $ay + bx + c = 0$.

(vii) The image or reflection of a point with respect to the line $y = x\tan\theta$

Let $P(\alpha,\beta)$ be any point and $Q(x_1, y_1)$ be its image about the line $y = x\tan\theta$ (RS), then $PQ \perp RS$

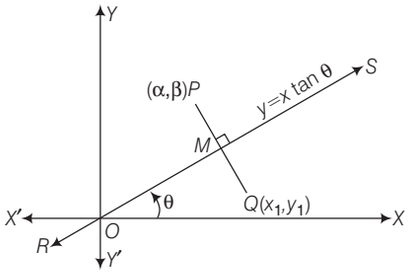
$\therefore$ (Slope of PQ) $\times$ (Slope of RS) $=-1$

or $$\frac{y_1-\beta}{x_1-\alpha}\times\tan\theta=-1$$

$\Rightarrow$ $$y_1-\beta=(\alpha-x_1)\cot\theta \quad ...(i)$$

and mid-point of PQ lie on $y = x\tan\theta$

i.e. $$\left(\frac{y_1+\beta}{2}\right)=\left(\frac{x_1+\alpha}{2}\right)\tan\theta$$



or $$y_1+\beta=(x_1+\alpha)\tan\theta \quad ...(ii)$$

Solving Eqs. (i) and (ii), we get

$$x_1=\alpha\cos 2\theta+\beta\sin 2\theta$$

and $$y_1=\alpha\sin 2\theta-\beta\cos 2\theta$$

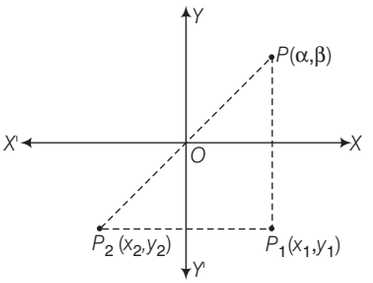
$\therefore$ $$Q\equiv(\alpha\cos 2\theta+\beta\sin 2\theta,\ \alpha\sin 2\theta-\beta\cos 2\theta)$$

Example 95. The point $P(\alpha,\beta)$ undergoes a reflection in the X-axis followed by a reflection in the Y-axis. Show that their combined effect is the same as the single reflection of $P(\alpha,\beta)$ in the origin when $\alpha,\beta>0$.

Sol. Let $P_1(x_1, y_1)$ be the image of (α,β) after reflection in the X-axis. Then

$$x_1=\alpha \quad \text{and} \quad y_1=-\beta \quad ...(i)$$

Now, let $P_2(x_2,y_2)$ be the image of $P_1(x_1, y_1)$ in the Y-axis. Then



$$x_2=-x_1,\ y_2=y_1$$

$\Rightarrow$ $$x_2=-\alpha,\ y_2=-\beta \quad \text{[from Eq. (i)]} \quad ...(ii)$$

further let $P_3(x_3, y_3)$ be the image of $P(\alpha,\beta)$ in the origin O. Then

$$x_3=-\alpha,\ y_3=-\beta \quad ...(iii)$$

From Eqs. (ii) and (iii) ,we get

$$x_3=x_2 \text{ and } y_3=y_2.$$

Hence the image of P_2 of P after successive reflection in their X-axis and Y-axis is the same as the single reflection of P in the origin.

Example 96. Find the image of the point $(-2,-7)$ under the transformations $(x, y)\to(x-2y,-3x+y)$.

Sol. Let (x_1, y_1) be the image of the point (x, y) under the given transformation. Then

$$x_1=x-2y=(-2)-2(-7)=12$$

$\therefore$ $x_1=12$ and $y_1=-3x+y=-3(-2)-7=-1$

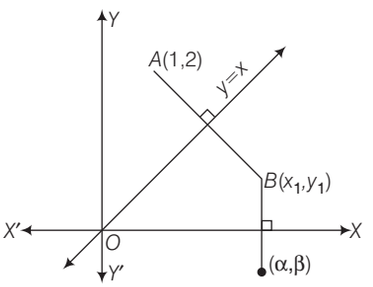
$\therefore$ $y_1=-1$

Hence, the image is $(12, -1)$.

Example 97. The image of the point $A(1,2)$ by the line mirror $y = x$ is the point B and the image of B by the line mirror $y = 0$ is the point (α,β). Find α and β.

Sol. Let (x_1, y_1) be the image of the point $(1, 2)$ about the line $y = x$.

Then $$x_1=2,\ y_1=1 \quad ...(i)$$



Also given image of $B(x_1, y_1)$ by the line mirror $y = 0$ is (α,β). Then $\alpha = x_1 = 2$

and $$\beta=-y_1=-1 \quad \text{[from Eq. (i)]}$$

Hence, $\alpha = 2$ and $\beta = -1$

Example 98. The point (4, 1) undergoes the following three transformations successively :

(i) Reflection about the line $y = x$.

(ii) Translation through a distance 2 units along the positive direction of X-axis.

(iii) Rotation through an angle $\pi/4$ about the origin in the anticlockwise direction.

Then, find the coordinates of the final position.

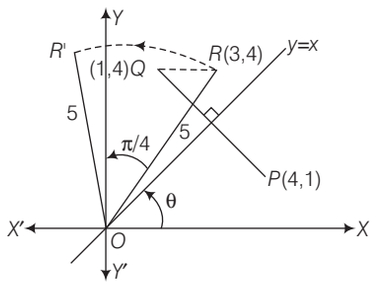
Sol. Let $Q(x_1, y_1)$ be the reflection of P about the line $y = x$.

Then

$$\left.\begin{aligned} x_1 &= 1 \\ y_1 &= 4 \end{aligned}\right\}$$

$\therefore$ Coordinates of Q is (1, 4).

Given that Q move 2 units along the positive direction of X-axis.



$\therefore$ Coordinates of R is $(x_1 + 2, y_1)$

or $R(3, 4)$

If OR makes an angle θ , then

$$\tan\theta = \frac{4}{3}$$

$$\therefore \quad \sin\theta = \frac{4}{5} \quad \text{and} \quad \cos\theta = \frac{3}{5}$$

After rotation of $\frac{\pi}{4}$ let new position of R is R' and

$$OR = OR' = \sqrt{3^2 + 4^2} = 5$$

$\therefore$ OR' makes an angle $(\pi/4 + \theta)$ with X-axis.

Coordinates of $R'\left(OR'\cos\left(\frac{\pi}{4}+\theta\right), OR'\sin\left(\frac{\pi}{4}+\theta\right)\right)$

i.e. $R'\left(OR'\left(\frac{1}{\sqrt{2}}\cos\theta - \frac{1}{\sqrt{2}}\sin\theta\right),\right.$

$\left. OR'\sin\left(\frac{1}{\sqrt{2}}\cos\theta + \frac{1}{\sqrt{2}}\sin\theta\right)\right)$

$$\Rightarrow \quad R'\left(5\left(\frac{3}{5\sqrt{2}} - \frac{4}{5\sqrt{2}}\right), 5\left(\frac{3}{5\sqrt{2}} + \frac{4}{5\sqrt{2}}\right)\right)$$

$$\Rightarrow \quad R'\left(-\frac{1}{\sqrt{2}}, \frac{7}{\sqrt{2}}\right)$$

Aliter (Use of complex number) :

Let Q be the reflection of $P(4, 1)$ about the line $y = x$, then $Q \equiv (1, 4)$

$\because$ Q move 2 units along the +ve direction of X-axis, if new point is ,R then $R \equiv (3, 4)$.

If $R(3, 4) = R(z_1)$

when $z_1 = (3 + 4i)$

then $R'(x, y) = R'(z_2)$

$\therefore$ $z_2 = z_1 e^{i\pi/4}$ $\left(\because \angle ROR' = \frac{\pi}{4}\right)$

$$= (3 + 4i)\left(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4}\right)$$

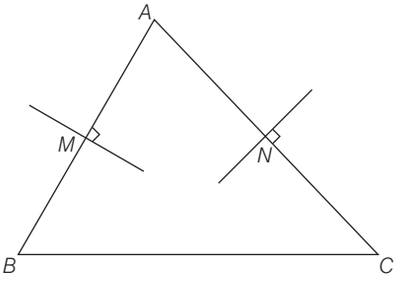
$$= (3 + 4i)\left(\frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}}\right) = \left(-\frac{1}{\sqrt{2}} + \frac{7i}{\sqrt{2}}\right)$$

Hence, new coordinates are $\left(-\frac{1}{\sqrt{2}}, \frac{7}{\sqrt{2}}\right)$.

Use of Image or Reflection

To make problems simpler and easier use Image or reflection.

Types of problems : (i) If vertex of a ΔABC and equations of perpendicular bisectors of AB and AC are given, then B and C are the images or reflections of A about the perpendicular bisectors of AB and AC (where M and N are the mid-points of AB and AC).



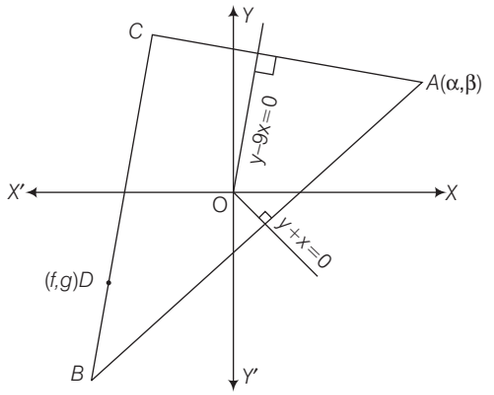
Example 99. The base of a triangle passes through a fixed point (f, g) and its sides are respectively bisected at right angles by the lines $y + x = 0$ and $y - 9x = 0$. Determine the locus of its vertex.

Sol. Let $A \equiv (\alpha, \beta)$ the image of $A(\alpha, \beta)$ about $y + x = 0$ is B, then $B \equiv (-\beta, -\alpha)$ and if image of $A(\alpha, \beta)$ about $y - 9x = 0$ is $C(x_2, y_2)$, then

$$\frac{x_2 - \alpha}{-9} = \frac{y_2 - \beta}{1} = \frac{-2(\beta - 9\alpha)}{1 + 81}$$

$$\therefore \quad x_2 = \frac{9\beta - 40\alpha}{41} \text{ and } y_2 = \frac{40\beta + 9\alpha}{41}$$

$$\therefore \quad C \equiv \left(\frac{9\beta - 40\alpha}{41}, \frac{40\beta + 9\alpha}{41}\right)$$



Hence, B, D, C are collinear, then

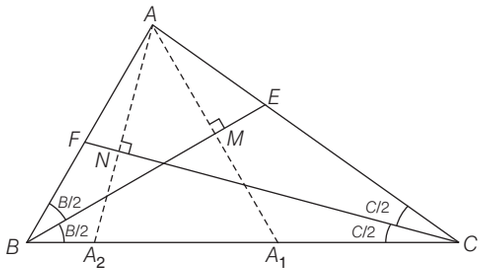
$$\frac{1}{2}\begin{vmatrix} -\beta & -\alpha & 1 \\ f & g & 1 \\ \frac{9\beta - 40\alpha}{41} & \frac{40\beta + 9\alpha}{41} & 1 \end{vmatrix} = 0$$

$$\Rightarrow \quad 4(\alpha^2 + \beta^2) + (4g + 5f)\alpha + (4f - 5g)\beta = 0$$

Hence, locus of vertex is

$$4(x^2 + y^2) + (4g + 5f)x + (4f - 5g)y = 0$$

(ii) The images or reflections of vertex A of a ΔABC about the angular bisectors of angles B and C lie on the side BC. (By congruence) A_1 and A_2 are the images of A about the angle bisectors BE and CF respectively, where M and N are the mid-points of AA_1 and AA_2.



Example 100. Find the equations of the sides of the triangle having $(3, -1)$ as a vertex, $x - 4y + 10 = 0$ and $6x + 10y - 59 = 0$ being the equations of an angle bisector and a median respectively drawn from different vertices.

Sol. Let BE be the angle bisector and CF be the median. Given equations of BE and CF are $x - 4y + 10 = 0$ and $6x + 10y - 59 = 0$ respectively.

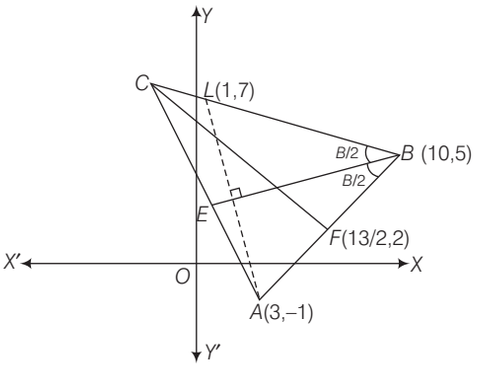
Since, image of A with respect to BE lie on BC. If image of A is $L(h, k)$.

then $$\frac{h-3}{1} = \frac{k+1}{-4} = \frac{-2(3+4+10)}{1^2 + (-4)^2} = -2$$

i.e. $h = 1, k = 7$

$\therefore \quad L \equiv (1, 7)$

$\because$ F be the mid-point of AB.



Let $F \equiv (\alpha, \beta)$

then $B \equiv (2\alpha - 3, 2\beta + 1)$

$\because$ B lie on BE, then

$$(2\alpha - 3) - 4(2\beta + 1) + 10 = 0$$

i.e. $2\alpha - 8\beta + 3 = 0$ ...(i)

and F lie on CF, then

$$6\alpha + 10\beta - 59 = 0 \quad \text{...(ii)}$$

Solving Eqs. (i) and (ii), we get

$$\alpha = \frac{13}{2}, \beta = 2$$

then $F \equiv \left(\frac{13}{2}, 2\right)$

and $B = (10, 5)$

Equation of AB is

$$y + 1 = \frac{2+1}{\frac{13}{2} - 3}(x - 3)$$

$$\Rightarrow \quad y + 1 = \frac{6}{7}(x - 3)$$

or $6x - 7y - 25 = 0$

Equation of BC is

$$y - 5 = \frac{7-5}{1-10}(x - 10)$$

$$\Rightarrow \quad y - 5 = -\frac{2}{9}(x - 10)$$

or $2x + 9y - 65 = 0$

$\because$ CA is the family of lines of CB and CF

then $(2x + 9y - 65) + \lambda(6x + 10y - 59) = 0$ ...(iii)

it pass through $A(3, -1)$

then $(6 - 9 - 65) + \lambda(18 - 10 - 59) = 0$

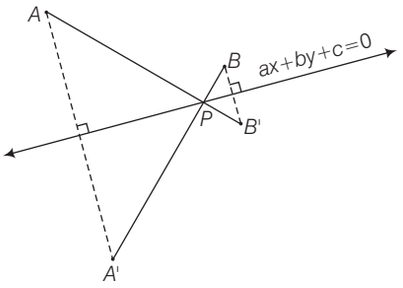
$\therefore \quad \lambda = -\frac{4}{3}$

From Eq. (iii), we get equation of AC is

$$18x + 13y - 41 = 0$$

(iii) Optimization (Minimization or Maximization)

(a) **Minimization :** Let A and B are two given points on the same side of $ax + by + c = 0$. Suppose we want to determine a point P on $ax + by + c = 0$ such that $PA + PB$ is minimum. Then find the image of A or B about the line $ax + by + c = 0$ (say A' or B') then join B' with A or A' with B wherever it intersects $ax + by + c = 0$ is the required point.



$\therefore \quad PA + PB = PA + PB'$

or $\quad PA + PB = PA' + PB$

Remark

By triangle in equality

Sum of two sides of a triangle > Third side

i.e. $|PA + PB| = |PA + PB'| = |AB'|$ (minimum value).

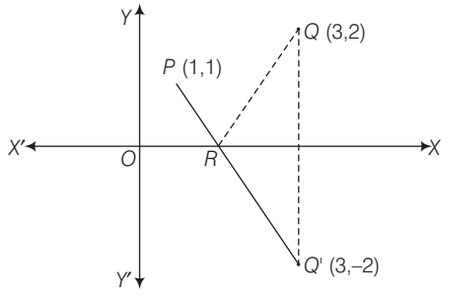
Example 101. Find a point R on the X-axis such that $PR + RQ$ is the minimum, when $P \equiv (1, 1)$ and $Q \equiv (3, 2)$.

Sol. Since P and Q lie on the same side of X-axis.

The image of $Q(3, 2)$ about X-axis is $Q'(3, -2)$ then the equation of line PQ' is

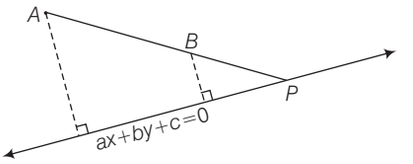
$$y - 1 = \frac{-2-1}{3-1}(x - 1)$$

$\Rightarrow \quad 3x + 2y - 5 = 0$



This line meets X-axis at $R\left(\frac{5}{3}, 0\right)$ which is the required point.

(b) **Maximization :** Let A and B are two given points on the same side of $ax + by + c = 0$. Suppose we want to determine a point P on $ax + by + c = 0$ such that $|PA - PB|$ is maximum, then find the equation of line AB wherever it intersects $ax + by + c = 0$ is the required point.



Remark

By triangle inequality

Difference of two sides of a triangle < Third side

i.e. $\quad |PA - PB| = |AB|$ (maximum value)

Example 102. Find a point P on the line $3x + 2y + 10 = 0$ such that $|PA - PB|$ is maximum where A is (4, 2) and B is (2, 4).

Sol. Let, $\quad L(x, y) = 3x + 2y + 10$

$\therefore \quad L(4, 2) = 12 + 4 + 10 = 26$

and $\quad L(2, 4) = 6 + 8 + 10 = 24$

$\therefore$ A and B lie on the same side of the line

$$3x + 2y + 10 = 0 \qquad \text{...(i)}$$

Equation of line AB is

$$y - 2 = \frac{4-2}{2-4}(x - 4)$$

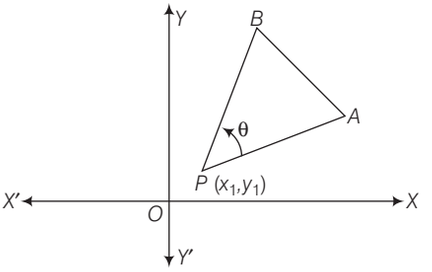
or $\quad x + y - 6 = 0 \qquad$ ...(ii)

This line Eq. (ii) meets Eq. (i) at $P \equiv (-22, 28)$ which is the required point.

Aliter

Let $\quad$ P be (x_1, y_1) and $\angle APB = \theta$

then $\quad \cos\theta = \dfrac{(PA)^2 + (PB)^2 - (AB)^2}{2PA \cdot PB}$



since $\cos\theta \le 1$

$$\Rightarrow \quad \frac{(PA)^2 + (PB)^2 - (AB)^2}{2PA \cdot PB} \le 1$$

$$\Rightarrow \quad (PA - PB)^2 \le (AB)^2$$

$$\Rightarrow \quad |PA - PB| \le |AB|$$

$$\Rightarrow \quad |PA - PB| \le 2\sqrt{2}$$

Maximum value of $|PA - PB|$ is $2\sqrt{2}$

when, $\theta = 0$.

i.e. P lies on the line AB as well as on the given line.

$\therefore$ Equation of AB is

$$y - 2 = \frac{4-2}{2-4}(x - 4)$$

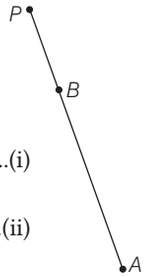
$$\Rightarrow \quad y - 2 = -x + 4$$

$$\Rightarrow \quad x + y = 6 \qquad \text{...(i)}$$

and given line

$$3x + 2y + 10 = 0 \qquad \text{...(ii)}$$

Solving Eqs. (i) and (ii), we get $P(-22, 28)$.



Exercise for Session 5

1. The coordinates of the foot of the perpendicular from $(2, 3)$ to the line $3x + 4y - 6 = 0$ are

(a) $\left(-\frac{14}{25}, -\frac{27}{25}\right)$ (b) $\left(\frac{14}{25}, -\frac{17}{25}\right)$

(c) $\left(-\frac{14}{25}, \frac{17}{25}\right)$ (d) $\left(\frac{14}{25}, \frac{27}{25}\right)$

2. If the foot of the perpendicular from the origin to a straight line is at the point $(3, -4)$. Then the equation of the line is

(a) $3x - 4y = 25$ (b) $3x - 4y + 25 = 0$

(c) $4x + 3y - 25 = 0$ (d) $4x - 3y + 25 = 0$

3. The coordinates of the foot of the perpendicular from (a, 0) on the line $y = mx + \frac{a}{m}$ are

(a) $\left(0, -\frac{1}{a}\right)$ (b) $\left(0, \frac{a}{m}\right)$ (c) $\left(0, -\frac{a}{m}\right)$ (d) $\left(0, \frac{1}{a}\right)$

4. If the equation of the locus of a point equidistant from the points (a_1, b_1) and (a_2, b_2) is $(a_1 - a_2)x + (b_1 - b_2)y + c = 0$, then the value of c is

(a) $a_1^2 - a_2^2 + b_1^2 - b_2^2$ (b) $\sqrt{(a_1^2 + b_1^2 - a_2^2 - b_2^2}$

(c) $\frac{1}{2}(a_1^2 + a_2^2 + b_1^2 + b_2^2)$ (d) $\frac{1}{2}(a_2^2 + b_2^2 - a_1^2 - b_1^2)$

5. The image of the point (3, 8) in the line $x + 3y = 7$ is

(a) (1, 4) (b) (4, 1) (c) (–1, – 4) (d) (–4, – 1)

6. The image of the point (4, –3) with respect to the line $y = x$ is

(a) (–4, – 3) (b) (3, 4) (c) (–4, 3) (d) (–3, 4)

7. The coordinates of the image of the origin O with respect to the straight line $x + y + 1 = 0$ are

(a) $\left(-\frac{1}{2}, -\frac{1}{2}\right)$ (b) (–2, – 2)

(c) (1, 1) (d) (–1, – 1)

8. If $(-2, 6)$ is the image of the point (4, 2) with respect to the line $L = 0$, then $L \equiv$

(a) $6x - 4y - 7 = 0$ (b) $2x - 3y - 5 = 0$

(c) $3x - 2y + 5 = 0$ (d) $3x - 2y + 10 = 0$

9. The image of $P(a, b)$ on the line $y = -x$ is Q and the image of Q on the line $y = x$ is R. Then the mid-point of PR is

(a) $(a + b, a + b)$ (b) $\left(\frac{a+b}{2}, \frac{b+2}{2}\right)$

(c) $(a - b, b - a)$ (d) $(0, 0)$

10. The nearest point on the line $3x - 4y = 25$ from the origin is

(a) $(3, 4)$ (b) $(3, -4)$ (c) $(3, 5)$ (d) $(-3, 5)$

11. Consider the points $A(0, 1)$ and $B(2, 0)$, P be a point on the line $4x + 3y + 9 = 0$. The coordinates of P such that $|PA - PB|$ is maximum are

(a) $\left(-\frac{12}{5}, \frac{17}{5}\right)$ (b) $\left(-\frac{84}{5}, \frac{13}{5}\right)$ (c) $\left(-\frac{6}{5}, \frac{17}{5}\right)$ (d) $(0, -3)$

12. Consider the points $A(3, 4)$ and $B(7, 13)$. If P is a point on the line $y = x$ such that $PA + PB$ is minimum, then the coordinates of P are

(a) $\left(\frac{12}{7}, \frac{12}{7}\right)$ (b) $\left(\frac{13}{7}, \frac{13}{7}\right)$ (c) $\left(\frac{31}{7}, \frac{31}{7}\right)$ (d) $(0, 0)$

13. The image of a point $P(2, 3)$ in the line mirror $y = x$ is the point Q and the image of Q in the line mirror $y = 0$ is the point $R(x, y)$. Find the coordinates of R.

14. The equations of perpendicular bisector of the sides AB and AC of a ΔABC are $x - y + 5 = 0$ and $x + 2y = 0$ respectively. If the point A is $(1, -2)$, find the equation of line BC.

15. In a ΔABC, the equation of the perpendicular bisector of AC is $3x - 2y + 8 = 0$. If the coordinates of the point A and B are $(1, -1)$ and $(3, 1)$ respectively, find the equation of the line BC and the centre of the circumcircle of ΔABC.

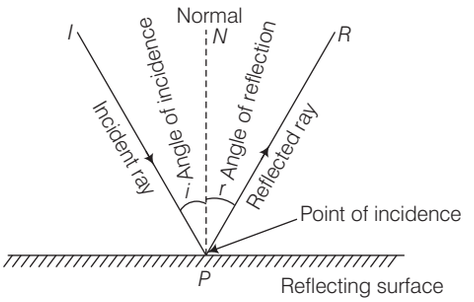
16. Is there a real value of λ for which the image of the point $(\lambda, \lambda - 1)$ by the line mirror $3x + y = 6\lambda$ is the point $(\lambda^2 + 1, \lambda)$? If so find λ.

Session 6

Reflection of Light, Refraction of Light, Conditions of Collinearity if Three Given Points be in Cyclic Order

Reflection of Light

When a ray of light falls on a smooth polished surface (Mirror) separating two media, a part of it is reflected back into the first medium.



IP is the incident ray and PR is the reflected ray. A perpendicular drawn to the surface, at the point of incidence P is called the normal. Hence PN is the normal. The angle between the incident ray and the normal ($\angle IPN$) is called the **angle of incidence** which is represented by $\angle i$

i.e. $\angle IPN = \angle i$ = Angle of incidence and the angle between the reflected ray and the normal ($\angle IPR$) is called the **angle of reflection** which is represented by $\angle r$.

i.e. $\angle IPR = \angle r$ = Angle of reflection.

Laws of Reflection :

(i) The incident ray, normal and the reflected ray to a surface at the point of incidence all lie in the same plane.

(ii) The angle of incidence = angle of reflection

i.e. $\angle i = \angle r$

Example 103. A ray of light is sent along the line $x - 2y - 3 = 0$. Upon reaching the line $3x - 2y - 5 = 0$, the ray is reflected from it. Find the equation of the line containing the reflected ray.

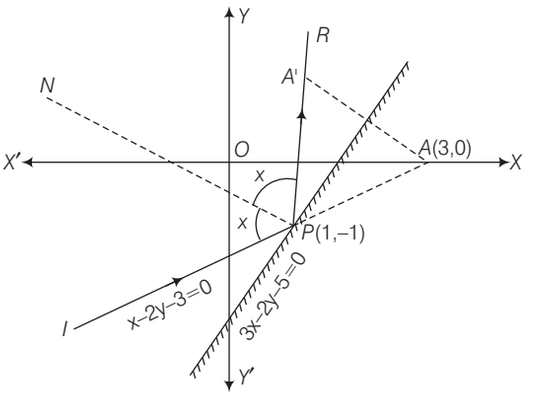
Sol. To get coordinates of point P, we solve the given equation of lines together as

$$x - 2y - 3 = 0$$

$$3x - 2y - 5 = 0$$

$\therefore \quad x = 1, y = -1$

$\therefore$ Coordinates of P are $(1, -1)$.



Let slope of reflected ray be m.

Since, slope of line mirror is 3/2.

$\therefore$ Slope of $PN = -2/3$ and

slope of $IP = 1/2$, line PN is equally inclined to IP and PR, then

$$\left(\frac{m-\left(-\frac{2}{3}\right)}{1+m\left(-\frac{2}{3}\right)}\right) = -\left(\frac{\frac{1}{2}-\left(-\frac{2}{3}\right)}{1+\frac{1}{2}\left(-\frac{2}{3}\right)}\right)$$

$$\Rightarrow \quad \frac{3m+2}{3-2m} = -\frac{7}{4}$$

$$\Rightarrow \quad 12m + 8 = -21 + 14m$$

$$\therefore \quad 2m = 29$$

$$\Rightarrow \quad m = \frac{29}{2}$$

$\therefore$ Equation of reflected ray $y + 1 = \frac{29}{2}(x - 1)$

$$\Rightarrow \quad 2y + 2 = 29x - 29$$

$$\Rightarrow \quad 29x - 2y - 31 = 0.$$

Aliter (Image method) : Take A (3, 0) be any point on IP and if $A'(\alpha, \beta)$ be the image of A about the mirror line $3x - 2y - 5 = 0$, then

$$\frac{\alpha - 3}{3} = \frac{\beta - 0}{-2} = \frac{-2(9 - 0 - 5)}{9 + 4}$$

$$\therefore \qquad \alpha = \frac{15}{13} \quad \text{and} \quad \beta = \frac{16}{13}$$

$$\therefore \qquad A' \equiv \left(\frac{15}{13}, \frac{16}{13}\right)$$

$\therefore$ Equation of $A'P$ is the equation of the reflected ray then its equation is,

$$y + 1 = \frac{\left(\frac{16}{13} + 1\right)}{\left(\frac{15}{13} - 1\right)}(x - 1)$$

$$\Rightarrow \qquad y + 1 = \frac{29}{2}(x - 1) \text{ or } 29x - 2y - 31 = 0$$

Example 104. A light beam, emanating from the point (3, 10) reflects from the straight line $2x + y - 6 = 0$ and, then passes through the point (7, 2). Find the equations of the incident and reflected beams.

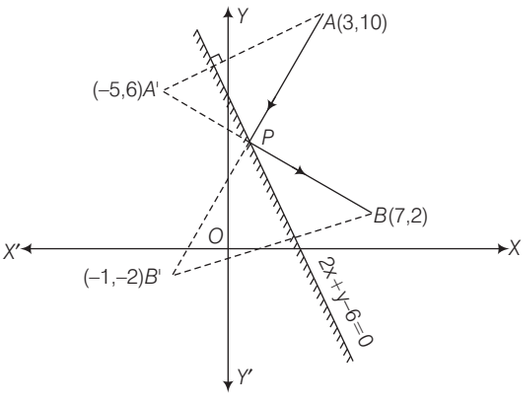
Sol. Let images of A and B about the line $2x + y - 6 = 0$ are $A'(\alpha, \beta)$ and $B'(\gamma, \delta)$ respectively.

Then, $$\frac{\alpha - 3}{2} = \frac{\beta - 10}{1} = \frac{-2(6 + 10 - 6)}{2^2 + 1^2}$$

$$= -4$$

$$\therefore \qquad \alpha = -5, \beta = 6$$

i.e. $$A' \equiv (-5, 6)$$



and $$\frac{\gamma - 7}{2} = \frac{\delta - 2}{1} = \frac{-2(14 + 2 - 6)}{2^2 + 1^2} = -4$$

$$\therefore \qquad \gamma = -1, \delta = -2$$

i.e. $$B' \equiv (-1, -2).$$

$\therefore$ Equation of incident ray AB' is

$$y + 2 = \frac{10 + 2}{3 + 1}(x + 1) \text{ or } 3x - y + 1 = 0$$

and equation of reflected ray $A'B$ is

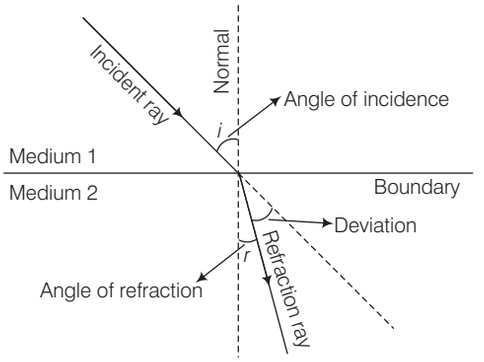
$$y - 6 = \frac{2 - 6}{7 + 5}(x + 5)$$

$$\Rightarrow \qquad y - 6 = -\frac{1}{3}(x + 5)$$

or $$x + 3y - 13 = 0$$

Refraction of Light

When a ray of light falls on the boundary separating the two transparent media, there is a change in direction of ray. This phenomenon is called refraction.



Laws of Refraction

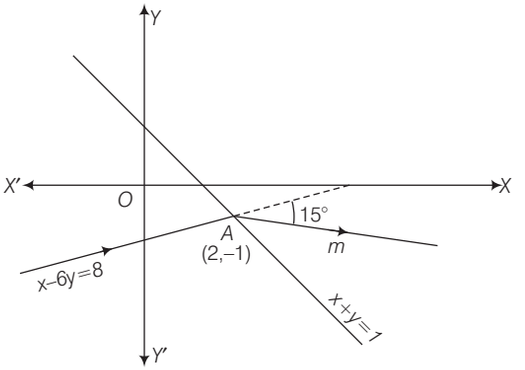
(i) The incident ray, normal and the refracted ray to the surface separating the two transparent media all lie in the same plane.

(ii) The ratio of sine of angle of incidence to the sine of the angle of refraction is constant for the two given media. The constant is called the refractive index of medium 2 with respect to medium 1.

i.e. $$_1\mu_2 = \frac{\sin i}{\sin r}$$

Example 105. A ray of light is sent along the line $x - 6y = 8$. After refracting across the line $x + y = 1$ it enters the opposite side after turning by 15° away from the line $x + y = 1$. Find the equation of the line along which the refracted ray travels.

Sol. The point of intersection of $x - 6y = 8$ and $x + y = 1$ is $A \equiv (2, -1)$. Let the required ray have the slope $= m$, then



$$\tan 15° = \left|\frac{m - \frac{1}{6}}{1 + \frac{m}{6}}\right|$$

$$\Rightarrow \qquad 2-\sqrt{3}=\pm\left(\frac{6m-1}{m+6}\right)$$

then, $$\frac{6m-1}{m+6}=2-\sqrt{3} \text{ or } \sqrt{3}-2$$

$$\Rightarrow \qquad m=\frac{70-37\sqrt{3}}{13}$$

or $$m=\frac{37\sqrt{3}-70}{61}$$

Let the angle between $x+y=1$ and the line through $A(2,-1)$ with the slope $\frac{70-37\sqrt{3}}{13}$ be α, then

$$\tan\alpha=\left|\frac{\frac{70-37\sqrt{3}}{13}-(-1)}{1-\left(\frac{70-37\sqrt{3}}{13}\right)}\right|=\left|\frac{83-37\sqrt{3}}{37\sqrt{3}-57}\right|$$

$$=\frac{83-37\sqrt{3}}{37\sqrt{3}-57}$$

and if angle between $x+y=1$ and the line through $A(2,-1)$ with the slope $\frac{37\sqrt{3}-70}{61}$ be β, then

$$\tan\beta=\left|\frac{\frac{37\sqrt{3}-70}{61}-(-1)}{1-\left(\frac{37\sqrt{3}-70}{61}\right)}\right|=\left|\frac{37\sqrt{3}-9}{131-37\sqrt{3}}\right|$$

$$=\frac{37\sqrt{3}-9}{131-37\sqrt{3}}$$

Here $\tan\alpha>\tan\beta, \therefore \alpha>\beta$

therefore the slope of the refracted ray $=\frac{70-37\sqrt{3}}{13}$

$\therefore$ The equation of the refracted ray is

$$y+1=\frac{(70-37\sqrt{3})}{13}(x-2)$$

$$\Rightarrow \qquad 13y+13=(70-37\sqrt{3})\,x-140+74\sqrt{3}$$

or $$(70-37\sqrt{3})\,x-13y-153+74\sqrt{3}=0$$

Conditions of Collinearity if Three given points are in Cyclic Order

Let the three given points

$$A\equiv(f(a),g(a)),\ B\equiv(f(b),g(b))$$

and $C\equiv(f(c),g(c))$ lie on the line

$lx+my+n=0$, where l,m and n are constants.

Then $$lf(t)+m\,g(t)+n=0 \qquad \text{...(i)}$$

where, $t=a,b,c$

i.e. a, b, c are the roots of the Eq. (i).

In this case Eq. (i) must be cubic in t.

$$At^3+Bt^2+Ct+D=0 \qquad \text{(say)}$$

then $$a+b+c=-\frac{B}{A}, ab+bc+ca=\frac{C}{A}$$

and $$abc=-\frac{D}{A}$$

which are the required conditions.

Example 106. If the points $\left(\frac{a^3}{a-1},\frac{a^2-3}{a-1}\right),\left(\frac{b^3}{b-1},\frac{b^2-3}{b-1}\right)$ and $\left(\frac{c^3}{c-1},\frac{c^2-3}{c-1}\right)$ are collinear for three distinct values a,b,c and different from 1, then show that $abc-(bc+ca+ab)+3(a+b+c)=0$.

Sol. Let the three given points lie on the line

$$lx+my+n=0, \qquad \text{where } l, m \text{ and } n \text{ are constants.}$$

Then, $$l\left(\frac{t^3}{t-1}\right)+m\left(\frac{t^2-3}{t-1}\right)+n=0$$

$$\Rightarrow \qquad lt^3+mt^2+nt-(3m+n)=0$$

for $t=a, b, c$

i.e. a, b, c are the roots of

$$lt^3+mt^2+nt-3m-n=0$$

then $$a+b+c=-\frac{m}{l}, ab+bc+ca=\frac{n}{l}$$

and $$abc=\left(\frac{3m+n}{l}\right)$$

Now, $abc-(bc+ca+ab)+3(a+b+c)$

$$=\left(\frac{3m+n}{l}\right)-\frac{n}{l}-\frac{3m}{l}=0$$

Hence, $abc-(bc+ca+ab)+3(a+b+c)=0$

Example 107. If t_1,t_2 and t_3 are distinct, the points $(t_1,2at_1+at_1^3),(t_2,2at_2+at_2^3)$ and $(t_3,2at_3+at_3^3)$ are collinear, then prove that $t_1+t_2+t_3=0$.

Sol. Let the three given points lie on the line $lx+my+n=0$, where l, m and n are constants. Then,

$$l(t)+m(2at+at^3)+n=0$$

$$\Rightarrow \qquad (am)\,t^3+(2am+l)\,t+n=0 \qquad \text{...(i)}$$

for $t=t_1,t_2,t_3$

i.e., t_1, t_2, t_3 are the roots of Eq. (i), then

$$t_1+t_2+t_3=0$$

Exercise for Session 6

1. A ray of light passing through the point (1, 2) is reflected on the X-axis at a point P and passes through the point (5, 3). The abscissae of the point P is

(a) 3 (b) $\frac{13}{3}$ (c) $\frac{13}{5}$ (d) $\frac{13}{4}$

2. The equation of the line segment AB is $y = x$. If A and B lie on the same side of the line mirror $2x - y = 1$, then the image of AB has the equation

(a) $x + y = 2$ (b) $8x + y = 9$ (c) $7x - y = 6$ (d) None of these

3. A ray of light travelling along the line $x + y = 1$ is incident on the X-axis and after refraction it enters the other side of the X-axis by turning $\pi / 6$ away from the X-axis. The equation of the line along which the refracted ray travels is

(a) $x + (2 - \sqrt{3})\, y = 1$ (b) $x\,(2 + \sqrt{3}) + y = 2 + \sqrt{3}$
(c) $(2 - \sqrt{3})x + y = 1$ (d) $x + (2 + \sqrt{3})y = (2 + \sqrt{3})$

4. All the points lying inside the triangle formed by the points $(0, 4)$, $(2, 5)$ and $(6, 2)$ satisfy

(a) $3x + 2y + 8 \geq 0$ (b) $2x + y - 10 \geq 0$
(c) $2x - 3y - 11 \geq 0$ (d) $-2x + y - 3 \geq 0$

5. Let O be the origin and let $A(1, 0)$, $B(0, 1)$ be two points. If $P(x, y)$ is a point such that $xy > 0$ and $x + y < 1$ then

(a) P lies either inside in ΔOAB or in third quadrant (b) P cannot be inside in ΔOAB
(c) P lies inside the ΔOAB (d) None of these

6. A ray of light coming along the line $3x + 4y - 5 = 0$ gets reflected from the line $ax + by - 1 = 0$ and goes along the line $5x - 12y - 10 = 0$ then

(a) $a = \frac{64}{115}, b = \frac{112}{15}$ (b) $a = -\frac{64}{115}, b = \frac{8}{115}$
(c) $a = \frac{64}{115}, b = \frac{8}{115}$ (d) $a = -\frac{64}{115}, b = \frac{-8}{115}$

7. Two sides of a triangle have the joint equation $x^2 - 2xy - 3y^2 + 8y - 4 = 0$. The third side, which is variable, always passes through the point $(-5, -1)$. Find the range of values of the slope of the third side, so that the origin is an interior point of the triangle.

8. Determine the range of values of $\theta \in [0, 2\pi]$ for which $(\cos\theta, \sin\theta)$ lies inside the triangle formed by the lines $x + y - 2 = 0$, $x - y - 1 = 0$ and $6x + 2y - \sqrt{10} = 0$.

9. Let $P(\sin\theta, \cos\theta)$, where $0 \leq \theta \leq 2\pi$ be a point and let OAB be a triangle with vertices (0, 0), $\left(\frac{\sqrt{3}}{2}, 0\right)$ and $\left(0, \frac{\sqrt{3}}{2}\right)$. Find θ if P lies inside the ΔOAB.

10. Find all values of θ for which the point $(\sin^2\theta, \sin\theta)$ lies inside the square formed by the line $xy = 0$ and $4xy - 2x - 2y + 1 = 0$.

11. Determine whether the point $(-3, 2)$ lies inside or outside the triangle whose sides are given by the equations $x + y - 4 = 0$, $3x - 7y + 8 = 0$, $4x - y - 31 = 0$.

12. A ray of light is sent along the line $x - 2y + 5 = 0$, upon reaching the line $3x - 2y + 7 = 0$, the ray is reflected from it. Find the equation of the line containing the reflected ray.

Shortcuts and Important Results to Remember

1. Area of parallelogram formed by the lines $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + d_1 = 0$, $a_1x + b_1y + c_2 = 0$ and $a_2x + b_2y + d_2 = 0$ is

$$\frac{|c_1 - c_2||d_1 - d_2|}{\left|\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}\right|}$$

2. Area of parallelogram formed by the lines $y = m_1x + c_1$, $y = m_2x + d_1$, $y = m_1x + c_2$ and $y = m_2x + d_2$ is

$$\frac{|c_1 - c_2||d_1 - d_2|}{|m_1 - m_2|}$$

3. If $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ are the vertices of a ΔABC, then angle A is acute or obtuse according as

$$(x_1 - x_2)(x_1 - x_3) + (y_1 - y_2)(y_1 - y_3) > 0 \quad \text{or} \quad < 0$$

Similarly, for $\angle B$

$$(x_2 - x_3)(x_2 - x_1) + (y_2 - y_3)(y_2 - y_1) > 0 \quad \text{or} \quad < 0$$

and for $\angle C$

$$(x_3 - x_1)(x_3 - x_2) + (y_3 - y_1)(y_3 - y_2) > 0 \quad \text{or} \quad < 0$$

4. If the origin lies in the acute angle or obtuse angle between the lines

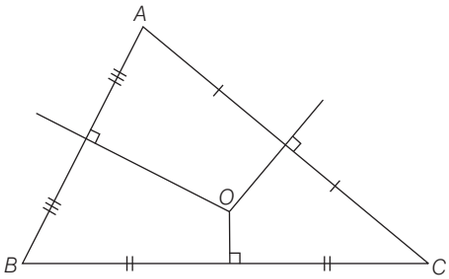
$$a_1x + b_1y + c_1 = 0$$

and $\quad a_2x + b_2y + c_2 = 0$

according as $\quad (a_1a_2 + b_1b_2)c_1c_2 < 0$ or > 0.

5. If $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ are the vertices of a ΔABC then the equations of the right bisectors (perpendicular bisectors) of the sides BC, CA and AB are

$$y(y_2 - y_3) + x(x_2 - x_3) = \left(\frac{x_2^2 - x_3^2}{2}\right) + \left(\frac{y_2^2 - y_3^2}{2}\right);$$



$$y(y_3 - y_1) + x(x_3 - x_1) = \left(\frac{x_3^2 - x_1^2}{2}\right) + \left(\frac{y_3^2 - y_1^2}{2}\right)$$

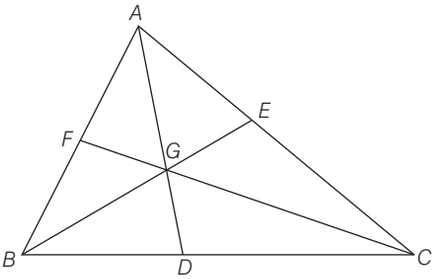
and $\quad y(y_1 - y_2) + x(x_1 - x_2) = \left(\frac{x_1^2 - x_2^2}{2}\right) + \left(\frac{y_1^2 - y_2^2}{2}\right)$

respectively. Where O is the circumcentre of ΔABC.

6. If $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ are the vertices of a ΔABC then the equations of medians AD, BE and CF are

$$y(x_2 + x_3 - 2x_1) - x(y_2 + y_3 - 2y_1)$$
$$= y_1(x_2 + x_3) - x_1(y_2 + y_3);$$
$$y(x_3 + x_1 - 2x_2) - x(y_3 + y_1 - 2y_2)$$
$$= y_2(x_3 + x_1) - x_2(y_3 + y_1)$$

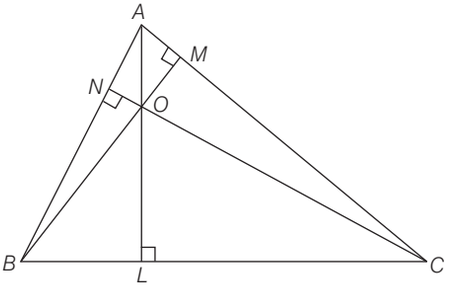
and $y(x_1 + x_2 - 2x_3) - x(y_1 + y_2 - 2y_3) = y_3(x_1 + x_2) - x_3(y_1 + y_2)$ respectively.



Where, G is the centroid of ΔABC.

7. If $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ are the vertices of a ΔABC then the equations of the altitudes AL, BM and CN are

$$y(y_2 - y_3) + x(x_2 - x_3) = y_1(y_2 - y_3) + x_1(x_2 - x_3);$$
$$y(y_3 - y_1) + x(x_3 - x_1) = y_2(y_3 - y_1) + x_2(x_3 - x_1)$$



and $\quad y(y_1 - y_2) + x(x_1 - x_2) = y_3(x_1 - x_2) + x_3(x_1 - x_2)$

respectively. Where O is the orthocentre of ΔABC.

8. If sides of a triangle ABC are represented by

$$BC : a_1x + b_1y + c_1 = 0,$$
$$CA : a_2x + b_2y + c_2 = 0$$

and $\quad AB : a_3x + b_3y + c_3 = 0$

then $\quad |BC| : |CA| : |AB|$

$$= \sqrt{(a_1^2 + b_1^2)}\left|\begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix}\right|$$

$$: \sqrt{(a_2^2 + b_2^2)}\left|\begin{vmatrix} a_3 & b_3 \\ a_1 & b_1 \end{vmatrix}\right| : \sqrt{(a_3^2 + b_3^2)}\left|\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}\right|$$

JEE Type Solved Examples :
Single Option Correct Type Questions

■ This section contains **10 multiple choice examples**. Each example has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

● ***Ex. 1*** *A rectangle ABCD has its side AB parallel to $y = x$ and vertices A, B and D lie on $y = 1$, $x = 2$ and $x = -2$ respectively, then locus of vertex C is*

(a) $x = 5$ (b) $x - y = 5$

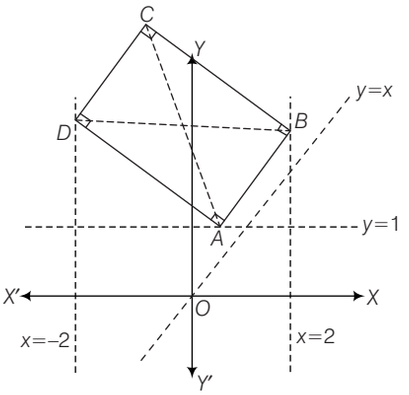
(c) $y = 5$ (d) $x + y = 5$

Sol. (c) Since AB is parallel to $y = x$.

$\therefore$ Equation of AB is $y = x + a$ (say)

$\because$ A lies on $y = 1$

$\therefore$ $A \equiv (1 - a, 1)$



Again, B lies on $x = 2$

$\therefore$ $B = (2, 2 + a)$

$\Rightarrow$ Equation of AD is

$y - 1 = -[x - (1 - a)]$ or $y = 2 - x - a$

$\because$ D lies on $x = -2$

$\therefore$ $D \equiv (-2, 4 - a)$

Let $C \equiv (h, k)$

$\because$ Diagonals of rectangle bisects to each other

$\therefore$ $h + 1 - a = 2 - 2 \Rightarrow a = 1 + h$

and $k + 1 = 2 + a + 4 - a$

$\Rightarrow$ $k = 5$

$\therefore$ Locus of C is $y = 5$

● ***Ex. 2*** *The line $(\lambda + 1)^2 x + \lambda y - 2\lambda^2 - 2 = 0$ passes through a point regardless of the value λ. Which of the following is the line with slope 2 passing through the point?*

(a) $y = 2x - 8$ (b) $y = 2x - 5$

(c) $y = 2x - 4$ (d) $y = 2x + 8$

Sol. (a)

$\because$ $(\lambda + 1)^2 x + \lambda y - 2\lambda^2 - 2 = 0$

or $(\lambda^2 + 2\lambda + 1)x + \lambda y - 2\lambda^2 - 2 = 0$

or $(\lambda^2 + 1)(x - 2) + \lambda(2x + y) = 0$

$\therefore$ For fixed point

$x - 2 = 0$ and $2x + y = 0$

$\therefore$ Fixed point is $(2, -4)$

$\therefore$ Equation of required line is $y + 4 = 2(x - 2)$

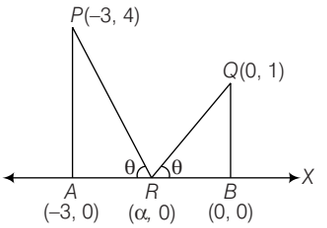
or $y = 2x - 8$

● ***Ex. 3*** *A man starts from the point $P(-3, 4)$ and reaches point $Q(0, 1)$ touching X-axis at R such that $PR + RQ$ is minimum, then the point R is*

(a) $\left(\frac{3}{5}, 0\right)$ (b) $\left(-\frac{3}{5}, 0\right)$ (c) $\left(-\frac{2}{5}, 0\right)$ (d) $(-2, 0)$

Sol. (b) Let $R = (\alpha, 0)$

For $PR + PQ$ to be minimum it should be the path of light and thus we have



$\Delta APR \sim \Delta BQR$

$\Rightarrow$ $\frac{AR}{RB} = \frac{PA}{QB} \Rightarrow \frac{\alpha + 3}{0 - \alpha} = \frac{4}{1} \Rightarrow \alpha = -\frac{3}{5}$

Hence, $R \equiv \left(-\frac{3}{5}, 0\right)$

● ***Ex. 4*** *If the point $P(a, a^2)$ lies inside the triangle formed by the lines $x = 0$, $y = 0$ and $x + y = 2$, then exhaustive range of 'a' is*

(a) $(0, 1)$ (b) $(1, \sqrt{2})$

(c) $(\sqrt{2} - 1, 1)$ (d) $(\sqrt{2} - 1, 2)$

Sol. (a) Since the point $P(a, a^2)$ lies on $y = x^2$

Solving, $y = x^2$

and $x + y = 2$, we get

$x^2 + x - 2 = 0$

$\Rightarrow$ $(x + 2)(x - 1) = 0$

$\Rightarrow$ $x = -2, 1$

It is clear from figure,

$A \equiv (1, 1)$

also $a > 0$ for I quadrant.

$\therefore$ $a \in (0, 1)$

● **Ex. 5** *If* $5a + 4b + 20c = t$, *then the value of* t *for which the line* $ax + by + c - 1 = 0$ *always passes through a fixed point is*

(a) 0 (b) 20

(c) 30 (d) None of these

Sol. (b) Equation of line $\frac{ax}{c-1} + \frac{by}{c-1} + 1 = 0$ has two independent parameters. It can pass through a fixed point if it contains only one independent parameter. Now there must be one relation between $\frac{a}{c-1}$ and $\frac{b}{c-1}$ independent of a, b and c so that $\frac{a}{c-1}$ can be expressed in terms of $\frac{b}{c-1}$ and straight line contains only one independent parameter. Now that given relation can be expressed as $\frac{5a}{c-1} + \frac{4b}{c-1} = \frac{t-20c}{c-1}$.

RHS is independent of c if $t = 20$.

● **Ex. 6** *If the straight lines,* $ax + amy + 1 = 0$, $bx + (m+1)by + 1 = 0$ *and* $cx + (m+2)cy + 1 = 0$, $m \neq 0$ *are concurrent, then* a, b, c *are in*

(a) AP only for $m = 1$ (b) AP for all m

(c) GP for all m (d) HP for all m

Sol. (d) The three lines are concurrent if

$$\begin{vmatrix} a & am & 1 \\ b & m+1 & 1 \\ c & (m+2)c & 1 \end{vmatrix} = 0$$

Applying $C_2 \to C_2 - mC_1$, then

$$\begin{vmatrix} a & 0 & 1 \\ b & b & 1 \\ c & 2c & 1 \end{vmatrix} = 0$$

or $a(b - 2c) - 0 + 1(2bc - bc) = 0$

or $b = \frac{2ac}{a+c}$, which is independent of m.

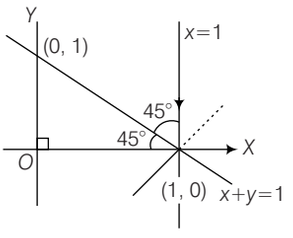
$\therefore$ a, b, c are in HP for all m.

● **Ex. 7** *If a ray travelling the line* $x = 1$ *gets reflected the line* $x + y = 1$, *then the equation of the line along which the reflected ray travels is*

(a) $y = 0$ (b) $x - y = 1$

(c) $x = 0$ (d) None of these

Sol. (a) Reflected ray is X-axis.



$\therefore$ Equation $y = 0$

● **Ex. 8** *Through the point* $P(\alpha, \beta)$, *when* $\alpha\beta > 0$, *the straight line* $\frac{x}{a} + \frac{y}{b} = 1$ *is drawn so as to form with coordinate axes a triangle of area* Δ. *If* $ab > 0$, *then the least value of* Δ *is*

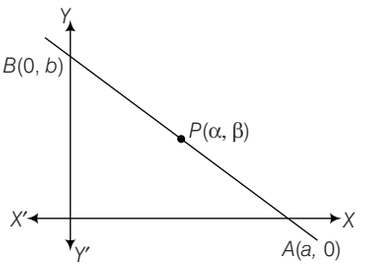
(a) $\alpha\beta$ (b) $2\alpha\beta$

(c) $4\alpha\beta$ (d) $8\alpha\beta$

Sol. (b) Given line is

$$\frac{x}{a} + \frac{y}{b} = 1 \qquad \ldots(i)$$

$\therefore$ $A \equiv (a, 0), B \equiv (0, b)$



$\because$ Area of $(\Delta AOB) = \Delta$

$\therefore$ $\frac{1}{2}|ab| = \Delta \Rightarrow ab = 2\Delta$ $(\because ab > 0)$

Since, the line (i) passes through the point $P(\alpha, \beta)$.

$\therefore$ $\frac{\alpha}{a} + \frac{\beta}{b} = 1 \Rightarrow \frac{\alpha}{a} + \frac{a\beta}{2\Delta} = 1$ $\left(\because b = \frac{2\Delta}{a}\right)$

$\Rightarrow$ $\alpha^2\beta - 2a\Delta + 2\Delta\alpha = 0$

$\because a$ is real

$\therefore$ $D \geq 0$

$\Rightarrow$ $4\Delta^2 - 4\beta(2\Delta\alpha) \geq 0$ or $\Delta \geq 2\alpha\beta$

$\therefore$ Least value of Δ is $2\alpha\beta$.

● **Ex. 9** *The coordinates of the point* P *on the line* $2x + 3y + 1 = 0$, *such that* $|PA - PB|$ *is maximum, where* A *is* $(2, 0)$ *and* B *is* $(0, 2)$ *is*

(a) $(5, -3)$ (b) $(7, -5)$

(c) $(9, -7)$ (d) $(11, -9)$

Sol. (b) $|PA - PB| \leq |AB|$

Maximum value of $|PA - PB|$ is $|AB|$, which is possible only when P, A, B are collinear

if $P(x, y)$, then equation AB is

$$\frac{x}{2} + \frac{y}{2} = 1$$

$\Rightarrow$ $x + y = 2$ ...(i)

Now solving Eq. (i)

and $2x + 3y + 1 = 0$ ...(ii)

Then, we get,

$$x = 7, y = -5$$

$\therefore$ $P \equiv (7, -5)$

● ***Ex. 10*** *Equation of the straight line which belongs to the system of straight lines* $a(2x+y-3)+b(3x+2y-5)=0$ *and is farthest from the point (4, −3) is*

(a) $4x+11y-15=0$ (b) $3x-4y+1=0$

(c) $7x+y-8=0$ (d) None of these

Sol. (b) The system of straight lines $a(2x+y-3)+b(3x+2y-5)=0$ passes through the point of intersection of the lines $2x+y-3=0$ and $3x+2y-5=0$ i.e. (1, 1)

The line of this family which is farthest from $(4,-3)$ is the line through (1, 1) and perpendicular to the line joining (1, 1) and $(4,-3)$

∴ The required line is

$$y-1=\frac{3}{4}(x-1)$$

or $$3x-4y+1=0$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **5 multiple choice examples**. Each example has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

● ***Ex. 11*** *The vertices of a square inscribed in the triangle with vertices* $A(0,0)$, $B(2,1)$ *and* $C(3,0)$, *given that two of its vertices are on the side AC, are*

(a) $\left(\frac{3}{2},0\right)$ (b) $\left(\frac{3}{2},\frac{3}{4}\right)$ (c) $\left(\frac{9}{4},\frac{3}{4}\right)$ (d) $\left(\frac{9}{4},0\right)$

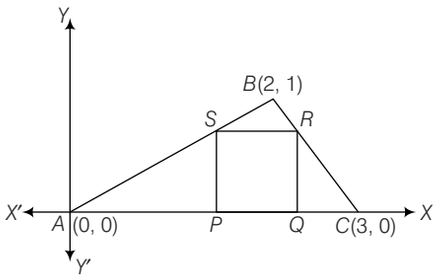
Sol. (a, b, c, d)

Let $PQRS$ be a square inscribed in ΔABC and

$$PQ=QR=RS=SP=\lambda \quad \text{(say)}$$

Let $P\equiv(a,0)$,

∴ $Q\equiv(a+\lambda,\lambda)$, $R\equiv(a+\lambda,\lambda)$ and $S\equiv(a,\lambda)$



Now equation of AB is

$$x-2y=0 \quad \text{...(i)}$$

and equation of BC is

$$x+y-3=0 \quad \text{...(ii)}$$

∵ S lies on AB, then

$$a-2\lambda=0 \quad \text{...(iii)}$$

and R lies on BC, then

$$a+\lambda+\lambda-3=0 \text{ or } a+2\lambda-3=0 \quad \text{...(iv)}$$

From Eqs. (iii) and (iv), we get $a=\frac{3}{2}, \lambda=\frac{3}{4}$

Hence, $P\equiv\left(\frac{3}{2},0\right)$, $Q\equiv\left(\frac{9}{4},0\right)$,

$R\equiv\left(\frac{9}{4},\frac{3}{2}\right)$, $S=\left(\frac{3}{2},\frac{3}{4}\right)$

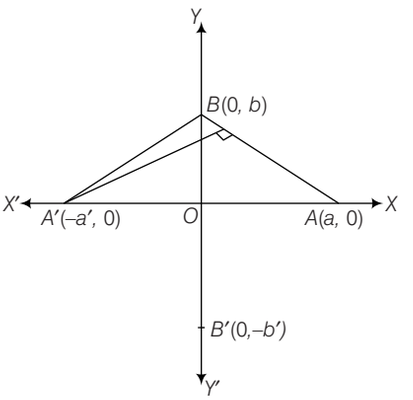
● ***Ex. 12*** *Line* $\frac{x}{a}+\frac{y}{b}=1$ *cuts the coordinate axes at* $A(a,0)$ *and* $B(0,b)$ *and the line* $\frac{x}{a'}+\frac{y}{b'}=-1$ *at* $A'(-a',0)$ *and* $B'(0,-b')$. *If the points A, B, A′, B′ are concyclic, then the orthocentre of the triangle ABA′ is*

(a) (0, 0) (b) $(0, b')$

(c) $\left(0,\frac{-aa'}{b}\right)$ (d) $\left(0,\frac{bb'}{a}\right)$

Sol. (b, c)

∵ A, B, A', B' are concyclic then,



$$OA\cdot OA'=OB\cdot OB'$$

or $$(a)\cdot(-a')=(b)\cdot(-b')$$

or $$aa'=bb' \quad \text{...(i)}$$

The equation of altitude through A' is

$$y-0=\frac{a}{b}(x+a')$$

It intersects the altitude

$$x=0 \text{ at } y=\frac{aa'}{b}$$

∴ Orthocentre is $\left(0,\frac{aa'}{b}\right)$ or $(0,b')$ [from Eq. (i)]

● ***Ex. 13*** *Two straight lines $u=0$ and $v=0$ passes through the origin and angle between them is $\tan^{-1}\left(\frac{7}{9}\right)$. If the ratio of the slope of $v=0$ and $u=0$ is $\frac{9}{2}$, then their equations are*

(a) $y=3x$ and $3y=2x$
(b) $2y=3x$ and $3y=x$
(c) $y+3x=0$ and $3y+2x=0$
(d) $2y+3x=0$ and $3y+x=0$

Sol. (a, b, c, d)

Let the slope of $u=0$ be m, then the slope of $v=0$ is $\frac{9m}{2}$.

Therefore, $$\left|\frac{m-\frac{9m}{2}}{1+m\times\frac{9m}{2}}\right|=\frac{7}{9}$$

or $$\left|\frac{-7m}{2+9m^2}\right|=\frac{7}{9}$$

$\Rightarrow$ $$9m^2+9m+2=0 \quad \text{or} \quad 9m^2-9m+2=0$$

$\Rightarrow$ $$m=-\frac{2}{3},-\frac{1}{3} \text{ or } m=\frac{2}{3},\frac{1}{3}$$

Therefore, the equation of lines are
(i) $2x+3y=0$ and $3x+y=0$
(ii) $x+3y=0$ and $3x+2y=0$
(iii) $2x=3y$ and $3x=y$
(iv) $x=3y$ and $3x=2y$

● ***Ex. 14*** *Two sides of a rhombus OABC (lying entirely in the first or third quadrant) of are equal to 2 sq units are $y=\frac{x}{\sqrt{3}}$, $y=\sqrt{3}x$. Then the possible coordinates of B is/are (O being the origin)*

(a) $(1+\sqrt{3},1+\sqrt{3})$ (b) $(-1-\sqrt{3},-1-\sqrt{3})$
(c) $(3+\sqrt{3},3+\sqrt{3})$ (d) $(\sqrt{3}-1,\sqrt{3}-1)$

Sol. (a, b)

Here, $\angle COA=30°$

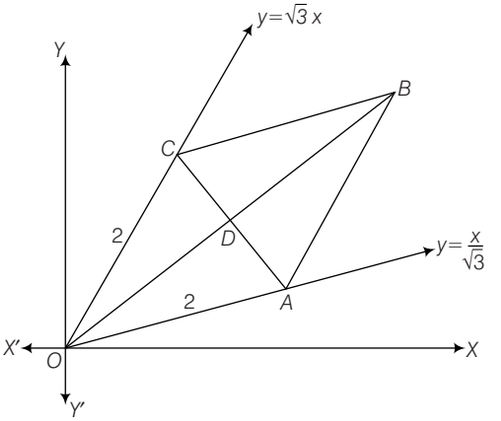
Let $OA=AB=BC=CO=x$

$\because$ Area of rhombus $OABC$

$$=2\times\frac{1}{2}\times x\times x\sin 30°$$

$$=\frac{x^2}{2}=2 \qquad \text{[given]}$$

$\therefore$ $x=2$



Coordinates of A and C are $(\sqrt{3},1)$ and $(1,\sqrt{3})$ in I quadrant and in III quadrant are $(-\sqrt{3},-1)$ and $(-1,-\sqrt{3})$

Hence, coordinates of B are $(\sqrt{3}+1,\sqrt{3}+1)$ and $(-\sqrt{3}-1,-\sqrt{3}-1)$

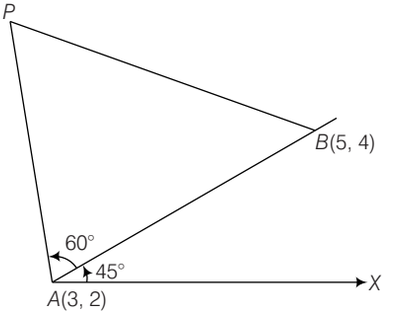
● ***Ex. 15*** *A and B are two fixed points whose coordinates are (3, 2) and (5, 4) respectively. The coordinates of a point P, if ABP is an equilateral triangle are*

(a) $(4-\sqrt{3},3+\sqrt{3})$ (b) $(4+\sqrt{3},3-\sqrt{3})$
(c) $(3-\sqrt{3},4+\sqrt{3})$ (d) $(3+\sqrt{3},4-\sqrt{3})$

Sol. (a, b)

$\because$ $AB=AP=BP=2\sqrt{2}$

$\therefore$ Coordinates of P are $(3+2\sqrt{2}\cos 105°,\ 2+2\sqrt{2}\sin 105°)$



or $(3-(\sqrt{3}-1),2+\sqrt{3}+1)$

or $(4-\sqrt{3},3+\sqrt{3})$

If P below AB, then coordinates of P are

$(3+2\sqrt{2}\cos 15°,2-2\sqrt{2}\sin 15°)$

or $[(3+\sqrt{3}+1,2-(\sqrt{3}-1)]$

or $(4+\sqrt{3},3-\sqrt{3})$

JEE Type Solved Examples : Paragraph Based Questions

- This section contains **2 solved paragraphs** based upon each of the paragraph **3 multiple choice questions** have to be answered. Each of these question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Paragraph I

(Q. Nos. 16 to18)

Let $d(P, OA) \le \min\cdot\{d(P, AB), d(P, BC), d(P, OC)\}$, where d denotes the distance from the point to the corresponding the line and R be the region consisting of all those points P inside the rectangle OABC such that $O \equiv (0, 0)$, $A \equiv (3, 0)$, $B \equiv (3, 2)$ and $C \equiv (0, 2)$. Let M be the peak of region R.

16. Length of the perpendicular from M to OA is

(a) 4 (b) 3 (c) 2 (d) 1

17. If λ be the perimeter of region R, then λ is

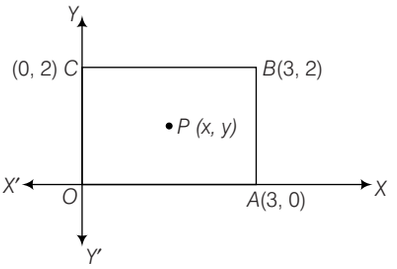
(a) $4 - \sqrt{2}$ (b) $4 + \sqrt{2}$ (c) $4 + 2\sqrt{2}$ (d) 10

18. If Δ be the area of region R, then Δ is

(a) 2 (b) 4 (c) 6 (d) 8

Sol. Let $P \equiv (x, y)$

$\because$ $d(P, OA) \le \min\cdot\{d(P, AB), d(P, BC), d(P, OC)\}$



$\Rightarrow$ $|y| \le \min\{|3 - x|, |2 - y|, |x|\}$

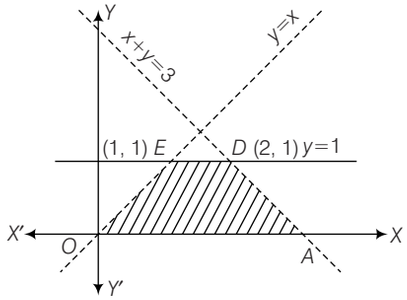
As the rectangle $OABC$ lies in I quadrant,

$\therefore$ $y \le \min\cdot[3 - x, 2 - y. x]$

We draw the graph of

$y = 3 - x, y = 2 - y, y = x$

or $x + y = 3, y = 1, y = x$



$\therefore$ $E \equiv (1, 1)$ and $D \equiv (2, 1)$

16. (d) $\because$ M lie on $y = 1$

$\therefore$ Length of $\perp$ from M to OA is 1.

17. (c) λ = Perimeter of region R

$= OA + AD + DE + EO$

$= 3 + \sqrt{2} + 1 + \sqrt{2}$

$= 4 + 2\sqrt{2}$

18. (a) Δ = Area of region R

$= \frac{1}{2}(OA + ED) \times 1$

$= \frac{1}{2}(3 + 1) = 2$

Paragraph II

(Q. Nos. 19 to 21)

A variable straight line 'L' is drawn through $O(0, 0)$ to meet this lines $L_1 : y - x - 10 = 0$ and $L_2 : y - x - 20 = 0$ at the points A and B respectively.

19. A point P is taken on 'L' such that $\frac{2}{OP} = \frac{1}{OA} + \frac{1}{OB}$, then the locus of P is

(a) $3x + 3y - 40 = 0$ (b) $3x + 3y + 40 = 0$

(c) $3x - 3y - 40 = 0$ (d) $3x - 3y + 40 = 0$

20. A point P is taken on 'L' such that $(OP)^2 = OA \cdot OB$, then the locus of P is

(a) $(y - x)^2 = 25$ (b) $(y - x)^2 = 50$

(c) $(y - x)^2 = 100$ (d) $(y - x)^2 = 200$

21. A point P is taken on 'L' such that $\frac{1}{(OP)^2} = \frac{1}{(OA)^2} + \frac{1}{(OB)^2}$, then locus of P is

(a) $(y - x)^2 = 32$ (b) $(y - x)^2 = 64$

(c) $(y - x)^2 = 80$ (d) $(y - x)^2 = 100$

Sol. Let the equation of line 'L' through origin is

$$\frac{x - 0}{\cos\theta} = \frac{y - 0}{\sin\theta} = r$$

$\therefore$ $P \equiv (r\cos\theta, r\sin\theta)$

Let $OA = r_1$ and $OB = r_2$

$\therefore$ $A \equiv (r_1\cos\theta, r_1\sin\theta)$

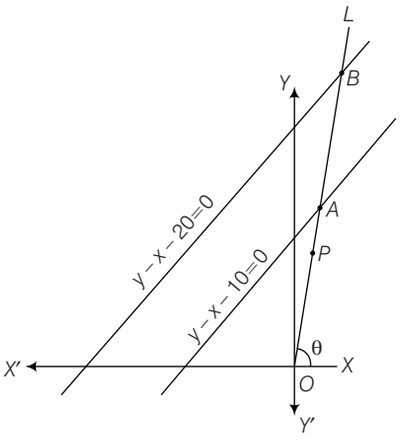
and $B \equiv (r_2\cos\theta, r_2\sin\theta)$

A lies on $L_1 : y - x - 10 = 0$

$\therefore$ $r_1\sin\theta - r_1\cos\theta - 10 = 0$

$\Rightarrow$ $r_1 = \frac{10}{\sin\theta - \cos\theta}$ ...(i)

$\Rightarrow$ B lies on $L_1 : y - x - 20 = 0$



$\therefore \quad r_2 \sin\theta - r_2 \cos\theta - 20 = 0$

$\Rightarrow \quad r_2 = \dfrac{20}{\sin\theta - \cos\theta}$ ...(ii)

19. (d) $\because \quad \dfrac{2}{OP} = \dfrac{1}{OA} + \dfrac{1}{OB} \Rightarrow \dfrac{2}{r} = \dfrac{1}{r_1} + \dfrac{1}{r_2}$

$\Rightarrow \quad \dfrac{2}{r} = \dfrac{\sin\theta - \cos\theta}{10} + \dfrac{\sin\theta - \cos\theta}{20}$ [from Eqs. (i) and (ii)]

or $\quad 2 = \dfrac{r\sin\theta - r\cos\theta}{10} + \dfrac{r\sin\theta - r\cos\theta}{20}$

or $\quad 2 = \dfrac{y - x}{10} + \dfrac{y - x}{20}$ $[\because P \equiv (r\cos, r\sin\theta)]$

$\therefore$ Locus of P is $3x - 3y + 40 = 0$

20. (d) $\because (OP)^2 = OA \cdot OB$

$\Rightarrow \quad r^2 = r_1 \cdot r_2$

$\Rightarrow \quad r^2 = \dfrac{10}{(\sin\theta - \cos\theta)} \cdot \dfrac{20}{(\sin\theta - \cos\theta)}$ [from Eqs. (i) and (ii)]

or $\quad (r\sin\theta - r\cos\theta)^2 = 200$

$\therefore$ Locus of P is $(y - x)^2 = 200$

21. (c) $\because \quad \dfrac{1}{(OP)^2} = \dfrac{1}{(OA)^2} + \dfrac{1}{(OB)^2}$

$\Rightarrow \quad \dfrac{1}{r^2} = \dfrac{1}{r_1^2} + \dfrac{1}{r_2^2}$

$\Rightarrow \quad \dfrac{1}{r^2} = \dfrac{(\sin\theta - \cos\theta)^2}{100} + \dfrac{(\sin\theta - \cos\theta)^2}{400}$

or $\quad 400 = 4(r\sin\theta - r\cos\theta)^2 + (r\sin\theta - r\cos\theta)^2$

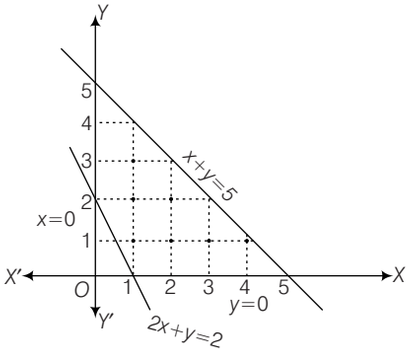
$\therefore$ Locus of P is $(y - x)^2 = 80$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **2 examples**. The answer to each example is **a single digit integer,** ranging from 0 to 9 (both inclusive).

● ***Ex. 22*** *$P(x, y)$ is called a natural point if $x, y \in N$. The total number of points lying inside the quadrilateral formed by the lines $2x + y = 2$, $x = 0$, $y = 0$ and $x + y = 5$ is*

Sol. (6) First, we construct the graph of the given quadrilateral.



It is clear from the graph that there are six points lying inside the quadrilateral.

● ***Ex. 23*** *The distance of the point (x, y) from the origin is defined as $d = \max\cdot\{|x|, |y|\}$. Then the distance of the common point for the family of lines $x(1 + \lambda) + \lambda y + 2 + \lambda = 0$ (λ being parameter) from the origin is*

Sol. (2) Given family of lines is

$$x(1 + \lambda) + \lambda y + 2 + \lambda = 0$$

$\Rightarrow \quad (x + 2) + \lambda(x + y + 1) = 0$

for common point or fixed point

$$x + 2 = 0$$

and $\quad x + y + 1 = 0$

or $\quad x = -2, y = 1$

$\therefore$ Common point is $(-2, 1)$

or $\quad d = \max\{|-2|, |1|\}$

$= \max\{2, 1\} = 2$

JEE Type Solved Examples :
Matching Type Questions

- This section contains **2 examples**. Examples 24 and 25 has four statements (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

● ***Ex. 24*** *Consider the following linear equations x and y*

$$ax + by + c = 0$$
$$bx + cy + a = 0$$
$$cx + ay + b = 0$$

	Column I		Column II
(A)	$a+b+c \neq 0$ and $a^2+b^2+c^2 = ab+bc+ca$	(p)	Lines are sides of a triangle
(B)	$a+b+c = 0$ and $a^2+b^2+c^2 \neq ab+bc+ca$	(q)	Lines are different and concurrent
(C)	$a+b+c \neq 0$ and $a^2+b^2+c^2 \neq ab+bc+ca$	(r)	Number of pair (x, y) satisfying the equations are infinite
(D)	$a+b+c = 0$ and $a^2+b^2+c^2 = ab+bc+ca$	(s)	Lines are identical

Sol. (A) $\rightarrow (r, s)$; (B) $\rightarrow (q)$; (C) $\rightarrow (p)$; (D) $\rightarrow (r)$

(A) if $a+b+c \neq 0$ and $a^2+b^2+c^2 = ab+bc+ca$

or $\frac{1}{2}\{(a-b)^2+(b-c)^2+(c-a)^2\} = 0$

or $a-b=0, b-c=0, c-a=0$

or $a=b=c \Rightarrow$ All the lines an identical

and number of pair (x, y) are infinite.

(B) If $a+b+c=0$ and $a^2+b^2+c^2 \neq ab+bc+ca$

$\Rightarrow a+b+c=0$, but a, b, c are not simultaneously equal.

Hence, lines are different and concurrent.

(C) If $a+b+c \neq 0$ and $a^2+b^2+c^2 \neq ab+bc+ca$

$$\Rightarrow \Delta = \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} \neq 0$$ and a, b, c are not all simultaneously equal.

$\therefore$ Lines are sides of a triangle.

(D) If $a+b+c=0$ and $a^2+b^2+c^2 = ab+bc+ca$

$\Rightarrow \Delta = 0$ and $a=b=c$

$\therefore$ Equations are satisfied for any (x, y).

● ***Ex. 25*** *The equation of the sides of a triangle are* $x+2y+1=0, 2x+y+2=0$ *and* $px+qy+1=0$ *and area of triangle is* Δ.

	Column I		Column II
(A)	$p=2, q=3$, then 8Δ is divisible by	(p)	3
(B)	$p=3, q=2$, then 8Δ is divisible by	(q)	4
(C)	$p=3, q=4$, then 10Δ is divisible by	(r)	6
(D)	$p=4, q=3$, then 20Δ is divisible by	(s)	9

Sol. (A) $\rightarrow (p)$; (B) $\rightarrow (p, q, r)$; (C) $\rightarrow (p, r)$; (D) $\rightarrow (p, s)$

$\because$ $\Delta = \frac{D^2}{2|C_1\ C_2\ C_3|}$, where

$$D = \begin{vmatrix} 1 & 2 & 1 \\ 2 & 1 & 2 \\ p & q & 1 \end{vmatrix} = 3(p-1)$$

and C_1, C_2, C_3 are co-factors of third column, then

$C_1 = 2q-p, C_2 = 2p-q, C_3 = -3$

$\therefore$ $\Delta = \frac{3(p-1)^2}{2|2q-p||2p-q|}$

(A) for $p=2, q=3$

$\Rightarrow \Delta = \frac{3}{8}$

$\therefore 8\Delta = 3$

(B) for $p=3, q=2$

$\Rightarrow \Delta = \frac{3}{2}$

$\therefore 8\Delta = 12$

(C) for $p=3, q=4$

$\Rightarrow \Delta = \frac{6}{10}$

$\therefore 10\Delta = 6$

(D) for $p=4, q=3$

$\Rightarrow \Delta = \frac{27}{20}$

$\therefore 20\Delta = 27$

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** (Ex. Nos. 26 and 27) are Assertion-Reason type examples. Each of these examples contains two statements.

Statement I (Assertion) and **Statement II** (Reason)

Each of these examples also has four alternative choices. Only one of which is the correct answer. You have to select the correct choice as given below.

(a) Statement I is true, statement II is true; statement II is a correct explanation for statement I.

(b) Statement I is true, statement II is true; statement II is not a correct explanation for statement I.

(c) Statement I is true, statement II is false.

(d) Statement I is false, statement II is true.

● ***Ex. 26*** *Consider the lines,* $L_1 : \frac{x}{3} + \frac{y}{4} = 1; L_2 : \frac{x}{4} + \frac{y}{3} = 1;$ $L_3 : \frac{x}{3} + \frac{y}{4} = 2$ *and* $L_4 : \frac{x}{4} + \frac{y}{3} = 2$

Statement I : The quadrilateral formed by these four lines is a rhombus.

Statement II : If diagonals of a quadrilateral formed by any four lines are unequal and intersect at right angle, then it is a rhombus.

Sol. (c) $\because$ L_1, L_3 are parallel.

$\therefore$ Distance between L_1 and $L_3 = \dfrac{1}{\sqrt{\left(\frac{1}{9} + \frac{1}{16}\right)}} = \dfrac{12}{5}$ and

L_2, L_4 are parallel.

$\therefore$ Distance between L_2 and $L_4 = \dfrac{1}{\sqrt{\left(\frac{1}{16} + \frac{1}{9}\right)}} = \dfrac{12}{5}$

$\therefore$ Distance between L_1 and L_3 = Distance between L_2 and L_4.

$\therefore$ Quadrilateral formed by L_1, L_2, L_3, L_4 is a rhombus.

Hence, statement I is true and statement II is false.

● ***Ex. 27***

Statement I : Incentre of the triangle formed by the lines whose sides are $3x + 4y = 0; 5x - 12y = 0$ and $y - 15 = 0$ is the point P whose coordinates are (1, 8).

Statement II : Point P equidistant from the three lines forming the triangle.

Sol. (b) Let $L_1 \equiv 3x + 4y = 0$,

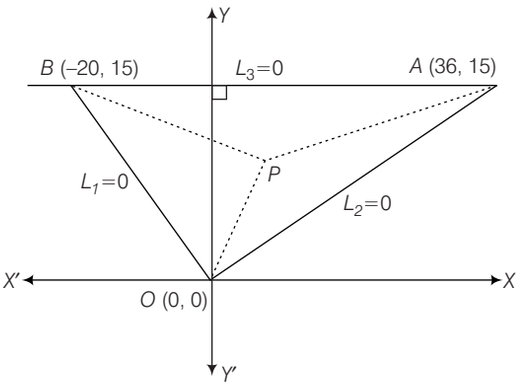
$L_2 \equiv 5x - 12y = 0$ and $L_3 \equiv y - 15 = 0$

Length of $\perp$ from P to $L_1 = \dfrac{3 + 32}{5} = 7$

Length of $\perp$ from P to $L_2 = \dfrac{|5 - 96|}{13} = 7$

and Length of $\perp$ from P to $L_3 = \dfrac{|8 - 15|}{1} = 7$

$\therefore$ Statement II is true



Also, Area of $\Delta OPA = \dfrac{1}{2} \times OA \times 7$

$= \dfrac{1}{2} \times 39 \times 7 = \Delta_1$

Area of $\Delta OPB = \dfrac{1}{2} \times OB \times 7$

$= \dfrac{1}{2} \times 25 \times 7 = \Delta_2$

and Area of $\Delta APB = \dfrac{1}{2} \times AB \times 7$

$= \dfrac{1}{2} \times 56 \times 7 = \Delta_3$

$\therefore$ $\Delta_1 + \Delta_2 + \Delta_3 = \dfrac{7}{2}(39 + 25 + 56)$

$= \dfrac{7 \times 120}{2} = \dfrac{1}{2} \times 56 \times 15 =$ Area of ΔAOB

$\Rightarrow P$ inside the triangle.

Hence, both statements are true and statement II is not correct explanation of statement I.

Subjective Type Examples

■ In this section, there are **15 subjective solved examples**.

● ***Ex. 28.*** *If x-coordinates of two points B and C are the roots of equation $x^2 + 4x + 3 = 0$ and their y-coordinates are the roots of equation $x^2 - x - 6 = 0$. If x-coordinate of B is less than x-coordinate of C and y-coordinate of B is greater than the y-coordinate of C and coordinates of a third point A be $(3, -5)$. Find the length of the bisector of the interior angle at A .*

Sol. $\because \quad x^2 + 4x + 3 = 0 \Rightarrow \quad x = -1, -3$

and $\quad x^2 - x - 6 = 0 \Rightarrow \quad x = -2, 3$

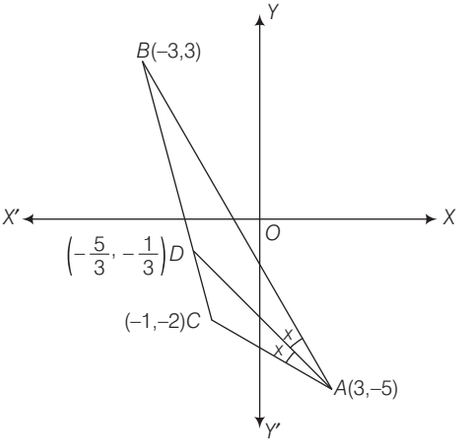
Also given that x and y-coordinates of B are respectively less than and greater than the corresponding coordinates of C.

$\therefore \quad B \equiv (-3, 3) \quad \text{and} \quad C \equiv (-1, -2)$

Now $\quad AB = \sqrt{(3+3)^2 + (-5-3)^2} = 10$

and $\quad AC = \sqrt{(3+1)^2 + (-5+2)^2} = 5$

$\therefore \quad \dfrac{AB}{AC} = \dfrac{2}{1}$



Let AD be the bisector of $\angle BAC$, then

$$\frac{BD}{DC} = \frac{AB}{AC} = \frac{2}{1}$$

Thus D divides BC internally in the ratio 2 : 1

$\therefore \quad D \equiv \left(\dfrac{2(-1) + 1(-3)}{2+1}, \dfrac{2(-2) + 1(3)}{2+1}\right)$

Thus, $\quad D \equiv \left(-\dfrac{5}{3}, -\dfrac{1}{3}\right)$

Now, $\quad AD = \sqrt{\left(3 + \dfrac{5}{3}\right)^2 + \left(-5 + \dfrac{1}{3}\right)^2}$

$$= \sqrt{\frac{196}{9} + \frac{196}{9}} = \frac{14\sqrt{2}}{3} \text{ units.}$$

● ***Ex. 29.*** *Let the sides of a parallelogram be $u = p, u = q, v = r$ and $v = s$ where, $u = lx + my + n$ and $v = l'x + m'y + n'$. Show that the equation of the diagonal through the point of intersection of $u = p$ and $v = r$ and $u = q$ and $v = s$, is given by* $\begin{vmatrix} u & v & 1 \\ p & r & 1 \\ q & s & 1 \end{vmatrix} = 0$

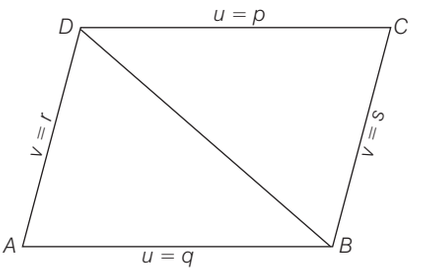
Sol. Equation of the line through point of intersection D of lines $u - p = 0$ and $v - r = 0$ is

$$(u - p) + \lambda (v - r) = 0 \qquad \ldots(i)$$

it is also passing through $u = q$ and $v = s$, then Eq. (i) becomes

$$(q - p) + \lambda (s - r) = 0$$

$\therefore \quad \lambda = -\dfrac{(q-p)}{(s-r)} \qquad \ldots(ii)$



From Eqs. (i) and (ii), we get

$$(u - p) - \frac{(q-p)}{(s-r)}(v - r) = 0$$

$$\Rightarrow \; u(s - r) - p(s - r) - v(q - p) + r(q - p) = 0$$

$$\Rightarrow \quad u(r - s) - v(p - q) + ps - qr = 0$$

$$\Rightarrow \quad \begin{vmatrix} u & v & 1 \\ p & r & 1 \\ q & s & 1 \end{vmatrix} = 0$$

● ***Ex. 30.*** *The vertices B and C of a triangle ABC lie on the lines $3y = 4x$ and $y = 0$ respectively and the side BC passes through the point $\left(\dfrac{2}{3}, \dfrac{2}{3}\right)$. If ABOC is a rhombus, O being the origin, find the equation of the line BC and the coordinates of A.*

Sol. Let the side of the rhombus be a

$\therefore \quad OB = BA = AC = CO = a$

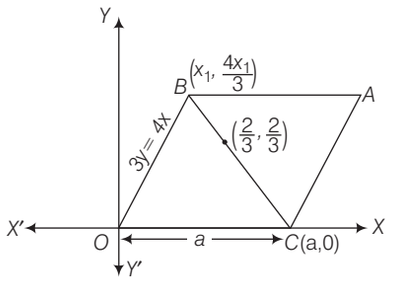
Co-ordinates of A is $\left(a + x_1, \dfrac{4x_1}{3}\right)$

$\therefore \quad (OB)^2 = (BA)^2 = (AC)^2 = (CO)^2 = a^2 \Rightarrow (OB)^2 = a^2$

$$\Rightarrow \quad x_1^2 + \frac{16x_1^2}{9} = a^2 \Rightarrow \frac{25x_1^2}{9} = a^2 \Rightarrow a = \frac{5x_1}{3}$$

$$\therefore \quad C \equiv \left(\frac{5x_1}{3}, 0\right), \quad A \equiv \left(\frac{8x_1}{3}, \frac{4x_1}{3}\right),$$

$$B \equiv \left(x_1, \frac{4x_1}{3}\right), \quad O \equiv (0, 0)$$



$\therefore$ Equation of BC

$$y - 0 = \frac{\frac{4x_1}{3} - 0}{x_1 - \frac{5x_1}{3}}\left(x - \frac{5x_1}{3}\right)$$

$$\Rightarrow \quad y = -2x + \frac{10x_1}{3} \qquad \ldots(1)$$

it is passing through $\left(\frac{2}{3}, \frac{2}{3}\right)$, then

$$\frac{2}{3} = -\frac{4}{3} + \frac{10x_1}{3}$$

$$\Rightarrow \quad 2 = \frac{10x_1}{3}$$

$$\therefore \quad x_1 = \frac{3}{5}$$

Hence, coordinates are

$$C \equiv (1, 0), \quad A \equiv \left(\frac{8}{5}, \frac{4}{5}\right)$$

$$B \equiv \left(\frac{3}{5}, \frac{4}{5}\right), \quad O \equiv (0, 0)$$

From Eq. (i), equation of BC is

$$y = -2x + 2$$

$$\Rightarrow \quad 2x + y = 2$$

● ***Ex. 31*** *The ends AB of a straight line segment of constant length c slide upon the fixed rectangular axes OX and OY respectively. If the rectangle OAPB be completed, then show that the locus of the foot of perpendicular drawn from P to AB is* $x^{2/3} + y^{2/3} = c^{2/3}$.

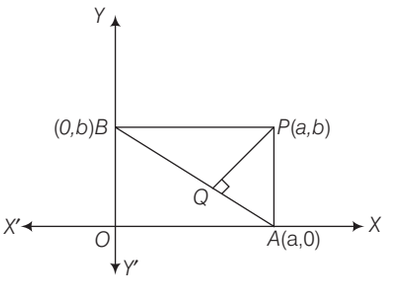
Sol. Let $A \equiv (a, 0)$, $B \equiv (0, b)$ then $P \equiv (a, b)$

Since $AB = c$

$$\sqrt{a^2 + b^2} = c$$

or $$a^2 + b^2 = c^2 \qquad \ldots(i)$$

and let $Q \equiv (x_1, y_1)$



$\because$ $PQ \perp AB$

$\therefore$ Slope of $PQ \times$ Slope of $AB = -1$

$$\Rightarrow \quad \left(\frac{b - y_1}{a - x_1}\right) \times \left(\frac{b - 0}{0 - a}\right) = -1$$

$$\Rightarrow \quad ax_1 - by_1 = a^2 - b^2 \qquad \ldots(ii)$$

$\because$ Equation of AB is $\frac{x}{a} + \frac{y}{b} = 1$

But Q lies on AB then $\frac{x_1}{a} + \frac{y_1}{b} = 1$

$$\Rightarrow \quad bx_1 + ay_1 = ab \qquad \ldots(iii)$$

From Eqs. (ii) and (iii), we get

$$x_1 = \frac{a^3}{a^2 + b^2}, \; y_1 = \frac{b^3}{a^2 + b^2}$$

Now, $$x_1^{2/3} + y_1^{2/3} = \frac{(a^2 + b^2)}{(a^2 + b^2)^{2/3}}$$

$$= (a^2 + b^2)^{1/3} = c^{2/3} \qquad \text{[from Eq. (i)]}$$

Hence, required locus is $x^{2/3} + y^{2/3} = c^{2/3}$.

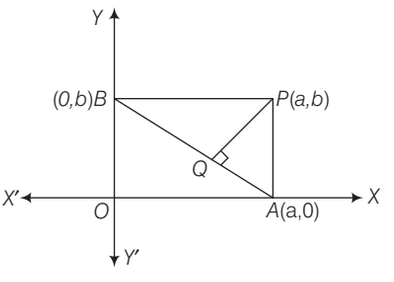
Aliter :

Since, $AB = c$

Let $\angle BAO = \theta$

$\therefore$ $OA = c\cos\theta$ and $OB = c\sin\theta$

$\because$ $OB = PA = c\sin\theta$



In ΔPQA, $$\sin\theta = \frac{QA}{PA} = \frac{QA}{c\sin\theta}$$

$\therefore$ $$QA = c\sin^2\theta$$

Now, in ΔQAM, $$\sin\theta = \frac{QM}{QA} = \frac{QM}{c\sin^2\theta}$$

$\therefore$ $$QM = c\sin^3\theta$$

and $$\cos\theta = \frac{MA}{QA} = \frac{MA}{c\sin^2\theta}$$

$\Rightarrow$ $$MA = c\sin^2\theta\cos\theta$$

If coordinates of Q be (x_1, y_1)

then $x_1 = OM = OA - MA = c\cos\theta - c\sin^2\theta\cos\theta$

$x_1 = c\cos^3\theta$ ...(i)

and $y_1 = MQ = c\sin^3\theta$ ...(ii)

From Eqs. (i) and (ii),

$$x_1^{2/3} + y_1^{2/3} = c^{2/3}\cos^2\theta + c^{2/3}\sin^2\theta = c^{2/3}$$

$\Rightarrow$ $x_1^{2/3} + y_1^{2/3} = c^{2/3}$

Hence, locus of Q is $x^{2/3} + y^{2/3} = c^{2/3}$

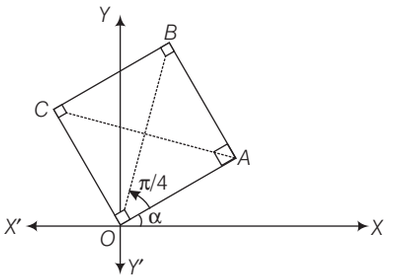
● ***Ex. 32*** *A square lies above the X-axis and has one vertex at the origin. The side passing through the origin makes an angle* $\alpha\ (0 < \alpha < \pi/4)$ *with the positive direction of the X-axis. Prove that the equation of its diagonals are*

$$y(\cos\alpha - \sin\alpha) = x(\sin\alpha + \cos\alpha)$$

and $y(\sin\alpha + \cos\alpha) + x(\cos\alpha - \sin\alpha) = a$

where, is the length of each side of the square.

Sol. Here, $OA = AB = BC = CO = a$



Equation of OB is $y - 0 = \tan\left(\frac{\pi}{4} + \alpha\right)(x - 0)$

$\Rightarrow$ $y\cos\left(\frac{\pi}{4} + \alpha\right) = x\sin\left(\frac{\pi}{4} + \alpha\right)$

$\Rightarrow$ $y(\cos\alpha - \sin\alpha) = x(\cos\alpha + \sin\alpha)$

Hence, equation of diagonal OB is

$$x(\cos\alpha + \sin\alpha) + y(\sin\alpha - \cos\alpha) = 0$$

Coordinates of A are $(a\cos\alpha, a\sin\alpha)$

Diagonal AC is perpendicular to the diagonal OB,

$$\text{Slope of } AC = -\frac{1}{\text{slope of } OB}$$

$$= -\frac{1}{\tan\left(\frac{\pi}{4} + \alpha\right)} = -\cot\left(\frac{\pi}{4} + \alpha\right)$$

Hence, equation of diagonal AC is

$$y - a\sin\alpha = -\cot\left(\frac{\pi}{4} + \alpha\right)(x - a\cos\alpha)$$

$\Rightarrow$ $y - a\sin\alpha = -\left(\frac{\cos\alpha - \sin\alpha}{\cos\alpha + \sin\alpha}\right)(x - a\cos\alpha)$

$\Rightarrow$ $y(\cos\alpha + \sin\alpha) - a\sin\alpha\cos\alpha - a\sin^2\alpha$

$$= -x(\cos\alpha - \sin\alpha) + a\cos^2\alpha - a\sin\alpha\cos\alpha$$

$\Rightarrow$ $x(\cos\alpha - \sin\alpha) + y(\cos\alpha + \sin\alpha) = a$

● ***Ex. 33*** *In a* ΔABC, $A \equiv (\alpha, \beta)$, $B \equiv (1, 2)$, $C \equiv (2, 3)$ *and point A lies on the line* $y = 2x + 3$, *where* $\alpha, \beta \in I$. *If the area of* ΔABC *be such that* $[\Delta] = 2$, *where [.] denotes the greatest integer function, find all possible coordinates of A.*

Sol. $\because$ (α, β) lies on $y = 2x + 3$

then $\beta = 2\alpha + 3$

Thus ,the coordinates of A are $(\alpha, 2\alpha + 3)$

$$\Delta = \frac{1}{2}\left|\begin{vmatrix}\alpha & 2\alpha+3\\ 1 & 2\end{vmatrix} + \begin{vmatrix}1 & 2\\ 2 & 3\end{vmatrix} + \begin{vmatrix}2 & 3\\ \alpha & 2\alpha+3\end{vmatrix}\right|$$

$$= |2\alpha - 2\alpha - 3 + 3 - 4 + 4\alpha + 6 - 3\alpha|$$

$$\Delta = \frac{1}{2}|\alpha + 2|$$

But $[\Delta] = \left[\frac{1}{2}|\alpha + 2|\right] = 2$ (given)

$\therefore$ $2 \le \frac{|\alpha + 2|}{2} < 3$

$\Rightarrow$ $4 \le |\alpha + 2| < 6$

$\Rightarrow$ $4 \le \alpha + 2 < 6$ or $-6 < \alpha + 2 \le -4$

$\Rightarrow$ $2 \le \alpha < 4$ or $-8 < \alpha \le -6$

$\therefore$ $\alpha = 2, 3, -7, -6$

then $\beta = 7, 9, -11, -9$

Hence, coordinates of A are $(2, 7), (3, 9), (-7, -11)$ and $(-6, -9)$.

● ***Ex. 34*** *Find the values of non-negative real numbers* $\lambda_1, \lambda_2, \lambda_3, \mu_1, \mu_2, \mu_3$ *such that the algebraic sum of the perpendiculars drawn from points* $(\lambda_1, 4), (\lambda_2, 5), (\lambda_3, -3), (2, \mu_1), (3, \mu_2)$ *and* $(7, \mu_3)$ *on a variable line passing through* $(2, 1)$ *is zero.*

Sol. Let the equation of the variable line be $ax + by + c = 0$. It is given that

$$\Rightarrow \frac{(a\lambda_1 + 4b + c)}{\sqrt{(a^2 + b^2)}} + \frac{(a\lambda_2 + 5b + c)}{\sqrt{(a^2 + b^2)}} + \frac{(a\lambda_3 - 3b + c)}{\sqrt{(a^2 + b^2)}} + \frac{(2a + b\mu_1 + c)}{\sqrt{(a^2 + b^2)}} + \frac{(3a + b\mu_2 + c)}{\sqrt{(a^2 + b^2)}} + \frac{(7a + b\mu_3 + c)}{\sqrt{(a^2 + b^2)}} = 0$$

$\Rightarrow$ $a(\lambda_1 + \lambda_2 + \lambda_3 + 12) + b(\mu_1 + \mu_2 + \mu_3 + 6) + 6c = 0$

$\Rightarrow$ $a\left(\frac{\lambda_1 + \lambda_2 + \lambda_3 + 12}{6}\right) + b\left(\frac{\mu_1 + \mu_2 + \mu_3 + 6}{6}\right) + c = 0$ ...(i)

But the line passes through (2,1), therefore

$$2a + b + c = 0 \quad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$\frac{\lambda_1 + \lambda_2 + \lambda_3 + 12}{6} = 2 \text{ and } \frac{\mu_1 + \mu_2 + \mu_3 + 6}{6} = 1$$

$\Rightarrow$ $\lambda_1 + \lambda_2 + \lambda_3 = 0$ and $\mu_1 + \mu_2 + \mu_3 = 0$

$\Rightarrow$ $\lambda_1 = \lambda_2 = \lambda_3$ and $\mu_1 = \mu_2 = \mu_3$ $[\because \lambda_i, \mu_i \ge 0$ for all i $]$

$\lambda_1 = \lambda_2 = \lambda_3 = \alpha$ (say)

and $\mu_1 = \mu_2 = \mu_3 = \beta$ (say)

where $\alpha \ge 0$ and $\beta \ge 0$.

● **Ex. 35** *The three sides of a triangle are* $L_r \equiv x\cos\theta_r + y\sin\theta_r - p_r = 0$, *where r= 1,2,3. Show that the orthocentre is given by* $L_1\cos(\theta_2 - \theta_3) = L_2\cos(\theta_3 - \theta_1) = L_3\cos(\theta_1 - \theta_2)$.

Sol. The given lines are

$$L_1 \equiv x\cos\theta_1 + y\sin\theta_1 - p_1 = 0$$
$$L_2 \equiv x\cos\theta_2 + y\sin\theta_2 - p_2 = 0$$
$$L_3 \equiv x\cos\theta_3 + y\sin\theta_3 - p_3 = 0$$

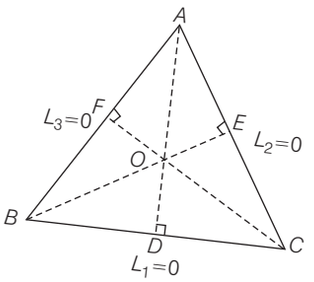
Now, equation of AD is $L_2 + \lambda L_3 = 0$ ...(i)

$\Rightarrow (x\cos\theta_2 + y\sin\theta_2 - p_2) + \lambda(x\cos\theta_3 + y\sin\theta_3 - p_3) = 0$

$\Rightarrow x(\cos\theta_2 + \lambda\cos\theta_3) + y(\sin\theta_2 + \lambda\sin\theta_3) - (p_2 + \lambda p_3) = 0$

$\therefore$ Slope of $AD = -\dfrac{(\cos\theta_2 + \lambda\cos\theta_3)}{(\sin\theta_2 + \lambda\sin\theta_3)}$

and Slope of $BC = -\dfrac{\cos\theta_1}{\sin\theta_1}$



Since, $AD \perp BC$

$\therefore$ Slope of $BC \times$ slope of $AD = -1$

$\Rightarrow -\dfrac{\cos\theta_1}{\sin\theta_1} \times \left[-\dfrac{(\cos\theta_2 + \lambda\cos\theta_3)}{(\sin\theta_2 + \lambda\sin\theta_3)}\right] = -1$

$\Rightarrow \cos\theta_1\cos\theta_2 + \lambda\cos\theta_3\cos\theta_1 = -\sin\theta_1\sin\theta_2 - \lambda\sin\theta_3\sin\theta_1$

$\Rightarrow \cos(\theta_1 - \theta_2) + \lambda\cos(\theta_3 - \theta_1) = 0$

$\therefore \lambda = -\dfrac{\cos(\theta_1 - \theta_2)}{\cos(\theta_3 - \theta_1)}$

Now from Eq. (i),

$$L_2 - \frac{\cos(\theta_1 - \theta_2)}{\cos(\theta_3 - \theta_1)} L_3 = 0$$

$\therefore$ $L_2\cos(\theta_3 - \theta_1) = L_3\cos(\theta_1 - \theta_2)$ ...(ii)

Similarly, we can obtain equation of altitude BE as

$$L_3\cos(\theta_1 - \theta_2) = L_1\cos(\theta_2 - \theta_3) \quad ...(iii)$$

From Eqs. (ii) and (iii), we get

$$L_1\cos(\theta_2 - \theta_3) = L_2\cos(\theta_3 - \theta_1) = L_3\cos(\theta_1 - \theta_2)$$

● **Ex. 36** *Let (h, k) be a fixed point, where* $h > 0, k > 0$. *A straight line passing through this point cuts the positive direction of the co-ordinate axes at the points P and Q. Find the minimum area of the triangle OPQ ,O being the origin.*

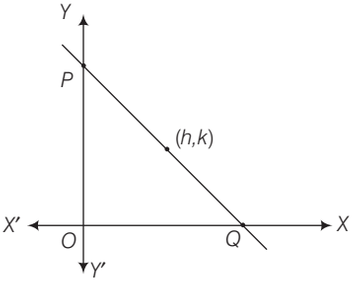
Sol. Equation of any line passing through the fixed point (h, k) and having slope m can be taken as

$$y - k = m(x - h) \quad ...(i)$$

$\Rightarrow \dfrac{y}{m} - \dfrac{k}{m} = x - h$ or $x - \dfrac{y}{m} = h - \dfrac{k}{m}$

$\Rightarrow \dfrac{x}{\left(h - \dfrac{k}{m}\right)} - \dfrac{y}{m\left(h - \dfrac{k}{m}\right)} = 1$

$\Rightarrow \dfrac{x}{\left(h - \dfrac{k}{m}\right)} + \dfrac{y}{(k - mh)} = 1$



$\therefore$ $OQ = h - \dfrac{k}{m}$ and $OP = k - mh$

Area of triangle $OPQ = \dfrac{1}{2}.OQ.OP = \dfrac{1}{2}.\left(h - \dfrac{k}{m}\right)(k - mh)$

$\Rightarrow = \dfrac{1}{2}\left(2hk - mh^2 - \dfrac{k^2}{m}\right)$

$\Rightarrow A(m) = hk - \dfrac{mh^2}{2} - \dfrac{k^2}{2m}$ ...(ii)

To minimise, $\dfrac{dA}{dm} = 0$

$\Rightarrow 0 - \dfrac{h^2}{2} + \dfrac{k^2}{2m^2} = 0 \Rightarrow m = \pm\dfrac{k}{h}$

$\therefore \left.\dfrac{d^2A}{dm^2}\right| = -\dfrac{2k^2}{2m^3}$

$$\left.\frac{d^2A}{dm^2}\right|_{m=-k/h} = \frac{h^3}{k} > 0 \qquad (\because h > 0, k > 0)$$

Hence for $m = -\dfrac{k}{h}$, $A(m)$ is minimum . Put $m = -\dfrac{k}{h}$ in Eq. (ii), we get minimum area.

$\Rightarrow$ Minimum area of $\Delta OPQ = hk + \dfrac{hk}{2} + \dfrac{hk}{2} = 2hk$

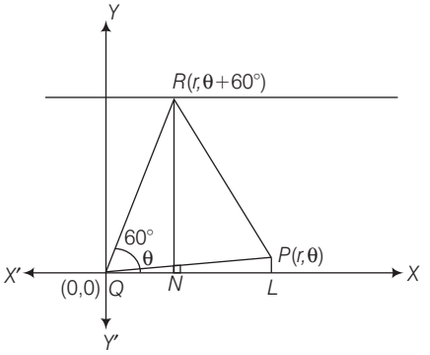
● **Ex. 37** *The distance between two parallel lines is unity. A point P lies between the lines at a distance a from one of them. Find the length of a side of an eqilateral triangle PQR, vertex Q of which lies on one of the parallel lines and vertex R lies on the other line.*

Sol. Let $PQ = QR = RP = r$

and $\angle PQL = \theta$

then $\angle XQR = \theta + 60°$

Given $PL = a$ and $RN = 1$ unit



In ΔPQL

$$\sin\theta = \frac{PL}{QP} = \frac{a}{r}$$

$\therefore$ $a = r\sin\theta$ ...(i)

and in ΔQRN,

$$r\sin(\theta + 60°) = \frac{RN}{QR} = \frac{1}{r}$$

$$\sin(\theta + 60°) = 1$$

$$(\sin\theta \cos 60° + \cos\theta \sin 60°) = 1$$

$\Rightarrow$ $$r\left(\frac{1}{2}\sin\theta + \frac{\sqrt{3}}{2}\cos\theta\right) = 1$$

$\Rightarrow$ $$r\left(\frac{1}{2}\times\frac{a}{r} + \frac{\sqrt{3}}{2}\times\sqrt{1-\frac{a^2}{r^2}}\right) = 1 \quad \text{[from Eq. (i)]}$$

$\Rightarrow$ $$\frac{a}{2} + \frac{\sqrt{3}}{2}\sqrt{(r^2 - a^2)} = 1$$

$\Rightarrow$ $$\frac{\sqrt{3}}{2}\sqrt{(r^2 - a^2)} = 1 - \frac{a}{2}$$

or $$\frac{3}{4}(r^2 - a^2) = 1 + \frac{a^2}{4} - a$$

$\Rightarrow$ $$3r^2 - 3a^2 = 4 + a^2 - 4a$$

$\Rightarrow$ $$3r^2 = 4(a^2 - a + 1)$$

$\therefore$ $$r = \frac{2}{\sqrt{3}}\sqrt{(a^2 - a + 1)}$$

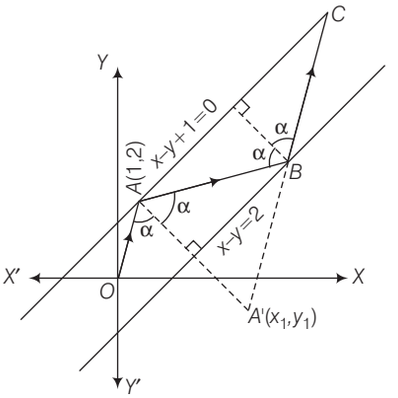
● ***Ex. 38*** *A ray of light travelling along the line OA (O being origin) is reflected by the line mirror $x - y + 1 = 0$, is the point of incidence being A (1, 2) the reflected ray, travelling along AB is again reflected by the line mirror $x - y = 2$, the point of incidence being B. If this reflected ray moves along BC, find the equation of the line BC.*

Sol. Since, slope of $OA = \frac{2-0}{1-0} = 2 = m_1$ (say)

and slope of normal to $x - y + 1 = 0$ is

$$-1 = m_2 \quad \text{(say)}$$

Now, let slope of AB is m



$\because$ OA and AB are equally inclined to normal of $x - y + 1 = 0$ then,

$$\left(\frac{m_1 - m_2}{1 + m_1 m_2}\right) = -\left(\frac{m - m_2}{1 + m m_2}\right)$$

$\Rightarrow$ $$\left(\frac{2-(-1)}{1+2(-1)}\right) = -\left(\frac{m-(-1)}{1+m(-1)}\right)$$

$\Rightarrow$ $3(1 - m) = m + 1$

or $$m = \frac{1}{2}$$

$\therefore$ Equation of AB is

$$y - 2 = \frac{1}{2}(x - 1)$$

or $$x - 2y + 3 = 0$$

Now, solving $x - 2y + 3 = 0$

and $$x - y = 2$$

then, we get $x = 7, y = 5$

i.e. $$B \equiv (7, 5)$$

$\because$ BC is parallel to OA

$\therefore$ Equation of BC is

$$y - 5 = m_1(x - 7)$$

$\Rightarrow$ $$y - 5 = 2(x - 7)$$

i.e. $$2x - y - 9 = 0$$

Aliter :

If image of $A(1, 2)$ with respect to line mirror $x - y = 2$ be $A'(x_1, y_1)$, then

$$\frac{x_1 - 1}{1} = \frac{y_1 - 2}{-1} = \frac{-2(1 - 2 - 2)}{1 + 1}$$

or $$x_1 = 4, y_1 = -1$$

i.e. $$A' \equiv (4, -1)$$

$\because$ BC is parallel to OA

then equation of BC = equation of $A'C$ is

$$y - y_1 = 2(x - x_1)$$

$\Rightarrow$ $$y + 1 = 2(x - 4)$$

or $$2x - y - 9 = 0$$

● ***Ex. 39*** *Consider two lines $L_1 \equiv x - y = 0$ and $L_2 \equiv x + y = 0$ and a moving point $P(x, y)$. Let $d(P, L_i)$, $i = 1, 2$ represents the distance of the point 'P' from L_i. If point 'P' moves in certain region 'R' in such a way $\sum_{i=1}^{2} d(P, L_i) \in [2, 4]$.*

Find the area of region 'R'.

Sol. $\because$ Given $\sum_{i=1}^{2} d(P, L_i) \in [2, 4]$

$$\Rightarrow \quad 2 \le \sum_{i=1}^{2} d(P, L_i) \le 4$$

$$\Rightarrow \quad 2 \le d(P, L_1) + d(P, L_2) \le 4$$

$$\Rightarrow \quad 2 \le \frac{|x-y|}{\sqrt{2}} + \frac{|x+y|}{\sqrt{2}} \le 4$$

$$\Rightarrow \quad 2\sqrt{2} \le |x-y| + |x+y| \le 4\sqrt{2}$$

Case I : If $x - y > 0$, $x + y > 0$

then $\quad 2\sqrt{2} \le (x-y) + (x+y) \le 4\sqrt{2}$

$\Rightarrow \quad 2\sqrt{2} \le 2x \le 4\sqrt{2}$ or $\sqrt{2} \le x \le 2\sqrt{2}$

Case II : If $x - y > 0$, $x + y < 0$

then $\quad 2\sqrt{2} \le (x-y) - (x+y) \le 4\sqrt{2}$

$\Rightarrow \quad 2\sqrt{2} \le -2y \le 4\sqrt{2}$

or $\quad -\sqrt{2} \ge y \ge -2\sqrt{2}$ or $-2\sqrt{2} \le y \le -\sqrt{2}$

Case III : If $x - y < 0$, $x + y > 0$

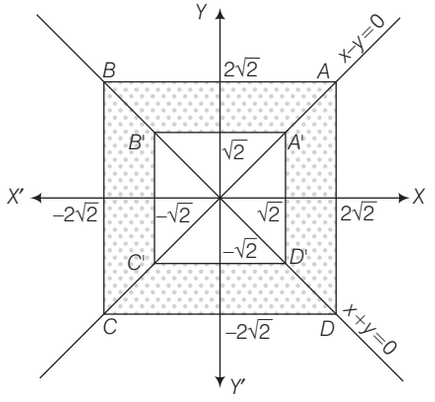
then $\quad 2\sqrt{2} \le -(x-y) + (x+y) \le 4\sqrt{2}$

$\Rightarrow \quad 2\sqrt{2} \le 2y \le 4\sqrt{2}$ or $\sqrt{2} \le y \le 2\sqrt{2}$

Case IV : If $x - y < 0$, $x + y < 0$

then $\quad 2\sqrt{2} \le -(x-y) - (x+y) \le 4\sqrt{2}$

$\Rightarrow \quad 2\sqrt{2} \le -2x \le 4\sqrt{2}$



or $\quad -\sqrt{2} \ge x \ge -2\sqrt{2}$

or $\quad -2\sqrt{2} \le x \le -\sqrt{2}$

Combining all cases, we get

$$x \in [-2\sqrt{2}, -\sqrt{2}] \cup [\sqrt{2}, 2\sqrt{2}]$$

and $\quad y \in [-2\sqrt{2}, -\sqrt{2}] \cup [\sqrt{2}, 2\sqrt{2}]$

Hence, area of the required region

$$= (4\sqrt{2})^2 - (2\sqrt{2})^2$$

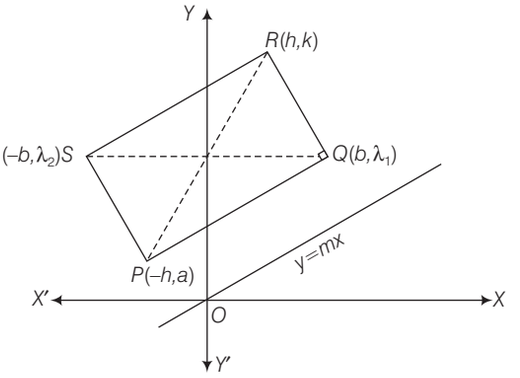
$$= 32 - 8 = 24 \text{ sq units.}$$

● ***Ex. 40*** *A rectangle PQRS has its side PQ parallel to the line $y = mx$ and vertices P, Q and S on the lines $y = a$, $x = b$ and $x = -b$ respectively. Find the locus of the vertex R.*

Sol. $\because$ PQ is parallel to $y = mx$

$\therefore$ Equation of PQ is $y = mx + \lambda$ ...(i)

$\because$ Diagonals bisect to each other



$\therefore$ x-coordinate of P is $-h$.

Suppose y-coordinate of Q and S are λ_1 and λ_2 respectively.

$\because$ Eq. (i) pass through $P(-h, a)$

then $\quad a = -mh + \lambda$

$\therefore \quad \lambda = a + mh$

$\Rightarrow \quad y = mx + a + mh$

Q also lie on it, then

$$\lambda_1 = mb + a + mh$$

$\therefore \quad Q \equiv (b, mb + a + mh)$

Also, slope of $PQ \times$ slope of $QR = -1$

$$m \times \frac{(k - (mb + a + mh))}{(h - b)} = -1$$

$$\Rightarrow \quad mk - m^2b - am - m^2h = -h + b$$

$$\Rightarrow \quad (m^2 - 1)h - mk + b(m^2 + 1) + am = 0$$

$\therefore$ Locus of R is

$$(m^2 - 1)x - my + b(m^2 + 1) + am = 0$$

● ***Ex. 41.*** *For points $P \equiv (x_1, y_1)$ and $Q \equiv (x_2, y_2)$ of the coordinate plane, a new distance $d(P, Q)$ is defined by $d(P, Q) = |x_1 - x_2| + |y_1 - y_2|$. Let $O \equiv (0, 0)$ and $A \equiv (3, 2)$. Prove that the set of the points in the first quadrant which are equidistant (with respect to the new distance) from O and A consists of the union of a line segment of finite length and an infinite ray. Sketch this set in a labelled diagram.*

Sol. Let $P(x, y)$ be any point in the first quadrant, we have

$x > 0$, $y > 0$

$$d(P, Q) = |x - 0| + |y - 0| = |x| + |y| = x + y$$

and $\quad d(P, A) = |x - 3| + |y - 2|$

Given, $\quad d(P, Q) = d(P, A)$

$$x + y = |x - 3| + |y - 2| \quad \text{...(i)}$$

Case I : $0 \le x < 3,\ 0 \le y < 2$

then Eq. (i) becomes

$$x + y = 3 - x + 2 - y$$

or $$x + y = 5/2$$

Case II : $0 \le x < 3,\ y \ge 2$

then Eq. (i) becomes

$$x + y = 3 - x + y - 2$$

or $$x = \frac{1}{2}$$

Case III : $x \ge 3,\ 0 \le y < 2$

then Eq. (i) becomes

$$x + y = x - 3 + 2 - y$$

$\Rightarrow$ $$y = -\frac{1}{2}$$ (Impossible)

Case IV : $x \ge 3,\ y \ge 2$

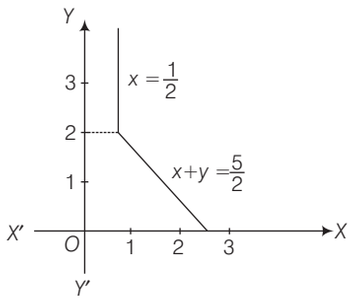
$$x + y = x - 3 + y - 2$$

$\Rightarrow$ $0 = -5$ (Impossible)

Combining all cases, then

$$x + y = 5/2;\ 0 \le x < 3,\ 0 \le y < 2$$

and $$x = \frac{1}{2};\ 0 \le x < 3,\ y \ge 2$$



The labelled diagram is given in adjoining figure.

● ***Ex. 42.*** *A line through the variable point $A(k+1, 2k)$ meets the lines $7x + y - 16 = 0, 5x - y - 8 = 0, x - 5y + 8 = 0$ at B, C, D respectively, prove that AC, AB, AD are in HP.*

Sol. Given lines are

$$7x + y - 16 = 0 \quad . \quad ..(i)$$

$$5x - y - 8 = 0 \quad ...(ii)$$

$$x - 5y + 8 = 0 \quad ...(iii)$$

Let the equation of line passing through $A(k+1, 2k)$ making an angle θ with the + ve direction of X-axis, be

$$\frac{x-(k+1)}{\cos\theta} = \frac{y-2k}{\sin\theta} = r_1, r_2, r_3 \quad (\text{if } AB = r_1,\ AC = r_2,\ AD = r_3)$$

$\therefore$ $$B \equiv [(k+1) + r_1 \cos\theta, 2k + r_1 \sin\theta]$$

$$C \equiv [(k+1) + r_2 \cos\theta, 2k + r_2 \sin\theta]$$

$$D \equiv [(k+1) + r_3 \cos\theta, 2k + r_3 \sin\theta]$$

Points B, C, D satisfying Eqs. (i), (ii) and (iii) respectively

then $$r_1 = \frac{9(1-k)}{7\cos\theta + \sin\theta}$$

$$r_2 = \frac{3(1-k)}{5\cos\theta - \sin\theta}$$

and $$r_3 = \frac{9(1-k)}{5\sin\theta - \cos\theta}$$

$\therefore$ $$\frac{1}{r_2} + \frac{1}{r_3} = \frac{(5\cos\theta - \sin\theta)}{3(1-k)} + \frac{(5\sin\theta - \cos\theta)}{9(1-k)}$$

$$= \frac{15\cos\theta - 3\sin\theta + 5\sin\theta - \cos\theta}{9(1-k)}$$

$$= \frac{14\cos\theta + 2\sin\theta}{9(1-k)} = \frac{2}{r_1}$$

Hence r_2, r_1, r_3 are in HP

i.e. AC, AB, AD are in HP.

The Straight Lines Exercise 1 :
Single Option Correct Type Questions

■ This section contains **30 multiple choice questions**. Each question has four choices (a), (b), (c), (d) out of which **ONLY ONE** is correct.

1. The straight line $y = x - 2$ rotates about a point where it cuts X-axis and becomes perpendicular on the straight line $ax + by + c = 0$, then its equation is
(a) $ax + by + 2a = 0$ (b) $ay - bx + 2b = 0$
(c) $ax + by + 2b = 0$ (d) None of these

2. If $\frac{2}{1!9!} + \frac{2}{3!7!} + \frac{1}{5!5!} = \frac{2^m}{n!}$, then orthocentre of the triangle having sides $x - y + 1 = 0$, $x + y + 3 = 0$ and $2x + 5y - 2 = 0$ is
(a) $(2m - 2n, m - n)$ (b) $(2m - 2n, n - m)$
(c) $(2m - n, m + n)$ (d) $(2m - n, m - n)$

3. If $f(x + y) = f(x)f(y) \forall\ x, y \in R$ and $f(1) = 2$, then area enclosed by $3|x| + 2|y| \le 8$ is
(a) $f(4)$ sq units (b) $\frac{1}{2}f(6)$ sq units
(c) $\frac{1}{3}f(6)$ sq units (d) $\frac{1}{3}f(5)$ sq units

4. The graph of the function $y = \cos x \cos(x + 2) - \cos^2(x + 1)$ is
(a) a straight line passing through $(0, -\sin^2 1)$ with slope 2
(b) a straight line passing through $(0, 0)$
(c) a parabola with vertex $(1, -\sin^2 1)$
(d) a straight line passing through the point $\left(\frac{\pi}{2}, -\sin^2 1\right)$ are parallel to the X-axis.

5. A line passing through the point (2, 2) and the axes enclose an area λ. The intercepts on the axes made by the line are given by the two roots of
(a) $x^2 - 2|\lambda|x + |\lambda| = 0$ (b) $x^2 + |\lambda|x + 2|\lambda| = 0$
(c) $x^2 - |\lambda|x + 2|\lambda| = 0$ (d) None of these

6. The set of value of 'b' for which the origin and the point (1, 1) lie on the same side of the straight line $a^2x + aby + 1 = 0 \forall a \in R, b > 0$ are
(a) $b \in (2, 4)$ (b) $b \in (0, 2)$
(c) $b \in [0, 2]$ (d) None of these

7. Line L has intercepts a and b on the co-ordinates axes, when the axes are rotated through a given angle; keeping the origin fixed, the same line has intercepts p and q, then
(a) $a^2 + b^2 = p^2 + q^2$ (b) $\frac{1}{a^2} + \frac{1}{b^2} = \frac{1}{p^2} + \frac{1}{q^2}$
(c) $a^2 + p^2 = b^2 + q^2$ (d) $\frac{1}{a^2} + \frac{1}{p^2} = \frac{1}{b^2} + \frac{1}{q^2}$

8. If the distance of any point (x, y) from the origin is defined as $d(x, y) = \max\{|x|, |y|\}$, $d(x, y) = a$ non-zero constant, then the locus is
(a) a circle (b) a straight line
(c) a square (d) a triangle

9. If p_1, p_2, p_3 be the perpendiculars from the points $(m^2, 2m), (mm', m + m')$ and $(m'^2, 2m')$ respectively on the line $x\cos\alpha + y\sin\alpha + \frac{\sin^2\alpha}{\cos\alpha} = 0$, then p_1, p_2, p_3 are in
(a) AP (b) GP
(c) HP (d) None of these

10. $ABCD$ is a square whose vertices A, B, C and D are (0, 0), (2, 0), (2, 2) and (0, 2) respectively. This square is rotated in the xy plane with an angle of 30° in anti-clockwise direction about an axis passing through the vertex A the equation of the diagonal BD of this rotated square is ..... . If E is the centre of the square, the equation of the circumcircle of the triangle ABE is
(a) $\sqrt{3}x + (1 - \sqrt{3})y = \sqrt{3}$, $x^2 + y^2 = 4$
(b) $(1 + \sqrt{3})x - (1 - \sqrt{2})y = 2$, $x^2 + y^2 = 9$
(c) $(2 - \sqrt{3})x + y = 2(\sqrt{3} - 1)$, $x^2 + y^2 - x\sqrt{3} - y = 0$
(d) None of the above

11. The point (4, 1) undergoes the following three successive transformations
(i) reflection about the line $y = x - 1$.
(ii) translation through a distance 1 unit along the positive direction of X-axis.
(iii) rotation through an angle $\frac{\pi}{4}$ about the origin in the anti-clockwise direction
Then, the coordinates of the final point are
(a) (4, 3) (b) $\left(\frac{7}{2}, \frac{7}{2}\right)$
(c) $(0, 3\sqrt{2})$ (d) (3, 4)

12. If the square $ABCD$, where $A(0, 0)$, $B(2, 0)$, $C(2, 2)$ and $D(0, 2)$ undergoes the following three transformations successively
(i) $f_1(x, y) \to (y, x)$
(ii) $f_2(x, y) \to (x + 3y, y)$
(iii) $f_3(x, y) \to \left(\frac{x - y}{2}, \frac{x + y}{2}\right)$
then the final figure is a
(a) square (b) parallelogram
(c) rhombus (d) None of these

13. The line $x + y = a$ meets the axes of x and y at A and B respectively. A triangle AMN is inscribed in the triangle OAB, O being the origin, with right angle at N, M and N lie respectively on OB and AB. If the area of the triangle AMN is $\frac{3}{8}$ of the area of the triangle OAB, then $\frac{AN}{BN}$ is equal to

(a) 1 (b) 2 (c) 3 (d) 4

14. If $P(1, 0)$, $Q(-1, 0)$ and $R(2, 0)$ are three given points, then the locus of point S satisfying the relation $(SQ)^2 + (SR)^2 = 2(SP)^2$ is

(a) a straight line parallel to X-axis
(b) a circle through the origin
(c) a circle with centre at the origin
(d) a straight line parallel to Y-axis

15. If $A\left(\frac{\sin\alpha}{3} - 1, \frac{\cos\alpha}{2} - 1\right)$ and $B(1, 1)$, $\alpha \in [-\pi, \pi]$ are two points on the same side of the line $3x - 2y + 1 = 0$, then α belongs to the interval

(a) $\left(-\pi, -\frac{3\pi}{4}\right] \cup \left(\frac{\pi}{4}, \pi\right)$ (b) $[-\pi, \pi]$

(c) ϕ (d) None of these

16. The line $x + y = 1$ meets X-axis at A and Y-axis at B, P is the mid-point of AB. P_1 is the foot of the perpendicular from P to OA; M_1 is that of P_1 from OP ; P_2 is that of M_1 from OA ; M_2 is that of P_2 from OP ; P_3 is that of M_2 from OA and so on. If P_n denotes the nth foot of the perpendicular on OA form M_{n-1}, then OP_n is equal to

(a) $\frac{1}{2n}$ (b) $\frac{1}{2^n}$

(c) $2^n - 1$ (d) $2^n + 3$

17. The line $x = c$ cuts the triangle with corners (0, 0); (1, 1) and (9, 1) into two regions. For the area of the two regions to be the same, then c must be equal to

(a) $\frac{5}{2}$ (b) 3

(c) $\frac{7}{2}$ (d) 3 or 15

18. If the straight lines $x + 2y = 9$, $3x - 5y = 5$ and $ax + by = 1$ are concurrent, then the straight line $5x + 2y = 1$, passes through the point

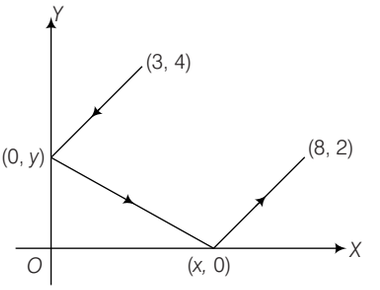
(a) $(a, -b)$ (b) $(-a, b)$
(c) (a, b) (d) $(-a, -b)$

19. The ends of the base of the isosceles triangle are at (2, 0) and (0, 1) and the equation of one side is $x = 2$, then the orthocentre of the triangle is

(a) $\left(\frac{3}{4}, \frac{3}{2}\right)$ (b) $\left(\frac{5}{4}, 1\right)$

(c) $\left(\frac{3}{4}, 1\right)$ (d) $\left(\frac{4}{3}, \frac{7}{12}\right)$

20. Suppose that a ray of light leaves the point (3, 4), reflects off the Y-axis towards the X-axis, reflects off the X-axis, and finally arrives at the point (8, 2). The value of x is



(a) $4\frac{1}{2}$ (b) $4\frac{1}{3}$ (c) $4\frac{2}{3}$ (d) $5\frac{1}{3}$

21. m, n are two integers with $0 < n < m$. A is the point (m, n) on the cartesian plane. B is the reflection of A in the line $y = x$. C is the reflection of B in the Y-axis, D is the reflection of C in the X-axis and E is the reflection of D in the Y-axis. The area of the pentagon $ABCDE$ is

(a) $2m(m + n)$ (b) $m(m + 3n)$
(c) $m(2m + 3n)$ (d) $2m(m + 3n)$

22. A straight line L with negative slope passes through the point (8, 2) and cuts the positive coordinates axes at points P and Q. As L varies, the absolute minimum value of $OP + OQ$ is (O is origin)

(a) 10 (b) 18 (c) 16 (d) 12

23. Drawn from origin are two mutually perpendicular lines forming an isosceles triangle together with the straight line $2x + y = a$, then the area of this triangle is

(a) $\frac{a^2}{2}$ sq units (b) $\frac{a^2}{3}$ sq units

(c) $\frac{a^2}{5}$ sq units (d) None of these

24. The number of integral values of m for which the x-coordinate of the point of intersection of the lines $3x + 4y = 9$ and $y = mx + 1$ is also an integer is

(a) 2 (b) 0 (c) 4 (d) 1

25. A ray of light coming from the point (1, 2) is reflected at a point A on the X-axis and then passes through the point (5, 3). The coordinates of the point A are

(a) $\left(\frac{13}{5}, 0\right)$ (b) $\left(\frac{5}{13}, 0\right)$

(c) (–7, 0) (d) None of these

26. Consider the family of lines $5x + 3y - 2 + \lambda(3x - y - 4) = 0$ and $x - y + 1 + \mu(2x - y - 2) = 0$. Equation of straight line that belong to both families is $ax + by - 7 = 0$, then $a + b$ is

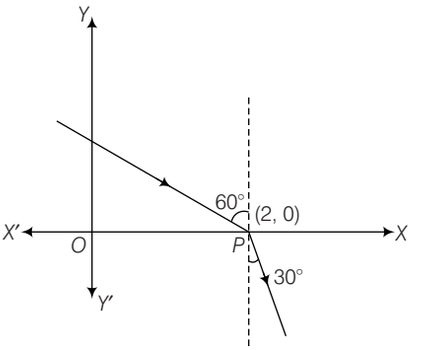
(a) 1 (b) 3 (c) 5 (d) 7

27. In ΔABC equation of the right bisectors of the sides AB and AC are $x + y = 0$ and $x - y = 0$ respectively. If $A \equiv (5, 7)$, then equation of side BC is
(a) $7y = 5x$ (b) $5x = y$
(c) $5y = 7x$ (d) $5y = x$

28. Two particles start from the point $(2, -1)$, one moving 2 units along the line $x + y = 1$ and the other 5 units along the line $x - 2y = 4$. If the particles move towards increasing y, then their new positions are
(a) $(2 - \sqrt{2}, \sqrt{2} - 1); (2\sqrt{2} + 2, \sqrt{5} - 1)$
(b) $(2\sqrt{2} + 2, \sqrt{5} - 1); (2\sqrt{2}, \sqrt{2} + 1)$
(c) $(2 + \sqrt{2}, \sqrt{2} + 1); (2\sqrt{2} + 2, \sqrt{5} + 1)$
(d) $(2 - \sqrt{2}, \sqrt{5} - 1); (\sqrt{2} - 1, 2\sqrt{2} + 2)$

29. Let P be $(5, 3)$ and a point R on $y = x$ and Q on the X-axis be such that $PQ + QR + RP$ is minimum, then the coordinates of Q are
(a) $\left(\frac{17}{8}, 0\right)$ (b) $\left(\frac{17}{4}, 0\right)$
(c) $\left(\frac{17}{2}, 0\right)$ (d) $(17, 0)$

30. In the adjacent figure combined equation of the incident and refracted ray is



(a) $(x-2)^2 + y^2 + \frac{4}{\sqrt{3}}(x-2)y = 0$
(b) $(x-2)^2 + y^2 - \frac{4}{\sqrt{3}}(x-2)y = 0$
(c) $(x-2)^2 + y^2 + \frac{y}{\sqrt{3}}(x-2) = 0$
(d) $(x-2)^2 + y^2 - \frac{y}{\sqrt{3}}(x-2) = 0$

The Straight Lines Exercise 2 :
More than One Correct Option Type Questions

- The section contains **15 multiple choice questions**. Each question has four choices (a), (b), (c), and (d) out of which **MORE THAN ONE** may be correct.

31. The point of intersection of the lines $\frac{x}{a} + \frac{y}{b} = 1$ and $\frac{x}{b} + \frac{y}{a} = 1$ lies on
(a) $x - y = 0$
(b) $(x + y)(a + b) = 2ab$
(c) $(lx + my)(a + b) = (l + m)ab$
(d) $(lx - my)(a + b) = (l - m)ab$

32. The equations $(b - c)x + (c - a)y + a - b = 0$ and $(b^3 - c^3)x + (c^3 - a^3)y + a^3 - b^3 = 0$ will represent the same line, if
(a) $b = c$ (b) $c = a$
(c) $a = b$ (d) $a + b + c = 0$

33. The area of a triangle is 5. Two of its vertices are (2, 1) and (3, –2). The third vertex lies on $y = x + 3$. The coordinates of the third vertex cannot be
(a) $\left(\frac{-3}{2}, \frac{3}{2}\right)$ (b) $\left(\frac{3}{4}, \frac{-3}{2}\right)$
(c) $\left(\frac{7}{2}, \frac{13}{2}\right)$ (d) $\left(\frac{-1}{4}, \frac{11}{4}\right)$

34. If the lines $x - 2y - 6 = 0, 3x + y - 4 = 0$ and $\lambda x + 4y + \lambda^2 = 0$ are concurrent, then
(a) $\lambda = 2$ (b) $\lambda = -3$ (c) $\lambda = 4$ (d) $\lambda = -4$

35. Equation of a straight line passing through the point of intersection of $x - y + 1 = 0$ and $3x + y - 5 = 0$ are perpendicular to one of them is
(a) $x + y + 3 = 0$ (b) $x + y - 3 = 0$
(c) $x - 3y - 5 = 0$ (d) $x - 3y + 5 = 0$

36. If one vertex of an equilateral triangle of side a lies at the origin and the other lies on the line $x - \sqrt{3}y = 0$, the coordinates of the third vertex are
(a) $(0, a)$ (b) $\left(\frac{\sqrt{3}a}{2}, \frac{-a}{2}\right)$ (c) $(0, -a)$ (d) $\left(\frac{-\sqrt{3}a}{2}, \frac{a}{2}\right)$

37. If the line $ax + by + c = 0, bx + cy + a = 0$ and $cx + ay + b = 0$ are concurrent $(a + b + c \neq 0)$ then
(a) $a^3 + b^3 + c^3 - 3abc = 0$ (b) $a = b$
(c) $a = b = c$ (d) $a^2 + b^2 + c^2 - bc - ca - ab = 0$

38. $A(1, 3)$ and $C(7, 5)$ are two opposite vertices of a square. The equation of a side through A is
(a) $x + 2y - 7 = 0$ (b) $x - 2y + 5 = 0$
(c) $2x + y - 5 = 0$ (d) $2x - y + 1 = 0$

39. If $6a^2 - 3b^2 - c^2 + 7ab - ac + 4bc = 0$, then the family of lines $ax + by + c = 0$ is concurrent at
(a) $(-2, -3)$ (b) $(3, -1)$
(c) $(2, 3)$ (d) $(-3, 1)$

40. Consider the straight lines $x + 2y + 4 = 0$ and $4x + 2y - 1 = 0$. The line $6x + 6y + 7 = 0$ is
(a) bisector of the angle including origin
(b) bisector of acute angle
(c) bisector of obtuse angle
(d) None of the above

41. Two roads are represented by the equations $y - x = 6$ and $x + y = 8$. An inspection bungalow has to be so constructed that it is at a distance of 100 from each of the roads. Possible location of the bungalow is given by
(a) $(100\sqrt{2} + 1, 7)$ (b) $(1 - 100\sqrt{2}, 7)$
(c) $(1, 7 + 100\sqrt{2})$ (d) $(1, 7 - 100\sqrt{2})$

42. If (a, b) be an end of a diagonal of a square and the other diagonal has the equation $x - y = a$, then another vertex of the square can be
(a) $(a - b, a)$ (b) $(a, 0)$
(c) $(0, -a)$ (d) $(a + b, b)$

43. Consider the equation $y - y_1 = m(x - x_1)$. If m and x_1 are fixed and different lines are drawn for different values of y_1, then
(a) the lines will pass through a fixed point
(b) there will be a set of parallel lines
(c) all the lines intersect the line $x = x_1$
(d) all the lines will be parallel to the line $y = x_1$

44. Let $L_1 \equiv ax + by + a\sqrt[3]{b} = 0$ and $L_2 \equiv bx - ay + b\sqrt[3]{a} = 0$ be two straight lines. The equations of the bisectors of the angle formed by the foci whose equations are $\lambda_1 L_1 - \lambda_2 L_2 = 0$ and $\lambda_1 L_1 + \lambda_2 L_2 = 0$, λ_1 and λ_2 being non-zero real numbers, are given by
(a) $L_1 = 0$ (b) $L_2 = 0$
(c) $\lambda_1 L_1 + \lambda_2 L_2 = 0$ (d) $\lambda_2 L_1 - \lambda_1 L_2 = 0$

45. The equation of the bisectors of the angles between the two intersecting lines $\frac{x-3}{\cos\theta} = \frac{y+5}{\sin\theta}$ and $\frac{x-3}{\cos\phi} = \frac{y+5}{\sin\phi}$ are $\frac{x-3}{\cos\alpha} = \frac{y+5}{\sin\alpha}$ and $\frac{x-3}{\beta} = \frac{y+5}{\gamma}$, then
(a) $\alpha = \frac{\theta + \phi}{2}$ (b) $\beta = -\sin\alpha$
(c) $\gamma = \cos\alpha$ (d) $\beta = \sin\alpha$

The Straight Lines Exercise 3 : Paragraph Based Questions

- The section contains **5 Paragraphs** based upon each of the paragraphs **3 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c), and (d) out of which **ONLY ONE** is correct.

Paragraph I

(Q. Nos. 46 to 48)

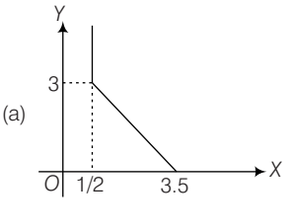
For points $P \equiv (x_1, y_1)$ and $Q = (x_2, y_2)$ of the coordinate plane, a new distance $d(P, Q)$ is defined by $d(P, Q) = |x_1 - x_2| + |y_1 - y_2|$
Let $O \equiv (0, 0)$, $A \equiv (1, 2)$, $B \equiv (2, 3)$ and $C \equiv (4, 3)$ are four fixed points on x-y plane.

46. Let $R(x, y)$, such that R is equidistant from the point O and A with respect to new distance and if $0 \le x < 1$ and $0 \le y < 2$, then R lie on a line segment whose equation is
(a) $x + y = 3$ (b) $x + 2y = 3$
(c) $2x + y = 3$ (d) $2x + 2y = 3$

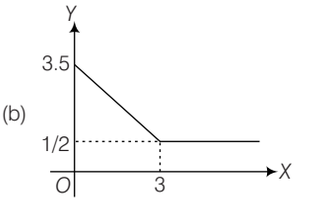
47. Let $S(x, y)$, such that S is equidistant from points O and B with respect to new distance and if $x \ge 2$ and $0 \le y < 3$, then locus of S is
(a) a line segment of finite length
(b) a line of infinite length
(c) a ray of finite length
(d) a ray of infinite length

48. Let $T(x, y)$, such that T is equidistant from point O and C with respect to new distance and if T lie in first quadrant, then T consists of the union of a line segment of finite length and an infinite ray whose labelled diagram is

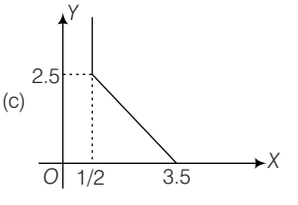
(a)



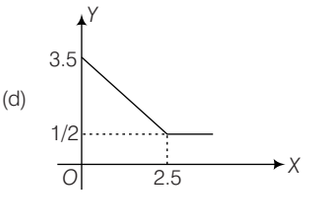
(b)



(c)



(d)



Paragraph II

(Q. Nos. 49 to 51)

In a triangle ABC, if the equation of sides AB, BC and CA are $2x - y + 4 = 0$, $x - 2y - 1 = 0$ *and* $x + 3y - 3 = 0$ *respectively.*

49. Tangent of internal angle A is equal to

(a) -7 (b) -3

(c) $\frac{1}{2}$ (d) 7

50. The equation of external bisector of angle B is

(a) $x - y - 1 = 0$ (b) $x - y + 1 = 0$

(c) $x + y - 5 = 0$ (d) $x + y + 5 = 0$

51. The image of point B w.r.t the side CA is

(a) $\left(-\frac{3}{5}, \frac{26}{5}\right)$ (b) $\left(-\frac{3}{5}, -\frac{26}{5}\right)$

(c) $\left(\frac{3}{5}, -\frac{26}{5}\right)$ (d) $\left(\frac{3}{5}, \frac{26}{5}\right)$

Paragraph III

(Q. Nos. 52 to 54)

$A(1, 3)$ *and* $C\left(-\frac{2}{5}, \frac{-2}{5}\right)$ *are the vertices of a triangle ABC and the equation of the angle bisector of* $\angle ABC$ *is* $x + y = 2$.

52. Equation of BC is

(a) $7x + 3y - 4 = 0$ (b) $7x + 3y + 4 = 0$

(c) $7x - 3y + 4 = 0$ (d) $7x - 3y - 4 = 0$

53. Coordinates of vertex B are

(a) $\left(\frac{3}{10}, \frac{17}{10}\right)$ (b) $\left(\frac{17}{10}, \frac{3}{10}\right)$

(c) $\left(-\frac{5}{2}, \frac{9}{2}\right)$ (d) $\left(\frac{9}{2}, -\frac{5}{2}\right)$

54. Equation of AB is

(a) $3x + 7y = 24$

(b) $3x + 7y + 24 = 0$

(c) $13x + 7y + 8 = 0$

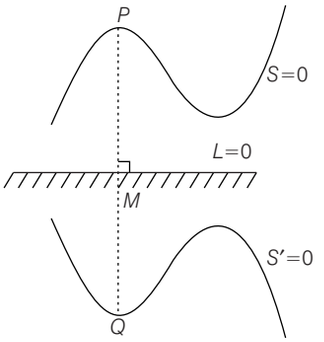
(d) $13x - 7y + 8 = 0$

Paragraph IV

(Q. Nos. 55 to 57)

Let $S' = 0$ *be the image or reflection of the curve* $S = 0$ *about line mirror* $L = 0$. *Suppose P be any point on the curve* $S = 0$ *and Q be the image or reflection about the line mirror* $L = 0$, *then Q will lie on* $S' = 0$.

How to find the image or reflection of a curve?



Let the given curve be $S : f(x, y) = 0$ *and line mirror* $L : ax + by + c = 0$. *We take a point P on the given curve in parametric form. Suppose Q be the image or reflection of point P about line mirror* $L = 0$, *which again contains the same parameter. Let* $Q \equiv (\phi(t), \psi(t))$, *where t is parameter. Now let* $x = \phi(t)$ *and* $y = \psi(t)$

Eliminating t, we get the equation of the reflected curve S′.

55. The image of the line $3x - y = 2$ in the line $y = x - 1$ is

(a) $x + 3y = 2$ (b) $3x + y = 2$

(c) $x - 3y = 2$ (d) $x + y = 2$

56. The image of the circle $x^2 + y^2 = 4$ in the line $x + y = 2$ is

(a) $x^2 + y^2 - 2x - 2y = 0$ (b) $x^2 + y^2 - 4x - 4y + 6 = 0$

(c) $x^2 + y^2 - 2x - 2y + 2 = 0$ (d) $x^2 + y^2 - 4x - 4y + 4 = 0$

57. The image of the parabola $x^2 = 4y$ in the line $x + y = a$ is

(a) $(x - a)^2 = 4(a - y)$ (b) $(y - a)^2 = 4(a - x)$

(c) $(x - a)^2 = 4(a + y)$ (d) $(y - a)^2 = 4(a + x)$

Paragraph V

(Q. Nos. 58 to 60)

In a ΔABC, the equation of the side BC is $2x - y = 3$ and its circumcentre and orhtocentre are (2, 4) and (1, 2) respectively.

58. Circumradius of ΔABC is

(a) $\sqrt{\frac{61}{5}}$ (b) $\sqrt{\frac{51}{5}}$ (c) $\sqrt{\frac{41}{5}}$ (d) $\sqrt{\frac{43}{5}}$

59. $\sin B \cdot \sin C =$

(a) $\frac{9}{2\sqrt{61}}$ (b) $\frac{9}{4\sqrt{61}}$ (c) $\frac{9}{\sqrt{61}}$ (d) $\frac{9}{5\sqrt{61}}$

60. The distance of orthocentre from vertex A is

(a) $\frac{1}{\sqrt{5}}$ (b) $\frac{6}{\sqrt{5}}$ (c) $\frac{3}{\sqrt{5}}$ (d) $\frac{2}{\sqrt{5}}$

The Straight Lines Exercise 4 : Single Integer Answer Type Questions

- The section contains **10 questions**. The answer to eaeh question is a **single digit integer**, ranging from 0 to 9 (both inclusive).

61. The number of possible straight lines passing through (2, 3) and forming a triangle with the coordinate axes, whose area is 12 sq units, is

62. The portion of the line $ax + 3y - 1 = 0$, intercepted between the lines $ax + y + 1 = 0$ and $x + 3y = 0$ subtend a right angle at origin, then the value of $|a|$ is

63. Let ABC be a triangle and $A \equiv (1, 2)$, $y = x$ be the perpendicular bisector of AB and $x - 2y + 1 = 0$ be the angle bisector of $\angle C$. If the equation of BC is given by $ax + by - 5 = 0$, then the value of $a - 2b$ is

64. A lattice point in a plane is a point for which both coordinates are integers. If n be the number of lattice points inside the triangle whose sides are $x = 0$, $y = 0$ and $9x + 223y = 2007$, then tens place digit in n is

65. The number of triangles that the four lines $y = x + 3$, $y = 2x + 3$, $y = 3x + 2$ and $y + x = 3$ form is

66. In a plane there are two families of lines : $y = x + n$, $y = -x + n$, where $n \in \{0, 1, 2, 3, 4\}$. The number of squares of the diagonal of length 2 formed by these lines is

67. Given $A(0, 0)$ and $B(x, y)$ with $x \in (0, 1)$ and $y > 0$. Let the slope of line AB be m_1. Point C lies on line $x = 1$ such that the slope of BC is equal to m_2, where $0 < m_2 < m_1$. If the area of triangle ABC can be expressed as $(m_1 - m_2)f(x)$ and the largest possible value of $f(x)$ is λ, then the value of $\frac{1}{\lambda}$ is

68. If $(\lambda, \lambda + 1)$ is an interior point of ΔABC, where $A \equiv (0, 3)$, $B \equiv (-2, 0)$ and $C \equiv (6, 1)$, then the number of integral values of λ is

69. For all real values of a and b, lines $(2a + b)x + (a + 3b)y + (b - 3a) = 0$ and $\lambda x + 2y + 6 = 0$ and $\lambda x + 2y + 6 = 0$ are concurrent, then the value of $|\lambda|$ is

70. If from point (4, 4) perpendiculars to the straight lines $3x + 4y + 5 = 0$ and $y = mx + 7$ meet at Q and R and area of triangle PQR is maximum, then the value of $3m$ is

The Straight Lines Exercise 5 : Matching Type Questions

- The section contains **5 questions**. Questions 1, 2 and 3 have four statement (A, B, C and D) given in **Column I** and four statements (p, q, r and s) in **Column II** and questions 74 and 75 have three statements (A, B and C) given in **Column I** and five statements (p, q, r, s and t) in **Column II**. Any given statement in **Column I** can have correct matching with one or more statement (s) given in **Column II**.

71. Let L_1, L_2, L_3 be three straight lines a plane and n be the number of circles touching all the lines.

	Column I		Column II
(A)	The lines are concurrent, then $n + 1$ is a	(p)	natural number
(B)	The lines are parallel, then $2n + 3$ is a	(q)	prime number
(C)	Two lines are parallel, then $n + 2$ is a	(r)	composite number
(D)	The lines are neither concurrent nor parallel, then $n + 2$ is a	(s)	perfect number

72. Match the Columns

	Column I		Column II
(A)	Lines $x - 2y - 6 = 0$, $3x + y - 4 = 0$ and $\lambda x + 4y + \lambda^2 = 0$ are concurrent, then the value of $\lvert\lambda\rvert$ is	(p)	2
(B)	The variable straight lines $3x(a + 1) + 4y(a - 1) - 3(a - 1) = 0$ for different value of 'a' passes through a fixed point (p, q) if $\lambda = p - q$, then the value of $4\lvert\lambda\rvert$	(q)	3
(C)	If the line $x + y - 1 - \left\lvert\frac{\lambda}{2}\right\rvert = 0$ passing through the intersection of $x - y + 1 = 0$ and $3x + y - 5 = 0$, is perpendicular to one of them, then the value of $\lvert\lambda + 1\rvert$ is	(r)	4
(D)	If the line $y - x - 1 + \lambda = 0$ is equidistant from the points $(1, -2)$ and $(3, 4)$, then the value of $\lvert\lambda\rvert$ is	(s)	5

73. Consider the triangle formed by the lines $y + 3x + 2 = 0$, $3y - 2x - 5 = 0$ and $4y + x - 14 = 0$

	Column I		Column II
(A)	If $(0, \lambda)$ lies inside the triangle, then integral values are less than $\lvert 3\lambda \rvert$	(p)	4
(B)	If $(1, \lambda)$ lies inside the triangle, then integral values are less than $\lvert 3\lambda \rvert$	(q)	5
(C)	If $(\lambda, 2)$ lies inside the triangle, then integral values of $\lvert 6\lambda \rvert$ are	(r)	6
(D)	If $(\lambda, 7/2)$ lies inside the triangle, then integral value of $\lvert 6\lambda \rvert$ are	(s)	7

74. Match the following

	Column I		Column II
(A)	The area bounded by the curve max. $\{\lvert x \rvert, \lvert y \rvert\} = 1$ is	(p)	0
(B)	If the point (a, a) lies between the lines $\lvert x + y \rvert = 6$, then $[\lvert a \rvert]$ is (where $[.]$ denotes the greatest integer function)	(q)	1
(C)	Number of integral values of b for which the origin and the point (1, 1) lie on the same side of the st. line $a^2x + aby + 1 = 0$ for all $a \in R \sim \{0\}$ is	(r)	2
		(s)	3
		(t)	4

75. Match the following

	Column I		Column II
(A)	If the distance of any point (x, y) from origin is defined as $d(x, y) = 2\lvert x \rvert + 3\lvert y \rvert$. If perimeter and area of figure bounded by $d(x, y) = 6$ are λ unit and μ sq units respectively, then	(p)	(λ, μ) lies on $x = 3y$
(B)	If the vertices of a triangle are (6, 0), (0, 6) and (6, 6). If distance between circumcentre and orthocentre and distance between circumcentre and centroid are λ unit and μ unit respectively, then	(q)	(λ, μ) lies on $x^2 - y^2 = 64$
(C)	The ends of the hypotenuse of a right angled triangle are (6, 0) and (0, 6). If the third vertex is (λ, μ), then	(r)	(λ, μ) lies on $x^2 + y^2 - 6x - 6y = 0$
		(s)	(λ, μ) lies on $x^2 - 16y = 16$
		(t)	(λ, μ) lies on $x^2 - y^2 = 16$

The Straight Lines Exercise 6 : Statement I and II Type Questions

■ **Directions** (Q. Nos 76 to 83) are Assertion-Reason type questions. Each of these question contains two statements.

Statement I (Assertion) and

Statement II (Reason)

Each of these questions has four alternative choices, only one of which is the correct answer.

You have to select the correct choice.

(a) Statement I is true, statement II is true; statement II is a correct explanation for statement I

(b) Statement I is true, statement II is true; statement II is not a correct explanation for statement I

(c) Statement I is true, statement II is false

(d) Statement I is false, statement II is true

76. **Statement I** The lines $x(a + 2b) + y(a + 3b) = a + b$ are concurrent at the point $(2, -1)$

Statement II The lines $x + y - 1 = 0$ and $2x + 3y - 1 = 0$ intersect at the point $(2, -1)$

77. **Statement I** The points (3, 2) and (1, 4) lie on opposite side of the line $3x - 2y - 1 = 0$

Statement II The algebraic perpendicular distance from the given point to the line have opposite sign.

78. **Statement I** If sum of algebraic distances from points $A(1, 2)$, $B(2, 3)$, $C(6, 1)$ is zero on the line $ax + by + c = 0$, then $2a + 3b + c = 0$

Statement II The centroid of the triangle is (3, 2)

79. **Statement I** Let $A \equiv (0, 1)$ and $B \equiv (2, 0)$ and P be a point on the line $4x + 3y + 9 = 0$, then the co-ordinates of P such that $\lvert PA - PB \rvert$ is maximum is $\left(-\frac{12}{5}, \frac{17}{5}\right)$.

Statement II $\lvert PA - PB \rvert \le \lvert AB \rvert$

80. **Statement I** The incentre of a triangle formed by the line $x\cos\left(\frac{\pi}{9}\right) + y\sin\left(\frac{\pi}{9}\right) = \pi$,

$x\cos\left(\frac{8\pi}{9}\right) + y\sin\left(\frac{8\pi}{9}\right)$

$= \pi$ and $x\cos\left(\frac{13\pi}{9}\right) + y\sin\left(\frac{13\pi}{9}\right) = \pi$ is (0, 0).

Statement II Any point equidistant from the given three non-concurrent straight lines in the plane is the incentre of the triangle.

81. **Statement I** Reflection of the point (5, 1) in the line $x + y = 0$ is $(-1, -5)$.

Statement II Reflection of a point $P(\alpha, \beta)$ in the line $ax + by + c = 0$ is $Q(\alpha', \beta')$, if $\left(\frac{\alpha + \alpha'}{2}, \frac{\beta + \beta'}{2}\right)$ lies on the line.

82. **Statement I** The internal angle bisector of angle C of a triangle ABC with sides AB, AC and BC as $y = 0$, $3x + 2y = 0$, and $2x + 3y + 6 = 0$, respectively, is $5x + 5y + 6 = 0$.

Statement II The image of point A with respect to $5x + 5y + 6 = 0$ lies on the side BC of the triangle.

83. **Statement I** If the point $(2a - 5, a^2)$ is on the same side of the line $x + y - 3 = 0$ as that of the origin, then $a \in (2, 4)$.

Statement II The point (x_1, y_1) and (x_2, y_2) lie on the same or opposite sides of the line $ax + by + c = 0$, as $ax_1 + by_1 + c$ and $ax_2 + by_2 + c$ have the same or opposite signs.

The Straight Lines Exercise 7 :
Subjective Type Questions

- In this section, there are **15 subjective questions**.

84. If $A(x_1, y_1)$, $B(x_2, y_2)$ and $C(x_3, y_3)$ are the vertices of a triangle, then show that the equation of the line joining A and the circumcentre is given by

$$(\sin 2B)\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix} + (\sin 2C)\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} = 0$$

85. Find the coordinates of the point at unit distance from the lines

$3x - 4y + 1 = 0, 8x + 6y + 1 = 0$.

86. A variable line makes intercepts on the coordinate axes, the sum of whose squares is constant and equal to k^2. Show that the locus of the foot of the perpendicular from the origin to this line is $(x^2 + y^2)^2 (x^{-2} + y^{-2}) = k^2$.

87. A variable line intersects n lines $y = mx, (m = 1, 2, 3, \ldots, n)$ in the points $A_1, A_2, A_3, \ldots, A_n$ respectively.

If $\sum_{p=1}^{n} \frac{1}{OA_p} = c$ (constant). Show that line passes through a fixed point. Find the coordinates of this fixed point (O being origin).

88. Given n straight lines and a fixed point O. A straight line is drawn through O meeting these lines in the points $R_1, R_2, R_3, \ldots, R_n$ and a point R is taken on it such that

$$\frac{n}{OR} = \sum_{r=1}^{n} \frac{1}{OR_r}$$

Prove that the locus of R is a straight line.

89. Prove that all lines represented by the equation

$$(2\cos\theta + 3\sin\theta)x + (3\cos\theta - 5\sin\theta)y = 5\cos\theta - 2\sin\theta$$

pass through a fixed point for all θ. What are the coordinates of this fixed point and its reflection in the line $x + y = \sqrt{2}$? Prove that all lines through reflection point can be represented by equation

$$(2\cos\theta + 3\sin\theta)x + (3\cos\theta - 5\sin\theta)y = (\sqrt{2} - 1)(5\cos\theta - 2\sin\theta)$$

90. P is any point on the line $x - a = 0$. If A is the point $(a, 0)$ and PQ, the bisector of the angle OPA, meets the X-axis in Q. Prove that the locus of the foot of the perpendicular from Q on OP is $(x - a)^2 (x^2 + y^2) = a^2 y^2$.

91. Having given the bases and the sum of the areas of a number of triangles is constant, which have a common vertex. Show that the locus of this vertex is a straight line.

92. $A(3, 0)$ and $B(6, 0)$ are two fixed points and $U(\alpha, \beta)$ is a variable point on the plane. AU and BU meet the y-axis at C and D respectively and AD meets OU at V. Prove that CV passes through (2, 0) for any position of U in the plane.

93. A variable line is drawn through O to cut two fixed straight lines L_1 and L_2 in R and S. A point P is chosen on the variable line such that $\frac{m+n}{OP} = \frac{m}{OR} + \frac{n}{OS}$. Show that the locus of P is a straight line passing through the point of intersection of L_1 and L_2.

94. A line through $A(-5, -4)$ meets the lines $x + 3y + 2 = 0, 2x + y + 4 = 0$ and $x - y - 5 = 0$ at the points B, C and D respectively, if

$$\left(\frac{15}{AB}\right)^2 + \left(\frac{10}{AC}\right)^2 = \left(\frac{6}{AD}\right)^2$$

find the equation of the line.

95. Two fixed straight lines X-axis and $y = mx$ are cut by a variable line in the points $A(a, 0)$ and $B(b, mb)$ respectively. P and Q are the feet of the perpendiculars drawn from A and B upon the lines $y = mx$ and X-axis. Show that, if AB passes through a fixed point (h, k), then PQ will also pass through a fixed point. Find the fixed point.

96. Find the equation of straight lines passing through point $(2, 3)$ and having an intercept of length 2 units between the straight lines $2x + y = 3, 2x + y = 5$.

97. Let $O(0, 0)$, $A(2, 0)$ and $B\left(1, \frac{1}{\sqrt{3}}\right)$ be the vertices of a triangle. Let R be the region consisting of all those points P inside ΔOAB which satisfy

$d(P, OA) \leq \min\{d(P, OB), d(P, AB)\}$

where d denotes the distance from the point to the corresponding line. Sketch the region R and find its area.

98. Two triangles ABC and PQR are such that the perpendiculars from A to QR, B to RP and C to PQ are concurrent. Show that the perpendicular from P to BC, Q to CA and R to AB are also concurrent.

The Straight Lines Exercise 8 : Questions Asked in Previous 13 Year's Exams

- This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to **2017**.

99. The line parallel to the X-axis and passing through the intersection of the lines $ax + 2by + 3b = 0$ and $bx - 2ay - 3a = 0$, where $(a, b) \neq (0, 0)$ is **[AIEEE 2005, 3M]**

(a) below the X-axis at a distance of $\frac{3}{2}$ from it

(b) below the X-axis at a distance of $\frac{2}{3}$ from it

(c) above the X-axis at a distance of $\frac{3}{2}$ from it

(d) above the X-axis at a distance of $\frac{2}{3}$ from it

100. A straight line through the point $A(3, 4)$ is such that its intercept between the axes is bisected at A. Its equation is **[AIEEE 2006, 4.5M]**

(a) $x + y = 7$ (b) $3x - 4y + 7 = 0$

(c) $4x + 3y = 24$ (d) $3x + 4y = 25$

101. If (a, a^2) falls inside the angle made by the lines $y = \frac{x}{2}$, $x > 0$ and $y = 3x$, $x > 0$, then a belong to **[AIEEE 2006, 6M]**

(a) $\left(0, \frac{1}{2}\right)$ (b) $(3, \infty)$

(c) $\left(\frac{1}{2}, 3\right)$ (d) $\left(-3, -\frac{1}{2}\right)$

102. Lines $L_1 : y - x = 0$ and $L_2 : 2x + y = 0$ intersect the line $L_3 : y + 2 = 0$ at P and Q respectively. The bisector of the acute angle between L_1 and L_2 intersects L_3 at R.

[IIT-JEE 2007, 3M]

Statement I The ratio $PR : RQ$ equals $2\sqrt{2} : \sqrt{5}$ because

Statement II In any triangle, bisector of an angle divides the triangle into two similar triangles.

(a) Statement I is true, statement II is true; statement II is not a correct explanation for statement I

(b) Statement I is true, statement II is true; statement II is not a correct explanation for statement I

(c) Statement I is true, statement II is false

(d) Statement I is false, statement II is true

103. Let $P = (-1, 0)$, $Q = (0, 0)$ and $R = (3, 3\sqrt{3})$ be three point. The equation of the bisector of the angle PQR is **[AIEEE 2007, 3M]**

(a) $\frac{\sqrt{3}}{2}x + y = 0$ (b) $x + \sqrt{3}y = 0$

(c) $\sqrt{3}x + y = 0$ (d) $x + \frac{\sqrt{3}}{2}y = 0$

104. Consider the lines given by

$$L_1 : x + 3y - 5 = 0$$
$$L_2 : 3x - ky - 1 = 0$$
$$L_3 : 5x + 2y - 12 = 0$$

Match the statements/Expressions in **Column I** with the statements/Expressions in **Column II**

	Column I		Column II
(A)	L_1, L_2, L_3 are concurrent, if	(p)	$k = -9$
(B)	one of L_1, L_2, L_3 is parallel to at least one of the other two, if	(q)	$k = -\frac{6}{5}$
(C)	L_1, L_2, L_3 form a triangle, if	(r)	$k = \frac{5}{6}$
(D)	L_1, L_2, L_3 do not form a triangle, if	(s)	$k = 5$

[IIT-JEE 2008, 6M]

105. The perpendicular bisector of the line segment joining $P(1, 4)$ and $Q(k, 3)$ has y-intercept -4. Then a possible value of k is **[AIEEE 2008, 3M]**

(a) 1 (b) 2 (c) -2 (d) -4

106. The lines $p(p^2+1)x - y + q = 0$ and $(p^2+1)^2 x + (p^2+1)y + 2q = 0$ are perpendicular to a common line for **[AIEEE 2009, 4M]**

(a) exactly one values of p (b) exactly two values of p
(c) more than two values of p (d) no value of p

107. The line L given by $\frac{x}{5} + \frac{y}{b} = 1$ passes through the point (13, 32). The line K is parallel to L and has the equation $\frac{x}{c} + \frac{y}{3} = 1$. Then the distance between L and K is **[AIEEE 2010, 4M]**

(a) $\sqrt{17}$ (b) $\frac{17}{\sqrt{15}}$
(c) $\frac{23}{\sqrt{17}}$ (d) $\frac{23}{\sqrt{15}}$

108. A straight line L through the point $(3, -2)$ is inclined at an angle 60° to the line $\sqrt{3}x + y = 1$. If L also intersects the X-axis, then the equation of L is **[IIT-JEE 2011, 3M]**

(a) $y + \sqrt{3}x + 2 - 3\sqrt{3} = 0$ (b) $y - \sqrt{3}x + 2 + 3\sqrt{3} = 0$
(c) $\sqrt{3}y - x + 3 + 2\sqrt{3} = 0$ (d) $\sqrt{3}y + x - 3 + 2\sqrt{3} = 0$

109. The lines $L_1 : y - x = 0$ and $L_2 : 2x + y = 0$ intersect the line $L_3 : y + 2 = 0$ at P and Q respectively. The bisector of the acute angle between L_1 and L_2 intersects L_3 at R. **[AIEEE 2011, 4M]**

Statement I : The ratio $PR : RQ$ equals $2\sqrt{2} : \sqrt{5}$

Statement II : In any triangle, bisector of an angle divides the triangle into two similar triangles.

(a) Statement I is true, statement II is true; statement II is not a correct explanation for statement I.
(b) Statement I is true, statement II is false.
(c) Statement I is false, statement II is true.
(d) Statement I is true, statement II is true; statement II is a correct explanation for statement I

110. If the line $2x + y = k$ passes through the point which divides the line segment joining the points (1, 1) and (2, 4) in the ratio 3 : 2, then k equals **[AIEEE 2012, 4M]**

(a) $\frac{29}{5}$ (b) 5
(c) 6 (d) $\frac{11}{5}$

111. A ray of light along $x + \sqrt{3}y = \sqrt{3}$ gets reflected upon reaching X-axis, the equation of the reflected ray is **[JEE Main 2013, 4M]**

(a) $y = x + \sqrt{3}$ (b) $\sqrt{3}y = x - \sqrt{3}$
(c) $y = \sqrt{3}x - \sqrt{3}$ (d) $\sqrt{3}y = x - 1$

112. For $a > b > c > 0$, the distance between (1, 1) and the point of intersection of the lines $ax + by + c = 0$ and $bx + ay + c = 0$ is less than $2\sqrt{2}$. Then **[JEE Advanced 2013, 3M]**

(a) $a + b - c > 0$ (b) $a - b + c < 0$
(c) $a - b + c > 0$ (d) $a + b - c < 0$

113. Let PS be the median of the triangle with vertices $P(2, 2)$, $Q(6, -1)$ and $R(7, 3)$. The equation of the line passing through $(1, -1)$ and parallel to PS is **[JEE Main 2014, 4M]**

(a) $4x + 7y + 3 = 0$ (b) $2x - 9y - 11 = 0$
(c) $4x - 7y - 11 = 0$ (d) $2x + 9y + 7 = 0$

114. Let a, b, c and d be non-zero numbers. If the point of intersection of the lines $4ax + 2ay + c = 0$ and $5bx + 2by + d = 0$ lies in the fourth quadrant and is equidistant from the two axes, then **[JEE Main 2014, 4M]**

(a) $3bc - 2ad = 0$ (b) $3bc + 2ad = 0$
(c) $2bc - 3ad = 0$ (d) $2bc + 3ad = 0$

115. For a point P in the plane, let $d_1(P)$ and $d_2(P)$ be the distance of the point P from the lines $x - y = 0$ and $x + y = 0$ respectively. The area of the region R consisting of all points P lying in the first quadrant of the plane and satisfying $2 \le d_1(P) + d_2(P) \le 4$, is **[JEE Advanced 2014, 3M]**

116. The number of points, having both co-ordinates as integers, that lie in the interior of the triangle with vertices (0, 0), (0, 41) and (41, 0) is **[JEE Advanced 2015, 4M]**

(a) 820 (b) 780
(c) 901 (d) 861

117. Two sides of a rhombus are along the lines, $x - y + 1 = 0$ and $7x - y - 5 = 0$. If its diagonals intersect at $(-1, -2)$, then which one of the following is a vertex of this rhombus? **[JEE Main 2016, 4M]**

(a) $\left(\frac{1}{3}, -\frac{8}{3}\right)$ (b) $\left(-\frac{10}{3}, -\frac{7}{3}\right)$
(c) $(-3, -9)$ (d) $(-3, -8)$

Solutions

1. Equation of line passing through (2, 0) and perpendicular to $ax + by + c = 0$

Then, required equation is

$$y - 0 = \frac{b}{a}(x - 2)$$

$$ay = bx - 2b$$

$$\Rightarrow \quad ay - bx + 2b = 0$$

2. $\because \frac{2}{1!9!} + \frac{2}{3!7!} + \frac{1}{5!5!} = \frac{2^m}{n!}$

$$\frac{1}{10!}\left\{\frac{2 \times 10!}{1!9!} + \frac{2 \times 10!}{3!7!} + \frac{10!}{5!5!}\right\} = \frac{2^m}{n!}$$

$$\Rightarrow \quad \frac{1}{10!}\{2^{10}C_1 + 2^{10}C_3 + {}^{10}C_5\} = \frac{2^m}{n!}$$

$$\frac{1}{10!}\{{}^{10}C_1 + {}^{10}C_3 + {}^{10}C_5 + {}^{10}C_7 + {}^{10}C_9\} = \frac{2^m}{n!}$$

$$\Rightarrow \quad \frac{1}{10!}(2)^{10-1} = \frac{2^m}{n!}$$

$$\therefore \quad m = 9 \text{ and } n = 10$$

Hence, $x - y + 1 = 0$ and $x + y + 3 = 0$ are perpendicular to each other, then orthocentre is the point of intersection which is $(-2, -1)$

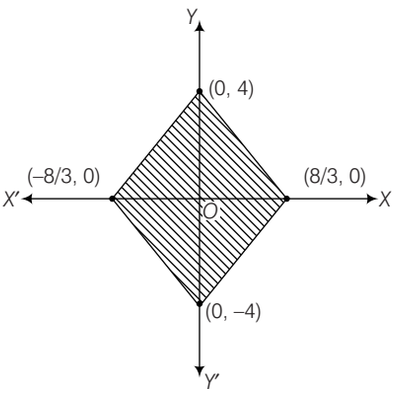
$\therefore \quad -2 = 2m - 2n$ and $-1 = m - n$

$\therefore$ Point is $(2m - 2n, m - n)$.

3. $\therefore$ Required area

$$= 4 \times \frac{1}{2}\left(\frac{8}{3} \times 4\right) = \frac{64}{3} = \frac{2^6}{3} \qquad \ldots(i)$$

$\because \quad f(x + y) = f(x)f(y)$



$$\therefore \quad f(2) = f(1)f(1) = 2^2$$

$$f(3) = f(1 + 2) = f(1)f(2) = 2^3$$

.....

.....

$$\therefore \quad f(n) = 2^n$$

$$\therefore \quad \text{Area} = \frac{2^6}{3} = \frac{f(6)}{3} \text{ sq units}$$

4. We have, $y = \cos x \cos(x + 2) - \cos^2(x + 1)$

$$y = \frac{1}{2}\{2\cos x \cos(x + 2) - 2\cos^2(x + 1)\}$$

$$= \frac{1}{2}\{\cos(2x + 2) + \cos 2 - 1 - \cos(2x + 2)\}$$

$$= \frac{1}{2}(\cos 2 - 1)$$

$$= \frac{1}{2}(1 - 2\sin^2 1 - 1)$$

$$= -\sin^2 1$$

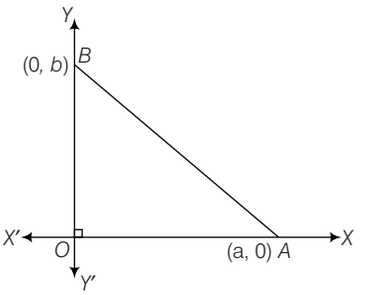
which is a straight line passing through $(\lambda, -\sin^2 1)$; $\forall\ \lambda \in R$ and parallel to the X-axis.

5. Let line $\frac{x}{a} + \frac{y}{b} = 1$ ...(i)

Its passes through (2, 2), then

$$\frac{2}{a} + \frac{2}{b} = 1$$

$$\Rightarrow \quad 2(a + b) = ab \qquad \ldots(ii)$$



$\because$ Area of $\Delta AOB = \frac{1}{2}ab = |\lambda|$ (given)

$$\therefore \quad ab = 2|\lambda|$$

from Eq. (ii), $\quad a + b = |\lambda|$

Hence, required equation is

$$x^2 - (a + b)x + ab = 0$$

or $\quad x^2 - |\lambda| x + 2|\lambda| = 0$

6. $\frac{\text{Value of } (a^2x + aby + 1) \text{ at } (1, 1)}{\text{Value of } (a^2x + aby + 1) \text{ at } (0, 0)} > 0$

or $\quad \frac{a^2 + ab + 1}{1} > 0;\ \forall\ a \in R$

or $\quad a^2 + ab + 1 > 0;\ \forall\ a \in R$

$$\therefore \quad D < 0$$

$$\Rightarrow \quad b^2 - 4 < 0$$

$$\Rightarrow \quad -2 < b < 2 \text{ but } b > 0$$

$$\therefore \quad 0 < b < 2$$

i.e. $\quad b \in (0, 2)$

7. Equation of L is $\frac{x}{a}+\frac{y}{b}=1$ and let the axis be rotated through an angle θ and let (X, Y) be the new coordinates of any point $P(x, y)$ in the plane, then
$x = X\cos\theta - Y\sin\theta$, $y = X\sin\theta + Y\cos\theta$, the equation of the line with reference to original coordinates is

$$\frac{x}{a}+\frac{y}{b}=1$$

i.e. $$\frac{X\cos\theta - Y\sin\theta}{a}+\frac{X\sin\theta + Y\cos\theta}{b}=1 \quad \ldots(i)$$

and with reference to new coordinates is

$$\frac{X}{p}+\frac{Y}{q}=1 \quad \ldots(ii)$$

Comparing Eqs. (i) and (ii), we get

$$\frac{\cos\theta}{a}+\frac{\sin\theta}{b}=\frac{1}{p} \quad \ldots(iii)$$

and $$-\frac{\sin\theta}{a}+\frac{\cos\theta}{b}=\frac{1}{q} \quad \ldots(iv)$$

Squaring and adding Eqs. (iii) and (iv), we get

$$\frac{1}{a^2}+\frac{1}{b^2}=\frac{1}{p^2}+\frac{1}{q^2}$$

8. $d(x, y) = \max\{|x|, |y|\}$ ...(i)

but $d(x, y) = a$ ...(ii)

From Eqs. (i) and (ii), we get

$a = \max\{|x|, |y|\}$

if $|x| > |y|$, then $a = |x|$

$\therefore$ $x = \pm a$

and if $|y| > |x|$, then $a = |y|$

$\therefore$ $y = \pm a$

Therefore locus represents a straight line.

9. $P_1 = |m^2\cos\alpha + 2m\sin\alpha + \frac{\sin^2\alpha}{\cos\alpha}|$

$$= \frac{(m\cos\alpha + \sin\alpha)^2}{|\cos\alpha|}$$

$$p_2 = \left|mm'\cos\alpha + (m+m')\sin\alpha + \frac{\sin^2\alpha}{\cos\alpha}\right|$$

$$= \frac{|(m\cos\alpha + \sin\alpha)|\,|m'\cos\alpha + \sin\alpha|}{|\cos\alpha|}$$

and $p_3 = |m'^2\cos\alpha + 2m'\sin\alpha + \frac{\sin^2\alpha}{\cos\alpha}|$

$$= \frac{(m'\cos\alpha + \sin\alpha)^2}{|\cos\alpha|}$$

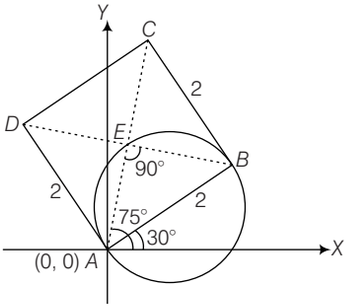
$\because$ $p_2^2 = p_1 p_3$

Hence, p_1, p_2, p_3 are in GP.

10. Side of the square = 2 unit

Coordinates of B, C and D are $(\sqrt{3}, 1)$, $(\sqrt{3}-1, \sqrt{3}+1)$ and $(-1, \sqrt{3})$ respectively.

Slope of $BD = \frac{\sqrt{3}-1}{-1-\sqrt{3}} = \frac{(\sqrt{3}-1)(\sqrt{3}-1)}{-2} = \sqrt{3}-2$



$\therefore$ Equation of BD is

$$y-1 = (\sqrt{3}-2)(x-\sqrt{3})$$

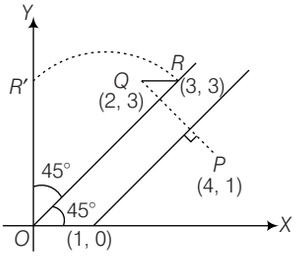
$\Rightarrow$ $$(2-\sqrt{3})x + y = 2(\sqrt{3}-1)$$

and equation of the circumcircle of the triangle ABE (Apply diametric form as AB is diameter)

$$(x-0)(x-\sqrt{3}) + (y-0)(y-1) = 0$$

$\Rightarrow$ $$x^2 + y^2 - x\sqrt{3} - y = 0$$

11. If (α, β) be the image of $(4, 1)$ w.r.t $y = x-1$, then $(\alpha, \beta) = (2, 3)$, say point Q



After translation through a distance 1 unit along the positive direction of X-axis at the point whose coordinate are $R \equiv (3, 3)$.

After rotation through are angle $\frac{\pi}{4}$ about the origin in the anticlockwise direction, then R goes to R' such that

$$OR = OR' = 3\sqrt{2}$$

$\therefore$ The coordinates of the final point are $(0, 3\sqrt{2})$.

12. $\because$ $A \equiv (0, 0)$; $B \equiv (2, 0)$; $C \equiv (2, 2)$; $D \equiv (0, 2)$

(i) $f_1(x, y) \to (y, x)$, then

$A \equiv (0, 0)$; $B \equiv (0, 2)$; $C \equiv (2, 2)$, $D \equiv (2, 0)$

(ii) $f_2(x, y) \to (x + 3y, y)$, then

$A \equiv (0, 0)$; $B \equiv (6, 2)$; $C \equiv (8, 2)$, $D \equiv (2, 0)$

(iii) $f_3(x, y) \to \left(\frac{x-y}{2}, \frac{x+y}{2}\right)$, then

$A \equiv (0, 0)$; $B \equiv (2, 4)$; $C \equiv (3, 5)$, $D \equiv (1, 1)$

Now, $AB = DC = 2\sqrt{5}$, $AD = BC = \sqrt{2}$

and $AC = \sqrt{34}$, $BD = \sqrt{10}$

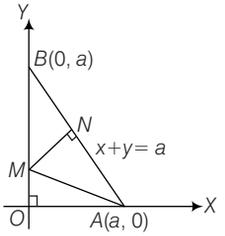
i.e. $AC \neq BD$

$\therefore$ Final figure is a parallelogram.

13. Let $\frac{AN}{BN} = \lambda$

Then, coordinate of N are $\left(\frac{a}{1+\lambda}, \frac{a\lambda}{1+\lambda}\right)$

$\because$ Slope of $AB = -1$



$\therefore$ Slope of $MN = 1$

$\therefore$ Equation on MN is

$$y - \frac{a\lambda}{1+\lambda} = x - \frac{a}{1+\lambda} \Rightarrow x - y = a\left(\frac{1-\lambda}{\lambda+1}\right)$$

So, the coordinates of M are $\left(0, a\left(\frac{\lambda-1}{\lambda+1}\right)\right)$

Therefore, area of $\Delta AMN = \frac{3}{8}$ area of ΔOAB

$$\Rightarrow \quad \frac{1}{2}\cdot AN \cdot MN = \frac{3}{8}\cdot\frac{1}{2}a\cdot a$$

$$\Rightarrow \quad \frac{1}{2}\cdot\left|\frac{a\lambda\sqrt{2}}{1+\lambda}\cdot\frac{a\sqrt{2}}{1+\lambda}\right| = \frac{3}{8}\cdot\frac{1}{2}a\cdot a$$

$$\Rightarrow \quad \frac{a^2\lambda}{(1+\lambda)^2} = \frac{3}{8}\cdot\frac{1}{2}a^2$$

$$\therefore \quad \lambda = 3 \quad \text{or} \quad \lambda = \frac{1}{3}$$

For $\lambda = \frac{1}{3}$, then M lies outside the segment OB and hence the required value of $\lambda = 3$.

14. Let $S = (x, y)$, given $(SQ)^2 + (SR)^2 = 2(SP)^2$

$$\Rightarrow \quad (x+1)^2 + y^2 + (x-2)^2 + y^2 = 2[(x-1^2) + y^2]$$

$$\Rightarrow \quad 2x^2 + 2y^2 - 2x + 5 = 2(x^2 + y^2 - 2x + 1)$$

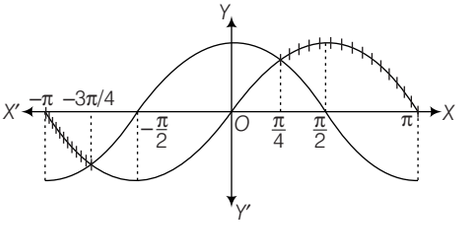
$$\Rightarrow \quad 2x + 3 = 0 \Rightarrow x = -\frac{3}{2}$$

A straight line parallel to Y-axis.

15. $$\frac{\text{Value of}(3x-2y+1) \text{ at } A}{\text{Value of } (3x-2y+1) \text{ at } B} > 0$$

$$\Rightarrow \quad \frac{(\sin\alpha - 3) - (\cos\alpha - 2) + 1}{(3-2+1)} > 0$$

$$\Rightarrow \quad \sin\alpha - \cos\alpha > 0 \Rightarrow \sin\alpha > \cos\alpha$$



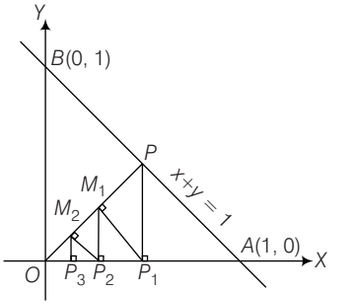
It is clear from the figure

$$\alpha \in \left(-\pi, \frac{-3\pi}{4}\right) \cup \left(\frac{\pi}{4}, \pi\right).$$

16. $\because$ Equation of AB is $x + y = 1$, then coordinates of A and B are (1, 0) and (0, 1) respectively.

$\therefore$ Coordinates of P are $\left(\frac{1}{2}, \frac{1}{2}\right)$

$\because$ PP_1 is perpendicular to OA



Equation of OP is $y = x$

Then, $$OP_1 = PP_1 = \frac{1}{2}$$

We have, $$(OM_{n-1})^2 = (OP_n)^2 + (P_nM_{n-1})^2$$

$$= 2(OP_n)^2 \qquad \{\because y = x\}$$

$$= 2\alpha_n^2 \text{ (say)}$$

Also, $$(OP_{n-1})^2 = (OM_{n-1})^2 + (P_{n-1}M_{n-1})^2$$

$$\alpha_{n-1}^2 = 2\alpha_n^2 + \frac{1}{2}\alpha_{n-1}^2$$

$$\Rightarrow \quad \frac{1}{2}\alpha_{n-1}^2 = 2\alpha_n^2$$

$$\Rightarrow \quad \alpha_n = \frac{1}{2}\alpha_{n-1}$$

$$\therefore \quad OP_n = \alpha_n = \frac{1}{2}\alpha_{n-1}$$

$$= \frac{1}{2^2}\alpha_{n-2} = \frac{1}{2^3}\alpha_{n-3}$$

.....

.....

.....

$$= \frac{1}{2^{n-1}}\alpha_1$$

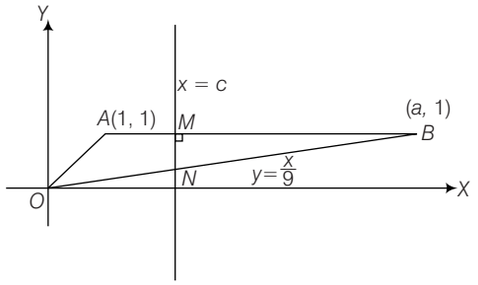
$$= \frac{1}{2^{n-1}}\left(\frac{1}{2}\right) = \frac{1}{2^n}.$$

17. Let $O \equiv (0, 0)$, $A \equiv (1, 1)$ and $B \equiv (9, 1)$

Area of $\Delta OAB = \frac{1}{2} \times 8 \times 1 = 4$

It is clear that $1 < c < 9$

and $$M \equiv (c, 1) \text{ and } N \equiv \left(c, \frac{c}{9}\right)$$



$\therefore$ Area of $\Delta BMN = 2$ (given)

$\Rightarrow \quad \frac{1}{2} \times (9 - c) \times \left(1 - \frac{c}{9}\right) = 2$

or $\quad (9 - c)^2 = 36$

or $\quad 9 - c = \pm 6 \Rightarrow c = 3$ or 15

but $\quad 1 < c < 9$

$\therefore \quad c = 3$

18. The three lines are concurrent if

$$\begin{vmatrix} 1 & 2 & -9 \\ 3 & -5 & -5 \\ a & b & -1 \end{vmatrix} = 0$$

or $\quad 5a + 2b = 1$

which is three of the line $5x + 2y = 1$ passes through (a, b).

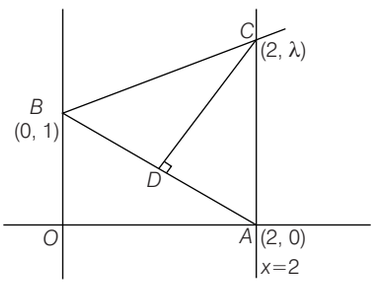
19. $\because BC = AC$

$\Rightarrow \quad 2^2 + (\lambda - 1)^2 = \lambda^2$

$\Rightarrow \quad 4 = \lambda^2 - (\lambda - 1)^2$

$= (2\lambda - 1)(1)$

$\therefore \quad \lambda = \frac{5}{2}$



$\because$ Equation. of AB is $\frac{x}{2} + \frac{y}{1} = 1$, $D \equiv \left(1, \frac{1}{2}\right)$ (mid-point of AB)

$\therefore$ Equation of CD is $2x - y = \mu$

$\because$ CD pass through D, thus

$$2 - \frac{1}{2} = \mu \text{ or } \mu = \frac{3}{2}$$

$\therefore$ Equation of CD is $\quad 2x - y = \frac{3}{2}$ ...(i)

and Eq. (i) of line $\perp$ to AC and pass through B is $y = 1$ ...(ii)

from Eqs. (i) and (ii), we get

Orthocentre $\equiv \left(\frac{5}{4}, 1\right)$

20. Let $A \equiv (3, 4)$, $B \equiv (0, y)$, $C \equiv (x, 0)$, $D \equiv (8, 2)$

$\therefore$ Slope of $AB = -$ Slope of BC

$\Rightarrow \quad \frac{y - 4}{0 - 3} = -\left(\frac{0 - y}{x - 0}\right)$

or $\quad 4x - xy = 3y$ ...(i)

and slope of $BC = -$ slope of CD

$\Rightarrow \quad \left(\frac{0 - y}{x - 0}\right) = -\left(\frac{2 - 0}{8 - x}\right)$

or $\quad 2x + xy = 8y$ ...(ii)

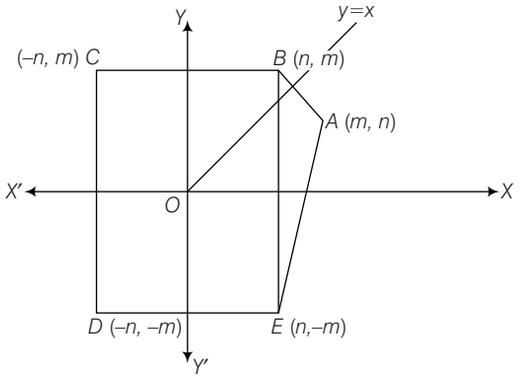
adding Eqs. (i) and (ii), we get

$$6x = 11y \quad \text{...(iii)}$$

from Eqs. (ii) and (iii), we get

$$x = \frac{13}{3} = 4\frac{1}{3}$$

21.



Area of rectangle $BCDE = (2n)(2m)$

$= 4mn$

and area of $\Delta ABE = \frac{1}{2} \times 2m \times (m - n)$

$= m(m - n)$

$\therefore$ Area of pentagon $= 4mn + m(m - n)$

$= m(m + 3n)$

22. The equation of the line L, be $y - 2 = m(x - 8)$, $m < 0$

coordinates of P and Q are $P\left(8 - \frac{2}{m}, 0\right)$ and $Q(0, 2 - 8m)$.

So, $\quad OP + OQ = 8 - \frac{2}{m} + 2 - 8m$

$= 10 + \frac{2}{(-m)} + 8(-m) \geq$

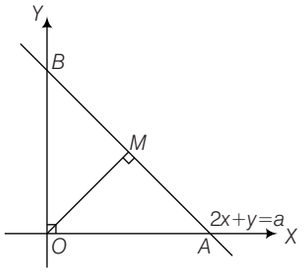
$10 + 2\sqrt{\frac{2}{(-m)} \times 8(-m)} \geq 18$

So, absolute minimum value of $OP + OQ = 18$

23. Let the two perpendiculars through the origin intersect $2x + y = a$ at A and B so that the triangle OAB is isosceles.

OM = length of perpendicular from O to

AB, $OM = \frac{a}{\sqrt{5}}$.



Also, $AM = MB = OM$

$\Rightarrow \quad AB = \dfrac{2a}{\sqrt{5}}$

Area of $\Delta OAB = \dfrac{1}{2} \cdot AB \cdot OM$

$= \dfrac{1}{2} \cdot \dfrac{2a}{\sqrt{5}} \cdot \dfrac{a}{\sqrt{5}} = \dfrac{a^2}{5}$ sq units

24. Solving given equations, we get

$$x = \frac{5}{3 + 4m}$$

x is an integer, if $3 + 4m = 1, -1, 5, -5$

or $\quad m = \dfrac{-2}{4}, \dfrac{-4}{4}, \dfrac{2}{4}, \dfrac{-8}{4}$

or $\quad m = -\dfrac{1}{2}, -1, \dfrac{1}{2}, -2$

Hence, m has two integral values.

25. Let the coordinates of A be $(a, 0)$. Then the slope of the reflected ray is

$$\frac{3-0}{5-a} = \tan\theta \qquad \text{(say) ...(i)}$$

Then the slope of the incident ray

$$= \frac{2-0}{1-a} = \tan(\pi - \theta)$$

From Eqs. (i) and (ii), we get

$$\tan\theta + \tan(\pi - \theta) = 0$$

$\Rightarrow \quad \dfrac{3}{5-a} + \dfrac{2}{1-a} = 0$

$\Rightarrow \quad 3 - 3a + 10 - 2a = 0$

$$a = \frac{13}{5}$$

Thus, the coordinate of A is $\left(\dfrac{13}{5}, 0\right)$

26. Lines $5x + 3y - 2 + \lambda(3x - y - 4) = 0$ are concurrent at $(1, -1)$ and lines

$x - y + 1 + \mu(2x - y - 2) = 0$ are concurrent at $(3, 4)$.

Thus equation of line common to both family is

$$y + 1 = \frac{4+1}{3-1}(x - 1)$$

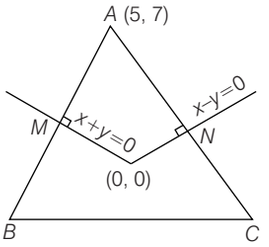
or $\quad 5x - 2y - 7 = 0$

$\therefore \quad a = 5, b = -2 \Rightarrow a + b = 3$

27. $\because$ B is the reflection of $A(5, 7)$ w.r.t the line $x + y = 0$

$\therefore \quad B \equiv (-7, -5)$

and C is the reflection of $A(5, 7)$ w.r.t the line $x - y = 0$



$\therefore \quad C \equiv (7, 5)$

$\therefore$ Equation of BC is $y + 5 = \dfrac{5+5}{7+7}(x + 7)$ or $7y = 5x$

28. Let $P \equiv (2, -1)$

$P(2, -1)$ goes 2 units along $x + y = 1$ upto A and 5 units along $x - 2y = 4$ upto B.

Now, slope of $x + y = -1$ is $-1 = \tan\theta$ (say)

$\therefore \quad \theta = 135°$

and slope $x - 2y = 4$ is $\dfrac{1}{2} = \tan\phi$ (say)

$\therefore \quad \sin\phi = \dfrac{1}{\sqrt{5}}, \cos\phi = \dfrac{2}{\sqrt{5}}$

The coordinates of A

i.e. $\quad (2 + 2\cos 135°, -1 + 2\sin 135°)$

or $\quad (2 - \sqrt{2}, \sqrt{2} - 1)$

The coordinates of B

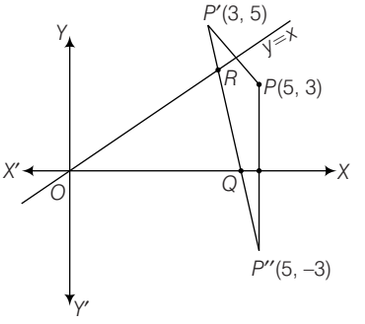
i.e. $(2 + 5\cos\phi, -1 + 5\sin\phi)$ or $(2 + 2\sqrt{5}, \sqrt{5} - 1)$

29. $\because \quad P \equiv (5, 3)$

Let P' and P'' be the images of P w.r.t $y = x$ and $y = 0$ (X-axis) respectively, then $P' \equiv (3, 5)$ and $P'' \equiv (5, -3)$

$\because \quad PQ + QR + RP$ is minimum

$\therefore \quad P', R, Q, P''$ are collinear.



$\therefore$ Equation of $P'P''$ is

$$y + 3 = \left(\frac{5+3}{3-5}\right)(x - 5)$$

or $\quad 4x + y = 17$

$\therefore \quad Q \equiv \left(\dfrac{17}{4}, 0\right)$ $(\because Q$ on Y-axis)

30. Equation of incident ray is

$$y - 0 = \tan(90° + 60°)(x - 2)$$

or $$y = -\frac{1}{\sqrt{3}}(x - 2)$$

or $$(x - 2) + y\sqrt{3} = 0$$

and equation of refracted ray is

$$y - 0 = -\tan 60°(x - 2)$$

or $$y = -\sqrt{3}(x - 2)$$

or $$(x - 2) + \frac{y}{\sqrt{3}} = 0$$

$\therefore$ Combined equation is

$$[(x - 2) + y\sqrt{3}]\left((x - 2) + \frac{y}{\sqrt{3}}\right) = 0$$

i.e. $$(x - 2)^2 + y^2 + \frac{4}{\sqrt{3}}(x - 2)y = 0$$

31. Point of intersection of $\frac{x}{a} + \frac{y}{b} = 1$ and $\frac{x}{b} + \frac{y}{a} = 1$ is $P\left(\frac{ab}{a+b}, \frac{ab}{a+b}\right)$, this point P satisfies alternates (a), (b), (c) and (d).

32. The two lines will be identical if their exists some real number k such that

$b^3 - c^3 = k(b - c)$, $c^3 - a^3 = k(c - a)$ and $a^3 - b^3 = k(a - b)$

$\Rightarrow$ $b - c = 0$ or $b^2 + c^2 + bc = k$

$c - a = 0$ or $c^2 + a^2 + ca = k$

and $a - b = 0$ or $a^2 + b^2 + ab = k$

$\Rightarrow$ $a = b$ or $b = c$ or $c = a$

or $b^2 + c^2 + bc = c^2 + a^2 + ca$

$\Rightarrow$ $b = c$ or $c = a$

or $a = b$ or $a + b + c = 0$

33. As the third vertex lies on the line $y = x + 3$, its coordinates are of the form $(x, x + 3)$. The area of the triangle with vertices $(2, 1)$, $(3, -2)$ and $(x, x + 3)$ is given by

$$\frac{1}{2}\left|\begin{vmatrix} x & x+3 & 1 \\ 2 & 1 & 1 \\ 3 & -2 & 1 \end{vmatrix}\right| = |2x - 2| = 5 \qquad \text{(given)}$$

$\therefore$ $2x - 2 = \pm 5 \Rightarrow x = \frac{-3}{2}, \frac{7}{2}$

Thus, the coordinates of the third vertex are $\left(\frac{7}{2}, \frac{13}{2}\right)$ or $\left(\frac{-3}{2}, \frac{3}{2}\right)$.

34. $\begin{vmatrix} 1 & -2 & -6 \\ 3 & 1 & -4 \\ \lambda & 4 & \lambda^2 \end{vmatrix} = 0$

$\Rightarrow$ $\lambda^2 + 2\lambda - 8 = 0$

$\therefore$ $(\lambda + 4)(\lambda - 2) = 0$

$\Rightarrow$ $\lambda = -4, 2$

35. Equation of any line through the point of intersection of the given lines is $(3x + y - 5) + \lambda(x - y + 1) = 0$.

Since this line is perpendicular to one of the given lines

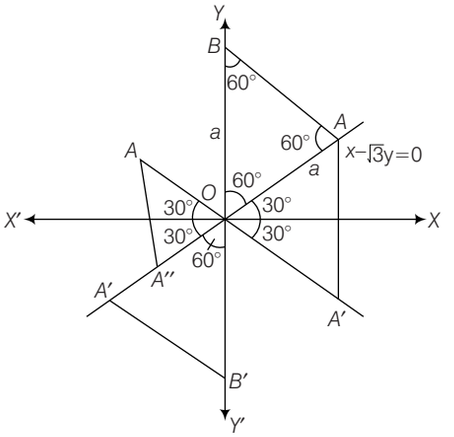
$$\frac{3 + \lambda}{\lambda - 1} = -1 \text{ or } \frac{1}{3}$$

$\Rightarrow \lambda = -1$ or -5, therefore the required straight line is

$$x + y - 3 = 0$$

or $$x - 3y + 5 = 0$$

36. If B lies on Y-axis, then coordinates of B are $(0, a)$ or $(0, -a)$



If third vertex in IV quadrant or in II quadrant, then its coordinates are $(a\cos 30°, -a\sin 30°)$ and $(-a\cos 30°, a\sin 30°)$

i.e. $$\left(\frac{a\sqrt{3}}{2}, -\frac{a}{2}\right) \text{ and } \left(-\frac{a\sqrt{3}}{2}, \frac{a}{2}\right),$$

37. Since, $ax + by + c = 0$, $bx + cy + a = 0$ and $cx + ay + b = 0$ are concurrent

$\therefore$ $$\begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = 0$$

$\Rightarrow$ $3abc - a^3 - b^3 - c^3 = 0$

$\Rightarrow$ $-(a + b + c)(a^2 + b^2 + c^2 - ab - bc - ca) = 0$

$a + b + c \neq 0$

$\therefore$ $a^2 + b^2 + c^2 - ab - bc - ca = 0$

$$\frac{1}{2}\{(a - b)^2 + (b - c)^2 + (c - a)^2\} = 0$$

As a, b, c are real numbers

$\therefore$ $b - c = 0, c - a = 0, a - b = 0$

$\Rightarrow$ $a = b = c$

38. $\because$ $E \equiv (4, 4)$

$\therefore z_C = 7 + 5i, z_E = 4 + 4i$

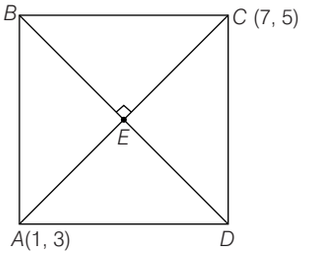
Now, (in ΔBEC)

$$\frac{z_B - z_E}{z_C - z_E} = e^{i\frac{\pi}{2}} = i$$

$\Rightarrow$ $z_B - 4 - 4i = i(7 + 5i - 4 - 4i)$

or $z_B = 3 + 7i$

$\therefore$ $B \equiv (3, 7)$, then $D \equiv (5, 1)$



Equation of AB is

$$y - 3 = \frac{7-3}{3-1}(x-1) \text{ or } 2x - y + 1 = 0$$

and equation of AD is

$$y - 3 = \frac{1-3}{5-1}(x-1) \text{ or } x + 2y - 7 = 0$$

39. Given,

$$6a^2 - 3b^2 - c^2 + 7ab - ac + 4bc = 0$$

$$\Rightarrow \quad 6a^2 + (7b - c)a - (3b^2 - 4bc + c^2) = 0$$

$$\Rightarrow \quad a = \frac{-(7b-c) \pm \sqrt{(7b-c)^2 + 24\,(3b^2 - 4bc + c^2)}}{12}$$

$$\Rightarrow \qquad 12a + 7b - c = \pm (11b - 5c)$$

$$\Rightarrow \qquad 12a - 4b + 4c = 0$$

or $\qquad 12a + 18b - 6c = 0$

$$\Rightarrow \qquad 3a - b + c = 0$$

or $\qquad -2a - 3b + c = 0$

Hence $(3, -1)$ or $(-2, -3)$ lies on the line $ax + by + c = 0$,

40. $x + 2y + 4 = 0$ and $4x + 2y - 1 = 0$

$$\Rightarrow \qquad x + 2y + 4 = 0$$

and $\qquad -4x - 2y + 1 = 0$

Here, $\qquad (1)(-4) + (2)(-2) = -8 < 0$

$\therefore$ Bisector of the angle including the acute angle bisectors and origin is

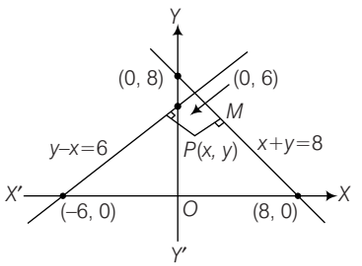
$$\frac{x + 2y + 4}{\sqrt{5}} = \frac{(-4x - 2y + 1)}{2\sqrt{5}}$$

$$\Rightarrow \qquad 6x + 6y + 7 = 0$$

41. Let position of bunglow is $P(x_1, y_1)$, then $PM = 100$ and $PN = 100$

$\therefore$ $\qquad \dfrac{x_1 + y_1 - 8}{\sqrt{2}} = \pm\, 100$

and $\qquad \dfrac{x_1 - y_1 + 6}{\sqrt{2}} = \pm\, 100$



After solving, we get

$$x_1 = 1 \pm 100\sqrt{2}, 1$$

and $\qquad y_1 = 7, 7 \pm 100\sqrt{2}$

Hence, $\qquad (1 + 100\sqrt{2}, 7), (1 - 100\sqrt{2}, 7),$

$$(1, 7 + 100\sqrt{2}), (1, 7 - 100\sqrt{2})$$

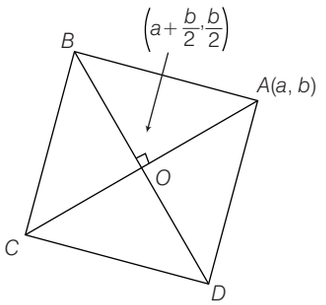
42. Equation of the other diagonal is $x + y = \lambda$ which pass through (a, b), then

$$a + b = \lambda$$

$\therefore$ Equation of other diagonal is

$$x + y = a + b$$

i.e. then centre of the square is the point of intersection of $x - y = a$ and $x + y = a + b$ is $\left(a + \dfrac{b}{2}, \dfrac{b}{2}\right)$, then vertex



$$C \equiv (2a + b - a, b - b)$$

$\therefore$ $\qquad C \equiv (a + b, 0)$

If $\qquad B \equiv z$

Then, $\qquad \dfrac{z - \left(a + \dfrac{b}{2} + \dfrac{ib}{2}\right)}{(a + ib) - \left(a + \dfrac{b}{2} + \dfrac{ib}{2}\right)} = \dfrac{BO}{AO} e^{i\frac{\pi}{2}} = i \quad (\because BO = AO)$

$$\Rightarrow \qquad z - \left(a + \frac{b}{2} + \frac{ib}{2}\right) = i\left(-\frac{b}{2} + \frac{ib}{2}\right) = -\frac{ib}{2} - \frac{b}{2}$$

$\therefore$ $\qquad z = a$

$\therefore$ $\qquad B \equiv (a, 0)$

then, $\qquad D \equiv (a + b, b)$

Hence, other vertices are $(a + b, 0), (a, 0)$ and $(a + b, b)$.

43. $(y - y_1) - m(x - x_1) = 0$ is family of lines

$\therefore$ $\qquad y - y_1 = 0, x - x_1 = 0$

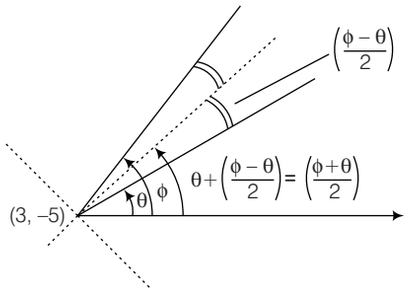
Then, $\qquad y = y_1$ and $x = x_1$

44. Given lines $L_1 = 0$ and $L_2 = 0$ are perpendicular and given bisectors are $\lambda_1 L_1 - \lambda_2 L_2 = 0$ and $\lambda_1 L_1 + \lambda_2 L_2 = 0$

$\therefore$ bisectors are perpendicular to each other.

Hence, bisectors of $\lambda_1 L_1 - \lambda_2 L_2 = 0$ and $\lambda_1 L_1 + \lambda_2 L_2 = 0$ are $L_1 = 0$ and $L_2 = 0$.

45. $\therefore$ One bisector makes an angle $\left(\dfrac{\theta + \phi}{2}\right)$ with X-axis, then other bisector makes an angle $90° + \left(\dfrac{\theta + \phi}{2}\right)$ with X-axis.



$\therefore$ Equations of bisectors are

$$\frac{x-3}{\cos\left(\frac{\theta+\phi}{2}\right)}=\frac{y+5}{\sin\left(\frac{\theta+\phi}{2}\right)} \quad \ldots(i)$$

and $$\frac{x-3}{\cos\left(\frac{\pi}{2}+\frac{\theta+\phi}{2}\right)}=\frac{y+5}{\sin\left(\frac{\pi}{2}+\frac{\theta+\phi}{2}\right)}$$

$\Rightarrow$ $$\frac{x-3}{-\sin\left(\frac{\theta+\phi}{2}\right)}=\frac{y+5}{\cos\left(\frac{\theta+\phi}{2}\right)} \quad \ldots(ii)$$

But given bisector are $\frac{x-3}{\cos\alpha}=\frac{y+5}{\sin\alpha}$

$\therefore$ $\alpha=\frac{\theta+\phi}{2}$ and $\frac{x-3}{\beta}=\frac{y+5}{\gamma}$ [from Eq. (i)]...(iii)

$\therefore$ $\beta=-\sin\left(\frac{\theta+\phi}{2}\right)=-\sin\alpha$ [from Eq. (ii)]

and $\gamma=\cos\left(\frac{\theta+\phi}{2}\right)=\cos\alpha$

46. $\because OR = AR$

$\Rightarrow$ $|x-0|+|y-0|=|x-1|+|y-2|$

$\Rightarrow$ $|x|+|y|=|x-1|+|y-2|$

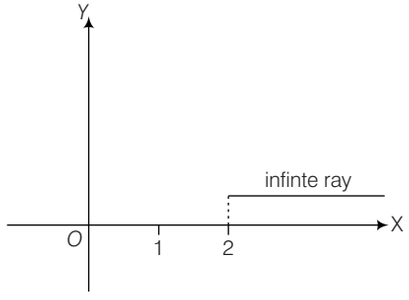
$\because$ $0 \le x < 1$ and $0 \le y < 2$

$\therefore$ $x+y=-(x-1)-(y-2)$

$\Rightarrow$ $2x+2y=3$

47. $OS = BS$

$\Rightarrow$ $|x-0|+|y-0|=|x-2|+|y-3|$



$\Rightarrow$ $|x|+|y|=|x-2|+|y-3|$

$\because$ $x \ge 2$ and $0 \le y < 3$

$\therefore$ $x+y=x-2+3-y$

$\Rightarrow$ $2y=1$

$\therefore$ $y=\frac{1}{2}$

48. $\because OT = CT$

$\Rightarrow$ $|x-0|+|y-0|=|x-4|+|y-3|$

$\because$ $x \ge 0, y \ge 0$

$\Rightarrow$ $x+y=|x-4|+|y-3|$

Case I : If $0 \le x \le 4$ and $0 \le y \le 3$

$x+y=4-x+3-y$

$\Rightarrow$ $x+y=\frac{7}{2}$

Case II : If $0 \le x \le 4$ and $y \ge 3$

$x+y=4-x+y-3$

$\Rightarrow$ $x=\frac{1}{2}$

Case III : If $x \ge 4$ and $0 \le y \le 3$

$x+y=x-4+3-y$

$y=-1/2$ (impossible)

Case IV : If $x \ge 4$ and $y \ge 3$

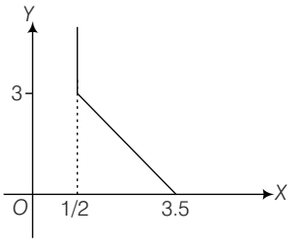
$x+y=x-4+y-3$

$\Rightarrow$ $0=-7$ (impossible)

Combining all cases, we get

$x+y=\frac{7}{2}, \forall\ 0 \le x \le 4$ and $0 \le y \le 3$

and $x=\frac{1}{2}, \forall\ 0 \le x \le 4$ and $y \ge 3$

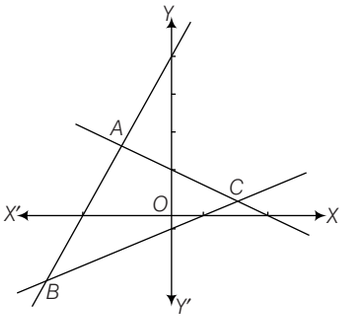


Sol. (Q. Nos. 49 to 51)

$AB : 2x-y+4=0,$

$BC : x-2y-1=0$

and $CA : x+3y-3=0$



$\therefore$ $m_{AB}=m_1=2$

$m_{BC}=m_2=\frac{1}{2}$

and $m_{CA}=m_3=-\frac{1}{3}$

$\because$ $m_1 > m_2 > m_3$

49. $\because \angle A$ is obtuse

$$\therefore \quad \tan A = \frac{m_3 - m_1}{1 + m_3 m_1}$$

$$= \frac{-\frac{1}{3} - 2}{1 - \frac{2}{3}} = -7$$

50. For external bisector of B

$$AB : 2x - y + 4 = 0$$

$$BC : -x + 2y + 1 = 0$$

$$\because \quad (2)(-1) + (-1)(2) = -4 < 0$$

$\therefore$ External bisector of B is

$$\left(\frac{2x - y + 4}{\sqrt{5}}\right) = -\frac{(-x + 2y + 1)}{\sqrt{5}}$$

or $$x + y + 5 = 0$$

51. Let (α, β) be the image of $B(-3, -2)$ w.r.t. the line $x + 3y - 3 = 0$, then

$$\frac{\alpha + 3}{1} = \frac{\beta + 2}{3} = \frac{-2(-3 - 6 - 3)}{1 + 9}$$

or $$\frac{\alpha + 3}{1} = \frac{\beta + 2}{3} = \frac{12}{5}$$

or $$\alpha = -\frac{3}{5} \text{ and } \beta = \frac{26}{5}$$

$\therefore$ Required image is $\left(-\frac{3}{5}, \frac{26}{5}\right)$,

Sol. (Q. Nos. 52 to 54)

Let $$B \equiv (\lambda, 2 - \lambda) \qquad (\because B \text{ lies on } x + y = 2)$$

Slope of line $AB = m_1 = \frac{1 + \lambda}{1 - \lambda}$

and Slope of line $BC = m_2 = \frac{5\lambda - 12}{-5\lambda - 2}$

$$= \frac{12 - 5\lambda}{2 + 5\lambda}$$

Let slope of bisector $(x + y = 2) = m_3 = -1$

Now, $$\frac{m_3 - m_1}{1 + m_3 m_1} = \frac{m_2 - m_3}{1 + m_2 m_3}$$

$$\Rightarrow \quad \frac{-1 - \frac{1 + \lambda}{1 - \lambda}}{1 - \frac{1 + \lambda}{1 - \lambda}} = \frac{\frac{12 - 5\lambda}{2 + 5\lambda} + 1}{1 - \frac{12 - 5\lambda}{2 + 5\lambda}}$$

or $$\frac{-2}{-2\lambda} = \frac{14}{-10 + 10\lambda}$$

or $$14\lambda = -10 + 10\lambda$$

$\therefore$ $$\lambda = \frac{-5}{2} \qquad \ldots(i)$$

52. Equation of BC is

$$y - (2 - \lambda) = \frac{-\frac{2}{5} - (2 - \lambda)}{-\frac{2}{5} - \lambda}(x - \lambda)$$

or $$y - 2 - \frac{5}{2} = \frac{-\frac{2}{5} - \frac{9}{2}}{-\frac{2}{5} + \frac{5}{2}}\left(x + \frac{5}{2}\right)$$

or $$7x + 3y + 4 = 0$$

53. Coordinates of vertex B are $(\lambda, 2 - \lambda)$

i.e. $$\left(-\frac{5}{2}, \frac{9}{2}\right) \qquad \text{[from Eq. (i)]}$$

54. $A \equiv (1, 3)$ and $B \equiv \left(-\frac{5}{2}, \frac{9}{2}\right)$

$\therefore$ Equation of AB is

$$y - 3 = \frac{\frac{9}{2} - 3}{-\frac{5}{2} - 1}(x - 1)$$

or $$3x + 7y = 24$$

55. Any point on the line $3x - y = 2$ is $(t, 3t - 2)$, t being parameter.
If (x, y) be image of the point $(t, 3t - 2)$ in the line $y = x - 1$ or $x - y - 1 = 0$, then

$$\frac{x - t}{1} = \frac{y - (3t - 2)}{-1}$$

$$= -\frac{2(t - 3t + 2 - 1)}{1 + 1}$$

$$\Rightarrow \quad \frac{x - t}{1} = \frac{y - 3t + 2}{-1} = 2t - 1$$

or $$x - t = 2t - 1$$

$$\Rightarrow \quad x + 1 = 3t \qquad \ldots(i)$$

and $$y - 3t + 2 = -2t + 1$$

$$\Rightarrow \quad y + 1 = t \qquad \ldots(ii)$$

From Eqs. (i) and (ii), we get

$$x + 1 = 3(y + 1)$$

$$\Rightarrow \quad x - 3y = 2$$

56. Any point on the circle $x^2 + y^2 = 4$ is $(2\cos\theta, 2\sin\theta)$, θ being parameter.
If (x, y) be image of the point $(2\cos\theta, 2\sin\theta)$, in the line $x + y = 2$, then

$$\frac{x - 2\cos\theta}{1} = \frac{y - 2\sin\theta}{1}$$

$$= \frac{-2(2\cos\theta + 2\sin\theta - 2)}{1 + 1}$$

or $$x - 2\cos\theta = y - 2\sin\theta$$

$$= -2\cos\theta - 2\sin\theta + 2 \qquad \ldots(i)$$

or $$x - 2\cos\theta = -2\cos\theta - 2\sin\theta + 2$$

$$\Rightarrow \quad x - 2 = -2\sin\theta$$

and $$y - 2\sin\theta = -2\cos\theta - 2\sin\theta + 2$$

$$\Rightarrow \quad y - 2 = -2\cos\theta \qquad \ldots(ii)$$

From Eqs. (i) and (ii),

$$(x - 2)^2 + (y - 2)^2 = 4$$

$$\Rightarrow \quad x^2 + y^2 - 4x - 4y + 4 = 0$$

57. Any point on the parabola $x^2 = 4y$ is $(2t, t^2)$, t being parameter.

If (x, y) be image of the point $(2t, t^2)$ in the $x + y = a$, then

$$\frac{x-2t}{1} + \frac{y-t^2}{1} = \frac{-2(2t + t^2 - a)}{1+1}$$

$$= -2t - t^2 + a$$

or $\quad x - 2t = -2t - t^2 + a$

$\Rightarrow \quad x - a = -t^2 \quad \ldots(i)$

and $\quad y - t^2 = -2t - t^2 + a$

$\Rightarrow \quad y - a = -2t \quad \ldots(ii)$

From Eqs. (i) and (ii) we get

$$(y-a)^2 = 4t^2 = -4(x-a)$$

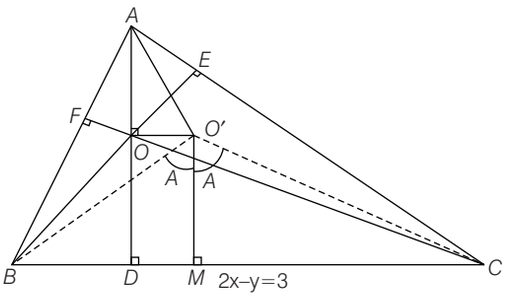
or $\quad (y-a)^2 = 4(a-x)$

Sol. (Q. Nos. 58 to 60)

Given orthocentre $O \equiv (1, 2)$

and circumcentre

$$O' = (2, 4)$$



$\because$ Slope of $OO' =$ Slope of $(2x - y = 3)$

and $\quad OD = O'M = \frac{3}{\sqrt{5}}$

Let R be the circumradius

$\therefore \quad O'M = R\cos A$

$\Rightarrow \quad R\cos A = \frac{3}{\sqrt{5}} \quad \ldots(i)$

58. $R = AO' = \sqrt{(AO)^2 + (OO')^2}$

$$= \sqrt{(2R\cos A)^2 + 5}$$

$$= \sqrt{\left(\frac{6}{\sqrt{5}}\right)^2 + 5} \qquad \text{[from Eq. (i)]}$$

$$= \sqrt{\frac{61}{5}}$$

59. $\because OD = 2R\cos B\cos C$

$\therefore \quad 2R\cos B\cos C = \frac{3}{\sqrt{5}}$

$= R\cos A \qquad$ [from Eq. (i)] ...(ii)

$\Rightarrow \quad \cos A = 2\cos B\cos C$

$\Rightarrow \quad -\cos(B + C) = 2\cos B\cos C \qquad (\because A + B + C = \pi)$

$\Rightarrow \quad -(\cos B\cos C - \sin B\sin C) = 2\cos B\cos C$

or $\quad \sin B\sin C = 3\cos B\cos C$

$$= 3 \times \frac{3}{2R\sqrt{5}}$$

$$= \frac{9}{2\sqrt{61}} \qquad \left(\because R = \sqrt{\frac{61}{5}}\right)$$

60. $\because AO = 2R\cos A$

$$= 2 \times \frac{3}{\sqrt{5}} \qquad \text{[from Eq. (i)]}$$

$$= \frac{6}{\sqrt{5}}$$

61. The equation of straight line through (2, 3) with slope m is

$$y - 3 = m(x - 2)$$

or $\quad mx - y = 2m - 3$

or $\quad \frac{x}{\left(\frac{2m-3}{m}\right)} + \frac{y}{(3-2m)} = 1$

Here, $\quad OA = \frac{2m-3}{m}$ or $OB = 3 - 2m$

$\because$ The area of $\Delta OAB = 12$

$\Rightarrow \quad \left|\frac{1}{2} \times OA \times OB\right| = 12$

or $\quad \frac{1}{2}\left(\frac{2m-3}{m}\right)(3-2m) = \pm 12$

or $\quad (2m-3)^2 = \pm 24m$

Taking positive sign, we get $4m^2 - 36m + 9 = 0$

Here $D > 0$, This is a quadratic in m which given two value of m, and taking negative sign, we get $(2m + 3)^2 = 0$.

This gives one line of m as $\frac{-3}{2}$.

Hence, three straight lines are possible.

62. $\because$ Point of intersection of $ax + 3y - 1 = 0$ and $ax + y + 1 = 0$ is $A\left(-\frac{2}{a}, 1\right)$ and point of intersection of $ax + 3y - 1 = 0$ and $x + 3y = 0$ is $B\left(\frac{1}{a-1}, -\frac{1}{3(a-1)}\right)$

$\Rightarrow \quad$ Slope of OA is $m_{OA} = -\frac{a}{2}$

and $\quad$ Slope of OB is $m_{OB} = -\frac{1}{3}$

$\because \quad m_{OA} \times m_{OB} = -1$

$\therefore \quad -\frac{a}{2} \times -\frac{1}{3} = -1$

or $\quad a = -6$

$\therefore \quad |a| = 6$

63. Here, B is the image of A w.r.t line $y = x$

$\therefore$ $B \equiv (2, 1)$ and C is the image of A w.r.t line $x - 2y + 1 = 0$ if $C \equiv (\alpha, \beta)$, then

$$\frac{\alpha - 1}{1} = \frac{\beta - 2}{-2} = \frac{-2(1 - 4 + 1)}{1 + 4}$$

or $\alpha = \frac{9}{5}$ and $\beta = \frac{2}{5}$

$\therefore$ $C \equiv \left(\frac{9}{5}, \frac{2}{5}\right)$

$\Rightarrow$ Equation of BC is

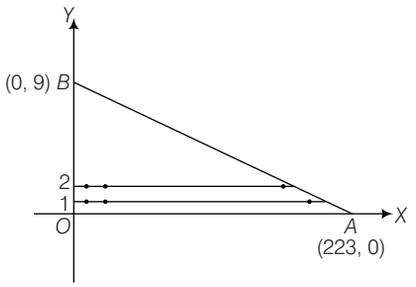
$$y - 1 = \frac{\left(\frac{2}{5} - 1\right)}{\left(\frac{9}{5} - 2\right)}(x - 2)$$

or $3x - y - 5 = 0$ ($\because$ Eq. of BC is $ax + by - 5 = 0$)

Here, $a = 3, b = -1$

$\therefore$ $a - 2b = 5$

64. On the line $y = 1$, the number of lattice points is $\left\lceil \frac{2007 - 223}{9} \right\rceil = 198$



Hence, the total number of points

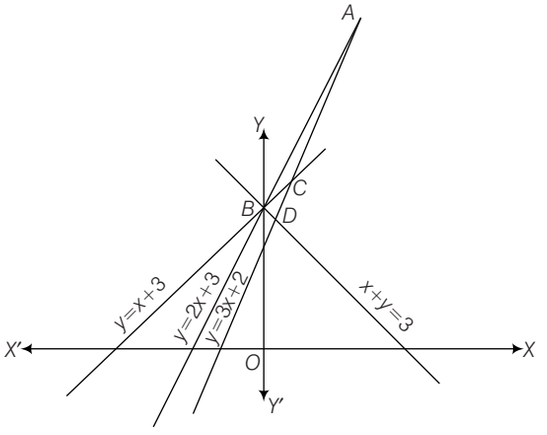
$$= \sum_{y=1}^{8} \left\lceil \frac{2007 - 223y}{9} \right\rceil$$

$$= 198 + 173 + 148 + 123 + 99 + 74 + 49 + 24 = 888$$

Hence, tens place digit is 8.

65. A rough sketch of the lines is given.

There are three triangle namely ABC, BCD and ABD



66. Let a be the length of side of square

$\therefore$ $a^2 + a^2 = 2^2 \Rightarrow a = \sqrt{2}$

i.e. distance between parallel lines is $\sqrt{2}$

Now, let two lines of family $y = x + n$ are $y = x + n$, and $y = x + n_2$, where

$n_1, n_2 \in \{0, 1, 2, 3, 4\}$

$\therefore$ $\frac{|n_1 - n_2|}{\sqrt{2}} = \sqrt{2}$

or $|n_1 - n_2| = 2$

$\Rightarrow$ $\{n_1, n_2\}$ are $\{0, 2\}$, $\{1, 3\}$ and $\{2, 4\}$

Hence, both the family have three such pairs. So, the number of squares possible is $3 \times 3 = 9$.

67. Let the coordinate of C be $(1, c)$, then

$$m_2 = \frac{c - y}{1 - x}$$

or $m_2 = \frac{c - m_1 x}{1 - x}$ ($\because$ slope of $AB = m_1$)

$\Rightarrow$ $m_2(1 - x) = c - m_1 x$

or $c = (m_1 - m_2)x + m_2$

Now, the area of ΔABC is $\frac{1}{2}|cx - y|$

$$= \frac{1}{2}|((m_1 - m_2)x + m_2)x - m_1 x| \quad (\because y = m_1 x)$$

$$= \frac{1}{2}(m_1 - m_2)(x - x^2) \quad [\because m_1 > m_2 \text{ and } x \in (0, 1)]$$

Hence, $f(x) = \frac{1}{2}(x - x^2)$

$\therefore$ $\frac{df(x)}{dx} = \frac{1}{2}(1 - 2x)$

and $\frac{d^2 f(x)}{dx^2} = -1 < 0$

For maximum of

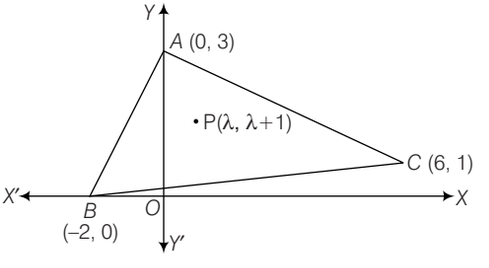
$$f(x), \frac{df(x)}{dx} = 0 \Rightarrow x = \frac{1}{2}$$

$\therefore$ $f(x)|_{\max} = \frac{1}{2}\left(\frac{1}{2} - \frac{1}{4}\right)$

$$= \frac{1}{8} = \lambda \quad \text{(given)}$$

$\Rightarrow$ $\frac{1}{\lambda} = 8$

68. Equation of AB is $3x - 2y + 6 = 0$



Equation of BC is $x - 8y + 2 = 0$,
Equation of CA is $x + 3y - 9 = 0$
Let $P \equiv (\lambda, \lambda + 1)$
$\because$ B and P lie on one side of AC, then

$$\frac{\lambda + 3(\lambda + 1) - 9}{-2 + 0 - 9} > 0$$

or $4\lambda - 6 < 0$

or $\lambda < \frac{3}{2}$ (i)

and C and P lie on one side of AB, then

$$\frac{3\lambda - 2(\lambda + 1) + 6}{18 - 2 + 6} > 0$$

or $\lambda + 4 > 0$

or $\lambda > -4$ ...(ii)

Finally, A and P lie on one side of BC, then

$$\frac{\lambda - 8(\lambda + 1) + 2}{0 - 24 + 2} > 0$$

or $-7\lambda - 6 < 0$

or $\lambda > -\frac{6}{7}$ ...(iii)

From Eqs. (i), (ii) and (iii), we get

$$-\frac{6}{7} < \lambda < \frac{3}{2}$$

Integral values of λ are 0 and 1.
Hence, number of integral values of λ is 2.

69. Lines

$$(2a + b)x + (a + 3b)y + b - 3a = 0$$

or $a(2x + y - 3) + b(x + 3y + 1) = 0$

are concurrent at the point of intersection of lines $2x + y - 3 = 0$ and $x + 3y + 1 = 0$ which is $(2, -1)$.
Now, line $\lambda x + 2y + 6 = 0$ must pass through $(2, -1)$, therefore,

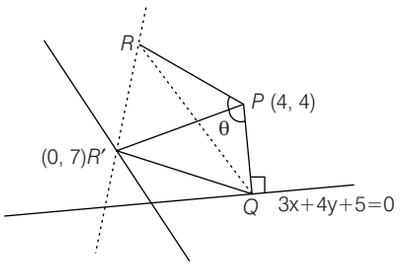
$$2\lambda - 2 + 6 \text{ or } \lambda = -2$$

$\therefore$ $|\lambda| = 2$

70. Since, PQ is of fixed length.

Area of $\Delta PQR = \frac{1}{2}|PQ|\,|RP|\sin\theta$

This will be maximum, if $\sin\theta = 1$ and RP is maximum.

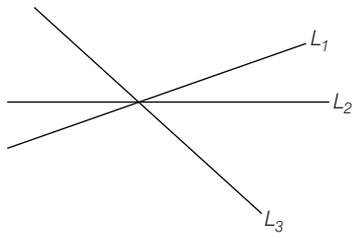


Since, line $y = mx + 7$ rotates about $(0, 7)$, if PR' is perpendicular to the line than PR' is maximum value of PR.

$\therefore$ $m = -\left(\frac{4 - 0}{4 - 7}\right) = \frac{4}{3}$

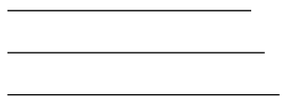
Hence, $3m = 4$

71. **(A)**



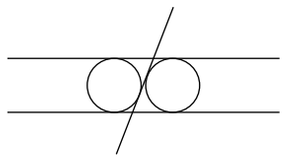
In this case no circle
$\therefore$ $n = 0 \Rightarrow n + 1 = 1$

(B)



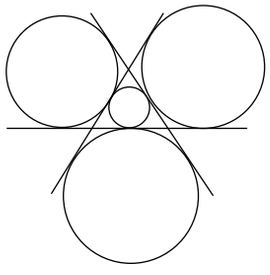
In this case no circle
$\therefore$ $n = 0 \Rightarrow 2n + 3 = 3$

(C)



In this case two circle which are touching all three lines
$\therefore$ $n = 2 \Rightarrow n + 2 = 4$

(D)



In this case four circle which are touching all three lines
$\therefore$ $n = 4 \Rightarrow n + 2 = 6$

72. **(A)** The given lines an concurrent. So,

$$\begin{vmatrix} 1 & -2 & -6 \\ 3 & 1 & -4 \\ \lambda & 4 & \lambda^2 \end{vmatrix} = 0$$

or $\lambda^2 + 2\lambda - 8 = 0$

or $\lambda = 2, -4$

$\therefore$ $|\lambda| = 2, 4$

(B) Given family is

$$3x(a + 1) + 4y(a - 1) - 3(a - 1) = 0$$

or $a(3x + 4y - 3) + (3x - 4y + 3) = 0$

for fixed point=

$$3x + 4y - 3 = 0$$

and $3x - 4y + 3 = 0$

$\therefore$ $x = 0, y = \frac{3}{4}$

Fixed point is $\left(0, \frac{3}{4}\right)$,

Here $p = 0, q = \frac{3}{4}$

$\therefore \quad 4|\lambda| = 4|p - q| = 3$

(C) The point of intersection of $x - y + 1 = 0$ and $3x + y - 5 = 0$ is $(1, 2)$. It lies on the line

$$x + y - 1 - \left|\frac{\lambda}{2}\right| = 0$$

$\Rightarrow \quad 1 + 2 - 1 - \left|\frac{\lambda}{2}\right| = 0$

or $\quad |\lambda| = 4 \text{ or } \lambda = -4, 4$

$\therefore \quad \lambda + 1 = -3, 5 \text{ or } |\lambda + 1| = 3, 5$

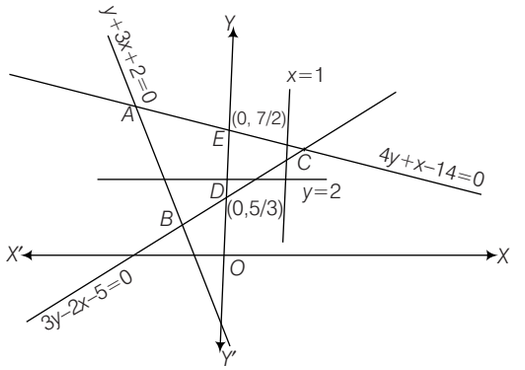
(D) The mid-point of $(1, -2)$ and $(3, 4)$ will satisfy

$$y - x - 1 + \lambda = 0$$

or $\quad 1 - 2 - 1 + \lambda = 0$

$\therefore \quad \lambda = 2 \text{ or } |\lambda| = 2$

73.



(A) The points on the line $x = 0$, whose y-coordinate lies between $\frac{5}{3}$ and $\frac{7}{2}$ inside the triangle ABC.

$\therefore \quad \frac{5}{3} < \lambda < \frac{7}{2} \text{ or } 5 < 3\lambda < 10.5$

$\therefore \quad |3\lambda| = 6, 7, 8, 9, 10$

(B) $\because C \equiv (2, 3)$

The points on the line $x = 1$, whose y-coordinate lies between

$\frac{8}{3}$ (put $x = 1$ in $3y - 2x - 5 = 0$)

and $\quad \frac{13}{4}$ (put $x = 1$ in $4y + x - 14 = 0$)

$\therefore \quad \frac{8}{3} < \lambda < \frac{13}{4} \text{ or } 8 < 3\lambda < 9.75$

$\therefore \quad |3\lambda| = 9$

(C) $\because B \equiv (-1, 1)$

The point on the line $y = 2$, whose x-coordinate lies between

$\frac{-4}{3}$ (put $y = 2$ in $y + 3x + 2 = 0$)

and $\quad \frac{1}{2}$ (put $y = 2$ in $3y - 2x - 5 = 0$)

$\therefore \quad \frac{-4}{3} < \lambda < \frac{1}{2} \text{ or } -8 < 6\lambda < 3$

Integral values of 6λ are

$-7, -6, -5, -4, -3, -2, -1, 0, 1, 2$

$\therefore \quad |6\lambda| = 7, 6, 5, 4, 3, 2, 1, 0$

(D) $\because A \equiv (-2, 4)$

The points on the line $y = \frac{7}{2}$, whose x-coordinates lies between

0 (put $y = \frac{7}{2}$ in $4y + x - 14 = 0$)

and $\quad \frac{-11}{6}$ (put $y = \frac{7}{2}$ in $y + 3x + 2 = 0$)

$\therefore \quad \frac{-11}{6} < \lambda < 0$

or $\quad -11 < 6\lambda < 0$

Integral value of 6λ are

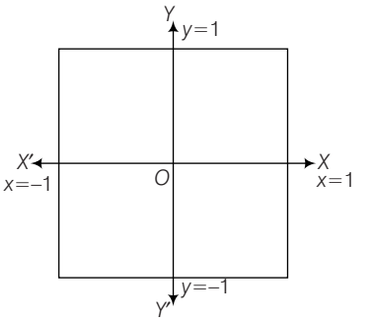
$-10, -9, -8, -7, -6, -3, -2, -1$

$\therefore \quad |6\lambda| = 10, 9, 8, 7, 6, 5, 4, 3, 2, 1$

74. **(A)** $\because \max.\{|x|, |y|\} = 1$

If $\quad |x| = 1$ and if $|y| = 1$

then $x = \pm 1$ and $y = \pm 1$



$\therefore \quad$ Required area $= 2 \times 2 = 4$ sq units

(B) The line $y = x$ cuts the lines $|x + y| = 6$

i.e. $\quad x + y = \pm 6$

at $\quad x = \pm 3, y = \pm 3$

or $\quad (-3, -3)$ and $(3, 3)$

then $\quad -3 < a < 3$

$\therefore \quad 0 \le |a| < 3$

$\therefore \quad [|a|] = 0, 1, 2$

(C) Since $(0, 0)$ and $(1, 1)$ lie on the same side.

So, $\quad a^2 + ab + 1 > 0$

$\because$ Coefficient of a^2 is > 0

$\therefore \quad D < 0$

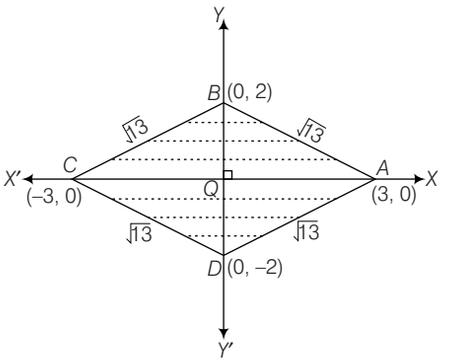
$b^2 - 4 < 0 \text{ or } -2 < b < 2$

$\Rightarrow \quad b = -1, 0, 1$

$\therefore$ Number of values of b is 3.

75. **(A)** $\because\ d(x, y) = 2|x| + 3|y| = 6$ (given)

$\therefore \qquad \dfrac{|x|}{3} + \dfrac{|y|}{2} = 1$



$\therefore$ Perimeter, $\lambda = 4\sqrt{13}$

and area, $\mu = 4 \times \dfrac{1}{2} \times 3 \times 2 = 12$

then $\dfrac{\lambda^2}{16} - \mu = 1$

and $\lambda^2 - \mu^2 = 64$

Hence, locus of (λ, μ) are

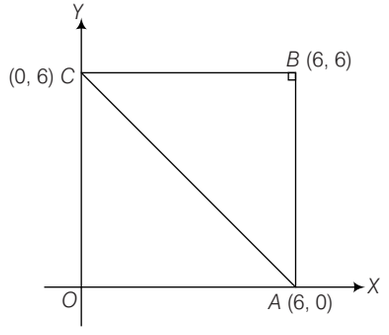
$x^2 - 16y = 16$

and $x^2 - y^2 = 64$

(B) It is clear that orthocentre is (6, 6)

$O' \equiv (6, 6)$,

Circumcentre is $C' \equiv (3, 3)$ and centroid is $G' \equiv (4, 4)$



$\therefore \qquad \lambda = O'C' = \sqrt{(0-3)^2 + (6-3)^2}$

$= \sqrt{9+9} = 3\sqrt{2}$

and $\mu = C'G' = \sqrt{(4-3)^2 + (4-3)^2}$

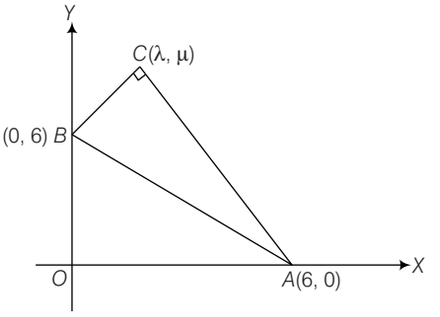
$= \sqrt{1+1} = \sqrt{2}$

$\therefore \quad \lambda^2 - \mu^2 = 16$ and $\lambda = 3\mu$

Hence, locus of (λ, μ) are

$x^2 - y^2 = 16$ and $x = 3y$

(C) $\therefore$ Slope of $AC \times$ slope of $BC = -1$



$\Rightarrow \qquad \left(\dfrac{\mu - 0}{\lambda - 6}\right) \times \left(\dfrac{\mu - 6}{\lambda - 0}\right) = -1$

$\Rightarrow \qquad \mu^2 - 6\mu = -\lambda^2 + 6\lambda$

or $\qquad \lambda^2 + \mu^2 - 6\lambda - 6\mu = 0$

Hence, locus of (λ, μ) is

$x^2 + y^2 - 6x - 6y = 0$

76. $\because \qquad x(a + 2b) + y(a + 3b) = a + b$

$\Rightarrow \qquad a(x + y - 1) + b(2x + 3y - 1) = 0$

then $\qquad x + y - 1 = 0$ and $2x + 3y - 1 = 0$

$\therefore$ point of intersection is $(2, -1)$

Hence, both statement are true and statement II is correct explanation for statement I.

77. $\because$ Algebraic perpendicular from (3, 2) to the line

$3x - 2y + 1 = 0$ is $\dfrac{9 - 4 + 1}{\sqrt{(9+4)}}$ i.e. $\dfrac{6}{\sqrt{13}} = p_1$ (say)

and algebraic perpendicular distance from (1, 4) to the line $3x - 2y + 1 = 0$ is

$\dfrac{3 - 8 + 1}{\sqrt{9+4}}$ i.e. $\dfrac{-4}{\sqrt{13}} = p_2$ (say)

$\therefore \qquad p_1 p_2 = \dfrac{6}{\sqrt{13}} \times \dfrac{-4}{\sqrt{13}} = \dfrac{-24}{13} < 0$

Hence, both statements are true and statement II is a correct explanation for statement I.

78. Sum of algebraic distances from points $A(1, 2)$, $B(2, 3)$, $C(6, 1)$ to the line $ax + by + c = 0$ is zero (given), then

$$\frac{a + 2b + c}{\sqrt{(a^2 + b^2)}} + \frac{(2a + 3b + c)}{\sqrt{(a^2 + b^2)}} + \frac{(6a + b + c)}{\sqrt{(a^2 + b^2)}} = 0$$

$\Rightarrow \qquad 9a + 6b + 3c = 0$

or $\qquad 3a + 2b + c = 0$

$\therefore$ Statement I is false.

Also, centroid of ΔABC is $\left(\dfrac{1 + 2 + 6}{3}, \dfrac{2 + 3 + 1}{3}\right)$

i.e. (3, 2)

$\therefore$ Statement II is true.

79. Equation of AB is

$$y-1=\frac{0-1}{2-0}(x-0) \Rightarrow x+2y-2=0$$

$\because \quad |PA-PB| \le |AB|$

$\Rightarrow |PA-PB|$ to be maximum, then A, B and P must be collinear.

Solving $\quad x+2y-2=0$

and $\quad 4x+3y+9=0,$

we get, $\quad P \equiv \left(\frac{24}{5}, \frac{17}{5}\right)$

Hence, Statement I is false and Statement II is obviously true.

80. Statement II is false as the point satisfying such a property can be the excentre of the triangle.

Let $\quad L_1 \equiv x\cos\left(\frac{\pi}{9}\right)+y\sin\left(\frac{\pi}{9}\right)-\pi=0,$

$$L_2 \equiv x\cos\left(\frac{8\pi}{9}\right)+y\sin\left(\frac{8\pi}{9}\right)-\pi=0 \text{ and}$$

$$L_3 \equiv x\cos\left(\frac{13\pi}{9}\right)+y\sin\left(\frac{8\pi}{9}\right)-\pi=0$$

and $\quad P \equiv (0, 0)$

Length $\perp$ from P to L_1 = Length of $\perp$ from P to L_2 = Length of $\perp$ from P to $L_3 = \pi$ and P lies inside the triangle.

$\therefore P(0, 0)$ is incentre of triangle.

Hence, statement I is true and statement II is false.

81. $\because$ Mid-point of $(5, 1)$ and $(-1, -5)$ i.e. $(2, -2)$ lies on $x+y=0$ and (slope of $x+y=0$) $\times$ (slope of line joining $(5, 1)$ and $(-1, -5)$) $= (-1)\times\frac{-6}{-6}$

$\therefore$ Statement I is true.

Statement II is also true.

Hence, both statements are true but statement II is not correct explanation of statement I.

82. Equation of AC and BC are $3x+2y=0$ and $2x+3y+6=0$

$\because (3)(2)+(2)(3)=12>0$

$\therefore$ Internal angle bisector of C is

$$\left(\frac{3x+2y}{\sqrt{13}}\right)=-\left(\frac{2x+3y+6}{\sqrt{13}}\right)$$

or $\quad 5x+5y+6=0$

$\Rightarrow$ Statement I is true.

Also, the image of A about the angle bisectors of angle B and C lie on the side BC. (by congruence).

$\therefore$ Statement II is true.

Both statements are true and statement II is not correct explanation of statement I.

83. $\because$ Points (x_1, y_1) and (x_2, y_2) lie on the same or opposite sides of the line

$$ax+by+c=0, \text{ as}$$

$$\frac{ax_1+by_1+c}{ax_2+by_2+c}>0 \text{ or } <0$$

$\therefore$ Statement II is true.

Also, $(2a-5, a^2)$ and $(0, 0)$ on the same side of $x+y-3=0$, then

$$\frac{2a-5+a^2-3}{0+0-3}>0$$

$\Rightarrow \quad a^2+2a-8<0$

or $\quad (a+4)(a-2)<0$

$\therefore \quad a \in (-4, 2)$

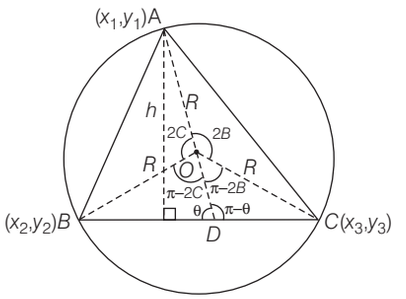
$\Rightarrow$ Statement I is false

Hence, statement I is false and statement II is true.

84. In ΔOBD, $\quad \frac{BD}{\sin(\pi-2C)}=\frac{R}{\sin\theta}$ ...(i)

In ΔODC, $\quad \frac{DC}{\sin(\pi-2B)}=\frac{R}{\sin(\pi-\theta)}$ ...(ii)

From Eqs. (i) and (ii), $\quad \frac{BD}{DC}=\frac{\sin 2C}{\sin 2B}$



$\therefore$ Coordinates of D are

$$\left(\frac{x_2\sin 2B+x_3\sin 2C}{\sin 2B+\sin 2C}, \frac{y_2\sin 2B+y_3\sin 2C}{\sin 2B+\sin 2C}\right)$$

Let (x, y) be any point on AD, then equation of AD is

$$\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ \frac{x_2\sin 2B+x_3\sin 2C}{\sin 2B+\sin 2C} & \frac{y_2\sin 2B+y_3\sin 2C}{\sin 2B+\sin 2C} & 1 \end{vmatrix}=0$$

or $$\begin{vmatrix} x & y & \\ x_1 & y_1 & \\ x_2\sin 2B+x_3\sin 2C & y_2\sin 2B+y_3\sin 2C & \end{vmatrix}$$

$$\begin{vmatrix} & & 1 \\ & & 1 \\ & & \sin 2B+\sin 2C \end{vmatrix}=0$$

or $$\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2\sin 2B & y_2\sin 2B & \sin 2B \end{vmatrix}$$

$$+\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3\sin 2C & y_3\sin 2C & \sin 2C \end{vmatrix}=0$$

or $$(\sin 2B)\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix}+(\sin 2C)\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}=0$$

85. Let (x_1, y_1) be the coordinates of a point at unit distance from each of the given lines.

$\Rightarrow \quad \dfrac{|3x_1 - 4y_1 + 1|}{\sqrt{3^2 + 4^2}} = 1$ and $\dfrac{|8x_1 + 6y_1 + 1|}{\sqrt{8^2 + 6^2}} = 1$

$\Rightarrow \quad 3x_1 - 4y_1 + 1 = \pm 5$ and $8x_1 + 6y_1 + 1 = \pm 10$

$\Rightarrow \quad 3x_1 - 4y_1 - 4 = 0$ ...(i)

or $\quad 3x_1 - 4y_1 + 6 = 0$ ...(ii)

$\quad 8x_1 + 6y_1 - 9 = 0$ ...(iii)

or $\quad 8x_1 + 6y_1 + 11 = 0$ ...(iv)

$(1) \cap (3)$

$\Rightarrow \quad x_1 / 60 = y_1 / -5 = 1 / 50,$

$\therefore \quad (x_1, y_1) = \left(\dfrac{6}{5}, -\dfrac{1}{10}\right)$

$(1) \cap (4)$

$\Rightarrow \quad x_1 / -20 = y_1 / -65 = 1 / 50,$

$\therefore \quad (x_1, y_1) = \left(-\dfrac{2}{5}, -\dfrac{13}{10}\right)$

$(2) \cap (3)$

$\Rightarrow \quad x_1 / 0 = y_1 / 75 = 1 / 50, \therefore (x_1, y_1) = (0, 3/2)$

$(2) \cap (4)$

$\Rightarrow \quad x_1 / -80 = y_1 / 15 = 1 / 50, \therefore (x_1, y_1) = \left(-\dfrac{8}{5}, \dfrac{3}{10}\right)$

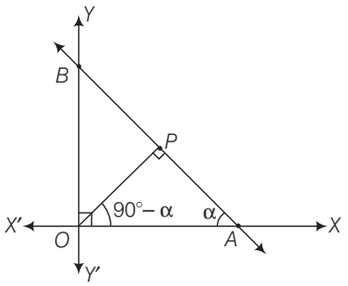
Hence, the required four points have the coordinates

$$\left(\frac{6}{5}, -\frac{1}{10}\right), \left(-\frac{2}{5}, -\frac{13}{10}\right), \left(0, \frac{3}{2}\right), \left(-\frac{8}{5}, \frac{3}{10}\right).$$

86. Let $\angle OAB = \alpha$

$\therefore \quad OA = AB \cos\alpha$ and $OB = AB \sin\alpha$

$\because \quad (OA)^2 + (OB)^2 = k^2$



i.e. $\quad (AB)^2 (\cos^2\alpha + \sin^2\alpha) = k^2$

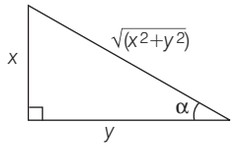
or $\quad AB = k$

then $\quad OA = k \cos\alpha$ and $OB = k \sin\alpha$

$\therefore$ Equation of AB is $\dfrac{x}{k\cos\alpha} + \dfrac{y}{k\sin\alpha} = 1$

or $\quad \dfrac{x}{\cos\alpha} + \dfrac{y}{\sin\alpha} = k$ ...(i)

Let P be the foot of perpendicular from O on AB.



$\therefore$ Equation of OP is $y = x \tan(90° - \alpha)$

or $\quad \cot\alpha = \dfrac{y}{x}$

$\therefore \quad \sin\alpha = \dfrac{x}{\sqrt{(x^2 + y^2)}}$

and $\quad \cos\alpha = \dfrac{y}{\sqrt{(x^2 + y^2)}}$ ...(ii)

Substituting the values of $\sin\alpha$ and $\cos\alpha$ from Eq. (i) in (i) then we get the required locus of P

$\therefore \quad \dfrac{x}{y / \sqrt{(x^2 + y^2)}} + \dfrac{y}{x / \sqrt{(x^2 + y^2)}} = k$

$\Rightarrow \quad (x^2 + y^2)\sqrt{(x^2 + y^2)} = kxy$

Squaring both sides, we get

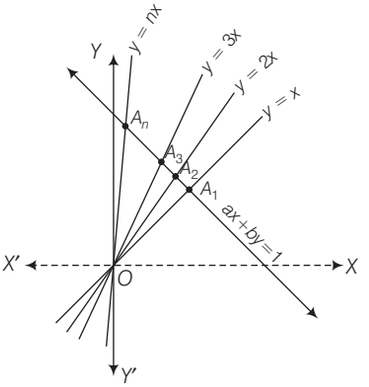
$$(x^2 + y^2)^2 (x^2 + y^2) = k^2 x^2 y^2$$

or $\quad (x^2 + y^2)^2 \left(\dfrac{x^2}{x^2y^2} + \dfrac{y^2}{x^2y^2}\right) = k^2$

or $\quad (x^2 + y^2)^2 (x^{-2} + y^{-2}) = k^2$

87. Let the equation of variable line be $ax + by = 1$. Then the coordinates of A_p will be

$$A_p \equiv \left(\frac{1}{a + bp}, \frac{p}{a + bp}\right)$$



$\therefore \quad OA_p = \dfrac{\sqrt{(1 + p^2)}}{|a + bp|}$ ...(i)

Given, $\quad \sum_{p=1}^{n} \dfrac{1}{OA_p} = c$

$\Rightarrow \quad \sum_{p=1}^{n} \dfrac{|a + bp|}{\sqrt{(1 + p^2)}} = c$ [from Eq. (1)]

$\Rightarrow \quad a\left(\pm \sum_{p=1}^{n} \dfrac{1}{\sqrt{(1 + p^2)}}\right) + b\left(\pm \sum_{p=1}^{n} \dfrac{p}{\sqrt{(1 + p^2)}}\right) = c$

or $\quad a\left(\pm \dfrac{\sum_{p=1}^{n} \dfrac{1}{\sqrt{(1 + p^2)}}}{c}\right) + b\left(\pm \dfrac{\sum_{p=1}^{n} \dfrac{p}{\sqrt{(1 + p^2)}}}{c}\right) = 1$

So, line always passes through a fixed point whose coordinates are

$$\left(\frac{\pm \sum_{p=1}^{n} \frac{1}{\sqrt{(1+p^2)}}}{c}, \frac{\pm \sum_{p=1}^{n} \frac{p}{\sqrt{(1+p^2)}}}{c} \right)$$

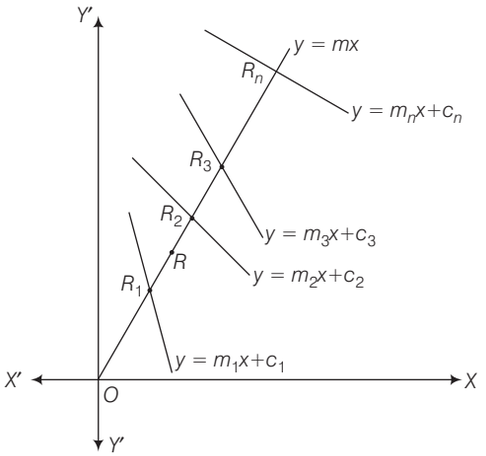
88. Let the equation of given n lines be

$$y = m_r x + c_r,$$

where $r = 1, 2, 3, \ldots, n$ ...(i)

Let equation of line through origin O is

$$y = mx \quad \text{...(ii)}$$



Solving Eqs. (i) and (ii) , we get

$$R_r \equiv \left(\frac{c_r}{m - m_r}, \frac{mc_r}{m - m_r} \right)$$

$$\therefore \quad OR_r = \sqrt{\left(\frac{c_r}{m - m_r} \right)^2 + \left(\frac{m\, c_r}{m - m_r} \right)^2}$$

$$= \left| \frac{c_r}{m - m_r} \right| \sqrt{(1 + m^2)} \quad \text{...(iii)}$$

Let $R \equiv (x_1, y_1)$

$$\therefore \quad y_1 = mx_1 \Rightarrow m = \frac{y_1}{x_1} \quad \text{...(iv)}$$

Given, $\frac{n}{OR} = \sum_{r=1}^{n} \frac{1}{OR_r}$

$$\Rightarrow \quad \frac{n}{\sqrt{(x_1^2 + y_1^2)}} = \sum_{r=1}^{n} \left| \frac{m - m_r}{c_r} \right| \frac{1}{\sqrt{(1 + m^2)}} \quad \text{[from Eq . (iii)]}$$

$$= \frac{1}{\sqrt{(1 + m^2)}} \left\{ m \left(\sum_{r=1}^{n} \left(\pm \frac{1}{c_r} \right) \right) + \sum_{r=1}^{n} \left(\mp \frac{m_r}{c_r} \right) \right\}$$

$$= \frac{1}{\sqrt{(1 + m^2)}} (ma + b)$$

$$\left\{ \text{where } a = \sum_{r=1}^{n} \left(\pm \frac{1}{c_r} \right) \text{ and } b = \sum_{r=1}^{n} \left(\mp \frac{m_r}{c_r} \right) \right.$$

then $\frac{n}{\sqrt{(x_1^2 + y_1^2)}} = \frac{\frac{y_1}{x_1} a + b}{\sqrt{1 + \left(\frac{y_1}{x_1} \right)^2}}$ [from Eq. (iv)]

$$\Rightarrow \quad n = ay_1 + bx_1$$

Hence, locus of point R is $bx + ay = n$.

89. First equation can be expressed as

$$(2x + 3y - 5) \cos\theta + (3x - 5y + 2) \sin\theta = 0$$

$$\Rightarrow \quad (2x + 3y - 5) + (3x - 5y + 2) \tan\theta = 0$$

It is clear that these lines will pass through the point of intersection of the lines

$$\left.\begin{aligned} 2x + 3y - 5 = 0 \\ 3x - 5y + 2 = 0 \end{aligned}\right\} \quad \text{...(i)}$$

for all values of θ.

Solving the system of Eq. (i), we get (1, 1).

Hence, the fixed point is P (1, 1). Let Q (α, β) be the reflection of P (1, 1) in the line $x + y = \sqrt{2}$.

Then $\frac{\alpha - 1}{1} = \frac{\beta - 1}{1} = \frac{-2(1 + 1 - \sqrt{2})}{1^2 + 1^2} = \sqrt{2} - 2$

$$\therefore \quad \alpha = \sqrt{2} - 1, \beta = \sqrt{2} - 1$$

i.e. $Q \equiv (\sqrt{2} - 1, \sqrt{2} - 1)$

If the required family of lines is

$$(2 \cos\theta + 3 \sin\theta)\, x + (3 \cos\theta - 5 \sin\theta)\, y = \lambda$$

in order that each member of the family pass through Q, we have

$$\lambda = (\sqrt{2} - 1)(2 \cos\theta + 3 \sin\theta + 3 \cos\theta - 5 \sin\theta)$$

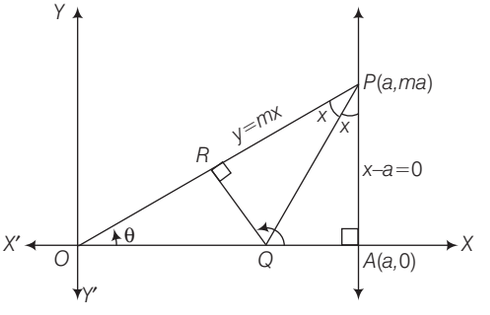
$$\lambda = (\sqrt{2} - 1)(5 \cos\theta - 2 \sin\theta)$$

Hence, equation of required family is

$$(2 \cos\theta + 3 \sin\theta)\, x + (3 \cos\theta - 5 \sin\theta)\, y = (\sqrt{2} - 1)(5 \cos\theta - 2 \sin\theta).$$

90. Let R (h, k) be the foot of perpendicular from Q on OP.

Let equation of OP be



$$y = mx$$

then $k = mh$

or $m = \frac{k}{h}$ ...(i)

and coordinates of $P \equiv (a, ma)$

$\because$ PQ is the bisector of OPA

$\therefore$ $\angle APQ = \angle RPQ$

and $\angle PAQ = \angle QRP = 90°$

$\therefore$ $PA = PR$

then $|ma| = \sqrt{(h-a)^2 + (k-ma)^2}$

From Eq. (i), $\left|\frac{ak}{h}\right| = \sqrt{(h-a)^2 + \left(k - \frac{ak}{h}\right)^2}$

$\Rightarrow$ $a|k| = |(h-a)|\sqrt{(h^2+k^2)}$

Hence, required locus is

$$(x-a)^2(x^2+y^2) = a^2y^2$$

91. Let the coordinates of the vertex be (h, k) and equations of the bases be

$x\cos\alpha_r + y\sin\alpha_r - p_r = 0$ where $r = 1, 2, 3, ..., n$

and their lengths be respectively $l_1, l_2, l_3, ..., l_n$.

$\because$ Length of perpendicular from (h, k) on $x\cos\alpha_r + y\sin\alpha_r - p_r = 0$ is

$$\frac{|h\cos\alpha_r + k\sin\alpha_r - p_r|}{\sqrt{(\cos^2\alpha + \sin^2\alpha)}},$$

i.e. $|h\cos\alpha_r + k\sin\alpha_r - p_r|$

Given, sum of areas of all triangles = constant

then

$$\sum_{r=1}^{n} \frac{1}{2} l_r \cdot |h\cos\alpha_r + k\sin\alpha_r - p_r| = C'$$

$\Rightarrow$ $\sum_{r=1}^{n} \frac{1}{2} . l_r . (\pm (h\cos\alpha_r + k\sin\alpha_r - p_r)) = C'$

$\Rightarrow$ $h\left(\sum_{r=1}^{n} \pm \frac{1}{2} l_r \cos\alpha_r\right) + k\left(\sum_{r=1}^{n} \pm \frac{1}{2} l_r . \sin\alpha_r\right)$

$$= \sum_{r=1}^{n} \pm \frac{1}{2} l_r . p_r + C'$$

$\Rightarrow$ $Ah + Bk = -C$

$\therefore$ Required locus is

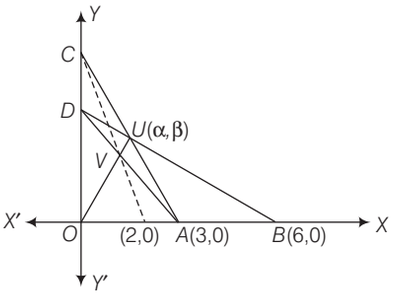
$$Ax + By + C = 0$$

where A, B, C are constants.

92. The equation of BU is

$$y - \beta = \frac{0-\beta}{6-\alpha}(x-\alpha)$$

So that the coordinates of D are $\left(0, \frac{6\beta}{6-\alpha}\right)$



Similarly, the coordinates of C are $\left(0, \frac{3\beta}{3-\alpha}\right)$

Now, the equation of AD is

$$\frac{x}{3} + \frac{(6-\alpha)}{6\beta} y = 1 \quad ...(i)$$

and the equation of OU is

$$\beta x = \alpha y \quad ...(ii)$$

Solving Eqs. (i) and (ii), we get

$$x = \frac{6\alpha}{6+\alpha}, \; y = \frac{6\beta}{6+\alpha}$$

Hence, coordinates of V are $\left(\frac{6\alpha}{6+\alpha}, \frac{6\beta}{6+\alpha}\right)$

Then, the equation of CV is

$$y - \frac{3\beta}{3-\alpha} = \frac{\frac{6\beta}{6+\alpha} - \frac{3\beta}{3-\alpha}}{\frac{6\alpha}{6+\alpha} - 0}(x-0)$$

$\Rightarrow$ $y - \frac{3\beta}{3-\alpha} = \frac{-9\alpha\beta}{6\alpha(3-\alpha)} x$

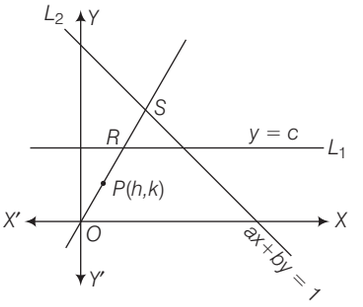
$\Rightarrow$ $y = \frac{3\beta}{(3-\alpha)}\left(1 - \frac{x}{2}\right)$

which pass through the point $(2, 0)$ for all values of (α, β).

93. Let the equation of the variable line through `O' be

$$\frac{x}{\cos\theta} = \frac{y}{\sin\theta}$$

and let $OR = r_1$, $OS = r_2$ and $OP = r_3$



Then coordinates of R, S and P are :

$R(r_1\cos\theta, r_1\sin\theta)$, $S(r_2\cos\theta, r_2\sin\theta)$, $P(r_3\cos\theta, r_3\sin\theta)$

R lies on L_1 and S lies on L_2.

Let $L_1 \equiv y - c = 0$

and $L_2 \equiv ax + by - 1 = 0$

$\therefore$ $r_1\sin\theta = c$ and $ar_2\cos\theta + br_2\sin\theta = 1$

$\therefore$ $r_1 = \frac{c}{\sin\theta}$ and $r_2 = \frac{1}{a\cos\theta + b\sin\theta}$

From the given condition

$$\frac{m+n}{r_3} = \frac{m}{r_1} + \frac{n}{r_2}$$

$\Rightarrow$ $\frac{m+n}{r_3} = \frac{m\sin\theta}{c} + n(a\cos\theta + b\sin\theta)$ ...(i)

Let the coordinates of P be (h, k), then

$$h = r_3 \cos\theta,\ k = r_3 \sin\theta$$

From Eq. (i), $\quad m + n = \dfrac{mr_3 \sin\theta}{c} + n(ar_3 \cos\theta + br_3 \sin\theta)$

$$\Rightarrow \quad m + n = \frac{mk}{c} + n(ah + bk)$$

Locus of P is $\ n(ax + by) + \dfrac{my}{c} = (m + n)$

$$\Rightarrow \quad n(ax + by - 1) + \frac{m}{c}(y - c) = 0$$

$$\Rightarrow \quad (ax + by - 1) + \frac{m}{nc}(y - c) = 0$$

$$\Rightarrow \quad L_2 + \lambda L_1 = 0 \quad \left(\text{where, } \lambda = \frac{m}{nc}\right)$$

Hence, locus of P is a point of intersection of L_1 and L_2.

94. The given lines are

$$x + 3y + 2 = 0 \quad \text{...(i)}$$

$$2x + y + 4 = 0 \quad \text{...(ii)}$$

$$x - y - 5 = 0 \quad \text{...(iii)}$$

Equation of the line passing through $A(-5, -4)$ and making an angle θ with the positive direction of X-axis is

$$\frac{x + 5}{\cos\theta} = \frac{y + 4}{\sin\theta} = r \ (AB,\ AC,\ AD) \quad \text{...(iv)}$$

$\therefore$ Points $(-5 + AB\cos\theta, -4 + AB\sin\theta)$, $(-5 + AC\cos\theta, -4 + AC\sin\theta)$ and $(-5 + AD\cos\theta, -4 + AD\sin\theta)$ lie on Eqs. (i), (ii) and (iii) respectively.

$$(-5 + AB\cos\theta) + 3(-4 + AB\sin\theta) + 2 = 0$$

$$\Rightarrow \quad AB(\cos\theta + 3\sin\theta) = 15$$

$$\Rightarrow \quad \frac{15}{AB} = \cos\theta + 3\sin\theta$$

Similarly, $\quad \dfrac{10}{AC} = 2\cos\theta + \sin\theta$

and $\quad \dfrac{6}{AD} = \cos\theta - \sin\theta$

From given condition

$$\left(\frac{15}{AB}\right)^2 + \left(\frac{10}{AC}\right)^2 = \left(\frac{6}{AD}\right)^2$$

we get $(\cos\theta + 3\sin\theta)^2 + (2\cos\theta + \sin\theta)^2 = (\cos\theta - \sin\theta)^2$

$$\Rightarrow \quad 4\cos^2\theta + 9\sin^2\theta + 12\sin\theta\cos\theta = 0$$

$$\Rightarrow \quad (2\cos\theta + 3\sin\theta)^2 = 0$$

$$\therefore \quad \tan\theta = -\frac{2}{3}$$

Hence the equation of the line from Eq. (iv) is

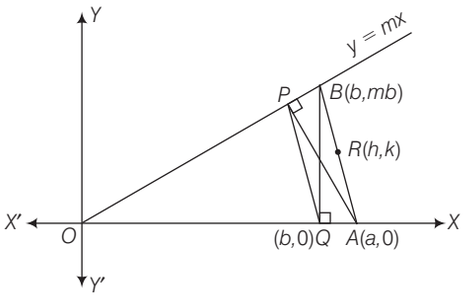
$$y + 4 = -\frac{2}{3}(x + 5) \Rightarrow 2x + 3y + 22 = 0$$

95. $\because$ A, R and B are collinear

then, $\quad \dfrac{k - 0}{h - a} = \dfrac{mb - 0}{b - a}$

$$\therefore \quad \frac{a}{b}k - am + mh - k = 0 \quad \text{...(i)}$$

Let $P \equiv (\alpha, \beta)$



$\because$ P be the foot of perpendicular from A on $y = mx$, then

$$\frac{\alpha - a}{-m} = \frac{\beta - 0}{1} = \frac{-(0 - ma)}{(1 + m^2)}$$

$$\therefore \quad \alpha = \frac{a}{1 + m^2},\ \beta = \frac{am}{1 + m^2}$$

i.e. $\quad P \equiv \left(\dfrac{a}{1 + m^2}, \dfrac{am}{1 + m^2}\right)$

$\therefore$ Equation of PQ is

$$y - 0 = \frac{\frac{am}{1 + m^2} - 0}{\frac{a}{1 + m^2} - b}(x - b)$$

$$\Rightarrow \quad \frac{a}{b}(y - mx) + am - (1 + m^2)y = 0 \quad \text{...(ii)}$$

Adding Eqs. (i) and (ii), then

$$\frac{a}{b}(y - mx + k) + (mh - k - (1 + m^2)y) = 0$$

$$\Rightarrow \quad (mh - k - (1 + m^2)y) + \lambda(y - mx + k) = 0$$

$$\left(\text{where, } \lambda = \frac{a}{b}\right)$$

Hence PQ pass through a fixed point.

For fixed point

$$mh - k - (1 + m^2)y = 0,\ y - mx + k = 0$$

$$y = \frac{mh - k}{(1 + m^2)},\ x = \frac{h + mk}{(1 + m^2)}$$

Hence, fixed point is $\left(\dfrac{h + mk}{1 + m^2}, \dfrac{mh - k}{1 + m^2}\right)$.

96. Given lines are parallel and distance between them < 2

Given lines are

$$2x + y = 3 \quad \text{...(i)}$$

and $\quad 2x + y = 5 \quad \text{...(ii)}$

Equation of any line through Eqs. (ii) and (iii) is

$$y - 3 = m(x - 2)$$

or $\quad y = mx - 2m + 3 \quad \text{...(iii)}$

Let line (iii) cut lines (i) and (ii) at A and B respectively.

Solving Eqs. (i) and (iii), we get

$$A \equiv \left(\frac{2m}{m + 2}, \frac{6 - m}{m + 2}\right)$$

and solving Eqs. (ii) and (iii), we get

$$B \equiv \left(\frac{2m+2}{m+2}, \frac{m+6}{m+2}\right)$$

According to question $AB = 2$

$$\Rightarrow \quad (AB)^2 = 4$$

$$\Rightarrow \quad \left(\frac{2}{m+2}\right)^2 + \left(\frac{2m}{m+2}\right)^2 = 4$$

$$\Rightarrow \quad 1 + m^2 = m^2 + 4m + 4 \qquad \text{...(iv)}$$

Case I : When m is finite (line is not perpendicular to X-axis) then from Eq. (iv).

$$1 = 4m + 4$$

$$\therefore \quad m = -\frac{3}{4}$$

Case II : When m is infinite (line is perpendicular to X-axis) then from Eq. (iv),

$$\frac{1}{m^2} + 1 = 1 + \frac{4}{m} + \frac{4}{m^2}$$

$$0 + 1 = 1 + 0 + 0$$

$$1 = 1 \text{ which is true}$$

Hence $m \to \infty$ acceptable.

Hence, equation of the required lines are

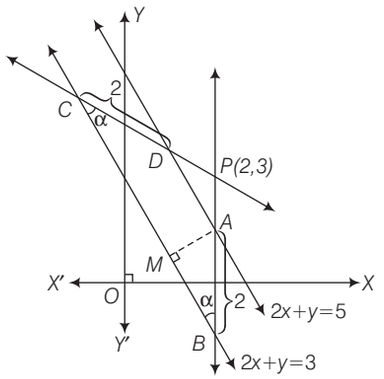
$$y - 3 = -\frac{3}{4}(x - 2)$$

and $$\frac{y-3}{\infty} = x - 2 \quad \Rightarrow x - 2 = 0$$

i.e. $3x + 4y = 18$ and $x - 2 = 0$

Aliter I :

$\because$ $2x + y = 3$ cuts Y-axis at $(0, 3)$ and line $2x + y = 5$ cuts Y-axis at $(0, 5)$



Therefore intercept on Y-axis is 2.

Also, $AM =$ distance between parallel lines

$$= \frac{|-5+3|}{\sqrt{2^2+1^2}} = \frac{2}{\sqrt{5}}$$

$$\therefore \quad MB = \sqrt{(AB)^2 - (AM)^2} = \sqrt{4 - \frac{4}{5}} = \frac{4}{\sqrt{5}}$$

then $\tan\alpha = \frac{AM}{MB} = \frac{1}{2}$

Also $\tan\theta = -2$ (slope of $2x + y = 5$)

Now, equation of required lines are

$$y - 3 = \tan(\theta \pm \alpha)(x - 2)$$

$$\Rightarrow \quad y - 3 = \left(\frac{\tan\theta \pm \tan\alpha}{1 \mp \tan\theta \tan\alpha}\right)(x - 2)$$

$$\Rightarrow \quad y - 3 = \frac{(-2) \pm \frac{1}{2}}{1 \mp (-2)\left(\frac{1}{2}\right)}(x-2)$$

$$\Rightarrow \quad y - 3 = \frac{\left(-2 \pm \frac{1}{2}\right)}{1 \mp (-1)}(x - 2)$$

$$\Rightarrow (1 \mp (-1))(y - 3) = \left(-2 \pm \frac{1}{2}\right)(x - 2)$$

$$\Rightarrow \quad x - 2 = 0 \quad \text{and} \quad 2y - 6 = -\frac{3}{2}(x - 2)$$

i.e. $x - 2 = 0$ and $3x + 4y - 18 = 0$

Aliter II : Any line through $(2, 3)$ is

$$\frac{x-2}{\cos\theta} = \frac{y-3}{\sin\theta} = r$$

Suppose this line cuts $2x + y = 5$ and $2x + y = 3$ at D and C respectively but given $DC = 2$

then $D \equiv (2 + r\cos\theta, 3 + r\sin\theta)$

and $C \equiv (2 + (r+2)\cos\theta, 3 + (r+2)\sin\theta)$

$\because$ D and C lies on

$$2x + y = 5 \quad \text{and} \quad 2x + y = 3$$

then $2(2 + r\cos\theta) + (3 + r\sin\theta) = 5$ ... (v)

and $2(2 + (r+2)\cos\theta) + (3 + (r+2)\sin\theta) = 3$ ... (vi)

Subtracting Eq. (v) from Eq. (vi), then

$$4\cos\theta + 2\sin\theta = -2$$

or $$2\cos\theta + \sin\theta = -1$$

$$\Rightarrow \quad 2\left(\frac{1 - \tan^2\left(\frac{\theta}{2}\right)}{1 + \tan^2\left(\frac{\theta}{2}\right)}\right) + \left(\frac{2\tan\left(\frac{\theta}{2}\right)}{1 + \tan^2\left(\frac{\theta}{2}\right)}\right) = -1$$

$$\Rightarrow \quad 2 - 2\tan^2\left(\frac{\theta}{2}\right) + 2\tan\left(\frac{\theta}{2}\right) = -1 - \tan^2\left(\frac{\theta}{2}\right)$$

$$\Rightarrow \quad \tan^2\left(\frac{\theta}{2}\right) - 2\tan\left(\frac{\theta}{2}\right) - 3 = 0$$

$$\therefore \quad \tan\left(\frac{\theta}{2}\right) = -1 \text{ or } 3$$

$$\therefore \quad \tan\theta = \infty \quad \text{or} \quad -\frac{3}{4}$$

$\therefore$ Required lines are

$$y - 3 = \infty(x - 2)$$

and $$y - 3 = -\frac{3}{4}(x - 2)$$

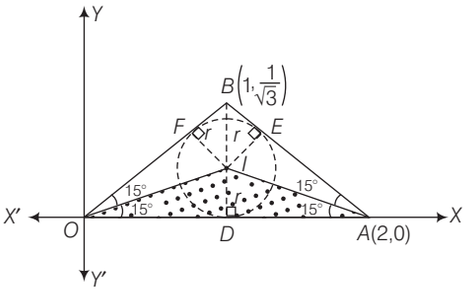
i.e. $x - 2 = 0$

and $3x + 4y - 18 = 0$

97. If I be the incentre of ΔOAB.

If inradius $= r$

then $ID = IE = IF = r$



If P at I,then

$$d(P, OA) = d(P, OB) = d(P, AB) = r$$

But $d(P,OA) \le \min\{d(P, OB), d(P, AB)\}$

which is possible only when P lies in the ΔOIA.

$$\therefore \quad \tan 15^\circ = \frac{ID}{OD} = \frac{r}{1}$$

$$\Rightarrow \quad r = (2 - \sqrt{3})$$

$\therefore$ Required area $= \frac{1}{2} \cdot 2 \cdot r = r = (2 - \sqrt{3})$ sq units.

98. Let $A \equiv (x_1, y_1)$, $B \equiv (x_2, y_2)$ and $C \equiv (x_3, y_3)$ are the vertices of a triangle ABC and $P \equiv (a_1, b_1)$, $Q \equiv (a_2, b_2)$ and $R \equiv (a_3, b_3)$ are the vertices of triangle PQR.

Equation of perpendicular from A to QR is

$$y - y_1 = -\frac{(a_2 - a_3)}{(b_2 - b_3)}(x - x_1)$$

or $(a_2 - a_3)\, x + (b_2 - b_3)\, y - x_1 (a_2 - a_3) - y_1 (b_2 - b_3) = 0$ ...(i)

Similarly, equations of perpendiculars from B to RP and C to PQ are respectively,

$(a_3 - a_1)\, x + (b_3 - b_1)\, y - x_2 (a_3 - a_1) - y_2 (b_3 - b_1) = 0$ ...(ii)

and $(a_1 - a_2)\, x + (b_1 - b_2)\, y - x_3 (a_1 - a_2) - y_3 (b_1 - b_2) = 0$ ...(iii)

Given that lines (i), (ii) and (iii) are concurrent, then adding, we get

$$(x_2 - x_3)\, a_1 + (x_3 - x_1)\, a_2 + (x_1 - x_2)\, a_3 + (y_2 - y_3)\, b_1 + (y_3 - y_1) b_2 + (y_1 - y_2)\, b_3 = 0 \quad \text{...(iv)}$$

Now, equation of perpendicular from P to BC is

$$y - b_1 = -\frac{(x_2 - x_3)}{(y_2 - y_3)}(x - a_1)$$

or $(x_2 - x_3)\, x + (y_2 - y_3)\, y - a_1 (x_2 - x_3) - b_1 (y_2 - y_3) = 0$ ...(v)

Similarly, equations of perpendiculars from Q to CA and R to AB are respectively,

$$(x_3 - x_1)\, x + (y_3 - y_1)\, y - a_2 (x_3 - x_1) - b_2 (y_3 - y_1) = 0 \quad \text{...(vi)}$$

and $(x_1 - x_2)\, x + (y_1 - y_2)\, y - a_3 (x_1 - x_2) - b_3 (y_1 - y_2) = 0$ ...(vii)

Adding Eqs. (v), (vi) and (vii), we get

LHS = 0 (identically) [from Eq. (iv)]

Hence perpendiculars from P to BC, Q to CA and R to AB are concurrent.

99. The line passing through the intersection of lines $ax + 2by + 3b = 0$ and $bx - 2ay - 3a = 0$ is

$$ax + 2by + 3b + \lambda(bx - 2ay - 3a) = 0$$

$$\Rightarrow (a + b\lambda)x + (2b - 2a\lambda)y + 3b - 3\lambda a = 0$$

As this line is parallel to X-axis.

$$\therefore \quad a + b\lambda = 0 \Rightarrow \lambda = -\frac{a}{b}$$

$$\Rightarrow \quad ax + 2by + 3a - \frac{a}{b}(bx - 2ay - 3a) = 0$$

$$\Rightarrow \quad ax + 2by + 3b - ax + \frac{2a^2}{b}y + \frac{3a^2}{b} = 0$$

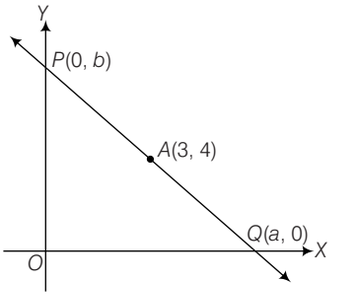
$$y\left(2b + \frac{2a^2}{b}\right) + 3b + \frac{3a^2}{b} = 0$$

$$y\left(\frac{2b^2 + 2a^2}{b}\right) = -\left(\frac{3b^2 + 3a^2}{b}\right)$$

$$y = \frac{-3(a^2 + b^2)}{2(b^2 + a^2)} = \frac{-3}{2}$$

So, it is $\frac{3}{2}$ units below X-axis.

100.



$\because$ A is the mid-point of PQ, therefore

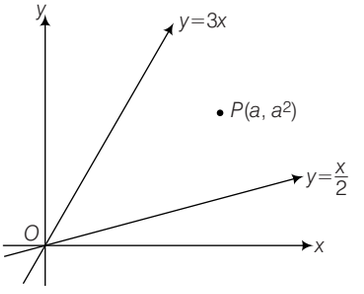
$$\frac{a + 0}{2} = 3, \frac{0 + b}{2} = 4$$

$$\Rightarrow \quad a = 6, b = 8$$

$\therefore$Equation of line is $\frac{x}{6} + \frac{y}{8} = 1$

or $4x + 3y = 24$

101. Clearly for point P,

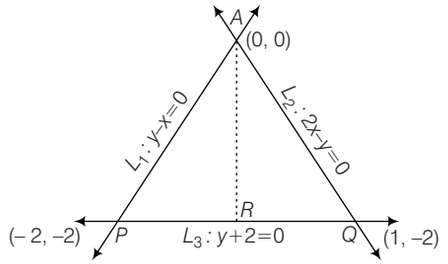


$$a^2 - 3a < 0 \text{ and } a^2 - \frac{a}{2} > 0$$

$$\Rightarrow \quad \frac{1}{2} < a < 3$$

102. Point of intersection of L_1 and L_2 is $A(0, 0)$.

Also $P(-2, -2)$, $Q(1, -2)$



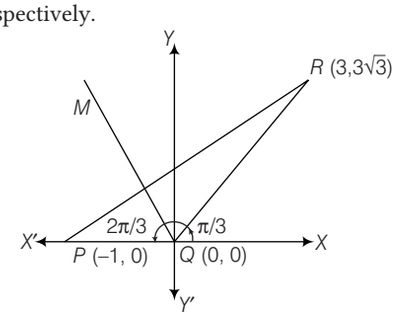
$\because$ AR is the bisector of $\angle PAQ$, therefore R divides PQ in the same ratio as $AP : AQ$.

Thus $PR : RQ = AP : AQ = 2\sqrt{2} : \sqrt{5}$

$\therefore$ Statement I is true.

Statement II is clearly false.

103. Given : The coordinates of points P, Q, R are $(-1, 0)$, $(0, 0)$, $(3, 3\sqrt{3})$ respectively.



Slope of equation $QR = \dfrac{y_2 - y_1}{x_2 - x_1} = \dfrac{3\sqrt{3}}{3}$

$\Rightarrow \quad \tan\theta = \sqrt{3} \Rightarrow \theta = \dfrac{\pi}{3}$

$\Rightarrow \quad \angle RQX = \dfrac{\pi}{3}$

$\therefore \quad \angle RQP = \pi - \dfrac{\pi}{3} = \dfrac{2\pi}{3}$

Let QM bisects the $\angle PQR$,

$\therefore$ Slope of the line $QM = \tan\dfrac{2\pi}{3} = -\sqrt{3}$

$\therefore$ Equation of line QM is $(y - 0) = -\sqrt{3}(x - 0)$

$\Rightarrow \quad y = -\sqrt{3}x \Rightarrow \sqrt{3}x + y = 0$

104. **(A)** $\because$ L_1, L_2, L_3 are concurrent, then

$$\begin{vmatrix} 1 & 3 & -5 \\ 3 & -k & -1 \\ 5 & 2 & -12 \end{vmatrix} = 0 \Rightarrow k = 5$$

(B) slope of (L_1) = slope of (L_2)

$\Rightarrow \quad -\dfrac{1}{3} = \dfrac{3}{k} \quad \therefore \; k = -9$

and slope of (L_3) = slope of (L_2)

$\Rightarrow \quad -\dfrac{5}{2} = \dfrac{3}{k} \quad \therefore \; k = -\dfrac{6}{5}$

(C) Lines are not concurrent or not parallel, then

$$k \neq 5, k \neq -9, k \neq -\frac{6}{5}$$

$\therefore \quad k = \dfrac{5}{6}$

(D) The given lines do not form a triangle if they are concurrent or any two of them are parallel.

$\therefore \quad k = 5, k = -9, k = -\dfrac{6}{5}$

105. Slope of $PQ = \dfrac{3-4}{k-1} = \dfrac{-1}{k-1}$

$\therefore$ Slope of perpendicular bisector of $PQ = (k-1)$

Also mid-point of $PQ \left(\dfrac{k+1}{2}, \dfrac{7}{2}\right)$

$\therefore$ Equation of perpendicular bisector is

$$y - \frac{7}{2} = (k-1)\left(x - \frac{k+1}{2}\right)$$

$\Rightarrow \quad 2y - 7 = 2(k-1)x - (k^2 - 1)$

$\Rightarrow \quad 2(k-1)x - 2y + (8 - k^2) = 0$

$\therefore \quad Y$-intercept $= -\dfrac{8-k^2}{-2} = -4$

$\Rightarrow \quad 8 - k^2 = -8$ or $k^2 = 16 \Rightarrow k = \pm 4$

106. If the line $p(p^2 + 1)x - y + q = 0$

and $\quad (p^2 + 1)^2 x + (p^2 + 1)y + 2q = 0$

are perpendicular to a common line, then these lines must be parallel to each other,

$\therefore \quad m_1 = m_2 \Rightarrow -\dfrac{p(p^2+1)}{-1} = -\dfrac{(p^2+1)^2}{p^2+1}$

$\Rightarrow \quad (p^2 + 1)(p + 1) = 0$

$\Rightarrow \quad p = -1$

$\therefore p$ can have exactly one value.

107. Slope of line $L = -\dfrac{b}{5}$

Slope of line $K = -\dfrac{3}{c}$

Line L is parallel to line K.

$\Rightarrow \quad \dfrac{b}{5} = \dfrac{3}{c} \Rightarrow bc = 15$

$(13, 32)$ is a point on L.

$\therefore \quad \dfrac{13}{5} + \dfrac{32}{b} = 1 \Rightarrow \dfrac{32}{b} = -\dfrac{8}{5}$

$\Rightarrow \quad b = -20 \Rightarrow c = -\dfrac{3}{4}$

Equation of $K : y - 4x = 3$

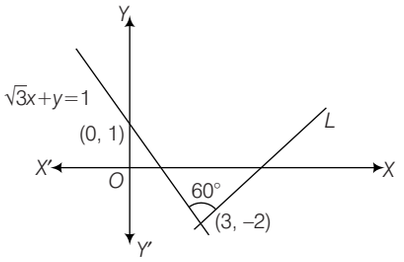
$\Rightarrow \quad 4x - y + 3 = 0$

Distance between L and $K = \dfrac{|52 - 32 + 3|}{\sqrt{17}}$

$= \dfrac{23}{\sqrt{17}}$

108. Let the slope of line L be m.

Then $$\left|\frac{m+\sqrt{3}}{1-\sqrt{3}m}\right| = \sqrt{3}$$



$$\Rightarrow \quad m+\sqrt{3} = \pm(\sqrt{3}-3m)$$

$$\Rightarrow \quad 4m = 0 \text{ or } 2m = 2\sqrt{3}$$

$$\Rightarrow \quad m = 0 \text{ or } m = \sqrt{3}$$

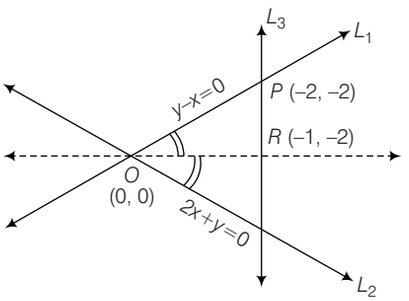
$\because$ L intersects X-axis,

$$\therefore \quad m = \sqrt{3}$$

$\therefore$ Equation of L is $y+2 = \sqrt{3}(x-3)$

or $$\sqrt{3}x - y - (2+3\sqrt{3}) = 0$$

109.



$$L_1 : y - x = 0, \quad L_2 : 2x + y = 0, \quad L_3 : y + 2 = 0$$

On solving the equation of lines L_1 and L_2, we get their point of intersection (0, 0) i.e. origin O.

On solving the equation of lines L_1 and L_3,

we get $P = (-2, -2)$

Similarly, we get $Q = (-1, -2)$

We know that bisector of an angle of a triangle, divide the opposite side the triangle in the ratio of the sides including the angle [Angle Bisector Theorem of a Triangle]

$$\therefore \quad \frac{PR}{RQ} = \frac{OP}{OQ} = \frac{\sqrt{(-2)^2+(-2)^2}}{\sqrt{(-1)^2+(-2)^2}} = \frac{2\sqrt{2}}{\sqrt{5}}$$

110. Let the joining points be $A(1, 1)$ and $B(2, 4)$.

Let point C divides line AB in the ratio 3 : 2. So, by section formula we have

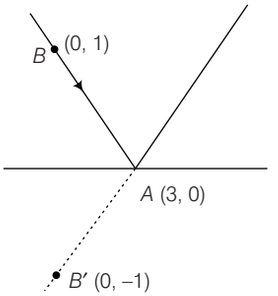
$$C = \left(\frac{3\times 2 + 2\times 1}{3+2}, \frac{3\times 4 + 2\times 1}{3+2}\right) = \left(\frac{8}{5}, \frac{14}{5}\right)$$

Since Line $2x + y = k$ passes through $C\left(\frac{8}{5}, \frac{14}{5}\right)$

$\therefore C$ satisfies the equation $2x + y = k$.

$$\Rightarrow \quad \frac{2+8}{5} + \frac{14}{5} = k \Rightarrow k = 6$$

111. Suppose $B(0, 1)$ be any point on given line and coordinate of A is $(\sqrt{3}, 0)$. So, equation of



Reflected ray is $\frac{-1-0}{0-\sqrt{3}} = \frac{y-0}{x-\sqrt{3}}$

$$\Rightarrow \quad \sqrt{3}y = x - \sqrt{3}$$

112. The intersection point of two lines is $\left(\frac{-c}{a+b}, \frac{-c}{a+b}\right)$

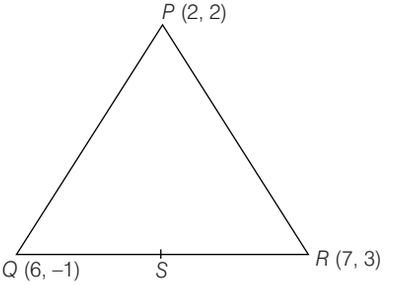
Distance between (1, 1) and $\left(\frac{-c}{a+b}, \frac{-c}{a+b}\right) < 2\sqrt{2}$

$$\Rightarrow \quad 2\left(1+\frac{c}{a+b}\right)^2 < 8$$

$$\Rightarrow \quad 1 + \frac{c}{a+b} < 2$$

$$\Rightarrow \quad a + b - c > 0$$

113. Let P, Q, R, be the vertices of ΔPQR



Since, PS is the median, S is mid-point of QR

So, $$S = \left(\frac{7+6}{2}, \frac{3-1}{2}\right) = \left(\frac{13}{2}, 1\right)$$

Now, slope of $PS = \frac{2-1}{2-\frac{13}{2}} = -\frac{2}{9}$

Since, required line is parallel to PS therefore slope of required line = slope of PS Now, eqn of line passing through $(1, -1)$ and having slope $-\frac{2}{9}$ is

$$y - (-1) = -\frac{2}{9}(x-1)$$

$$9y + 9 = -2x + 2$$

$$\Rightarrow \quad 2x + 9y + 7 = 0$$

114. Given lines are

$$4ax + 2ay + c = 0$$
$$5bx + 2by + d = 0$$

The point of intersection will be

$$\frac{x}{2ad - 2bc} = \frac{-y}{4ad - 5bc} = \frac{1}{8ab - 10ab}$$

$$\Rightarrow \quad x = \frac{2(ad - bc)}{-2ab} = \frac{bc - ad}{ab}$$

$$\Rightarrow \quad y = \frac{5bc - 4ad}{-2ab} = \frac{4ad - 5bc}{2ab}$$

$\because$ Point of intersection is in fourth quadrant so x is positive and y is negative.

Also distance from axes is same

So $x = -y$ ($\because$ distance from X-axis is $-y$ as y is negative)

$$\frac{bc - ad}{ab} = \frac{5bc - 4ad}{2ab} \Rightarrow 3bc - 2ad = 0$$

115. Let the point P be (x, y)

Then $d_1(P) = \left|\frac{x - y}{\sqrt{2}}\right|$ and $d_2(P) = \left|\frac{x + y}{\sqrt{2}}\right|$

For P lying in first quadrant $x > 0, y > 0$.

Also $2 \le d_1(P) + d_2(P) \le 4$

$$\Rightarrow \quad 2 \le \left|\frac{x - y}{\sqrt{2}}\right| + \left|\frac{x + y}{\sqrt{2}}\right| \le 4$$

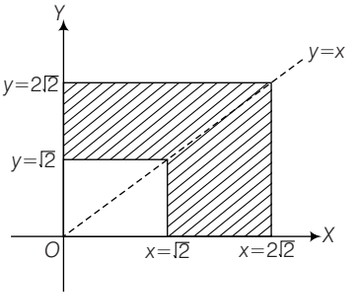
If $x > y$, then

$$2 \le \frac{x - y + x + y}{\sqrt{2}} \le 4 \text{ or } \sqrt{2} \le x \le 2\sqrt{2}$$

If $x < y$, then

$$2 \le \frac{y - x + x + y}{2} \le 4 \text{ or } \sqrt{2} \le y \le 2\sqrt{2}$$

The required region is the shaded region in the figure given below.



$\therefore$ Required area $= (2\sqrt{2})^2 - (\sqrt{2})^2 = 8 - 2 = 6$ sq units

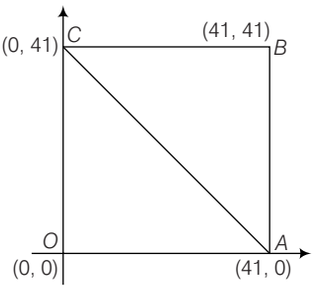
116. Total number of integral points inside the square $OABC$

$= 40 \times 40 = 1600$

Number of integral points on AC

= Number of integral points on OB

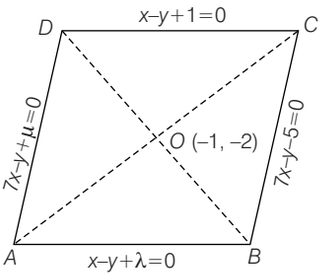
$= 40$ [namely (1, 1), (2, 2) ... (40, 40)]



$\therefore$ Number of integral points inside the ΔOAC

$$= \frac{1600 - 40}{2} = 780$$

117.



Let other two sides of rhombus are

$$x - y + \lambda = 0$$

and $7x - y + \mu = 0$

then O is equidistant from AB and DC and from AD and BC

$\therefore \quad |-1 + 2 + 1| = |-1 + 2 + \lambda| \Rightarrow \lambda = -3$

and $\quad |-7 + 2 - 5| = |-7 + 2 + \mu| \Rightarrow \mu = 15$

$\therefore$Other two sides are

$$x - y - 3 = 0$$

and $7x - y + 15 = 0$

On solving the equation of sides pairwise, we get the vertices as $\left(\frac{1}{3}, \frac{-8}{3}\right)$, $(1, 2)$, $\left(\frac{-7}{3}, \frac{-4}{3}\right)$, $(-3, -6)$

Session 1

Introduction, Homogeneous Equation in Two Variables

Introduction

Let the equation of two lines be

$$ax + by + c = 0 \quad \text{...(i)}$$

and $$a_1x + b_1y + c_1 = 0 \quad \text{...(ii)}$$

Hence, $(ax + by + c)(a_1x + b_1y + c_1) = 0$ is called the joint equation of lines Eqs. (i) and (ii) and conversely, if joint equation of two lines be

$$(ax + by + c)(a_1x + b_1y + c_1) = 0,$$

then their separate equations will be

$$ax + by + c = 0 \quad \text{and} \quad a_1x + b_1y + c_1 = 0$$

Remark

In order to find the joint equation of two lines, make RHS of two lines equal to zero and then multiply the two equations.

Example 1 Find the joint equation of lines $y = x$ and $y = -x$.

Sol. The given lines can be rewritten as

$$x - y = 0 \quad \text{and} \quad x + y = 0$$

$\therefore$ Joint equation of lines is $(x - y)(x + y) = 0$

or $$x^2 - y^2 = 0$$

Wrong process : Since, the lines are

$$y = x \quad \text{and} \quad y = -x$$

Then joint equation is $$y^2 = -x^2$$

$\Rightarrow$ $$x^2 + y^2 = 0$$

This process is wrong, since RHS of two equations are not equal to zero.

Remark

In order to find the separate equations of two lines when their joint equation is given, first of all make RHS equal to zero and then resolve LHS into two linear factors or use Shri Dharacharya method. The two factors equated to zero will give the separate equations of lines.

Example 2 Find the separate equation of lines represented by the equation $x^2 - 6xy + 8y^2 = 0$.

Sol. Separate equation of lines represented by the equation

$$x^2 - 6xy + 8y^2 = 0$$

i.e. $$(x - 4y)(x - 2y) = 0$$

$\Rightarrow$ $x - 4y = 0$ and $x - 2y = 0$

Aliter :

We have, $$x^2 - 6xy + 8y^2 = 0$$

By Shri Dharacharya method, $x = \dfrac{6y \pm \sqrt{(-6y)^2 - 4 \cdot 8y^2}}{2}$

$\Rightarrow$ $$x = 3y \pm y\sqrt{(9 - 8)}$$

$$x = 3y \pm y$$

$\therefore$ $$x = 4y \quad \text{and} \quad x = 2y$$

Hence, the lines are

$$x - 4y = 0 \quad \text{and} \quad x - 2y = 0.$$

Homogeneous Equation in Two Variables

An equation of the form

$$a_0y^n + a_1y^{n-1}x + a_2y^{n-2}x^2 + ... + a_nx^n = 0 \quad \text{...(i)}$$

in which the sum of the powers of x and y in every term is the same (here n), is called a **homogeneous** equation (of degree n).

We will prove that Eq. (i) represents n straight lines passing through the origin.

$$a_0y^n + a_1y^{n-1}x + a_2y^{n-2}x^2 + ... + a_nx^n = 0$$

Dividing each term by x^n, we get

$$a_0\left(\frac{y}{x}\right)^n + a_1\left(\frac{y}{x}\right)^{n-1} + a_2\left(\frac{y}{x}\right)^{n-2} + ... + a_n = 0$$

Above is an equation of nth degree in $\dfrac{y}{x}$. Let the roots of this equation be $m_1, m_2, m_3, ..., m_n$.

Then, the above equation will be identical with

$$a_0\left(\frac{y}{x} - m_1\right)\left(\frac{y}{x} - m_2\right)\left(\frac{y}{x} - m_3\right)...\left(\frac{y}{x} - m_n\right) = 0$$

$\Rightarrow a_0(y - m_1x)(y - m_2x)(y - m_3x)....(y - m_nx) = 0$

Hence, Eq. (i) represents n straight lines

$$y - m_1 x = 0, y - m_2 x = 0,$$
$$y - m_3 x = 0, \ldots, y - m_n x = 0$$

all of which clearly pass through the origin.

Corollary : Since, $ax^2 + 2hxy + by^2 = 0$ is a homogeneous equation of second degree, it represents two straight lines through origin. The given equation is

$$ax^2 + 2hxy + by^2 = 0 \quad \ldots(i)$$

Dividing by x^2, we get

$$a + 2h\left(\frac{y}{x}\right) + b\left(\frac{y}{x}\right)^2 = 0$$

$$\Rightarrow \quad b\left(\frac{y}{x}\right)^2 + 2h\left(\frac{y}{x}\right) + a = 0 \quad \ldots(ii)$$

Putting $\frac{y}{x} = m$

then, $bm^2 + 2hm + a = 0 \quad \ldots(iii)$

If m_1 and m_2 be two roots, then

$$m_1 + m_2 = -\frac{2h}{b} = -\frac{\text{coefficient of } xy}{\text{coefficient of } y^2}$$

and $$m_1 m_2 = \frac{a}{b} = \frac{\text{coefficient of } x^2}{\text{coefficient of } y^2}$$

$$\therefore \quad |m_1 - m_2| = \sqrt{\{(m_1 + m_2)^2 - 4m_1 m_2\}}$$
$$= \frac{2}{|b|}\sqrt{(h^2 - ab)}$$

Thus, $y = m_1 x$ and $y = m_2 x$ are two straight lines which are given by Eq. (i). Also, from Eq. (iii),

$$m = \frac{-2h \pm 2\sqrt{(h^2 - ab)}}{2b}$$
$$= \frac{-h \pm \sqrt{(h^2 - ab)}}{b} = \frac{y}{x} \qquad \left[\because m = \frac{y}{x}\right]$$

$$\therefore \quad by = \{-h + \sqrt{(h^2 - ab)}\}x$$

and $$by = \{-h - \sqrt{(h^2 - ab)}\}x$$

are two lines represented by Eq. (i).

(i) The lines are real and distinct, if $h^2 - ab > 0$.
(ii) The lines are coincident, if $h^2 - ab = 0$.
(iii) The lines are imaginary, if $h^2 - ab < 0$.

Remarks

1. In further discussions, we will consider only real cases.
2. **Two very useful identities** When lines represented by $ax^2 + 2hxy + by^2 = 0$ pass through the origin, let their equations be
$y = m_1 x$ and $y = m_2 x$
then, $(y - m_1 x)$ and $(y - m_2 x)$
must be factors of $ax^2 + 2hxy + by^2 = 0$
then $ax^2 + 2hxy + by^2 = b(y - m_1 x)(y - m_2 x)$
[Making coefficient of y^2 equal on both sides]
Now, comparing both sides, we get
$2h = -b(m_1 + m_2)$ and $a = bm_1 m_2$
$\therefore \quad m_1 + m_2 = -\frac{2h}{b}$ and $m_1 m_2 = \frac{a}{b}$

Example 3 Find the condition that the slope of one of the lines represented by $ax^2 + 2hxy + by^2 = 0$ should be n times the slope of the other.

Sol. Let the lines represented by
$ax^2 + 2hxy + by^2 = 0$ are $y = m_1 x$ and $y = m_2 x$.

Therefore, $m_1 + m_2 = -\frac{2h}{b} \quad \ldots(i)$

and $m_1 m_2 = \frac{a}{b} \quad \ldots(ii)$

Given, $m_2 = nm_1$

From Eq. (i), $m_1 + nm_1 = -\frac{2h}{b}$

$\therefore \quad m_1 = -\frac{2h}{b(1+n)} \quad \ldots(iii)$

and from Eq. (ii), $m_1(nm_1) = \frac{a}{b}$

$\therefore \quad nm_1^2 = \frac{a}{b}$

$\Rightarrow \quad n\left\{\frac{-2h}{b(1+n)}\right\}^2 = \frac{a}{b}$ [from Eq. (iii)]

$\Rightarrow \quad \frac{4nh^2}{b^2(1+n)^2} = \frac{a}{b}$

$\Rightarrow \quad 4nh^2 = ab(1+n)^2 \quad \ldots(iv)$

This is the required condition.

Corollary : If slope of one line is double of the other, then put $n = 2$ in Eq. (iv), we have

$$8h^2 = 9ab.$$

Example 4 If the slope of one of the lines represented by $ax^2 + 2hxy + by^2 = 0$ be the nth power of the other, prove that, $(ab^n)^{\frac{1}{n+1}} + (a^n b)^{\frac{1}{n+1}} + 2h = 0$.

Sol. Let m and m^n be the slopes of the lines represented by
$ax^2 + 2hxy + by^2 = 0$

then $m + m^n = -\frac{2h}{b} \quad \ldots(i)$

and $m \cdot m^n = \frac{a}{b} \Rightarrow m^{n+1} = \frac{a}{b}$

$\Rightarrow m = \left(\frac{a}{b}\right)^{\frac{1}{(n+1)}}$ ...(ii)

Substituting the value of m from Eq. (ii) in Eq. (i), then

$$\left(\frac{a}{b}\right)^{\frac{1}{(n+1)}} + \left(\frac{a}{b}\right)^{\left(\frac{n}{n+1}\right)} = -\frac{2h}{b}$$

$\Rightarrow a^{\frac{1}{n+1}} \cdot b^{\frac{n}{n+1}} + a^{\frac{n}{n+1}} \cdot b^{\frac{1}{n+1}} + 2h = 0$

Corollary **:** If slope of one line is square of the other, then put $n = 2$, then

$$(ab^2)^{\frac{1}{3}} + (a^2b)^{\frac{1}{3}} = -2h$$

On cubing both sides, we get

$$ab^2 + a^2b + 3(ab^2)^{\frac{1}{3}}(a^2b)^{\frac{1}{3}}\left((ab^2)^{\frac{1}{3}} + (a^2b)^{\frac{1}{3}}\right) = -8h^3$$

$\Rightarrow ab(a+b) + 3ab(-2h) = -8h^3$

$\therefore \frac{(a+b)}{h} + \frac{8h^2}{ab} = 6.$

Example 5 Find the product of the perpendiculars drawn from the point (x_1, y_1) on the lines $ax^2 + 2hxy + by^2 = 0$.

Sol. Let the lines represented by $ax^2 + 2hxy + by^2 = 0$ be $y = m_1x$ and $y = m_2x$.

Therefore, $m_1 + m_2 = -\frac{2h}{b}$ and $m_1m_2 = \frac{a}{b}$

The lengths of the perpendiculars from (x_1, y_1) on these lines are

$$\frac{|y_1 - m_1x_1|}{\sqrt{1+m_1^2}} \quad \text{and} \quad \frac{|y_1 - m_2x_1|}{\sqrt{1+m_2^2}}$$

Their product $= \frac{|y_1 - m_1x_1|}{\sqrt{1+m_1^2}} \times \frac{|y_1 - m_2x_1|}{\sqrt{1+m_2^2}}$

$$= \frac{|(y_1 - m_1x_1)(y_1 - m_2x_1)|}{\sqrt{(1+m_1^2)(1+m_2^2)}}$$

$$= \frac{|y_1^2 - (m_1+m_2)x_1y_1 + m_1m_2x_1^2|}{\sqrt{1+m_1^2+m_2^2+m_1^2m_2^2}}$$

$$= \frac{|y_1^2 - (m_1+m_2)x_1y_1 + m_1m_2x_1^2|}{\sqrt{1+(m_1+m_2)^2 - 2m_1m_2 + (m_1m_2)^2}}$$

$$= \frac{|y_1^2 + \frac{2h}{b}x_1y_1 + \frac{a}{b}x_1^2|}{\sqrt{\left(1 + \frac{4h^2}{b^2} - \frac{2a}{b} + \frac{a^2}{b^2}\right)}}$$

$$= \frac{|ax_1^2 + 2hx_1y_1 + by_1^2|}{\sqrt{\{(a-b)^2 + 4h^2\}}}$$

Example 6 Find the condition that one of the lines given by $ax^2 + 2hxy + by^2 = 0$ may be perpendicular to one of the lines given by $a'x^2 + 2h'xy + b'y^2 = 0$.

Sol. Since, both pair are passing through origin, let $y = mx$ be one of the lines represented by

$$ax^2 + 2hxy + by^2 = 0$$

then, $ax^2 + 2hx(mx) + b(mx)^2 = 0$

$\Rightarrow bm^2 + 2hm + a = 0$ ...(i)

then, $y = -\frac{1}{m}x$ be one of the line represented by

$$a'x^2 + 2h'xy + b'y^2 = 0$$

$$\left[\because y = -\frac{1}{m}x \text{ is perpendicular to } y = mx \text{ and passing through origin}\right]$$

then $a'x^2 + 2h'x\left(-\frac{1}{m}x\right) + b'\left(-\frac{1}{m}x\right)^2 = 0$

$\Rightarrow a'm^2 - 2h'm + b' = 0$ ...(ii)

On solving Eqs. (i) and (ii), by cross-multiplication rule i.e.

$$\begin{array}{cccccc} m^2 & m & 1 & m^2 & m \\ b & 2h & a & b & 2h \\ a' & -2h' & b' & a' & -2h' \end{array}$$

$$\Rightarrow \frac{m^2}{2hb' + 2h'a} = \frac{m}{aa' - bb'} = \frac{1}{-2h'b - 2a'h}$$

$\therefore m^2 = -\frac{(hb' + h'a)}{(h'b + a'h)}, m = \frac{(bb' - aa')}{2(a'h + h'b)}$

On eliminating m, we obtain

$$4(ha' + h'b)(h'a + hb') + (bb' - aa')^2 = 0.$$

Example 7 Show that the centroid (x', y') of the triangle with sides $ax^2 + 2hxy + by^2 = 0$ and $lx + my = 1$, is given by

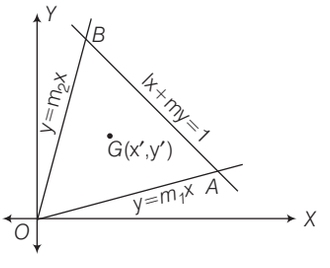
$$\frac{x'}{bl - hm} = \frac{y'}{am - hl} = \frac{2}{3(am^2 - 2hlm + bl^2)}.$$

Sol. Let the lines represented by

$$ax^2 + 2hxy + by^2 = 0$$

be $y = m_1x$

and $y = m_2x$.



Therefore, $m_1 + m_2 = -\frac{2h}{b}$

and $m_1 m_2 = \frac{a}{b}$

Coordinates of A and B are

$$\left(\frac{1}{l+mm_1}, \frac{m_1}{l+mm_1}\right) \text{ and } \left(\frac{1}{l+mm_2}, \frac{m_2}{l+mm_2}\right)$$

Since, centroid $= (x', y')$,

then, $x' = \left(\frac{\frac{1}{l+mm_1}+\frac{1}{l+mm_2}+0}{3}\right)$

$$= \left(\frac{2l + m(m_1+m_2)}{3\{l^2 + ml(m_1+m_2) + m^2 m_1 m_2)\}}\right)$$

$$= \left(\frac{2l - \frac{2hm}{b}}{3\left(l^2 - \frac{2hml}{b} + \frac{m^2 a}{b}\right)}\right)$$

$$= \frac{2}{3}\cdot\frac{(bl - hm)}{(am^2 - 2hlm + bl^2)} \quad \ldots(i)$$

and $y' = \left(\frac{\frac{m_1}{l+mm_1}+\frac{m_2}{l+mm_2}+0}{3}\right)$

$$= \left(\frac{l(m_1+m_2) + 2mm_1m_2}{3\{l^2 + lm(m_1+m_2) + m^2 m_1 m_2)\}}\right)$$

$$= \left(\frac{-\frac{2hl}{b}+\frac{2ma}{b}}{3\left(l^2 - \frac{2hlm}{b} + \frac{m^2 a}{b}\right)}\right)$$

$$= \frac{2}{3}\cdot\frac{(am - hl)}{(am^2 - 2hlm + bl^2)} \quad \ldots(ii)$$

From Eqs. (i) and (ii), we get

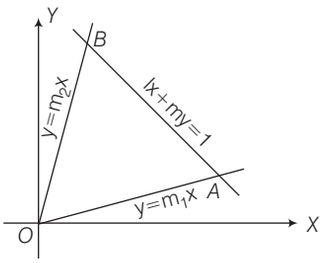
$$\frac{x'}{bl - hm} = \frac{y'}{am - hl} = \frac{2}{3(am^2 - 2hlm + bl^2)}$$

Example 8 Show that the area of the triangle formed by the lines $ax^2 + 2hxy + by^2 = 0$ and $lx + my + n = 0$ is $\frac{n^2\sqrt{(h^2 - ab)}}{|(am^2 - 2hlm + bl^2)|}$.

Sol. Let equation of lines represented by

$ax^2 + 2hxy + by^2 = 0$ be $y = m_1 x$ and $y = m_2 x$

therefore, $m_1 + m_2 = -\frac{2h}{b}$ and $m_1 m_2 = \frac{a}{b}$.



Coordinates of A and B are

$$\left(\frac{-n}{l+mm_1}, \frac{-nm_1}{l+mm_1}\right) \text{ and } \left(\frac{-n}{l+mm_2}, \frac{-nm_2}{l+mm_2}\right),$$

respectively.

Then, required area

$$= \frac{1}{2}\left|\left(\frac{-n}{l+mm_1}\right)\left(\frac{-nm_2}{l+mm_2}\right) - \left(\frac{-n}{l+mm_2}\right)\left(\frac{-nm_1}{l+mm_1}\right)\right|$$

[$\because$ if coordinates are $(0,0), (x_1, y_1)$ and, (x_2, y_2), then area $= \frac{1}{2}|x_1 y_2 - x_2 y_1|$]

$$= \frac{1}{2}\left|\frac{n^2(m_2 - m_1)}{|l^2 + lm(m_1+m_2) + m^2 m_1 m_2|}\right|$$

$$= \frac{1}{2}\left|\frac{n^2\sqrt{(m_1+m_2)^2 - 4m_1m_2}}{|l^2 + lm(m_1+m_2) + m^2 m_1 m_2|}\right|$$

$$= \frac{1}{2}\left|\frac{n^2\sqrt{\left(\frac{4h^2}{b^2} - \frac{4a}{b}\right)}}{l^2 - \frac{2hlm}{b} + \frac{m^2 a}{b}}\right|$$

$$= \frac{n^2\sqrt{(h^2 - ab)}}{|(am^2 - 2hlm + bl^2)|}$$

Example 9 Show that the two straight lines $x^2(\tan^2\theta + \cos^2\theta) - 2xy\tan\theta + y^2\sin^2\theta = 0$ move with the axis of x angles such that the difference of their tangents is 2.

Sol. Given equation is

$$x^2(\tan^2\theta + \cos^2\theta) - 2xy\tan\theta + y^2\sin^2\theta = 0 \quad \ldots(i)$$

and homogeneous equation of second degree

$$ax^2 + 2hxy + by^2 = 0 \quad \ldots(ii)$$

On comparing Eqs. (i) and (ii), we get

$$a = \tan^2\theta + \cos^2\theta$$

$$h = -\tan\theta$$

and $b = \sin^2\theta$

Let separate lines of Eq. (ii) are

$$y = m_1 x$$

and $y = m_2 x$

where, $m_1 = \tan\theta_1$ and $m_2 = \tan\theta_2$

therefore, $m_1 + m_2 = -\frac{2h}{b} = \frac{2\tan\theta}{\sin^2\theta}$

and $m_1 \cdot m_2 = \frac{a}{b} = \frac{\tan^2\theta + \cos^2\theta}{\sin^2\theta}$

$\therefore \quad m_1 \sim m_2 = \sqrt{(m_1 + m_2)^2 - 4m_1m_2}$

$\Rightarrow \quad \tan\theta_1 \sim \tan\theta_2 = \sqrt{\frac{4\tan^2\theta}{\sin^4\theta} - \frac{4(\tan^2\theta + \cos^2\theta)}{\sin^2\theta}}$

$= \frac{2}{\sin^2\theta}\sqrt{\tan^2\theta - \sin^2\theta(\tan^2\theta + \cos^2\theta)}$

$= \frac{2\sin\theta}{\sin^2\theta}\sqrt{(\sec^2\theta - \tan^2\theta - \cos^2\theta)}$

$= \frac{2\sin\theta}{\sin^2\theta}\sqrt{(1 - \cos^2\theta)}$

$= \frac{2}{\sin\theta}\sin\theta = 2$

Exercise for Session 1

1. The lines given by the equation $(2y^2 + 3xy - 2x^2)(x + y - 1) = 0$ form a triangle which is

(a) equilateral (b) isosceles

(c) right angled (d) obtuse angled

2. Area of the triangle formed by the lines $y^2 - 9xy + 18x^2 = 0$ and $y = 9$ is

(a) 27/4 (b) 0

(c) 9 / 4 (d) 27

3. The equation $3x^2 + 2hxy + 3y^2 = 0$ represents a pair of straight lines passing through the origin. The two lines are

(a) real and distinct, if $h^2 > 3$ (b) real and distinct, if $h^2 > 9$

(c) real and coincident, if $h^2 = 3$ (d) real and coincident, if $h^2 > 3$

4. If one of the lines of the pair $ax^2 + 2hxy + by^2 = 0$ bisects the angle between positive directions of the axes, then a, b, h satisfy the relation

(a) $a + b = 2|h|$ (b) $a + b = -2h$

(c) $a - b = 2|h|$ (d) $(a - b)^2 = 4h^2$

5. If the slope of one of the lines given by $a^2x^2 + 2hxy + b^2y^2 = 0$ be three times of the other, then h is equal to

(a) $2\sqrt{3}ab$ (b) $-2\sqrt{3}ab$

(c) $\frac{2}{\sqrt{3}}ab$ (d) $-\frac{2}{\sqrt{3}}ab$

6. Find the separate equations of two straight lines whose joint equation is $ab(x^2 - y^2) + (a^2 - b^2)xy = 0$.

7. Find the coordinates of the centroid of the triangle whose sides are $12x^2 - 20xy + 7y^2 = 0$ and $2x - 3y + 4 = 0$.

8. If the lines $ax^2 + 2hxy + by^2 = 0$ be two sides of a parallelogram and the line $lx + my = 1$ be one of its diagonal, show that the equation of the other diagonal is $y(bl - hm) = x(am - hl)$.

9. Find the condition that one of the lines given by $ax^2 + 2hxy + by^2 = 0$ may coincide with one of the lines given by $a'x^2 + 2h'xy + b'y^2 = 0$.

Session 2

Angle between the Pair of Lines $ax^2 + 2hxy + by^2$

Angle between the Pair of Lines $ax^2 + 2hxy + by^2$

Theorem The angle θ between the pair of lines represented by $ax^2 + 2hxy + by^2 = 0$

is given by $\theta = \tan^{-1}\left\{\dfrac{2\sqrt{(h^2 - ab)}}{|a + b|}\right\}$.

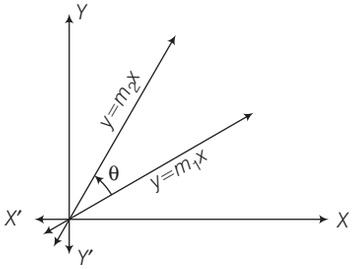
Proof Let $y = m_1 x$ and $y = m_2 x$ be the lines represented by

$$ax^2 + 2hxy + by^2 = 0.$$

Then, $m_1 + m_2 = -\dfrac{2h}{b}, m_1 m_2 = \dfrac{a}{b}$

Since, θ be the angle between the lines

$$y = m_1 x \quad \text{and} \quad y = m_2 x.$$



Then, $\tan\theta = \left|\dfrac{m_1 - m_2}{1 + m_1 m_2}\right| = \dfrac{\sqrt{(m_1 + m_2)^2 - 4m_1 m_2}}{|1 + m_1 m_2|}$

$$= \frac{\sqrt{\left(\dfrac{-2h}{b}\right)^2 - 4\left(\dfrac{a}{b}\right)}}{\left|1 + \dfrac{a}{b}\right|} = \frac{2\sqrt{(h^2 - ab)}}{|a + b|}$$

$\therefore \quad \theta = \tan^{-1}\left\{\dfrac{2\sqrt{(h^2 - ab)}}{|a + b|}\right\}$

Remark

$$\theta = \sin^{-1}\left\{\frac{2\sqrt{h^2 - ab}}{\sqrt{(a - b)^2 + 4h^2}}\right\}$$

Corollary 1 *Condition for the lines to be perpendicular.*

The lines are perpendicular if the angle between them is $\dfrac{\pi}{2}$.

i.e. $\theta = \dfrac{\pi}{2}$

$\Rightarrow \quad \cot\theta = \cot\dfrac{\pi}{2}$

$\Rightarrow \quad \cot\theta = 0$

$\Rightarrow \quad \dfrac{|a + b|}{2\sqrt{(h^2 - ab)}} = 0 \quad \Rightarrow \quad a + b = 0$

i.e. Coefficient of x^2 + Coefficient of $y^2 = 0$

Hence, the lines represented by $ax^2 + 2hxy + by^2 = 0$ are perpendicular, iff $a + b = 0$ i.e. coefficient of x^2 + coefficient of $y^2 = 0$.

Remark

Pair of any two perpendicular lines through the origin.

$\because$ Lines represented by $ax^2 + 2hxy + by^2 = 0$

be perpendicular, then $a + b = 0$ or $b = -a$

Hence, the equation becomes $ax^2 + 2hxy - ay^2 = 0$

$\Rightarrow \quad x^2 + \left(\dfrac{2h}{a}\right)xy - y^2 = 0$

$\Rightarrow \quad x^2 + pxy - y^2 = 0,$ (Remember)

where, p is any constant.

Corollary 2 *Pair of lines perpendicular to the lines represented by*

$$ax^2 + 2hxy + by^2 = 0$$

and through origin.

Let lines represented by

$ax^2 + 2hxy + by^2 = 0$ be $y = m_1 x$ and $y = m_2 x$

then $\quad m_1 + m_2 = -\dfrac{2h}{b}$

and $\quad m_1 m_2 = \dfrac{a}{b}$

lines perpendiculars to $y = m_1 x$

and $y = m_2 x$

and passing through origin are

$$y = -\frac{1}{m_1} x$$

and $$y = -\frac{1}{m_2} x$$

then, pair is $$\left(y + \frac{x}{m_1}\right)\left(y + \frac{x}{m_2}\right) = 0$$

$$\Rightarrow \quad x^2 + xy\,(m_1 + m_2) + m_1 m_2\, y^2 = 0$$

$$\Rightarrow \quad x^2 - \frac{2hxy}{b} + \frac{a}{b} y^2 = 0$$

$$\therefore \quad bx^2 - 2hxy + ay^2 = 0$$

Aid to memory For perpendicular pairs interchange the coefficients of x^2 and y^2 and change the sign of xy.

***Corollary* 3** *Condition for the lines to be coincident.*

The lines are coincident, if the angle between them is $0°$ (or π)

i.e. $$\theta = 0 \text{ (or } \pi)$$

$$\therefore \quad \tan\theta = 0°$$

$$\Rightarrow \quad \frac{2\sqrt{(h^2 - ab)}}{|a + b|} = 0$$

$$\Rightarrow \quad h^2 - ab = 0$$

$$\Rightarrow \quad h^2 = ab$$

Hence, the lines represented by $ax^2 + 2hxy + by^2 = 0$ are coincident, iff $h^2 = ab$, then $ax^2 + 2hxy + by^2$ is a perfect square.

Remark

The parallel lines will be coincident only as both pass through a point.

Example 10 Find the angle between the lines $(x^2 + y^2)\sin^2\alpha = (x\cos\beta - y\sin\beta)^2$.

Sol. Given equation is

$$(x^2 + y^2)\sin^2\alpha = (x\cos\beta - y\sin\beta)^2$$

$$\Rightarrow \quad x^2(\sin^2\alpha - \cos^2\beta) + 2xy\sin\beta\cos\beta + y^2(\sin^2\alpha - \sin^2\beta) = 0 \quad \text{...(i)}$$

The homogeneous equation of second degree is

$$ax^2 + 2hxy + by^2 = 0 \quad \text{...(ii)}$$

On comparing Eqs. (i) and (ii), we get

$a = \sin^2\alpha - \cos^2\beta$, $h = \sin\beta\cos\beta$,

$b = \sin^2\alpha - \sin^2\beta$

Let the angle between the lines representing by Eq. (i) is θ.

$$\therefore \tan\theta = 2\frac{\sqrt{h^2 - ab}}{|a + b|}$$

$$= 2\frac{\sqrt{\sin^2\beta\cos^2\beta - (\sin^2\alpha - \cos^2\beta)(\sin^2\alpha - \sin^2\beta)}}{|\sin^2\alpha - \cos^2\beta + \sin^2\alpha - \sin^2\beta|}$$

$$= 2\frac{\sqrt{\{\sin^2\beta\cos^2\beta - \sin^4\alpha + \sin^2\alpha\sin^2\beta + \sin^2\alpha\cos^2\beta - \sin^2\beta\cos^2\beta\}}}{|(2\sin^2\alpha - 1)|}$$

$$= 2\frac{\sqrt{\sin^2\alpha(1 - \sin^2\alpha)}}{|-\cos 2\alpha|}$$

$$= \frac{2\sin\alpha\cos\alpha}{|-\cos 2\alpha|} = \tan 2\alpha$$

$$\therefore \quad \theta = 2\alpha$$

Example 11 Show that the angle between the lines given by $(a + 2hm + bm^2)x^2 + 2\{(b - a)m - (m^2 - 1)h\}xy + (am^2 - 2hm + b)y^2 = 0$ is the same whatever be the value of m.

Sol. Given equation is

$$(a + 2hm + bm^2)x^2 + 2\{(b - a)m - (m^2 - 1)h\}xy + (am^2 - 2hm + b)y^2 = 0 \quad \text{...(i)}$$

The homogeneous equation of second degree

$$Ax^2 + 2Hxy + By^2 = 0 \quad \text{...(ii)}$$

On comparing Eqs. (i) and (ii), we get

$A = a + 2hm + bm^2$, $H = (b - a)m - (m^2 - 1)h$,

$B = am^2 - 2hm + b$

Let the angle between the lines representing by Eq. (i) is θ.

$$\therefore \quad \tan\theta = \frac{2\sqrt{(H^2 - AB)}}{|A + B|}$$

$$= \frac{2\sqrt{\{(b - a)m - (m^2 - 1)h\}^2 - (a + 2hm + bm^2)(am^2 - 2hm + b)}}{|a + 2hm + bm^2 + am^2 - 2hm + b|}$$

$$= \frac{2\sqrt{(m^2 + 1)^2(h^2 - ab)}}{|a + b|(m^2 + 1)} = \frac{2\sqrt{(h^2 - ab)}}{|a + b|}$$

$$\Rightarrow \quad \theta = \tan^{-1}\left\{\frac{2\sqrt{(h^2 - ab)}}{|a + b|}\right\}$$

which is independent of m. Hence, the angle between the lines representing by Eq. (i) is same for all values of m.

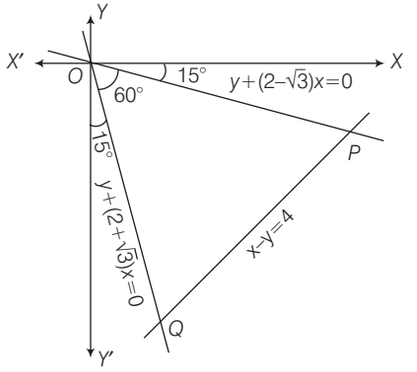
Example 12 Show that the straight lines $x^2 + 4xy + y^2 = 0$ and the line $x - y = 4$ form an equilateral triangle.

Sol. Equation $x^2 + 4xy + y^2 = 0$ ...(i)

is a homogeneous equation of second degree in x and y. Therefore, it represents two lines OP and OQ through the origin.

Equation, $x - y = 4$ ...(ii)

represent the line PQ.



Let $\angle POQ = \theta$.

then, $\tan\theta = \dfrac{2\sqrt{[(2)^2 - 1\cdot 1]}}{|1+1|} = \sqrt{3}$

$\therefore \quad \theta = 60°$

From Eq. (i), $x^2 + 4xy + y^2 = 0$

$\Rightarrow \quad \left(\dfrac{y}{x}\right)^2 + 4\left(\dfrac{y}{x}\right) + 1 = 0$

$\Rightarrow \quad \dfrac{y}{x} = \dfrac{-4 \pm \sqrt{(4^2 - 4)}}{2} = -2 \pm \sqrt{3}$

$\Rightarrow \quad y = (-2 \pm \sqrt{3})\, x$

i.e. $OP : y + (2 - \sqrt{3})\, x = 0$

and $OQ : y + (2 + \sqrt{3})\, x = 0$

$\because$ Slope of $PQ = 1$ and Slope of $OP = -(2 - \sqrt{3})$.

If $\angle OPQ = \alpha$

then $\tan\alpha = \left|\dfrac{1 - (-2 + \sqrt{3})}{1 - 2 + \sqrt{3}}\right| = \left|\dfrac{3 - \sqrt{3}}{-1 + \sqrt{3}}\right| = \sqrt{3}$

$\therefore \quad \alpha = 60°$

Hence, $\angle OQP = 180° - (60° + 60°) = 60°$

Hence, ΔOPQ is an equilateral triangle.

Example 13 Show that the condition that two of the three lines represented by $ax^3 + bx^2y + cxy^2 + dy^3 = 0$ may be at right angles is $a^2 + ac + bd + d^2 = 0$.

Sol. The given equation being homogeneous of third degree represents three straight lines through the origin. Since, two of these lines are to be at right angles.

Let pair of these lines be $(x^2 + pxy - y^2)$, p is constant and the other factor is $(ax - dy)$.

Hence, $ax^3 + bx^2y + cxy^2 + dy^3 = (x^2 + pxy - y^2)(ax - dy)$

Comparing the coefficients of similar terms, we get

$b = ap - d$ ...(i)

$c = -pd - a$ ...(ii)

Multiplying Eq. (i) by d and Eq. (ii) by a and adding, we get

$bd + ac = -d^2 - a^2$

$\Rightarrow \quad a^2 + ac + bd + d^2 = 0$

Aliter :

Let $y = m_1x$, $y = m_2x$ and $y = m_3x$ be the lines represented by the equation

$ax^3 + bx^2y + cxy^2 + dy^3 = 0.$

Then

$ax^3 + bx^2y + cxy^2 + dy^3 = d\,(y - m_1x)\,(y - m_2x)\,(y - m_3x)$ ...(i)

On equating the coefficients of x^3, x^2y and xy^2 on both sides, we get

$m_1 + m_2 + m_3 = -\dfrac{c}{d}$

$m_1m_2 + m_2m_3 + m_3m_1 = \dfrac{b}{d}$

and $m_1m_2m_3 = -\dfrac{a}{d}$ ...(ii)

Let the perpendicular lines be $y = m_1x$ and $y = m_2x$, then

$m_1m_2 = -1$

From Eq. (ii), $m_3 = \dfrac{a}{d}$ ...(iii)

On putting $y = m_3x$ in Eq. (i), we get

$ax^3 + bm_3x^3 + cm_3^2x^3 + dm_3^3x^3 = 0$

$\Rightarrow \quad dm_3^3 + cm_3^2 + bm_3 + a = 0$

$\Rightarrow \quad d\left(\dfrac{a}{d}\right)^3 + c\left(\dfrac{a}{d}\right)^2 + b\left(\dfrac{a}{d}\right) + a = 0$ [from Eq. (iii)]

Hence, $a^2 + ac + bd + d^2 = 0$

Exercise for Session 2

1. The angle between the pair of straight lines $y^2 \sin^2\theta - xy \sin^2\theta + x^2(\cos^2\theta - 1) = 0$ is

(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$ (c) $\frac{\pi}{3}$ (d) $\frac{2\pi}{3}$

2. The angle between the lines given by the equation $ay^2 - (1+\lambda^2)\,xy - ax^2 = 0$ is same as the angle between the lines

(a) $5x^2 + 2xy - 3y^2 = 0$ (b) $x^2 - 2xy - 3y^2 = 0$

(c) $x^2 - y^2 = 100$ (d) $xy = 0$

3. Which of the following pair of straight lines intersect at right angles ?

(a) $2x^2 = y\,(x + 2y)$ (b) $(x + y)^2 = x\,(y + 3x)$

(c) $2y\,(x + y) = xy$ (d) $y = \mp 2x$

4. If $h^2 = ab$, then the lines represented by $ax^2 + 2hxy + by^2 = 0$ are

(a) parallel (b) perpendicular

(c) coincident (d) None of these

5. Equation $ax^3 - 9x^2y - xy^2 + 4y^3 = 0$ represents three straight lines. If the two of the lines are perpendicular, then a is equal to

(a) –5 (b) 5

(c) –4 (d) 4

6. Find the angle between the lines whose joint equation is $2x^2 - 3xy + y^2 = 0$.

7. Show that the lines $(1 - \cos\theta \tan\alpha)\,y^2 - (2\cos\theta + \sin^2\theta \tan\alpha)\,xy + \cos\theta\,(\cos\theta + \tan\alpha)\,x^2 = 0$ include an angle α between them.

8. Find the angle between the lines represented by the equation $x^2 - 2pxy + y^2 = 0$.

9. Show that the lines $x^2 - 4xy + y^2 = 0$ and $x + y = 1$ form an equilateral triangle and find its area.

10. Prove that the triangle formed by the lines $ax^2 + 2hxy + by^2 = 0$ and $lx + my = 1$ is isosceles, if $h\,(l^2 - m^2) = (a - b)\,m$.

Session 3

Bisectors of the Angle between the Lines Given by a Homogeneous Equation

Bisectors of the Angle between the Lines Given by a Homogeneous Equation

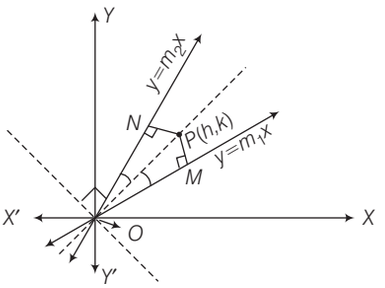
Theorem The joint equation of the bisectors of the angles between the lines represented by the equation

$$ax^2 + 2hxy + by^2 = 0 \quad \text{is} \quad \frac{x^2 - y^2}{a - b} = \frac{xy}{h}.$$

Proof Let the lines represented by $ax^2 + 2hxy +$ be $y - m_1 x = 0$ and $y - m_2 x = 0$, then

$$m_1 + m_2 = -\frac{2h}{b} \quad \text{and} \quad m_1 m_2 = \frac{a}{b}$$

Since, the bisectors of the angles between the lin locus of a point which is equidistant from the tw lines.



Let $P(h, k)$ be a point on a bisector of the angle between the given lines. Then, $PM = PN$

$$\Rightarrow \quad \frac{|k - m_1 h|}{\sqrt{(1 + m_1^2)}} = \frac{|k - m_2 h|}{\sqrt{(1 + m_2^2)}}$$

$$\Rightarrow \quad \frac{(k - m_1 h)}{\sqrt{(1 + m_1^2)}} = \pm \frac{(k - m_2 h)}{\sqrt{(1 + m_2^2)}}$$

Hence, the locus of a $P(h, k)$ is

$$\frac{(y - m_1 x)}{\sqrt{(1 + m_1^2)}} = \pm \frac{(y - m_2 x)}{\sqrt{(1 + m_2^2)}}$$

$\therefore$ The pair of bisectors is

$$\left(\frac{(y - m_1 x)}{\sqrt{(1 + m_1^2)}} + \frac{(y - m_2 x)}{\sqrt{(1 + m_2^2)}}\right)\left(\frac{(y - m_1 x)}{\sqrt{(1 + m_1^2)}} - \frac{(y - m_2 x)}{\sqrt{(1 + m_2^2)}}\right) = 0$$

$$\Rightarrow \quad \frac{(y - m_1 x)^2}{(1 + m_1^2)} - \frac{(y - m_2 x)^2}{(1 + m_2^2)} = 0$$

$$\Rightarrow \quad (1 + m_2^2)(y^2 + m_1^2 x^2 - 2m_1 xy) - (1 + m_1^2)(y^2 + m_2^2 x^2 - 2m_2 xy) = 0$$

$$m_1^2)y^2 - (m_2^2 - m_1^2)x^2 + 2xy(m_2 - m_1) - 2m_1 m_2 (m_2 - m_1)xy = 0$$

$$+ m_1)(y^2 - x^2) + 2xy - 2m_1 m_2 xy = 0 \qquad [\because m_1 - m_2 \neq 0]$$

$$\Rightarrow \quad (x^2 - y^2)\left(-\frac{2h}{b}\right) = 2xy\left(1 - \frac{a}{b}\right) \qquad \left[\because m_1 + m_2 = -\frac{2h}{b},\ m_1 m_2 = \frac{a}{b}\right]$$

$$\therefore \quad \frac{x^2 - y^2}{a - b} = \frac{xy}{h} \qquad [b \neq 0]$$

Aliter :

Let the equation $ax^2 + 2hxy + by^2 = 0$ represent two lines L_1OM_1 and L_2OM_2 making angles θ_1 and θ_2 with the positive direction of X-axis.

If slopes of L_1OM_1 and L_2OM_2 are m_1 and m_2, then

$$m_1 = \tan\theta_1 \quad \text{and} \quad m_2 = \tan\theta_2$$

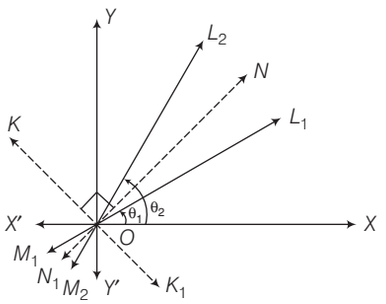
and $$m_1 + m_2 = -\frac{2h}{b}, m_1 m_2 = \frac{a}{b} \qquad \text{...(i)}$$

Let NON_1 and KOK_1 are the required bisectors,

Since $$\angle NOL_1 = \angle NOL_2 = \frac{\theta_2 - \theta_1}{2}$$

$$\angle NOX = \theta_1 + \frac{\theta_2 - \theta_1}{2} = \frac{\theta_1 + \theta_2}{2}$$

Since, $$\angle NOK = \frac{\pi}{2}$$



$$\therefore \qquad \angle KOX = \frac{\pi}{2} + \angle NOX = \frac{\pi}{2} + \left(\frac{\theta_1 + \theta_2}{2}\right)$$

Equation of bisectors are $y = x \tan\left(\frac{\theta_1 + \theta_2}{2}\right)$

$$\Rightarrow \qquad y - x \tan\left(\frac{\theta_1 + \theta_2}{2}\right) = 0 \qquad \text{...(ii)}$$

and
$$y = x \tan\left(\frac{\pi}{2} + \frac{\theta_1 + \theta_2}{2}\right)$$

$$\Rightarrow \qquad y = -x \cot\left(\frac{\theta_1 + \theta_2}{2}\right)$$

$$\Rightarrow \qquad y + x \cot\left(\frac{\theta_1 + \theta_2}{2}\right) = 0 \qquad \text{...(iii)}$$

$\therefore$ Pair of bisectors

$$\left[y - x \tan\left(\frac{\theta_1 + \theta_2}{2}\right)\right]\left[y + x \cot\left(\frac{\theta_1 + \theta_2}{2}\right)\right] = 0$$

$$\Rightarrow \quad y^2 - x^2 + xy\left(\cot\left(\frac{\theta_1 + \theta_2}{2}\right) - \tan\left(\frac{\theta_1 + \theta_2}{2}\right)\right) = 0$$

$$\Rightarrow \qquad x^2 - y^2 = xy\left(\frac{1 - \tan^2\left(\frac{\theta_1 + \theta_2}{2}\right)}{\tan\left(\frac{\theta_1 + \theta_2}{2}\right)}\right)$$

$$\Rightarrow \qquad x^2 - y^2 = xy\left(\frac{2}{\tan(\theta_1 + \theta_2)}\right)$$

$$\Rightarrow \qquad x^2 - y^2 = 2xy\left(\frac{1 - \tan\theta_1 \tan\theta_2}{\tan\theta_1 + \tan\theta_2}\right)$$

$$\Rightarrow \qquad x^2 - y^2 = 2xy\left(\frac{1 - m_1 m_2}{m_1 + m_2}\right)$$

$$\Rightarrow \qquad x^2 - y^2 = 2xy\left(\frac{1 - a/b}{-2h/b}\right)$$

$$\therefore \qquad \frac{(x^2 - y^2)}{(a - b)} = \frac{xy}{h}$$

Remark

The joint equation of the bisectors is $\frac{x^2 - y^2}{a - b} = \frac{xy}{h}$

or $\qquad hx^2 - (a - b)\,xy - hy^2 = 0$

i.e. coefficient of x^2 + coefficient of $y^2 = 0$.

Hence, the bisectors of the angle between the lines are always perpendicular to each other.

Corollaries

1. If $a = b$, the bisectors are $x^2 - y^2 = 0$

   i.e. $\qquad x - y = 0,\ x + y = 0$

2. If $h = 0$, the bisectors are $xy = 0$

   i.e. $\qquad x = 0,\ y = 0$

Example 14 Find the equation of the bisectors of the angle between the lines represented by $3x^2 - 5xy + 4y^2 = 0$.

Sol. Given equation is

$$3x^2 - 5xy + 4y^2 = 0 \qquad \text{...(i)}$$

Comparing it with the equation

$$ax^2 + 2hxy + by^2 = 0 \qquad \text{...(ii)}$$

then $\qquad a = 3,\ h = -\frac{5}{2},\ b = 4$

Hence, the equation of bisectors of the angle between the pair of the lines (i) is

$$\frac{x^2 - y^2}{3 - 4} = \frac{xy}{-5/2}$$

$$\Rightarrow \qquad \frac{x^2 - y^2}{-1} = \frac{2xy}{-5}$$

$$\therefore \qquad 5x^2 - 2xy - 5y^2 = 0$$

Example 15 Show that the line $y = mx$ bisects the angle between the lines

$$ax^2 - 2hxy + by^2 = 0,$$

if $\qquad h(1 - m^2) + m(a - b) = 0.$

Sol. Equation of pair of bisectors of angles between lines $ax^2 - 2hxy + by^2 = 0$ is

$$\frac{x^2 - y^2}{a - b} = \frac{xy}{-h}$$

$$\Rightarrow \qquad -h(x^2 - y^2) = (a - b)\,xy \qquad \text{...(i)}$$

But $y = mx$ is one of these lines, then it will satisfy it. Substituting $y = mx$ in Eq. (i),

$$-h(x^2 - m^2x^2) = (a - b)x \cdot mx$$

Dividing by x^2, $h(1 - m^2) + m(a - b) = 0$

Example 16 If pairs of straight lines $x^2 - 2pxy - y^2 = 0$ and $x^2 - 2qxy - y^2 = 0$ be such that each pair bisects the angle between the other pair, then prove that $pq = -1$.

Sol. According to the question, the equation of the bisectors of the angle between the lines

$$x^2 - 2pxy - y^2 = 0 \quad \text{...(i)}$$

is $$x^2 - 2qxy - y^2 = 0 \quad \text{...(ii)}$$

$\therefore$ The equation of bisectors of the angle between the lines (i) is

$$\frac{x^2 - y^2}{1 - (-1)} = \frac{xy}{-p}$$

$$\Rightarrow \quad -px^2 - 2xy + py^2 = 0 \quad \text{...(iii)}$$

Since, Eqs. (ii) and (iii) are identical, comparing Eqs. (ii) and (iii), we get

$$\frac{1}{-p} = \frac{-2q}{-2} = \frac{-1}{p} \Rightarrow pq = -1$$

Remark

By taking the bisectors of the angles between the pair of lines (ii), we will get the same result.

Example 17 Prove that the angle between one of the lines given by $ax^2 + 2hxy + by^2 = 0$ and one of the lines $ax^2 + 2hxy + by^2 + \lambda(x^2 + y^2) = 0$ is equal to angle between other two lines of the system.

Sol. The equation of the bisectors of the angle between the lines

$$ax^2 + 2hxy + by^2 = 0 \quad \text{...(i)}$$

is $$\frac{x^2 - y^2}{a - b} = \frac{xy}{h}$$

and the equation of bisectors of the angle between the lines

$$ax^2 + 2hxy + by^2 + \lambda(x^2 + y^2) = 0 \quad \text{...(ii)}$$

$$\Rightarrow \quad (a + \lambda)x^2 + 2hxy + (b + \lambda)y^2 = 0$$

is $$\frac{x^2 - y^2}{(a + \lambda) - (b + \lambda)} = \frac{xy}{h} \Rightarrow \frac{x^2 - y^2}{a - b} = \frac{xy}{h}$$

$\therefore$ Bisectors of angles between lines given by Eqs. (i) and (ii) are the same. Hence the result.

Example 18 Show that the pair of lines given by $a^2x^2 + 2h(a+b)xy + b^2y^2 = 0$ is equally inclined to the pair given by $ax^2 + 2hxy + by^2 = 0$.

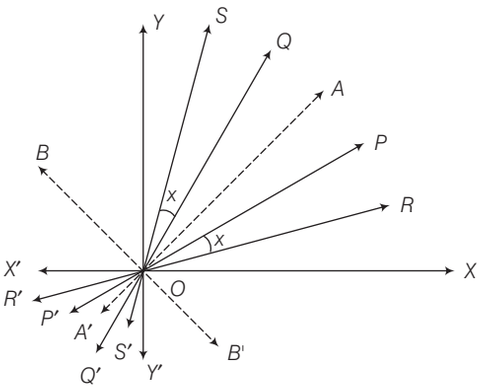
Sol. Given pair of lines are

$$a^2x^2 + 2h(a + b)xy + b^2y^2 = 0 \quad \text{...(i)}$$

and $$ax^2 + 2hxy + by^2 = 0 \quad \text{...(ii)}$$

Equation of bisectors of first pair is

$$\frac{x^2 - y^2}{a^2 - b^2} = \frac{xy}{h(a + b)} \Rightarrow \frac{x^2 - y^2}{a - b} = \frac{xy}{h}$$



which are also the bisectors of the second pair.

Let $P'OP$, $Q'OQ$, $R'OR$, $S'OS$ be the lines of the Eqs. (i) and (ii) pairs respectively and $A'OA$ and $B'OB$ be their bisectors. We have,

$$\angle ROA = \angle SOA$$

and $$\angle POA = \angle QOA$$

$$\Rightarrow \quad \angle ROA - \angle POA = \angle SOA - \angle QOA$$

$$\Rightarrow \quad \angle ROP = \angle SOQ$$

Hence the result.

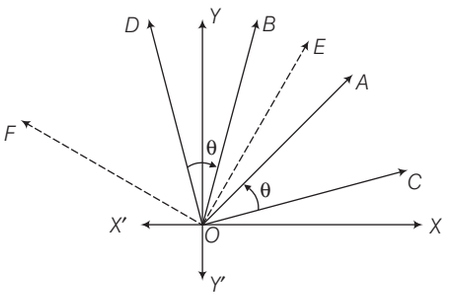
Example 19 If the lines represented by $x^2 - 2pxy - y^2 = 0$ are rotated about the origin through an angle θ, one in clockwise direction and the other in anti-clockwise direction, then find the equation of the bisectors of the angle between the lines in the new position.

Sol. Since, lines represented by $x^2 - 2pxy - y^2 = 0$ are perpendicular to each other. The bisectors of the angles between the lines in new position are same as the bisectors of the angles between their old positions. i.e.

OC, OD ; OA, OB be the old and new pairs respectively and OE and OF be their bisectors, we have

$$\angle COE = \angle DOE$$

and $$\angle COA = \angle DOB = \theta \quad \text{[given]}$$



$$\Rightarrow \quad \angle COE - \angle COA = \angle DOE - \angle DOB$$

$$\Rightarrow \quad \angle AOE = \angle BOE$$

Therefore, the required equation is $\frac{x^2 - y^2}{1 - (-1)} = \frac{xy}{-p}$

i.e. $px^2 + 2xy - py^2 = 0$.

Exercise for Session 3

1. If coordinate axes are the angle bisectors of the pair of lines $ax^2 + 2hxy + by^2 = 0$, then

(a) $a = b$ (b) $h = 0$

(c) $a^2 + b = 0$ (d) $a + b^2 = 0$

2. If the line $y = mx$ is one of the bisector of the lines $x^2 + 4xy - y^2 = 0$, then the value of m is

(a) $\frac{\sqrt{5} - 1}{2}$ (b) $\frac{\sqrt{5} + 1}{2}$

(c) $-\left(\frac{\sqrt{5} + 1}{2}\right)$ (d) $-\left(\frac{\sqrt{5} - 1}{2}\right)$

3. If one of the lines of $my^2 + (1 - m^2)\,xy - mx^2 = 0$ is a bisector of the angle between the lines $xy = 0$, then $\cos^{-1}(m)$ is

(a) 0 (b) $\pi/2$

(c) π (d) $3\pi / 2$

4. The bisectors of the angles between the lines $(ax + by)^2 = c\,(bx - ay)^2, c > 0$ are respectively parallel and perpendicular to the line

(a) $bx - ay + \mu = 0$ (b) $ax + by + \lambda = 0$

(c) $ax - by + \nu = 0$ (d) $bx + ay + \tau = 0$

5. If the pairs of straight lines $ax^2 + 2hxy - ay^2 = 0$ and $bx^2 + 2gxy - by^2 = 0$ be such that each bisects the angles between the other, then prove that $hg + ab = 0$.

6. Prove that the lines $2x^2 + 6xy + y^2 = 0$ are equally inclined to the lines $4x^2 + 18xy + y^2 = 0$.

7. Show that the lines bisecting the angle between the bisectors of the angles between the lines $ax^2 + 2hxy + by^2 = 0$ are given by $(a - b)(x^2 - y^2) + 4hxy = 0$.

8. Prove that the bisectors of the angle between the lines $ax^2 + acxy + cy^2 = 0$ and $\left(3 + \frac{1}{c}\right)x^2 + xy + \left(3 + \frac{1}{a}\right)y^2 = 0$ are always the same.

9. The lines represented by $x^2 + 2\lambda xy + 2y^2 = 0$ and the lines represented by $(1 + \lambda)x^2 - 8xy + y^2 = 0$ are equally inclined, find the values of λ.

Session 4

General Equation of Second Degree, Important Theorems

General Equation of Second Degree

The equation $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

is the general equation of second degree and represents a conics (pair of straight lines, circle, parabola, ellipse, hyperbola). It contains six constants a, b, c, f, g, h.

i.e. $a =$ coefficient of x^2, $b =$ coefficient of y^2,

$c =$ constant term, $g =$ half the coefficient of x,

$f =$ half the coefficient of y,

$h =$ half the coefficient of xy.

Theorem The necessary and sufficient condition for

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

to represent a pair of straight lines is that

$$abc + 2fgh - af^2 - bg^2 - ch^2 = 0 \text{ or } \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} = 0.$$

Proof **Necessary condition :** Let the equation be

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \quad \ldots(i)$$

represent a pair of lines. Assuming that these lines are not parallel, we suppose further that their point of intersection is (x_1, y_1). Shifting the origin at (x_1, y_1) without rotating the coordinate axes, we have the Eq. (i) transforms to

$$a(X + x_1)^2 + 2h(X + x_1)(Y + y_1) + b(Y + y_1)^2 + 2g(X + x_1) + 2f(Y + y_1) + c = 0 \quad \ldots(ii)$$

Now this Eq. (ii) represents a pair of lines through the new origin and consequently, it is homogeneous in X and Y.

Hence, the coefficients of X and Y and the constant term in Eq. (ii) must vanish separately.

i.e. coefficient of $X =$ coefficient of $Y =$ constant term $= 0$

$$\Rightarrow \quad ax_1 + hy_1 + g = 0 \quad \ldots(iii)$$

$$hx_1 + by_1 + f = 0 \quad \ldots(iv)$$

and $$ax_1^2 + 2hx_1y_1 + by_1^2 + 2gx_1 + 2fy_1 + c = 0 \quad \ldots(v)$$

Now, $ax_1^2 + 2hx_1y_1 + by_1^2 + 2gx_1 + 2fy_1 + c = 0$

$$\Rightarrow \quad x_1(ax_1 + hy_1 + g) + y_1(hx_1 + by_1 + f) + (gx_1 + fy_1 + c) = 0$$

$$\Rightarrow \quad x_1 \cdot 0 + y_1 \cdot 0 + gx_1 + fy_1 + c = 0 \quad \text{[from Eqs. (iii) and (iv)]}$$

$$\Rightarrow \quad gx_1 + fy_1 + c = 0 \quad \ldots(vi)$$

On eliminating x_1, y_1 from Eqs. (iii), (iv) and (vi), we get the determinant

$$\begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} = 0$$

$\therefore \; abc + 2fgh - af^2 - bg^2 - ch^2 = 0,$

as the required condition.

Remarks

1. **Without using determinant** On solving Eqs. (iii) and (iv), we get

$$(x_1, y_1) = \left(\frac{hf - bg}{ab - h^2}, \frac{gh - af}{ab - h^2} \right)$$

and then substituting the values of x_1 and y_1 in Eqs. (vi), we obtain

$$g\left(\frac{hf - bg}{ab - h^2} \right) + f\left(\frac{gh - af}{ab - h^2} \right) + c = 0$$

$$\Rightarrow \quad abc + 2fgh - af^2 - bg^2 - ch^2 = 0$$

2. By making $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

homogeneous with the help of a new variable z, i.e.

$ax^2 + 2hxy + by^2 + 2gxz + 2fyz + cz^2 = 0$

Let $f(x, y, z) \equiv ax^2 + 2hxy + by^2 + 2gxz + 2fyz + cz^2 = 0$

$$\therefore \quad \frac{\partial f}{\partial x} = 2ax + 2hy + 2gz = 0$$

$$\frac{\partial f}{\partial y} = 2hx + 2by + 2fz = 0$$

$$\frac{\partial f}{\partial z} = 2gx + 2fy + 2cz = 0$$

and finally putting $z = 1$, we obtain equations

$$ax + hy + g = 0, \; hx + by + f = 0, \; gx + fy + c = 0$$

which are same as Eqs. (iii), (iv) and (vi), respectively.

3. If $ab - h^2 = 0$, the lines given by Eq. (i) are parallel. In this case, the method followed in the above proof fails and we follow the following method.

Aliter I : (Proof)

Let the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \quad ...(i)$$

be $lx + my + n = 0$ and $l'x + m'y + n' = 0$

then $ax^2 + 2hxy + by^2 + 2gx + 2fy + c$

$$\equiv (lx + my + n)(l'x + m'y + n') \quad ...(ii)$$

Comparing the coefficients of similar terms in both sides of Eq. (ii), we get

$$\left.\begin{aligned} &ll' = a, mm' = b, nn' = c \\ &lm' + l'm = 2h, \ln' + l'n = 2g, \\ &mn' + m'n = 2f \end{aligned}\right\} \quad ...(iii)$$

We now eliminate l, m, n, l', m' and n' from these equations,

we have $\begin{vmatrix} l & l' & 0 \\ m & m' & 0 \\ n & n' & 0 \end{vmatrix} \times \begin{vmatrix} l' & l & 0 \\ m' & m & 0 \\ n' & n & 0 \end{vmatrix} = 0$

[$\because$ each determinant $= 0$]

$$\Rightarrow \begin{vmatrix} 2ll' & lm' + l'm & ln' + l'n \\ ml' + m'l & 2mm' & mn' + m'n \\ nl' + n'l & nm' + n'm & 2nn' \end{vmatrix} = 0$$

$$\Rightarrow \begin{vmatrix} 2a & 2h & 2g \\ 2h & 2b & 2f \\ 2g & 2f & 2c \end{vmatrix} = 0$$

$$\Rightarrow \Delta = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} = 0$$

$\therefore \quad \Delta = abc + 2fgh - af^2 - bg^2 - ch^2 = 0,$

which is the required necessary condition.

Remark

Without using determinant

Now, $(lm' + l'm)(\ln' + l'n)(mn' + m'n) = 2h \cdot 2g \cdot 2f$

$\Rightarrow \quad 2ll'mm'nn' + ll'(m^2n'^2 + m'^2n^2)$

$+ mm'(n^2l'^2 + n'^2l^2) + nn'(l^2m'^2 + l'^2m^2) = 8fgh$

$\Rightarrow \quad 2ll'mm'nn' + ll'\{(mn' + m'n)^2 - 2mm'nn'\}$

$+ mm'\{(nl' + n'l)^2 - 2nn'll'\} + nn'\{(lm' + l'm)^2 - 2ll'mm'\}$

$= 8fgh$ [from Eq. (iii)]

$\Rightarrow 2abc + a(4f^2 - 4bc) + b(4g^2 - 4ca) + c(4h^2 - 4ab) = 8fgh$

$\therefore \quad abc + 2fgh - af^2 - bg^2 - ch^2 = 0,$

which is the required necessary condition.

Aliter II : (Proof)

Given equation is

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \quad ...(i)$$

Case I If $a \neq 0$, then writing Eq. (i) as a quadratic equation in x, we get

$$ax^2 + 2x(hy + g) + by^2 + 2fy + c = 0$$

Solving, we have

$$x = \frac{-2(hy + g) \pm \sqrt{4(hy + g)^2 - 4a(by^2 + 2fy + c)}}{2a}$$

$$\therefore x = \frac{-(hy + g) \pm \sqrt{\{(h^2 - ab)y^2 + 2(gh - af)y + (g^2 - ac)\}}}{a}$$

Eq. (i), will represent two straight lines, if LHS of Eq. (i), can be resolved into two linear factors, therefore the expression under the square root should be a perfect square.

[$\because Ax^2 + Bx + C = 0$ is a perfect square $\Leftrightarrow B^2 - 4AC = 0$]

Hence, $4(gh - af)^2 - 4(h^2 - ab)(g^2 - ac) = 0$

or $\quad abc + 2fgh - af^2 - bg^2 - ch^2 = 0 \quad ...(ii)$

Ths is called discriminant of the Eq. (i).

Case II If $a = 0, b \neq 0$, then writing Eq. (i) as a quadratic equation in y

i.e. $\quad by^2 + 2y(hx + f) + 2gx + c = 0$

and proceeding above we get the condition

$$2fgh - bg^2 - ch^2 = 0$$

which is condition obtained by putting $a = 0$ in Eq. (ii).

Case III If $a = 0, b = 0$ but $h \neq 0$, then Eq. (i) becomes

$$2hxy + 2gx + 2fy + c = 0$$

Multiplying by $\frac{h}{2}$ [$\because h \neq 0$]

$$\Rightarrow \quad h^2xy + hgx + hfy + \frac{ch}{2} = 0$$

$$\Rightarrow \quad (hx + f)(hy + g) = fg - \frac{ch}{2}$$

Above equation represents two straight lines, if

$$fg - \frac{ch}{2} = 0 \quad \Rightarrow \quad 2fgh - ch^2 = 0$$

which is condition obtained by putting $a = 0, b = 0$ in Eq. (ii).

Hence in each case, the condition that

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

represents two straight lines is

$$abc + 2fgh - af^2 - bg^2 - ch^2 = 0$$

which is the required necessary condition.

Sufficient condition (Conversely)

Here, we have to show that the equation $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ represents a pair of straight lines.

$$\begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} = 0$$

i.e. lines $ax + hy + g = 0, hx + by + f = 0, \ gx + fy + c = 0$ are concurrent.

Let the point of concurrency be (x_1, y_1).

Then, $ax_1 + hy_1 + g = 0$ ...(iii)

$hx_1 + by_1 + f = 0$ ...(iv)

and $gx_1 + fy_1 + c = 0$ ...(v)

Now, shifting the origin at (x_1, y_1) without rotating the coordinate axes the equation

$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ reduces to

$$a(X + x_1)^2 + 2h(X + x_1)(Y + y_1) + b(Y + y_1)^2 + 2g(X + x_1) + 2f(Y + y_1) + c = 0$$

$$\Rightarrow \ aX^2 + 2hXY + bY^2 + 2X(ax_1 + hy_1 + g) + 2Y(hx_1 + by_1 + f) + x_1(ax_1 + hy_1 + g) + y_1(hx_1 + by_1 + f) + (gx_1 + fy_1 + c) = 0$$

$$\Rightarrow \ aX^2 + 2hXY + bY^2 + 0 + 0 + 0 + 0 + 0 = 0$$

[from Eqs. (iii), (iv) and (v)]

i.e. $aX^2 + 2hXY + bY^2 = 0$

It is homogeneous equation of second degree. So, it represents a pair of straight lines through the new origin.

Hence, the equation $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ represents a pair of straight lines, if

$$abc + 2fgh - af^2 - bg^2 - ch^2 = 0.$$

Some useful identities If $y = m_1x + c_1, y = m_2x + c_2$ be lines represented by Eq. (i). Then,

$$\begin{aligned} ax^2 + 2hxy + by^2 + 2gx + 2fy + c &= b(y - m_1x - c_1)(y - m_2x - c_2) \\ &= b(y^2 - (m_1 + m_2)xy + m_1m_2x^2 + (m_1c_2 + m_2c_1)x - (c_1 + c_2)y + c_1c_2) \end{aligned}$$

On equating coefficients, we get

$$m_1 + m_2 = -\frac{2h}{b}, m_1m_2 = \frac{a}{b}, m_1c_2 + m_2c_1 = \frac{2g}{b},$$

$$c_1 + c_2 = -\frac{2f}{b}, c_1c_1 = \frac{c}{b}$$

These five relations are very useful to solve many problems.

Important Theorems

Theorem 1 The angle between the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

is given by

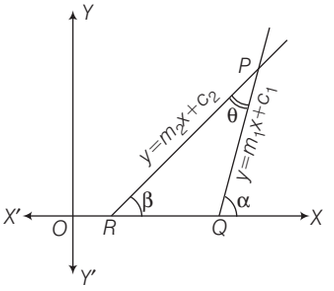
$$\theta = \tan^{-1}\left\{\frac{2\sqrt{(h^2 - ab)}}{|a + b|}\right\}.$$

Proof Let $y = m_1x + c_1$

and $y = m_2x + c_2$

be the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$



where, $m_1 = \tan\alpha, m_2 = \tan\beta$

Then, $ax^2 + 2hxy + by^2 + 2gx + 2fy + c \equiv (y - m_1x - c_1)(y - m_2x - c_2)$

Comparing coefficients of like powers, we obtain

$$m_1 + m_2 = -\frac{2h}{b}, m_1m_2 = \frac{a}{b}$$

Now, if θ be the acute angle between the lines $y = m_1x + c_1$ and $y = m_2x + c_2$, then

$$\tan\theta = \left|\frac{m_1 - m_2}{1 + m_1m_2}\right| = \frac{\sqrt{(m_1 + m_2)^2 - 4m_1m_2}}{|1 + m_1m_2|}$$

$$= \frac{\sqrt{\left(-\frac{2h}{b}\right)^2 - 4\left(\frac{a}{b}\right)}}{\left|1 + \frac{a}{b}\right|} = \frac{2\sqrt{(h^2 - ab)}}{|a + b|}$$

$$\therefore \quad \theta = \tan^{-1}\left\{\frac{2\sqrt{(h^2 - ab)}}{|a + b|}\right\}$$

***Corollary* 1.** The angle between the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

is the same as the angle between the lines represented by

$$ax^2 + 2hxy + by^2 = 0$$

***Corollary* 2.** The lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

are perpendicular iff $a + b = 0$ and parallel iff $h^2 = ab$.

Theorem 2 The lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

will be coincident, if $h^2 - ab = 0, g^2 - ac = 0$

and $f^2 - bc = 0.$

Proof Let the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

be $lx + my + n = 0$ and $l'x + m'y + n' = 0$

then $ax^2 + 2hxy + by^2 + 2gx + 2fy + c$

$$\equiv (lx + my + n)(l'x + m'y + n')$$

Comparing the coefficients of similar terms in both sides, we get

$$\left.\begin{aligned} &ll' = a, mm' = b, nn' = c \\ &lm' + l'm = 2h, \ln' + l'n = 2g \\ &mn' + m'n = 2f \end{aligned}\right\}$$

$\because$ Lines $lx + my + n = 0$ and $l'x + m'y + n' = 0$ are coincident, then $\frac{l}{l'} = \frac{m}{m'} = \frac{n}{n'}$.

Taking the ratios in pairs, then

$$lm' - l'm = 0, mn' - m'n = 0, \ln' - l'n = 0$$

$$\Rightarrow \quad \sqrt{(lm' + l'm)^2 - 4ll'mm'} = 0,$$

$$\sqrt{(mn' + m'n)^2 - 4mm'nn'} = 0$$

and $\sqrt{(ln' + l'n)^2 - 4ll'nn'} = 0$

i.e. $\sqrt{(4h^2 - 4ab)} = 0, \sqrt{(4f^2 - 4bc)} = 0$

and $\sqrt{(4g^2 - 4ac)} = 0$

i.e. $h^2 - ab = 0, f^2 - bc = 0, g^2 - ac = 0$

Theorem 3 The point of intersection of the lines represented by

$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ is

$$\left(\sqrt{\left(\frac{f^2 - bc}{h^2 - ab}\right)}, \sqrt{\left(\frac{g^2 - ca}{h^2 - ab}\right)}\right) \text{or} \left(\frac{bg - hf}{h^2 - ab}, \frac{af - gh}{h^2 - ab}\right).$$

Proof Let the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

be $lx + my + n = 0$ and $l'x + m'y + n' = 0$

then $ax^2 + 2hxy + by^2 + 2gx + 2fy + c$

$$\equiv (lx + my + n)(l'x + m'y + n')$$

Comparing the coefficients of similar terms in both sides

then $ll' = a, mm' = b, nn' = c$

$$lm' + l'm = 2h, \ln' + l'n = 2g, mn' + m'n = 2f$$

$$\Rightarrow \quad (lm' - l'm) = \sqrt{(lm' + l'm)^2 - 4ll'mm'} = 2\sqrt{(h^2 - ab)}$$

$$\Rightarrow \quad (nl' - n'l) = \sqrt{(ln' + l'n)^2 - 4ll'nn'} = 2\sqrt{(g^2 - ac)}$$

and $(mn' - m'n) = \sqrt{(mn' + m'n)^2 - 4mm'nn'}$

$$= 2\sqrt{(f^2 - bc)}$$

Now, solving $lx + my + n = 0$ and $l'x + m'y + n' = 0$

then $\frac{x}{(mn' - m'n)} = \frac{y}{(nl' - n'l)} = \frac{1}{(lm' - l'm)}$

$$\Rightarrow \quad \frac{x}{2\sqrt{(f^2 - bc)}} = \frac{y}{2\sqrt{(g^2 - ac)}} = \frac{1}{2\sqrt{(h^2 - ab)}}$$

$$\therefore \quad (x, y) = \left(\sqrt{\left(\frac{f^2 - bc}{h^2 - ab}\right)}, \sqrt{\left(\frac{g^2 - ac}{h^2 - ab}\right)}\right)$$

Also, $x = \sqrt{\left(\frac{f^2 - bc}{h^2 - ab}\right)} = \frac{\sqrt{(f^2 - bc)(h^2 - ab)}}{(h^2 - ab)}$

$$= \frac{\sqrt{f^2h^2 - abf^2 - bch^2 + b(abc)}}{(h^2 - ab)}$$

$$= \frac{\sqrt{f^2h^2 - abf^2 - bch^2 + b(af^2 + bg^2 + ch^2 - 2fgh)}}{(h^2 - ab)}$$

$$[\because abc + 2fgh - af^2 - bg^2 - ch^2 = 0]$$

$$= \frac{\sqrt{(f^2h^2 + b^2g^2 - 2bfgh)}}{(h^2 - ab)} = \frac{\sqrt{(bg - hf)^2}}{(h^2 - ab)}$$

$$= \left(\frac{bg - hf}{h^2 - ab}\right)$$

Similarly, $y = \left(\frac{af - gh}{h^2 - ab}\right)$

Hence, $(x, y) = \left(\frac{bg - hf}{h^2 - ab}, \frac{af - gh}{h^2 - ab}\right).$

Remembering Method (For second point)

Since, $\Delta = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix}$

taking first two rows (repeat first column)

$$\begin{matrix} a & h & g & a \\ h & b & f & h \end{matrix}$$

$\Rightarrow \quad ab - h^2, hf - bg, gh - af$

$\Rightarrow \quad h^2 - ab, bg - hf, af - gh$

$\Rightarrow \quad 1, \dfrac{bg - hf}{h^2 - ab}, \dfrac{af - gh}{h^2 - ab}$

Hence, point of intersection is $\left(\dfrac{bg - hf}{h^2 - ab}, \dfrac{af - gh}{h^2 - ab}\right)$.

OR

Cofactors of third column are C_{13}, C_{23}, C_{33}

$\because \quad C_{13} = \begin{vmatrix} h & b \\ g & f \end{vmatrix} = hf - bg$

$C_{23} = -\begin{vmatrix} a & h \\ g & f \end{vmatrix} = hg - af$

and $\quad C_{33} = \begin{vmatrix} a & h \\ h & b \end{vmatrix} = ab - h^2$

Point of intersection is $\left(\dfrac{C_{13}}{C_{33}}, \dfrac{C_{23}}{C_{33}}\right)$ i.e.

$$\left(\frac{hf - bg}{ab - h^2}, \frac{hg - af}{ab - h^2}\right) \quad \text{or} \quad \left(\frac{bg - hf}{h^2 - ab}, \frac{af - hg}{h^2 - ab}\right).$$

Remembering Mehod (For first point)

Cofactors of leading diagonal are

C_{11}, C_{22}, C_{33}

$\because \quad C_{11} = \begin{vmatrix} b & f \\ f & c \end{vmatrix} = bc - f^2,$

$C_{22} = \begin{vmatrix} a & g \\ g & c \end{vmatrix} = ac - g^2$

and $\quad C_{33} = \begin{vmatrix} a & h \\ h & b \end{vmatrix} = ab - h^2$

$\therefore$ Point of intersection are $\left(\sqrt{\dfrac{C_{11}}{C_{33}}}, \sqrt{\dfrac{C_{22}}{C_{33}}}\right)$

i.e. $\quad \left(\sqrt{\left(\dfrac{bc - f^2}{ab - h^2}\right)}, \sqrt{\left(\dfrac{ac - g^2}{ab - h^2}\right)}\right)$

or $\quad \left(\sqrt{\left(\dfrac{f^2 - bc}{h^2 - ab}\right)}, \sqrt{\left(\dfrac{g^2 - ac}{h^2 - ab}\right)}\right)$

Theorem 4 The pair of bisectors of the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0,$$

is $\quad \dfrac{(x - \alpha)^2 - (x - \beta)^2}{(a - b)} = \dfrac{(x - \alpha)(y - \beta)}{h}$

where (α, β) be the point of intersection of the pair of straight lines represented by Eq. (i).

Proof Since (α, β) be the point of intersection of the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \qquad \ldots(i)$$

Shifting the origin at (α, β) without rotating the coordinate axes, the Eq. (i) reduces to

$$a(X + \alpha)^2 + 2h(X + \alpha)(Y + \beta) + b(Y + \beta)^2 + 2g(X + \alpha) + 2f(Y + \beta) + c = 0$$

$[\because x = X + \alpha \text{ and } y = Y + \beta]$

$$\Rightarrow \quad (aX^2 + 2hXY + bY^2) + 2X(a\alpha + h\beta + g) + 2Y(h\alpha + b\beta + f) + a\alpha^2 + 2h\alpha\beta + b\beta^2 + 2g\alpha + 2f\beta + c = 0 \ldots(ii)$$

This equation represents a pair of straight lines passing through the new origin. So, it must be homogeneous equation of second degree in X and Y.

$\therefore \quad a\alpha + h\beta + g = 0 \qquad \ldots(iii)$

$h\alpha + b\beta + f = 0 \qquad \ldots(iv)$

and $a\alpha^2 + 2h\alpha\beta + b\beta^2 + 2g\alpha + 2f\beta + c = 0 \qquad \ldots(v)$

Now, from Eq. (ii), $\quad aX^2 + 2hXY + bY^2 = 0 \qquad \ldots(vi)$

The equation of the bisectors of the angles between the lines given by Eq. (vi) is

$$\frac{X^2 - Y^2}{a - b} = \frac{XY}{h} \qquad \ldots(vii)$$

[with reference to new origin]

Replacing X by $x - \alpha$ and Y by $y - \beta$ in Eq. (vii), then

$$\frac{(x - \alpha)^2 - (y - \beta)^2}{(a - b)} = \frac{(x - \alpha)(y - \beta)}{h}$$

[with reference to old origin]

which is the required equation of the bisectors of the angles between the lines given by Eq. (i).

Remark

If $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

represents two straight lines, then the equation of lines through the origin and parallel to them is $ax^2 + 2hxy + by^2 = 0$.

Example 20 For what value of λ does the equation $12x^2 - 10xy + 2y^2 + 11x - 5y + \lambda = 0$ represent a pair of straight lines? Find their equations and the angle between them.

Sol. Comparing the given equation with the equation

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0,$$

we get $a = 12, h = -5, b = 2, g = \frac{11}{2}, f = -\frac{5}{2}$ and $c = \lambda$

If the given equation represents a pair of straight lines, then

$$abc + 2fgh - af^2 - bg^2 - ch^2 = 0$$

$$\Rightarrow \quad 12 \times 2 \times \lambda + 2 \times \left(-\frac{5}{2}\right) \times \frac{11}{2} \times (-5) - 12 \times \frac{25}{4} - 2 \times \frac{121}{4} - \lambda \times 25 = 0$$

$\therefore \quad \lambda = 2$, also $h^2 - ab = 25 - 24 = 1 > 0$

$\therefore$ The given equation will represent a pair of straight lines, if $\lambda = 2$.

To find the two lines

First method

Substituting $\lambda = 2$ in the given equation, we get

$$12x^2 - 10xy + 2y^2 + 11x - 5y + 2 = 0 \qquad ...(i)$$

Since, $12x^2 - 10xy + 2y^2 = 2(3x - y)(2x - y)$

factors of Eq. (i) can be taken as

$2(3x - y + l)(2x - y + m)$

$$= 12x^2 - 10xy + 2y^2 + 2(2l + 3m)x + 2(-l - m)y + 2lm$$

On comparing, $2l + 3m = \frac{11}{2}, l + m = \frac{5}{2}, lm = 1$

Solving, we get $l = 2, m = \frac{1}{2}$.

Thus, the factors of Eq. (i) are

$$2(3x - y + 2)\left(2x - y + \frac{1}{2}\right) = 0$$

or $(3x - y + 2)(4x - 2y + 1) = 0.$

$\therefore$ The two straight lines represented by the given equation are

$$3x - y + 2 = 0 \quad \text{and} \quad 4x - 2y + 1 = 0.$$

Second Method

Writing Eq. (i) as quadratic equation in x, we get

$$12x^2 + (-10y + 11)x + 2y^2 - 5y + 2 = 0$$

$\therefore$

$$x = \frac{-(-10y + 11) \pm \sqrt{(-10y + 11)^2 - 48(2y^2 - 5y + 2)}}{24}$$

i.e. $$24x = (10y - 11) \pm \sqrt{(4y^2 + 20y + 25)}$$

$$= (10y - 11) \pm (2y + 5)$$

$\therefore \quad 24x = 12y - 6$, i.e. $4x - 2y + 1 = 0$

and $24x = 8y - 16$, i.e. $3x - y + 2 = 0$

are the required lines.

To find the angle between the lines

If θ be the angle between the lines, then

$$\tan\theta = \frac{2\sqrt{h^2 - ab}}{|a + b|} = \frac{2\sqrt{25 - 24}}{|12 + 2|} = \frac{1}{7}$$

$\therefore \quad \theta = \tan^{-1}\left(\frac{1}{7}\right).$

Example 21 ***Prove that the equation $8x^2 + 8xy + 2y^2 + 26x + 13y + 15 = 0$ represents a pair of parallel straight lines. Also, find the perpendicular distance between them.***

Sol. Given equation is

$$8x^2 + 8xy + 2y^2 + 26x + 13y + 15 = 0 \qquad ...(i)$$

Writing Eq. (i) as quadratic equation in x, we get

$$8x^2 + 2x(4y + 13) + 2y^2 + 13y + 15 = 0$$

$$\therefore \quad x = \frac{-2(4y + 13) \pm \sqrt{4(4y + 13)^2 - 32(2y^2 + 13y + 15)}}{16}$$

$$\Rightarrow \quad x = \frac{-(4y + 13) \pm \sqrt{(4y + 13)^2 - 8(2y^2 + 13y + 15)}}{8}$$

$$\Rightarrow \quad x = \frac{-(4y + 13) \pm 7}{8}$$

$\Rightarrow \quad 8x = -4y - 13 + 7$, i.e. $4x + 2y + 3 = 0$

and $8x = -4y - 13 - 7$, i.e. $2x + y + 5 = 0$

i.e. the given Eq. (i) represents two straight lines

$$2x + y + 5 = 0$$

and $$4x + 2y + 3 = 0$$

i.e. $$2x + y + \frac{3}{2} = 0$$

both lines are parallel.

$\therefore$ Distance between them $= \frac{\left|5 - \frac{3}{2}\right|}{\sqrt{2^2 + 1^2}} = \frac{7}{2\sqrt{5}}$

Aliter : Here, $\Delta = 8 \times 2 \times 15 + 2 \times \frac{13}{2} \times 13 \times 4 - 8 \times \left(\frac{13}{2}\right)^2 - 2 \times (13)^2 - 15 \times (4)^2 = 0$

and $h^2 = (4)^2 = 16 = 8 \times 2 = ab$

$\therefore$ Given equation

$$8x^2 + 8xy + 2y^2 + 26x + 13y + 15 = 0 \qquad ...(i)$$

represents two parallel straight lines.

Since, $8x^2 + 8xy + 2y^2 = 2(2x + y)^2$

factors of Eq. (i) can be taken as

$$2(2x + y + l)(2x + y + m)$$

$$= 8x^2 + 8xy + 2y^2 + 2(2m + 2l)x + 2(m + l)y + 2lm$$

On comparing, we get $l+m=\frac{13}{2}$ and $lm=\frac{15}{2}$

$\therefore$ Distance between them

$$=\frac{|l-m|}{\sqrt{(2^2+1^2)}}=\frac{\sqrt{(l+m)^2-4lm}}{\sqrt{5}}$$

$$=\frac{\sqrt{\frac{169}{4}-\frac{60}{2}}}{\sqrt{5}}=\frac{7}{2\sqrt{5}}$$

Remark

For comparing coefficients write equation in form

$$\begin{matrix}2x & + & y & + & l\\ 2x & + & y & + & m\end{matrix}$$

coefficient *of* x is $2m+2l$, cofficient of y is $l+m$ and coefficients of constant term is lm.

i.e. $l+m=\frac{13}{2}, lm=\frac{15}{2}$

Example 22 ***Find the combined equation of the straight lines passing through the point (1, 1) and parallel to the lines represented by the equation*** $x^2-5xy+4y^2+x+2y-2=0$.

Sol. Given equation of lines is

$$x^2-5xy+4y^2+x+2y-2=0. \quad ...(i)$$

Since, $x^2-5xy+4y^2=(x-4y)(x-y)$

Factors of Eq. (i) taken as $(x-4y+l)(x-y+m)$.

Now, equation of line through (1, 1) and parallel to

$$x-4y+l=0 \text{ is } x-4y+\lambda=0$$

i.e. $1-4+\lambda=0$

$\therefore$ $\lambda=3$

then line is $x-4y+3=0$ ...(ii)

and equation of line through (1, 1) and parallel to

$$x-y+m=0 \text{ is } x-y+\mu=0$$

i.e. $1-1+\mu=0$

$\therefore$ $\mu=0$

then line is $x-y=0$ ...(iii)

Hence, equation of lines Eqs. (ii) and (iii) is

$$(x-4y+3)(x-y)=0$$

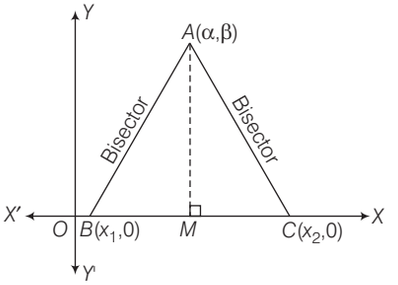
i.e. $x^2-5xy+4y^2+3x-3y=0$

Example 23 ***If*** $ax^2+2hxy+by^2+2gx+2fy+c=0$ ***represents a pair of lines, prove that the area of the triangle formed by their bisectors and axis of x is*** $\frac{\sqrt{(a-b)^2+4h^2}}{|2h|}\cdot\left|\frac{ca-g^2}{ab-h^2}\right|$.

Sol. Given $ax^2+2hxy+by^2+2gx+2fy+c=0$ ...(i)

The point of intersection of the lines given by Eq. (i) are

$$\alpha=\sqrt{\left(\frac{f^2-bc}{h^2-ab}\right)}, \beta=\sqrt{\left(\frac{g^2-ca}{h^2-ab}\right)}$$



Hence, equation of the bisectors of the lines given by Eq. (i) is

$$\frac{(x-\alpha)^2-(y-\beta)^2}{a-b}=\frac{(x-\alpha)(y-\beta)}{h}$$

For X-axis, $y=0$.

$\therefore$ $$\frac{(x-\alpha)^2-\beta^2}{a-b}=\frac{-\beta(x-\alpha)}{h}$$

or $h(x-\alpha)^2+\beta(x-\alpha)(a-b)-h\beta^2=0$ ...(ii)

Eq. (ii) is a quadratic in $(x-\alpha)$ and let two values of x be x_1 and x_2, so that its roots are

$$x_1-\alpha \text{ and } x_2-\alpha$$

$\therefore$ $(x_1-\alpha)+(x_2-\alpha)=$ Sum of roots $=\frac{-\beta(a-b)}{h}$

$(x_1-\alpha)(x_2-\alpha)=$ Products of roots $=-\beta^2$

$\therefore$ $|x_2-x_1|=|(x_2-\alpha)-(x_1-\alpha)|$

$$=\sqrt{[(x_2-\alpha)+(x_1-\alpha)]^2-4(x_2-\alpha)(x_1-\alpha)}$$

$\therefore$ $$|x_2-x_1|=\sqrt{\left\{\frac{\beta^2(a-b)^2}{h^2}+4\beta^2\right\}}$$

$$=\left|\frac{\beta}{h}\right|\sqrt{(a-b)^2+4h^2}$$

$\therefore$ Area of $\Delta ABC=\frac{1}{2}|BC||AM|$

$$=\frac{1}{2}|x_2-x_1||\beta|$$

$$=\frac{1}{2}\left|\frac{\beta}{h}\right|\sqrt{(a-b)^2+4h^2}\times|\beta|$$

$$=\frac{\sqrt{(a-b)^2+4h^2}}{|2h|}\cdot\beta^2$$

$$=\frac{\sqrt{(a-b)^2+4h^2}}{|2h|}\cdot\frac{ca-g^2}{ab-h^2}$$

Exercise for Session 4

1. If $\lambda x^2 + 10xy + 3y^2 - 15x - 21y + 18 = 0$ represents a pair of straight lines. Then, the value of λ is

(a) – 3 (b) 3 (c) 4 (d) – 4

2. The point of intersection of the straight lines given by the equation $3y^2 - 8xy - 3x^2 - 29x + 3y - 18 = 0$ is

(a) $\left(1, \frac{1}{2}\right)$ (b) $\left(1, -\frac{1}{2}\right)$ (c) $\left(-\frac{3}{2}, \frac{5}{2}\right)$ (d) $\left(-\frac{3}{2}, -\frac{5}{2}\right)$

3. If the equation $12x^2 + 7xy - py^2 - 18x + qy + 6 = 0$ represents two perpendicular lines, then the value of p and q are

(a) 12, 1 (b) 12, – 1 (c) 12, $\frac{23}{2}$ (d) 12, $-\frac{23}{2}$

4. If the angle between the two lines represented by $2x^2 + 5xy + 3y^2 + 7y + 4 = 0$ is $\tan^{-1}(m)$, then m is equal to

(a) $-\frac{1}{5}$ (b) $\frac{1}{5}$ (c) $-\frac{3}{5}$ (d) $\frac{3}{5}$

5. The equation of second degree $x^2 + 2\sqrt{2}xy + 2y^2 + 4x + 4\sqrt{2}\,y + 1 = 0$ represents a pair of straight lines, the distance between them is

(a) 2 (b) $2\sqrt{3}$ (c) 4 (d) $4\sqrt{3}$

6. Find the area of the parallelogram formed by the lines
$2x^2 + 5xy + 3y^2 = 0$ and $2x^2 + 5xy + 3y^2 + 3x + 4y + 1 = 0$.

7. Find the locus of the incentre of the triangle formed by
$xy - 4x - 4y + 16 = 0$ and $x + y = a$ ($a > 4, a \neq 4\sqrt{2}$ and a is the parameter).

8. If the equation $2hxy + 2gx + 2fy + c = 0$ represents two straight lines, then show that they form a rectangle of area $\frac{|fg|}{h^2}$ with the coordinate axes.

9. Find the area of the triangle formed by the lines represented by $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ and axis of x.

10. Find the equations of the straight lines passing through the point (1, 1) and parallel to the lines represented by the equation $x^2 - 5xy + 4y^2 + x + 2y - 2 = 0$.

Session 5

To Find the Point of Intersection of Lines Represented by $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ with the Help of Partial Differentiation, Removal of First Degree Terms, Equation of the Lines Joining the Origin to the Points of Intersection of a Given Line and a Given Curve

To Find the Point of Intersection of Lines Represented by $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

Let $\phi(x, y) \equiv ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

$\therefore \quad \dfrac{\partial \phi}{\partial x} = 2ax + 2hy + 2g$ [treating y as constant]

and $\quad \dfrac{\partial \phi}{\partial y} = 2hx + 2by + 2f$ [treating x as constant]

For point of intersection $\dfrac{\partial \phi}{\partial x} = 0$ and $\dfrac{\partial \phi}{\partial y} = 0$,

we obtain $\quad ax + hy + g = 0$ and $hx + by + f = 0$

Solving them $\quad \dfrac{x}{fh - bg} = \dfrac{y}{gh - af} = \dfrac{1}{ab - h^2}$

$$(x, y) = \left(\frac{bg - fh}{h^2 - ab}, \frac{af - gh}{h^2 - ab} \right)$$

Working rule In practice, therefore, the general equation of second degree $\phi = 0$, represents a pair of straight lines, we solve its partial derivatives $\dfrac{\partial \phi}{\partial x} = 0, \dfrac{\partial \phi}{\partial y} = 0$ for their intersecting point $(x, y) = (\alpha, \beta)$.

Remembering Method (without use of partial derivatives)

Since, $\quad \Delta = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix}$

from first two rows

$a \quad h \quad g \quad \Rightarrow \quad ax + hy + g = 0$

and $\quad h \quad b \quad f \quad \Rightarrow \quad hx + by + f = 0$ and then solve.

Example 24 Find the point of intersection of lines represented by $2x^2 - 7xy - 4y^2 - x + 22y - 10 = 0$.

Sol. Let $\quad \phi \equiv 2x^2 - 7xy - 4y^2 - x + 22y - 10 = 0$

$\therefore \quad \dfrac{\partial \phi}{\partial x} \equiv 4x - 7y - 1 = 0$

and $\quad \dfrac{\partial \phi}{\partial y} \equiv -7x - 8y + 22 = 0$

then, the point of intersection is $(x, y) = (2, 1)$.

Removal of First Degree Terms

Let point of intersection of lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \qquad \ldots(i)$$

is (α, β).

Here, $(\alpha, \beta) = \left(\dfrac{bg - fh}{h^2 - ab}, \dfrac{af - gh}{h^2 - ab} \right)$

For removal of first degree terms, shift the origin to (α, β).

i.e. Replacing x by $(X + \alpha)$ and y be $(Y + \beta)$ in Eq. (i).

Aliter : Direct equation after removal of first degree terms is

$aX^2 + 2hXY + bY^2 + (g\alpha + f\beta + c) = 0$

where, $\quad \alpha = \dfrac{bg - fh}{h^2 - ab}$

and $\quad \beta = \dfrac{af - gh}{h^2 - ab}$.

Example 25 Find the new equation of curve $12x^2 + 7xy - 12y^2 - 17x - 31y - 7 = 0$ after removing the first degree terms.

Sol. Let $\phi \equiv 12x^2 + 7xy - 12y^2 - 17x - 31y - 7 = 0$ ...(i)

$$\therefore \quad \frac{\partial \phi}{\partial x} = 24x + 7y - 17 = 0$$

and $$\frac{\partial \phi}{\partial y} \equiv 7x - 24y - 31 = 0$$

Their point of intersection is $(x, y) \equiv (1, -1)$

Here, $\alpha = 1, \beta = -1$

Shift the origin to $(1, -1)$ then replacing $x = X + 1$ and $y = Y - 1$ in Eq. (i) the required equation is

$$12(X+1)^2 + 7(X+1)(Y-1) - 12(Y-1)^2 - 17(X+1) - 31(Y-1) - 7 = 0$$

i.e. $12X^2 + 7XY - 12Y^2 = 0$

Aliter :

Here, $\alpha = 1$ and $\beta = -1$

and $$g = -\frac{17}{2}, f = -\frac{31}{2}, c = -7$$

$$\therefore \quad g\alpha + f\beta + c = -\frac{17}{2} \times 1 - \frac{31}{2} \times -1 - 7 = 0$$

$\therefore$ Removed equation is

$$aX^2 + 2hXY + by^2 + (g\alpha + f\beta + c) = 0$$

$$12X^2 + 7XY - 12Y^2 + 0 = 0$$

$$12X^2 + 7XY - 12Y^2 = 0.$$

Example 26 Transform the equation $x^2 + 4xy + y^2 - 2x + 2y + 4 = 0$ into the form $\frac{Y'^2}{b^2} - \frac{X'^2}{a^2} = 1$.

Sol. To remove the first degree terms, we shift the origin to the point (α, β).

Then, $$\alpha = \frac{bg - fh}{h^2 - ab} = \frac{1 \times (-1) - 1 \times 2}{4 - 1 \times 1} = -1$$

and $$\beta = \frac{af - gh}{h^2 - ab} = \frac{1 \times 1 - (-1) \times (2)}{4 - 1 \times 1} = 1$$

then, the transformed equation is

$$X^2 + 4XY + Y^2 + (g\alpha + f\beta + c) = 0$$

$$\Rightarrow X^2 + 4XY + Y^2 + (-1 \times (-1) + 1 \times 1 + 4) = 0$$

$$\therefore \quad X^2 + 4XY + Y^2 + 6 = 0 \qquad ...(i)$$

Now, to remove the XY term from Eq. (i), we rotate the axes through an angle θ given by

$$\cot 2\theta = \frac{a - b}{2h} = 0 \qquad [\because \text{here } a = b]$$

$$\Rightarrow \quad \cot 2\theta = 0$$

$$\Rightarrow \quad 2\theta = \frac{\pi}{2} \text{ or } \frac{3\pi}{2}$$

$$\Rightarrow \quad \theta = \frac{\pi}{4} \text{ or } \frac{3\pi}{4}$$

Taking $\theta = \frac{\pi}{4}$ $\left[\text{we can also take } \theta = \frac{3\pi}{4}\right]$

$$\Rightarrow \quad \cos\theta = \frac{1}{\sqrt{2}}, \sin\theta = \frac{1}{\sqrt{2}}$$

Now, if (X', Y') be the coordinates of the point when the axes are rotated through $\theta = \frac{\pi}{4}$, we have

$$X = \frac{X' - Y'}{\sqrt{2}}, \; Y = \frac{X' + Y'}{\sqrt{2}}$$

then Eq. (i) becomes

$$\frac{Y'^2}{6} - \frac{X'^2}{2} = 1 \Rightarrow \frac{Y'^2}{b^2} - \frac{X'^2}{a^2} = 1$$

where, $a^2 = 2$ and $b^2 = 6$.

Equation of the Lines Joining the Origin to the Points of Intersection of a Given Line and a Given Curve

Theorem The combined equation of the straight lines joining the origin to the points of intersection of a second degree curve

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

and a straight line $lx + my + n = 0$ is :

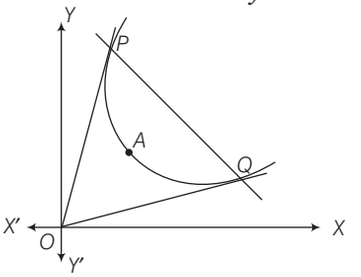
$$ax^2 + 2hxy + by^2 + 2gx\left(\frac{lx + my}{-n}\right) + 2fy\left(\frac{lx + my}{-n}\right) + c\left(\frac{lx + my}{-n}\right)^2 = 0$$

Proof The equation of the curve (PAQ) is

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \qquad ...(i)$$

and the equation of the line PQ be

$$lx + my + n = 0 \qquad ...(ii)$$



From the equation of the line Eq. (ii), find the value of '1' in terms of x and y,

i.e. $$\frac{lx + my}{-n} = 1 \qquad ...(iii)$$

Now, the Eq. (i) can be written as

or $ax^2 + 2hxy + by^2 + (2gx + 2fy)(1) + c(1)^2 = 0$

or $ax^2 + 2hxy + by^2 + (2gx + 2fy)\left(\frac{lx + my}{-n}\right) + c\left(\frac{lx + my}{-n}\right)^2 = 0$ ...(iv)

[replacing 1 by $\frac{lx + my}{-n}$ from Eq. (iii)]

Hence, the Eq. (iv) is homogeneous equation of second degree. Above Eq. (iv) on simplification will be of the form $Ax^2 + 2Hxy + By^2 = 0$ and will represent the required straight lines. If θ be the angle between them, then

$$\theta = \tan^{-1}\left(\frac{2\sqrt{(H^2 - AB)}}{|A + B|}\right)$$

Hence, the equation of pairs of straight lines passing through the origin and the points of intersection of a curve and a line is obtained by making the curve homogeneous with the help of the line.

Example 27 Prove that the angle between the lines joining the origin to the points of intersection of the straight line $y = 3x + 2$ with the curve $x^2 + 2xy + 3y^2 + 4x + 8y - 11 = 0$ is $\tan^{-1}\left(\frac{2\sqrt{2}}{3}\right)$.

Sol. Equation of curve is $x^2 + 2xy + 3y^2 + 4x + 8y - 11 = 0$ ...(i)

and line $y = 3x + 2 \Rightarrow \frac{y - 3x}{2} = 1$ ...(ii)

Making Eq. (i) homogeneous with the help of Eq. (ii), then

$$x^2 + 2xy + 3y^2 + 4x\left(\frac{y - 3x}{2}\right) + 8y\left(\frac{y - 3x}{2}\right) - 11\left(\frac{y - 3x}{2}\right)^2 = 0$$

$$\Rightarrow \quad x^2 + 2xy + 3y^2 + 2xy - 6x^2 + 4y^2 - 12xy - \frac{11}{4}(y - 3x)^2 = 0$$

$$\Rightarrow \quad -5x^2 - 8xy + 7y^2 - \frac{11}{4}(y^2 - 6xy + 9x^2) = 0$$

$$\Rightarrow \quad -20x^2 - 32xy + 28y^2 - 11y^2 + 66xy - 99x^2 = 0$$

$$\Rightarrow \quad 119x^2 - 34xy - 17y^2 = 0$$

$$\Rightarrow \quad 7x^2 - 2xy - y^2 = 0 \qquad ...(iii)$$

This is the equation of lines joining the origin to the points of intersection of Eqs. (i) and (ii).

Comparing Eq. (iii) with $ax^2 + 2hxy + by^2 = 0$

$$a = 7, h = -1, b = -1$$

If θ is the acute angle between pair of lines of Eq. (iii), then

$$\tan\theta = \frac{2\sqrt{h^2 - ab}}{|a + b|} = \frac{2\sqrt{(1 + 7)}}{|7 - 1|} = \frac{2\sqrt{8}}{6} = \frac{4\sqrt{2}}{6} = \frac{2\sqrt{2}}{3}$$

$$\therefore \quad \theta = \tan^{-1}\left(\frac{2\sqrt{2}}{3}\right)$$

Example 28 Find the condition that the pair of straight lines joining the origin to the intersections of the line $y = mx + c$ and the circle $x^2 + y^2 = a^2$ may be at right angles.

Sol. The equations of the line and the circle are

$$y = mx + c \qquad ...(i)$$

and $x^2 + y^2 = a^2$ ...(ii)

The pair of straight lines joining the origin to the intersections of Eqs. (i) and (ii), is obtained by making homogeneous Eq. (ii) with the help of Eq. (i).

$$\because \quad y = mx + c \Rightarrow \frac{y - mx}{c} = 1$$

$$\therefore \quad x^2 + y^2 = a^2(1)^2 \Rightarrow x^2 + y^2 = a^2\left(\frac{y - mx}{c}\right)^2$$

$$\Rightarrow x^2(c^2 - a^2m^2) + 2ma^2xy + y^2(c^2 - a^2) = 0 \qquad ...(iii)$$

The lines given by Eq. (iii), are at right angles, then coefficient of x^2 + coefficient of $y^2 = 0$

$$\Rightarrow \quad c^2 - a^2m^2 + c^2 - a^2 = 0$$

$$\therefore \quad 2c^2 = a^2(1 + m^2)$$

which is the required condition.

Example 29 Prove that the pair of lines joining the origin to the intersection of the curve $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ by the line $lx + my + n = 0$ are coincident, if a $a^2l^2 + b^2m^2 = n^2$.

Sol. The given curve is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ ...(i)

and line $lx + my + n = 0$

$$\Rightarrow \quad lx + my = -n$$

$$\Rightarrow \quad \frac{lx + my}{-n} = 1 \qquad ...(ii)$$

Making Eq. (i) homogeneous with the help of Eq. (ii), then

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = \left(\frac{lx + my}{-n}\right)^2$$

$$\Rightarrow \quad \frac{n^2x^2}{a^2} + \frac{n^2y^2}{b^2} = l^2x^2 + m^2y^2 + 2lmxy$$

$$\Rightarrow \quad \left(\frac{n^2}{a^2} - l^2\right)x^2 - 2lmxy + \left(\frac{n^2}{b^2} - m^2\right)y^2 = 0 \qquad ...(iii)$$

This is of the form $Ax^2 + 2Hxy + By^2 = 0$,

then $$A = \frac{n^2}{a^2} - l^2,\ H = -lm$$

and $$B = \frac{n^2}{b^2} - m^2$$

The lines given by Eq. (iii) will be coincident, if

$$H^2 - AB = 0 \Rightarrow H^2 = AB$$

$$\Rightarrow \quad l^2m^2 = \left(\frac{n^2}{a^2} - l^2\right)\left(\frac{n^2}{b^2} - m^2\right)$$

$$\Rightarrow \quad l^2m^2 = \frac{n^4}{a^2b^2} - \frac{n^2m^2}{a^2} - \frac{l^2n^2}{b^2} + l^2m^2$$

$$\Rightarrow \quad \frac{n^4}{a^2b^2} = \frac{n^2m^2}{a^2} + \frac{n^2l^2}{b^2}$$

$$\Rightarrow \quad n^2 = b^2m^2 + a^2l^2$$

$$\Rightarrow \quad a^2l^2 + b^2m^2 = n^2$$

Example 30 Show that the straight lines joining the origin to the points of intersection of curves

$$ax^2 + 2hxy + by^2 + 2gx = 0$$

and $$a'x^2 + 2h'xy + b'y^2 + 2g'x = 0$$

are at right angles, if $g'(a+b) = g(a'+b')$.

Sol. The two curves meet in two points and the required lines joining the origin to these points will be obtained by making one equation homogeneous with the help of the other.

$$ax^2 + 2hxy + by^2 + 2gx = 0 \quad \text{...(i)}$$

$$a'x^2 + 2h'xy + b'y^2 + 2g'x = 0 \quad \text{...(ii)}$$

Multiplying Eq. (i) by g' and Eq. (ii) by g and subtracting, we get $(ag' - a'g)x^2 + (2hg' - 2h'g)xy + (bg' - b'g)y^2 = 0$

If the lines are at right angles, then coefficient of x^2 + coefficient of $y^2 = 0$

$\Rightarrow \quad ag' - a'g + bg' - b'g = 0$

$\therefore \quad (a + b)g' = (a' + b')g.$

Exercise for Session 5

1. If the straight lines joining origin to the points of intersection of the line $x + y = 1$ with the curve $x^2 + y^2 + x - 2y - m = 0$ are perpendicular to each other, then the value of m should be

(a) $-\frac{1}{2}$ (b) 0 (c) $\frac{1}{2}$ (d) 1

2. The pair of straight lines joining the origin to the common points of $x^2 + y^2 = 4$ and $y = 3x + c$ are perpendicular, if c^2 is equal to

(a) –1 (b) 6 (c) 13 (d) 20

3. Mixed term xy is to be removed from the general equation of second degree $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$, one should rotate the axes through an angle θ, then $\tan 2\theta$ is equal to

(a) $\frac{(a - b)}{2h}$ (b) $\frac{2h}{(a + b)}$ (c) $\frac{(a + b)}{2h}$ (d) $\frac{2h}{(a - b)}$

4. The lines joining the origin to the points of intersection of $2x^2 + 3xy - 4x + 1 = 0$ and $3x + y = 1$ are given by

(a) $x^2 - y^2 - 5xy = 0$ (b) $x^2 - y^2 + 5xy = 0$ (c) $x^2 + y^2 - 5xy = 0$ (d) $x^2 + y^2 + 5xy = 0$

5. The equation of the line joining the origin to the point of intersection of the lines $2x^2 + xy - y^2 + 5x - y + 2 = 0$ is

(a) $x + y = 0$ (b) $x - y = 0$ (c) $x - 2y = 0$ (d) $2x + y = 0$

6. Find the equation of the lines joining the origin to the points of intersection of $3x - 2y = 1$ with $3x^2 + 5xy - 3y^2 + 2x + 3y = 0$ and show that they are at right angles.

7. If the straight line joining the origin and the points of intersection of $y = mx + 1$ and $x^2 + y^2 = 1$ be perpendicular to each other, then find the value of m.

8. Prove that the straight lines joining the origin to the points of intersection of the straight line $kx + hy = 2hk$ with the curve $(x - h)^2 + (y - k)^2 = c^2$ are at right angles, if $h^2 + k^2 = c^2$.

9. Show that for all values of λ, the lines joining the origin to the points common to $x^2 + 2hxy - y^2 + gx + fy = 0$ and $fx - gy = \lambda$ are at right angles.

10. Find the equations of the straight lines joining the origin to the points of intersection of $x^2 + y^2 - 4x - 2y = 0$ and $x^2 + y^2 - 2x - 4y = 4$.

Shortcuts and Important Results to Remember

1 If slope of one of the lines represented by $ax^2 + 2hxy + by^2 = 0$ should be n times the slope of the other, then $4nh^2 = ab(1+n)^2$.

2 If the slope of one of the lines represented by $ax^2 + 2hxy + by^2 = 0$ be the nth power of the other, then $(ab^n)^{1/n+1} + (a^n b)^{1/n+1} + 2h = 0$

3 If two of the three lines represented by $ax^3 + bx^2y + cxy^2 + dy^3 = 0$ may be at right angles, then $a^2 + ac + bd + d^2 = 0$

4 If pairs of straight lines $x^2 + 2m_1xy - y^2 = 0$ and $x^2 + 2m_2xy - y^2 = 0$ be such that each pair bisects the angle between the other pair, then $m_1m_2 = -1$

5 If the equation $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ represents a pair of parallel lines, then

(i) $h^2 = ab$, $bg^2 = af^2$.

(ii) the distance between them $= 2\sqrt{\dfrac{(g^2 - ac)}{a(a+b)}}$.

6 If $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ and $ax^2 + 2hxy + by^2 - 2gx - 2fy + c = 0$ each represent a pair of lines, then the area of the parallelogram enclosed by them is $\dfrac{2|c|}{\sqrt{(h^2 - ab)}}$.

JEE Type Solved Examples :
Single Option Correct Type Questions

■ This section contains **6 multiple choice examples**. Each example has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

● **Ex. 1** *If the pairs of lines* $x^2 + 2xy + \lambda y^2 = 0$ *and* $\lambda x^2 + 2xy + y^2 = 0$ *have exactly one line in common, then the joint equation of the other two lines is given by*

(a) $3x^2 + 8xy - 3y^2 = 0$ (b) $3x^2 + 10xy + 3y^2 = 0$

(c) $x^2 + 2xy - 3y^2 = 0$ (d) $3x^2 + 2xy - y^2 = 0$

Sol. (b) Let $y = mx$, be a line common to the given pairs of lines, then

$$\lambda m^2 + 2m + 1 = 0 \text{ and } m^2 + 2m + \lambda = 0$$

$$\Rightarrow \quad \frac{m^2}{2(\lambda - 1)} = \frac{m}{(1 - \lambda^2)} = \frac{1}{2(\lambda - 1)}$$

$$\Rightarrow \quad m^2 = 1 \text{ and } m = -\frac{1}{2}(\lambda + 1)$$

$$\Rightarrow \quad (\lambda + 1)^2 = 4 \Rightarrow \lambda + 1 = 2, -2$$

$$\therefore \quad \lambda = 1 \text{ or } -3$$

But for $\lambda = 1$, the two pairs have both the lines common.

So, $\lambda = -3$ and the slope m of the line common to both the pairs is 1. Now,

$$x^2 + 2xy + \lambda y^2 = x^2 + 2xy - 3y^2 = (x - y)(x + 3y)$$

and $\lambda x^2 + 2xy + y^2 = -3x^2 + 2xy + y^2 = -(x - y)(3x + y)$

Hence, the joint equation of other two lines is

$$(x + 3y)(3x + y) = 0 \text{ or } 3x^2 + 10xy + 3y^2 = 0.$$

● **Ex. 2** *The combined equation of the lines* l_1 *and* l_2 *is* $2x^2 + 6xy + y^2 = 0$ *and that of the lines* m_1 *and* m_2 *is* $4x^2 + 18xy + y^2 = 0$. *If the angle between* l_1 *and* m_2 *is* α, *then the angle between* l_2 *and* m_1 *will be*

(a) $\frac{\pi}{2} - \alpha$ (b) $\frac{\pi}{4} + \alpha$ (c) α (d) 2α

Sol. (c) The combined equation of the bisectors of the angles between the lines of the first pair is

$$\frac{x^2 - y^2}{2 - 1} = \frac{xy}{3} \Rightarrow x^2 - y^2 = \frac{1}{3}xy$$

and the combined equation of the bisectors of the angles between the lines of the second pair is

$$\frac{x^2 - y^2}{4 - 1} = \frac{xy}{9} \Rightarrow x^2 - y^2 = \frac{1}{3}xy$$

It is clear that the two pairs are equally inclined to each other.

Hence, the angle between l_2 and m_1 is α.

● **Ex. 3** *The pair of lines* $\sqrt{3}x^2 - 4xy + \sqrt{3}y^2 = 0$ *are rotated about the origin by* $\frac{\pi}{6}$ *in the anti-clockwise sense. The equation of the pair in the new position is*

(a) $x^2 - \sqrt{3}xy = 0$ (b) $y^2 - \sqrt{3}xy = 0$

(c) $\sqrt{3}x^2 - xy = 0$ (d) $\sqrt{3}y^2 - xy = 0$

Sol. (c) The given equation of pair of straight lines can be written as

$$(\sqrt{3}x - y)(x - \sqrt{3}y) = 0$$

$$\Rightarrow \quad y = \sqrt{3}x \text{ and } y = \frac{1}{\sqrt{3}}x$$

$$\Rightarrow \quad y = x \tan 60^\circ \text{ and } y = x \tan 30^\circ$$

After rotation, the separate equations are

$$y = x \tan 90^\circ \text{ and } y = x \tan 60^\circ$$

$$\Rightarrow \quad x = 0 \text{ and } y = x\sqrt{3}$$

Hence, the combined equation in the new position is

$$x(\sqrt{3}x - y) = 0$$

or $$\sqrt{3}x^2 - xy = 0.$$

● **Ex. 4** *If the pair of lines* $ax^2 - 2xy + by^2 = 0$ *and* $bx^2 - 2xy + ay^2 = 0$ *be such that each pair bisects the angle between the other pair, then* $|a - b|$ *equals to*

(a) 1 (b) 2

(c) 3 (d) 4

Sol. (b) According to the example, the equation of the bisectors of the angle between the lines

$$ax^2 - 2xy + by^2 = 0 \quad \text{...(i)}$$

is $$bx^2 - 2xy + ay^2 = 0 \quad \text{...(ii)}$$

∴ The equation of bisectors of the angle between the lines Eq. (i) is

$$\frac{x^2 - y^2}{a - b} = \frac{xy}{-1}$$

$$\Rightarrow \quad x^2 + (a - b)xy - y^2 = 0 \quad \text{...(iii)}$$

Since, Eqs. (ii) and (iii) are identical, comparing Eqs. (ii) and (iii), we get

$$\frac{b}{1} = \frac{-2}{a - b} = \frac{a}{-1}$$

$$\Rightarrow \quad (a - b)b = -2$$

and $$(a - b)a = 2$$

$$\therefore \quad (a - b)^2 = 4$$

or $$|a - b| = 2$$

● **Ex. 5** *The equation of line which is parallel to the line common to the pair of lines given by* $3x^2 + xy - 4y^2 = 0$ *and* $6x^2 + 11xy + 4y^2 = 0$ *and at a distance of* 2 *units from it is*

(a) $3x - 4y = -10$ (b) $x - y = 2$

(c) $3x + 4y = 10$ (d) $2x + y = -2$

Sol. (c) We have, $3x^2 + xy - 4y^2 = 0$

or $(x - y)(3x + 4y) = 0$ ...(i)

and $6x^2 + 11xy + 4y^2 = 0$

or $(2x + y)(3x + 4y) = 0$ ...(ii)

Equation of line common to Eqs. (i) and (ii) is

$$3x + 4y = 0 \quad \text{...(iii)}$$

Equation of any line parallel to Eq. (iii) is

$$3x + 4y = \lambda$$

Since, its distance from Eq. (iii) is 2, we have

$$\frac{|\lambda - 0|}{\sqrt{(3^2 + 4^2)}} = 2 \text{ or } \lambda = \pm 10$$

Hence, required lines are $3x + 4y = \pm 10$.

● **Ex. 6** *The lines joining the origin to the points of intersection of* $x^2 + y^2 + 2gx + c = 0$ *and* $x^2 + y^2 + 2fy - c = 0$ *are at right angles, if*

(a) $g^2 + f^2 = c$ (b) $g^2 - f^2 = c$

(c) $g^2 - f^2 = 2c$ (d) $g^2 + f^2 = c^2$

Sol. (c) Given,

$$x^2 + y^2 + 2gx + c = 0 \quad \text{...(i)}$$

and $x^2 + y^2 + 2fy - c = 0$ ...(ii)

On subtracting Eq. (ii) from Eq. (i), we get

$$2gx - 2fy + 2c = 0$$

or $$\frac{fy - gx}{c} = 1 \quad \text{...(iii)}$$

On adding Eqs. (i) and (ii), we get

$$2(x^2 + y^2 + gx + fy) = 0$$

or $x^2 + y^2 + gx + fy = 0$ ...(iv)

Homogenising Eq. (iv) with the help of Eq. (iii), then

$$x^2 + y^2 + (gx + fy)\left(\frac{fy - gx}{c}\right) = 0$$

∴ The lines will be at right angles, when

$$\left(1 - \frac{g^2}{c}\right) + \left(1 + \frac{f^2}{c}\right) = 0$$

$$\Rightarrow \quad g^2 - f^2 = 2c$$

JEE Type Solved Examples :
More than One Correct Option Type Questions

■ This section contains **3 multiple choice examples**. Each example has four choices (a), (b), (c) and (d) out of which **MORE THAN ONE** may be correct.

● **Ex. 7** *The lines joining the origin to the point of intersection of* $3x^2 + mxy - 4x + 1 = 0$ *and* $2x + y - 1 = 0$ *are at right angles. Which of the following is/are possible value of m?*

(a) -4 (b) 3 (c) 4 (d) 7

Sol. (a,b,c,d) Given line is $2x + y = 1$ ...(i)

and curve is $3x^2 + mxy - 4x + 1 = 0$ ...(ii)

Homogenising Eq. (ii) with the help of Eq. (i), then

$$3x^2 + mxy - 4x(2x + y) + (2x + y)^2 = 0$$

or $$-x^2 + mxy + y^2 = 0$$

the lines are at right angles as $a + b = 0$, when $h^2 > ab$

i.e. $$\frac{m^2}{4} + 1 > 0$$

which is true for all $m \in R$.

● **Ex. 8** *The lines* $(lx + my)^2 - 3(mx - ly)^2 = 0$ *and* $lx + my + n = 0$ *form*

(a) an isosceles triangle (b) a right angled triangle

(c) an equilateral triangle (d) None of these

Sol. (a,c) $(lx + my)^2 - 3(mx - ly)^2 = 0$

$$\Rightarrow (l^2 - 3m^2)x^2 + 8mlxy + (m^2 - 3l^2)y^2 = 0$$

$$\Rightarrow \{(l + m\sqrt{3})x + (m - l\sqrt{3})y\}\{(l - \sqrt{3}m)x + (m + \sqrt{3}l)y\} = 0$$

Let slope of $(l + m\sqrt{3})x + (m - l\sqrt{3})y = 0$ be m_1 and slope of $(l - m\sqrt{3})x + (m + l\sqrt{3})y = 0$ be m_2 and slope of $lx + my + n = 0$ is m_3.

Now, $$\tan\theta_1 = \left|\frac{m_3 - m_1}{1 + m_3 m_1}\right| = \left|\frac{-\frac{l}{m} + \frac{l + m\sqrt{3}}{m - l\sqrt{3}}}{1 + \frac{l}{m}\cdot\left(\frac{l + m\sqrt{3}}{m - l\sqrt{3}}\right)}\right|$$

$$= \left|\frac{\sqrt{3}(l^2 + m^2)}{(l^2 + m^2)}\right| = \sqrt{3}$$

$$\Rightarrow \quad \theta_1 = 60^\circ$$

Similarly, $\tan\theta_2 = \left|\frac{m_2 - m_1}{1 + m_2 m_1}\right| = \sqrt{3}$

$\Rightarrow \quad \theta_2 = 60°$

Hence, an equilateral triangle is formed which is also an isosceles one.

● ***Ex. 9*** *If the equation $ax^2 - 6xy + y^2 + bx + cy + d = 0$ represents a pair of lines whose slopes are m and m^2, then the value(s) of a is/are*

(a) -27 (b) -8
(c) 8 (d) 27

Sol. (a,c) $\because$ m and m^2 are the roots of the equation

$$\left(\frac{y}{x}\right)^2 - 6\left(\frac{y}{x}\right) + a = 0$$

$\therefore \quad m + m^2 = 6$ and $m \cdot m^2 = a$ ...(i)

Now, $(m + m^2)^3 = (6)^3$

$\Rightarrow m^3 + m^6 + 3m \cdot m^2 (m + m^2) = 216$

$\Rightarrow \quad a + a^2 + 3a(6) = 216$ [from Eq. (i)]

$\Rightarrow \quad a^2 + 19a - 216 = 0$

$\Rightarrow \quad (a + 27)(a - 8) = 0$

$\therefore \quad a = -27, 8$

JEE Type Solved Examples : Paragraph Based Questions

■ This section contains **one solved paragraph** based upon each paragraph **2 multiple choice questions** have to be answered. Each of these questions has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Paragraph

(Q. Nos. 10 to11)

Consider the equation of a pair of straight lines as $\lambda xy - 8x + 9y - 12 = 0$

10. The value of λ is

(a) 0 (b) 2
(c) 4 (d) 6

11. The point of intersection of lines is (α, β), then the equation whose roots are α, β, is

(a) $4x^2 + x - 8 = 0$ (b) $6x^2 + x - 12 = 0$
(c) $4x^2 - x - 8 = 0$ (d) $6x^2 - x - 12 = 0$

Sol. Given equation is,

$$\lambda xy - 8x + 9y - 12 = 0$$

Here, $a = 0, b = 0, c = -12,$

$$f = \frac{9}{2}, g = -4 \text{ and } h = \frac{\lambda}{2}$$

10. (d) For $\Delta = 0$,

$$0 + 2 \times \frac{9}{2} \times -4 \times \frac{\lambda}{2} - 0 - 0 + 12 \times \frac{\lambda^2}{4} = 0$$

$\Rightarrow \quad 3\lambda^2 - 18\lambda = 0$

$\therefore \quad \lambda = 0, 6$

Hence, $\lambda = 6$ [$\because$ for $\lambda = 0$, it will give an equation of first degree]

11. (b) Let $f(x,y) = 6xy - 8x + 9y - 12$ [$\because \lambda = 6$]

$\therefore \quad \frac{\partial f}{\partial x} = 6y - 8$ and $\frac{\partial f}{\partial y} = 6x + 9$

For point of intersection $\frac{\partial f}{\partial x} = 0$ and $\frac{\partial f}{\partial y} = 0$, we get

$$x = -\frac{3}{2}, y = \frac{4}{3}$$

$\therefore \quad \alpha = -\frac{3}{2}$ and $\beta = \frac{4}{3}$

Hence, required equation is

$$x^2 - \left(-\frac{3}{2} + \frac{4}{3}\right)x - 2 = 0$$

$\Rightarrow \quad 6x^2 + x - 12 = 0$

JEE Type Solved Examples :
Single Integer Answer Type Questions

- This section contains **2 examples**. The answer to each example is **a single digit integer**, ranging from 0 to 9 (both inclusive).

● ***Ex. 12*** *If the sum of the slopes of the lines given by* $x^2 - 2cxy - 7y^2 = 0$ *is four times their product, then the value of* c *is*

Sol. (2) Given, $m_1 + m_2 = 4m_1m_2$

$$\Rightarrow \quad -\frac{2h}{b} = 4 \cdot \frac{a}{b} \Rightarrow h = -2a$$

$$\therefore \quad -c = -2 \times 1 \Rightarrow c = 2$$

● ***Ex. 13*** *If one of the lines given by* $6x^2 - xy + 4cy^2 = 0$ *is* $3x + 4y = 0$, *then the value of* $|c|$ *is*

Sol. (3) $\because 3x + 4y = 0$ is one of the lines given by $6x^2 - xy + 4cy^2 = 0$, then

$$6x^2 - x\left(-\frac{3x}{4}\right) + 4c\left(-\frac{3x}{4}\right)^2 = 0 \qquad \left[\because y = -\frac{3x}{4}\right]$$

$$\Rightarrow \quad 6 + \frac{3}{4} + \frac{9c}{4} = 0 \; ; \quad \therefore \; c = -3$$

Hence, $|c| = 3$

JEE Type Solved Examples :
Matching Type Questions

- This section contains **one solved example**. This example has four statements (A, B, C and D) is **Column I** and four statements (p, q, r and s) in **Column II**. Any given statements in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

● ***Ex. 14*** *Match the following*

	Column I		Column II
(A)	If the slope of one of the lines represented by $ax^2 + 2hxy + by^2 = 0$ is the square of the other, then $\frac{a+b}{h} + \frac{8h^2}{ab}$ is a	(p)	Odd prime number
(B)	The product of perpendiculars drawn from the point (1, 2) to the pair of lines $x^2 + 4xy + y^2 = 0$ is λ units, then $[\lambda]$ is a (where $[\cdot]$ denotes the greatest integer function).	(q)	Composite number
(C)	Distance between two lines represented by the line pair $x^2 - 4xy + 4y^2 + x - 2y - 6 = 0$ is λ unit, then $[\lambda]$ is a (where $[\cdot]$ denotes the greatest integer function).	(r)	Even prime number
(D)	If the pairs $a_1x^2 + 2h_1xy + b_1y^2 = 0$ and $a_2x^2 + 2h_2xy + b_2y^2 = 0$ have one line common, then $\frac{(a_1b_2 - a_2b_1)^2}{(b_1h_2 - b_2h_1)(a_2h_1 - a_1h_2)}$ is a	(s)	Perfect number

Sol. (A) $\rightarrow$ (q, s); (B) $\rightarrow$ (p); (C) $\rightarrow$ (r); (D) $\rightarrow$ (q)

(A) Let m and m^2 be the slopes of the lines represented by $ax^2 + 2hxy + by^2 = 0$, then

$$m + m^2 = -\frac{2h}{b} \qquad \text{...(i)}$$

and $$m \cdot m^2 = \frac{a}{b} \qquad \text{...(ii)}$$

From Eq. (i), $(m + m^2)^3 = \left(-\frac{2h}{b}\right)^3$

$$\Rightarrow m^3 + m^6 + 3m \cdot m^2(m + m^2) = -\frac{8h^3}{b^3}$$

$$\Rightarrow \frac{a}{b} + \frac{a^2}{b^2} + \frac{3a}{b}\left(-\frac{2h}{b}\right) = -\frac{8h^3}{b^3} \quad \text{[from Eqs. (i) and (ii)]}$$

$$\Rightarrow \quad ab + a^2 - 6ah = -\frac{8h^3}{b}$$

$$\therefore \quad \frac{a+b}{h} + \frac{8h^2}{ab} = 6$$

(B) Let $y = m_1x$ and $y = m_2x$ lines represented by $x^2 + 4xy + y^2 = 0$, then $m_1 + m_2 = -4$, $m_1m_2 = 1$. Then, product of perpendiculars drawn from the point (1, 2)

$$= \frac{|(2 - m_1)(2 - m_2)|}{\sqrt{(1 + m_1^2)}\sqrt{(1 + m_2^2)}}$$

$$= \frac{|4 - 2(m_1 + m_2) + m_1m_2|}{\sqrt{1 + (m_1 + m_2)^2 - 2m_1m_2 + (m_1m_2)^2}}$$

$$= \frac{|4 + 8 + 1|}{\sqrt{(1 + 16 - 2 + 1)}} = \frac{13}{4} \text{ units}$$

$\because \quad \lambda = \frac{13}{4}$

$\therefore \quad [\lambda] = 3$

(C) Given, line pair is $x^2 - 4xy + 4y^2 + x - 2y - 6 = 0$

$\Rightarrow \quad (x - 2y)^2 + (x - 2y) - 6 = 0$

$\Rightarrow \quad (x - 2y + 3)(x - 2y - 2) = 0$

$\therefore$ Lines are $x - 2y + 3 = 0$ and $x - 2y - 2 = 0$

Hence, distance between lines $= \dfrac{|3 - (-2)|}{\sqrt{1 + 4}} = \sqrt{5}$ unit

$\therefore \quad \lambda = \sqrt{5}$

Hence, $[\lambda] = [\sqrt{5}] = 2$

(D) Let $y = mx$ be the common line, then

$b_1m^2 + 2h_1m + a_1 = 0$ and $b_2m^2 + 2h_2m + a_2 = 0$.

$$\Rightarrow \quad \begin{vmatrix} b_1 & 2h_1 \\ b_2 & 2h_2 \end{vmatrix} \times \begin{vmatrix} 2h_1 & a_1 \\ 2h_2 & a_2 \end{vmatrix} = \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}^2$$

$$\Rightarrow \quad 4(b_1h_2 - b_2h_1)(a_2h_1 - a_1h_2) = (a_1b_2 - a_2b_1)^2$$

$$\therefore \quad \frac{(a_1b_2 - a_2b_1)^2}{(b_1h_2 - b_2h_1)(a_2h_1 - a_1h_2)} = 4$$

JEE Type Solved Examples :
Statement I and II Type Questions

■ **Directions** (Ex. Nos. 15-16) Each of these examples contains two statements.

Statement I (Assertion) and

Statement II (Reason)

Each of these examples also has four alternative choices, only one of which is the correct answer. You have to select the correct choice, as given below :

(a) Statement I is true, Statement II is true and Statement II is a correct explanation for Statement I

(b) Statement I is true, Statement II is true and Statement II is not a correct explanation for Statement I

(c) Statement I is true, Statement II is false

(d) Statement I is false, Statement II is true

Ex. 15 **Statement I** *The combined equation of l_1, l_2 is $3x^2 + 6xy + 2y^2 = 0$ and that of m_1, m_2 is $5x^2 + 18xy + 2y^2 = 0$. If angle between l_1, m_2 is θ, then angle between l_2, m_1 is θ.*

Statement II *If the pairs of lines $l_1l_2 = 0, m_1m_2 = 0$ are equally inclinded that angle between l_1 and m_2 = angle between l_2 and m_1.*

Sol. (a) The pair of bisectors of $3x^2 + 6xy + 2y^2 = 0$ is

$\dfrac{x^2 - y^2}{3 - 2} = \dfrac{xy}{3}$, i.e. $3x^2 - xy - 3y^2 = 0$ and pair of bisectors of

$5x^2 + 18xy + 2y^2 = 0$ is $\dfrac{x^2 - y^2}{5 - 2} = \dfrac{xy}{9}$

i.e. $3x^2 - xy - 3y^2 = 0$ are coincides.

$\therefore$ Angle between l_1, m_2 is same as angle between l_2, m_1.

$\therefore$ Both statements are true and Statement II is a correct explanation for Statement I.

Ex. 16 **Statement I** *The equation $2x^2 - 3xy - 2y^2 + 5x - 5y + 3 = 0$ represents a pair of perpendicular straight lines.*

Statement II *A pair of lines given by $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ are perpendicular if $a + b = 0$.*

Sol. (d) Here, $\Delta \neq 0$, $h^2 > ab$ and $a + b = 0$

$\therefore \quad 2x^2 - 3xy - 2y^2 + 5x - 5y + 3 = 0$

represents a rectangular hyperbola.

$\therefore$ Statement I is false and Statement II is true.

Subjective Type Examples

■ In this section, there are **10 subjective solved examples**.

● ***Ex. 17*** *If the lines represented by $2x^2 - 5xy + 2y^2 = 0$ be the two sides of a parallelogram and the line $5x + 2y = 1$ be one of its diagonal. Find the equation of the other diagonal, and area of the parallelogram.*

Sol. Given pair of lines, $2x^2 - 5xy + 2y^2 = 0$

i.e. $\quad (x - 2y)(2x - y) = 0$

$\therefore \quad x - 2y = 0$ and $2x - y = 0$

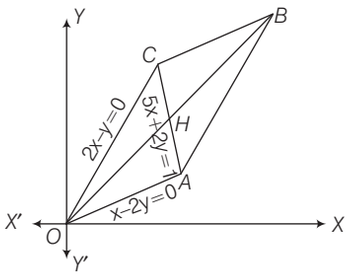
and the diagonal $5x + 2y = 1$ does not pass through origin, hence it is AC.

On solving, $x - 2y = 0$ and $5x + 2y = 1$, we get

$$A = \left(\frac{1}{6}, \frac{1}{12}\right)$$

and solving $2x - y = 0$ and $5x + 2y = 1$, we get

$$C \equiv \left(\frac{1}{9}, \frac{2}{9}\right).$$



Since, diagonals of parallelogram bisect each other, if bisect at H.

Then, $$H \equiv \left\{\frac{1}{2}\left(\frac{1}{6}+\frac{1}{9}\right), \frac{1}{2}\left(\frac{1}{12}+\frac{2}{9}\right)\right\}$$

i.e. $$H = \left(\frac{5}{36}, \frac{11}{72}\right)$$

Hence, the equation of other diagonal which passes through O and H is

$$y - 0 = \frac{\frac{11}{72} - 0}{\frac{5}{36} - 0}(x - 0)$$

$$\Rightarrow \quad y = \frac{11}{10}x$$

$$\Rightarrow \quad 11x - 10y = 0$$

Now, area of parallelogram = $2 \times$ Area of ΔOAC

$$= 2 \times \frac{1}{2}\left|\frac{1}{6} \times \frac{2}{9} - \frac{1}{9} \times \frac{1}{12}\right| = \frac{1}{36} \text{ sq units}$$

● ***Ex. 18*** *Prove that the equation* $(a + 2h + b)x^2 - 2(a - b)xy + (a - 2h + b)y^2 = 0$ *represents a pair of lines each inclined at an angle of* $45°$ *to one or other of the lines given by,* $ax^2 + 2hxy + by^2 = 0$.

Sol. Given equation is

$$ax^2 + 2hxy + by^2 = 0 \quad \ldots(i)$$

Let the lines represented by Eq. (i) are

$$y - m_1 x = 0 \quad \ldots(ii)$$

and $$y - m_2 x = 0 \quad \ldots(iii)$$

therefore, $m_1 + m_2 = -\frac{2h}{b}, m_1 m_2 = \frac{a}{b}$

If $m_1 = \tan\theta_1$ and $m_2 = \tan\theta_2$, the equation of lines through the origin making $45°$ with the lines Eqs. (ii) and (iii) will be

$$y - x\tan(\theta_1 - 45°) = 0$$

and $$y - x\tan(\theta_2 - 45°) = 0$$

Their combined equation is

$$\{y - x\tan(\theta_1 - 45°)\}\{y - x\tan(\theta_2 - 45°)\} = 0$$

$$\Rightarrow \quad \left(y - \frac{m_1 - 1}{1 + m_1}x\right)\left(y - \frac{m_2 - 1}{1 + m_2}x\right) = 0$$

$$\Rightarrow \quad \{(1 + m_1)y - (m_1 - 1)x\}\{(1 + m_2)y - (m_2 - 1)x\} = 0$$

$$\Rightarrow \quad (1 + m_1)(1 + m_2)y^2 - xy\{(1 + m_1)(m_2 - 1) + (m_1 - 1)(1 + m_2)\} + (m_1 - 1)(m_2 - 1)x^2 = 0$$

$$\Rightarrow \quad (1 + m_1 + m_2 + m_1 m_2)y^2 - 2xy(m_1 m_2 - 1) + \{m_1 m_2 - (m_1 + m_2) + 1\}x^2 = 0$$

$$\Rightarrow \quad \left(1 - \frac{2h}{b} + \frac{a}{b}\right)y^2 - 2xy\left(\frac{a}{b} - 1\right) + \left(\frac{a}{b} + \frac{2h}{b} + 1\right)x^2 = 0$$

$$\therefore \quad (a + 2h + b)x^2 - 2(a - b)xy + (a - 2h + b)y^2 = 0$$

● ***Ex. 19*** *If* $u \equiv ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ *represents a pair of straight lines, prove that the equation of the third pair of straight lines passing through the points where these meet the axes is* $cu + 4(fg - ch)xy = 0$.

Sol. $u \equiv ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$

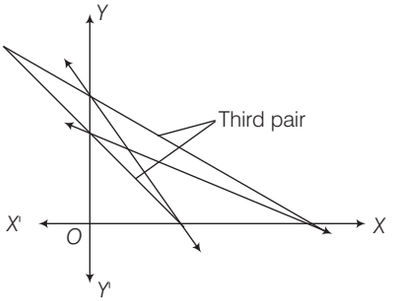
$\because$ u represents a pair of straight line, then $\Delta = 0$

$$\therefore \quad abc + 2fgh - af^2 - bg^2 - ch^2 = 0 \quad \ldots(i)$$

Combined equation of axes is $xy = 0$

Now, the curve through the intersection of $u = 0$ and $xy = 0$ is

$$u + \lambda xy = 0 \quad \ldots(ii)$$



i.e. $$ax^2 + 2hxy + by^2 + 2gx + 2fy + c + \lambda xy = 0$$

$$\Rightarrow \quad ax^2 + xy(2h + \lambda) + by^2 + 2gx + 2fy + c = 0$$

If it represents a pair of lines, then

$$abc + 2fg\left(h + \frac{\lambda}{2}\right) - af^2 - bg^2 - c\left(h + \frac{\lambda}{2}\right)^2 = 0$$

$$\Rightarrow (abc + 2fgh - af^2 - bg^2 - ch^2) + \lambda(fg - ch) - \frac{c\lambda^2}{4} = 0$$

$$\Rightarrow \quad 0 + \lambda(fg - ch) - \frac{c\lambda^2}{4} = 0 \quad \text{[from Eq. (i)]}$$

$$\therefore \quad \lambda = \frac{4(fg - ch)}{c} \quad \ldots(iii)$$

Hence, the equation of third pair from Eqs. (ii) and (iii) is

$$u + \frac{4(fg - ch)}{c}xy = 0$$

$$\therefore \quad cu + 4(fg - ch)xy = 0$$

● **Ex. 20** *If the equation* $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ *represents a pair of parallel lines, prove that*
(i) $h = \sqrt{ab}$ *and* $g\sqrt{b} = f\sqrt{a}$ *or* $(h = -\sqrt{ab}$ *and* $g\sqrt{b} = -f\sqrt{a})$.
(ii) the distance between them is $2\sqrt{\left(\frac{g^2 - ac}{a(a+b)}\right)}$.

Sol. Given equation is,

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \quad \ldots(i)$$

Let the equation of the parallel lines represented by Eq. (i) be

$$lx + my + n = 0 \quad \text{and} \quad lx + my + n_1 = 0.$$

Then, $(lx + my + n)(lx + my + n_1)$

$$\equiv ax^2 + 2hxy + by^2 + 2gx + 2fy + c$$

Equating the coefficients, we get

$$l^2 = a \quad \ldots(ii)$$

$$m^2 = b \quad \ldots(iii)$$

$$nn_1 = c \quad \ldots(iv)$$

$$2lm = 2h \quad \ldots(v)$$

$$(n + n_1)l = 2g \quad \ldots(vi)$$

$$m(n + n_1) = 2f \quad \ldots(vii)$$

Eq. (i) From Eq. (v)

$\Rightarrow \quad h = lm = \pm\sqrt{ab}$

Now, $\quad h = \sqrt{ab}$ or $h = -\sqrt{ab}$

$\because \quad abc + 2fgh - af^2 - bg^2 - ch^2 = 0$

$\Rightarrow abc + 2fg\sqrt{ab} - af^2 - bg^2 - c \cdot ab = 0$

[substituting the value of $h = \sqrt{ab}$]

$\Rightarrow \quad -(f\sqrt{a} - g\sqrt{b})^2 = 0 \Rightarrow f\sqrt{a} = g\sqrt{b}$

Thus, the given equation represents a pair of lines.

Also, if $h = -\sqrt{ab}$, then $g\sqrt{b} = -f\sqrt{a}$

(ii) The distance between parallel lines

$$= \frac{|n - n_1|}{\sqrt{(l^2 + m^2)}} = \frac{\sqrt{(n + n_1)^2 - 4nn_1}}{\sqrt{l^2 + m^2}}$$

$$= \frac{\sqrt{\left(\frac{4g^2}{l^2} - 4c\right)}}{\sqrt{(a+b)}} \quad \text{[from Eqs. (vi), (ii) and (iii)]}$$

$$= 2\sqrt{\left(\frac{g^2 - ac}{a(a+b)}\right)} \quad [\because l^2 = a]$$

Remark

In some books, the conditions for parallel lines are stated as $h^2 = ab$ and $bg^2 = af^2$ we show that by an example that these conditions are not sufficient because

$$h^2 = ab \Rightarrow h = \pm\sqrt{ab}$$

and $\quad bg^2 = af^2 \Rightarrow g\sqrt{b} = \pm f\sqrt{a}$

$\Rightarrow \quad h = \sqrt{ab}, g\sqrt{b} = f\sqrt{a}$ or $(h = -\sqrt{ab}, g\sqrt{b} = -f\sqrt{a})$

Consider, for example, $4x^2 + 4xy + y^2 + 4x - 2y + 5 = 0$

Here, $a = 4, h = 2, b = 1, g = 2, f = -1, c = 5$ and

$h = \sqrt{ab}, g\sqrt{b} = -f\sqrt{a}$

But $abc + 2fgh - af^2 - bg^2 - ch^2$

$= 4 \times 1 \times 5 + 2 \times (-1) \times 2 \times 2 - 4 \times (-1)^2 - 1 \times (2)^2 - 5 \times (2)^2$

$= 20 - 8 - 4 - 4 - 20 = -16 \neq 0$

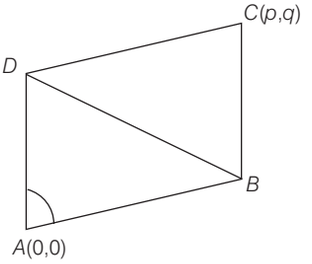
Hence, the Eq. (i) does not represent a pair of lines at all.

● **Ex. 21** *A parallelogram is formed by the lines* $ax^2 + 2hxy + by^2 = 0$ *and the lines through* (p, q) *parallel to them. Show that the equation of the diagonal of the parallelogram which does not pass through origin is* $(2x - p)(ap + hq) + (2y - q)(hp + bq) = 0$.
Show also that the area of the parallelogram is $|(ap^2 + 2hpq + bq^2)| / 2\sqrt{(h^2 - ab)}$.

Sol. The combined equation of AB and AD is

$$S_1 \equiv ax^2 + 2hxy + by^2 = 0$$

Now, equation of lines through (p, q) and parallel to $S_1 \equiv 0$ is $S_2 \equiv a(x - p)^2 + 2h(x - p)(y - q) + b(y - q)^2 = 0$



Hence, the equation of diagonal BD is $S_1 - S_2 = 0$

$$a(-2xp + p^2) + 2h(-py - qx + pq) + b(-2qy + q^2) = 0$$

$$-ap(2x - p) - hq(2x - p) - hp(2y - q) - bq(2y - q) = 0$$

[$\because 2hpq$ is written as $hpq + hpq$]

Hence, diagonal of BD is

$$(2x - p)(ap + hq) + (2y - q)(bq + hp) = 0$$

Area of parallelogram $= \frac{p_1 p_2}{\sin\theta}$

$\Rightarrow p_1 p_2$ = product of perpendiculars from (p, q) on AB and AD whose combined equation is

$$ax^2 + 2hxy + by^2 = 0$$

$$\therefore \quad p_1 p_2 = \frac{|ap^2 + 2hpq + bq^2|}{\sqrt{\{(a-b)^2 + 4h^2\}}}$$

$$\therefore \quad \tan\theta = \frac{2\sqrt{(h^2 - ab)}}{|(a+b)|}$$

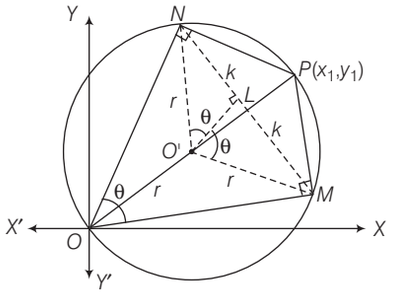
$$\therefore \quad \sin\theta = \frac{2\sqrt{(h^2 - ab)}}{\sqrt{(a-b)^2 + 4h^2}}$$

$$\therefore \text{ Required area} = \frac{|ap^2 + 2hpq + bq^2|}{2\sqrt{(h^2 - ab)}}$$

● ***Ex. 22*** *A point moves so that the distance between the feet of perpendiculars drawn from it to the lines* $ax^2 + 2hxy + by^2 = 0$ *is a constant* $2k$. *Show that the equation of its locus is* $(x^2 + y^2)(h^2 - ab) = k^2\{(a-b)^2 + 4h^2\}$.

Sol. $\because \angle ONP = \angle OMP = \frac{\pi}{2}$

$\therefore$ O, M, P, N are concyclic with diameter OP.



Let $P \equiv (x_1, y_1)$

$\therefore$ Coordinates of centre are $O' = \left(\frac{x_1}{2}, \frac{y_1}{2}\right)$

$\therefore$ Radius $r = O'N = OM = OO'$

$$= \sqrt{\left(\frac{x_1}{2}\right)^2 + \left(\frac{y_1}{2}\right)^2} = \frac{\sqrt{(x_1^2 + y_1^2)}}{2}$$

Let $\angle MON = \theta$

$\therefore \quad \angle MO'N = 2\theta \Rightarrow \angle NO'L = \angle MO'L = \theta$

and given $MN = 2k$, then $NL = LM = k$

Now, in $\Delta NO'L$,

$$\sin\theta = \frac{NL}{O'N} = \frac{k}{r} = \frac{k}{\frac{\sqrt{(x_1^2 + y_1^2)}}{2}} = \frac{2k}{\sqrt{(x_1^2 + y_1^2)}} \quad \text{...(i)}$$

But angle between the lines represented by

$ax^2 + 2hxy + by^2 = 0$ is $\tan\theta = \frac{2\sqrt{(h^2 - ab)}}{|a+b|}$.

$$\therefore \quad \sin\theta = \frac{2\sqrt{(h^2 - ab)}}{\sqrt{(a-b)^2 + 4h^2}} \quad \text{...(ii)}$$

From Eqs. (i) and (ii), we get

$$\frac{2\sqrt{(h^2 - ab)}}{\sqrt{(a-b)^2 + 4h^2}} = \frac{2k}{\sqrt{(x_1^2 + y_1^2)}}$$

On squaring both sides, we get

$$(x_1^2 + y_1^2)(h^2 - ab) = k^2\{(a-b)^2 + 4h^2\}$$

Hence, locus of $P(x_1, y_1)$ is

$$(x^2 + y^2)(h^2 - ab) = k^2\{(a-b)^2 + 4h^2\}.$$

● ***Ex. 23*** *Show that if two of the lines* $ax^3 + bx^2y + cxy^2 + dy^3 = 0 (a \neq 0)$ *make complementary angles with X-axis in anti-clockwise sense, then* $a(a-c) + d(b-d) = 0$.

Sol. The given equation can be written as

$$dm^3 + cm^2 + bm + a = 0, \text{ where } m = \frac{y}{x}$$

Let its roots be m_1, m_2, m_3.

$$\therefore \quad m_1 m_2 m_3 = -\frac{a}{d} \quad \text{...(i)}$$

If $m_1 = \tan\alpha$, then $m_2 = \tan(90° - \alpha)$

[$\because$ two lines makes complementary angles with X-axis]

$$\therefore \quad m_2 = \cot\alpha \text{ then } m_1 m_2 = 1$$

From Eq. (i), $\quad m_3 = -\frac{a}{d}$

Since, m_3 is root of the above cubic, we have

$$d\left(-\frac{a^3}{d^3}\right) + c\left(\frac{a^2}{d^2}\right) + b\left(-\frac{a}{d}\right) + a = 0$$

$$\Rightarrow \quad \left(-\frac{a^3}{d^2}\right) + \left(\frac{ca^2}{d^2}\right) - \left(\frac{ab}{d}\right) + a = 0$$

$$\Rightarrow \quad -a^3 + ca^2 - abd + ad^2 = 0$$

On dividing each by a, we get

$$-a^2 + ca - bd + d^2 = 0$$

$$\therefore \quad a(a-c) + d(b-d) = 0.$$

● ***Ex. 24*** *Show that the equation* $a(x^4 + y^4) - 4bxy(x^2 - y^2) + 6cx^2y^2 = 0$ *represents two pairs of lines at right angles and that if* $2b^2 = a^2 + 3ac$, *the two pairs will coincide.*

Sol. Given equation is

$$a(x^4 + y^4) - 4bxy(x^2 - y^2) + 6cx^2y^2 = 0 \quad \text{...(i)}$$

Eq. (i) is a homogeneous equation of fourth degree and since it represents two pairs at right angles. i.e. sum of the coefficients of x^2 and y^2 should be zero.

Let $a(x^4 + y^4) - 4bxy(x^2 - y^2) + 6cx^2y^2$

$$= (ax^2 + pxy - ay^2)(x^2 + qxy - y^2),$$

where, p and q are constants.

On comparing similar powers, we get

$$p + aq = -4b \quad \text{...(ii)}$$

$$-2a + pq = 6c \quad \text{...(iii)}$$

Again, given two pairs coincide, then

$$\frac{p}{a} = q$$

or $$p = aq \quad \ldots(iv)$$

From Eqs. (ii) and (iv),

$$q = -\frac{2b}{a}$$

and $$p = -2b$$

Substituting the values of p and q in Eq. (iii), we get

$$-2a + \frac{4b^2}{a} = 6c$$

$$\Rightarrow \quad -a^2 + 2b^2 = 3ac$$

$$\therefore \quad 2b^2 = a^2 + 3ac$$

● ***Ex. 25*** *Show that the locus of a point such that the product of the perpendiculars let fall from it on three lines represented by* $ay^3 + by^2x + cyx^2 + dx^3 = 0$ *is constant* $= k^3$, *is*

$ay^3 + by^2x + cyx^2 + dx^3 = k^3\sqrt{(a-c)^2 + (b-d)^2}$.

Sol. Let the three represented lines are

$$y = m_1x,\ y = m_2x \text{ and } y = m_3x$$

$$ay^3 + by^2x + cyx^2 + dx^3 = a(y - m_1x)(y - m_2x)(y - m_3x)$$

On comparing similar powers on both sides

$$\Rightarrow \quad m_1 + m_2 + m_3 = -\frac{b}{a} \quad \ldots(i)$$

$$m_1m_2 + m_2m_3 + m_3m_1 = \frac{c}{a} \quad \ldots(ii)$$

$$m_1m_2m_3 = -\frac{d}{a} \quad \ldots(iii)$$

Let the point $P(x_1, y_1)$, from given condition

$$\frac{(y_1 - m_1x_1)}{\sqrt{(1+m_1^2)}} \cdot \frac{(y_1 - m_2x_1)}{\sqrt{(1+m_2^2)}} \cdot \frac{(y_1 - m_3x_1)}{\sqrt{(1+m_3^2)}} = k^3$$

$$\Rightarrow \quad \frac{1}{a}(ay_1^3 + by_1^2x_1 + cy_1x_1^2 + dx_1^3)$$

$$= k^3\sqrt{(1+m_1^2)(1+m_2^2)(1+m_3^2)}$$

$$[\because ay^3 + by^2x + cyx^2 + dx^3$$

$$= a(y - m_1x)(y - m_2x)(y - m_3x)]$$

$$\Rightarrow (ay_1^3 + by_1^2x_1 + cy_1x_1^2 + dx_1^3)$$

$$= ak^3\sqrt{(1 + \Sigma m_1^2 + \Sigma m_1^2m_2^2 + m_1^2m_2^2m_3^2)}$$

$$= ak^3\sqrt{\{1 + (\Sigma m_1)^2 - 2\Sigma m_1m_2 + (\Sigma m_1m_2)^2 - 2m_1m_2m_3\Sigma m_1 + (m_1m_2m_3)^2\}}$$

$$= ak^3\sqrt{1 + \frac{b^2}{a^2} - \frac{2c}{a} + \frac{c^2}{a^2} + \frac{2d}{a} \cdot \left(-\frac{b}{a}\right) + \left(-\frac{d}{a}\right)^2}$$

$$= k^3\sqrt{(a^2 + b^2 - 2ac + c^2 - 2bd + d^2)}$$

$$= k^3\sqrt{\{(a-c)^2 + (b-d)^2\}}$$

Hence, locus of P is

$$(ay^3 + by^2x + cyx^2 + dx^3) = k^3\sqrt{\{(a-c)^2 + (b-d)^2\}}$$

● ***Ex. 26*** *If one of the lines given by the equation* $ax^2 + 2hxy + by^2 = 0$ *coincides with one of the lines given by* $a'x^2 + 2h'xy + b'y^2 = 0$ *and the other lines represented by them be perpendicular, then .*

$$\frac{ha'b'}{b'-a'} = \frac{h'ab}{b-a} = \frac{1}{2}\sqrt{(-aa'bb')}$$

Sol. Let the two lines represented by

$$ax^2 + 2hxy + by^2 = 0 \quad \ldots(i)$$

be $$y = m_1x$$

and $$y = m_2x$$

$$\therefore \quad m_1 + m_2 = -\frac{2h}{b} \quad \ldots(ii)$$

and $$m_1m_2 = \frac{a}{b} \quad \ldots(iii)$$

and the lines represented by

$$a'x^2 + 2h'xy + b'y^2 = 0 \quad \ldots(iv)$$

be $$y = -\frac{1}{m_1}x \quad \text{and} \quad y = m_2x$$

$$\therefore \quad -\frac{1}{m_1} + m_2 = -\frac{2h'}{b'} \quad \ldots(v)$$

and $$-\left(\frac{1}{m_1}\right)m_2 = \frac{a'}{b'} \quad \ldots(vi)$$

From Eqs. (iii) and (vi), we get

$$-m_2^2 = \frac{aa'}{bb'} \ \Rightarrow \ m_2 = \frac{\sqrt{(-aba'b')}}{bb'}$$

From Eqs. (iii), we get $\quad m_1 = -\frac{\sqrt{(-aba'b')}}{a'b}$

Substituting these values of m_1 and m_2 in Eqs. (ii) and (v), we get

$$-\frac{\sqrt{-aba'b'}}{a'b} + \frac{\sqrt{-aba'b'}}{bb'} = -\frac{2h}{b}$$

$$\Rightarrow \quad \frac{ha'b'}{b'-a'} = \frac{1}{2}\sqrt{-aa'bb'} \quad \ldots(vii)$$

and $$\frac{a'b}{\sqrt{-aba'b'}} + \frac{\sqrt{-aba'b'}}{bb'} = -\frac{2h'}{b'}$$

$$\frac{h'ab}{b-a} = \frac{1}{2}\sqrt{-aba'b'} \quad \ldots(viii)$$

From Eqs. (vii) and (viii), we get

$$\frac{ha'b'}{b'-a'} = \frac{h'ab}{b-a} = \frac{1}{2}\sqrt{-aba'b'}$$

Pair of Straight Lines Exercise 1 :
Single Option Correct Type Questions

- This section contains **12 multiple choice questions**. Each question has four choices (a), (b), (c), (d) out of which **ONLY ONE** is correct.

1. If the sum of the slopes of the lines given by $4x^2 + 2\lambda xy - 7y^2 = 0$ is equal to the product of the slopes, then λ is equal to
(a) -4 (b) -2 (c) 2 (d) 4

2. The equation $3ax^2 + 9xy + (a^2 - 2)y^2 = 0$ represents two perpendicular straight lines for
(a) only one value of a (b) for all values of a
(c) for only two values of a (d) for no value of a

3. The image of the pair of lines represented by $ax^2 + 2hxy + by^2 = 0$ by the line mirror $y = 0$ is
(a) $ax^2 - 2hxy - by^2 = 0$ (b) $bx^2 - 2hxy + ay^2 = 0$
(c) $bx^2 + 2hxy + ay^2 = 0$ (d) $ax^2 - 2hxy + by^2 = 0$

4. Number of points lying on the line $7x + 4y + 2 = 0$ which is equidistant from the lines $15x^2 + 56xy + 48y^2 = 0$ is
(a) 0 (b) 1
(c) 2 (d) 4

5. Orthocentre of the triangle formed by the lines $xy - 3x - 5y + 15 = 0$ and $3x + 5y = 15$ is
(a) $(-5, -3)$ (b) $(5, 3)$
(c) $(-3, -5)$ (d) $(3, 5)$

6. Two of the straight lines given by $3x^3 + 3x^2y - 3xy^2 + dy^3 = 0$ are at right angles, if d equal to
(a) -4 (b) -3
(c) -2 (d) -1

7. Two lines are given by $(x - 2y)^2 + \lambda(x - 2y) = 0$. The value of $|\lambda|$ so that the distance between them is 3, is
(a) $\sqrt{5}$ (b) $2\sqrt{5}$
(c) $3\sqrt{5}$ (d) $4\sqrt{5}$

8. The four straight lines given by the equations $12x^2 + 7xy - 12y^2 = 0$ and $12x^2 + 7xy - 12y^2 - x + 7y - 1 = 0$ lie along the sides of a
(a) square (b) rhombus
(c) rectangle (d) parallelogram

9. Distance between the parallel lines $4x^2 + 20xy + 25y^2 + 2x + 5y - 12 = 0$ is
(a) $\frac{3}{\sqrt{29}}$ (b) $\frac{5}{\sqrt{29}}$
(c) $\frac{7}{\sqrt{29}}$ (d) $\frac{9}{\sqrt{29}}$

10. The point of intersection of the two lines given by $2x^2 - 5xy + 2y^2 + 3x + 3y + 1 = 0$ is
(a) $(-2, 2)$ (b) $(-3, 3)$
(c) $(3, 3)$ (d) $(2, 2)$

11. If $\alpha, \beta > 0$ and $\alpha < \beta$ and $\alpha x^2 + 4\gamma xy + \beta y^2 + 4p(x + y + 1) = 0$ represents a pair of straight lines, then
(a) $\alpha \le p \le \beta$ (b) $p \le \alpha$
(c) $p \ge \alpha$ (d) $p \le \alpha$ or $p \ge \beta$

12. If the equation of the pair of straight lines passing through the point $(1, 1)$, one making an angle θ with the positive direction of the X-axis and the other making the same angle with the positive direction of the Y-axis, is $x^2 - (a+2)xy + y^2 + a(x + y - 1) = 0$, $a \neq -2$, then the value of $\sin 2\theta$ is
(a) $a - 2$ (b) $a + 2$
(c) $\frac{2}{(a + 2)}$ (d) $\frac{2}{a}$

Pair of Straight Lines Exercise 2 :
More than One Option Correct Type Questions

- This section contains **6 multiple choice questions**. Each questions has four choices (a), (b), (c), (d) out of which **MORE THAN ONE** may be correct.

13. The equation of image of pair of lines $y = |x - 1|$ in Y-axis is
(a) $y = |x + 1|$ (b) $y = |x - 1| + 3$
(c) $x^2 - y^2 + 2x + 1 = 0$ (d) $x^2 - y^2 + 2x - 1 = 0$

14. The equation $ax^2 + by^2 + cx + cy = 0$ represent a pair of straight lines, if
(a) $a + b = 0$
(b) $c = 0$
(c) $a + c = 0$
(d) $c(a + b) = 0$

15. If $x^2 + \alpha y^2 + 2\beta y = a^2$ represents a pair of perpendicular straight lines, then
(a) $\alpha = 1, \beta = a$
(b) $\alpha = 1, \beta = -a$
(c) $\alpha = -1, \beta = -a$
(d) $\alpha = -1, \beta = a$

16. If the pair of lines $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ intersect on Y-axis, then
(a) $f^2 = bc$
(b) $abc = 2fgh$
(c) $bg^2 \neq ch^2$
(d) $2fgh = bg^2 + ch^2$

17. Two pair of straight lines have the equations $y^2 + xy - 12x^2 = 0$ and $ax^2 + 2hxy + by^2 = 0$. One line will be common among them, if
(a) $a = -3(2h + 3b)$ (b) $a = 8(h - 2b)$
(c) $a = 2(b + h)$ (d) $a = -3(b + h)$

18. The combined equation of three sides of a triangle is $(x^2 - y^2)(2x + 3y - 6) = 0$. If $(-2, a)$ is an interior and $(b, 1)$ is an exterior point of the triangle, then
(a) $2 < a < \frac{10}{3}$ (b) $-2 < a < \frac{10}{3}$
(c) $-1 < b < \frac{9}{2}$ (d) $-1 < b < 1$

Pair of Straight Lines Exercise 3 : Paragraph Based Questions

- This section contains **3 paragraphs** based upon each of the paragraph, **3 multiple choice questions** have to be answered. Each of these question has four choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

Paragraph I

(Q. Nos. 19 to 21)

Consider the equation of a pair of straight lines as $x^2 - 3xy + \lambda y^2 + 3x - 5y + 2 = 0$

19. The value of λ is
(a) 1 (b) 2
(c) 3 (d) 4

20. The point of intersection of lines is (α, β), then the value of $\alpha^2 + \beta^2$ is
(a) 2 (b) 5
(c) 10 (d) 17

21. The angle between the lines is θ, then the value of $\cos 2\theta$ is
(a) $\frac{1}{3}$ (b) $\frac{2}{3}$
(c) $\frac{3}{5}$ (d) $\frac{4}{5}$

Paragraph II

(Q. Nos. 22 to 24)

Let $f_1(x, y) \equiv ax^2 + 2hxy + by^2 = 0$ *and let* $f_{i+1}(x, y) = 0$ *denote the equation of the bisectors of* $f_i(x, y) = 0$ *for all* $i = 1, 2, 3, \ldots$

22. $f_3(x, y) = 0$ is
(a) $hx^2 - (a - b)xy - hy^2 = 0$
(b) $(a - b)x^2 + 4hxy - (a - b)y^2 = 0$
(c) $ax^2 + 2hxy + by^2 = 0$
(d) None of the above

23. If $f_{i+1}(x, y) = 0$ represents the equation of a pair of perpendicular lines, then $f_3(x, y) = 0$ is same as
(a) $f_1(x, y) = 0$
(b) $f_2(x, y) = 0$
(c) $hx^2 - (a - b)xy - hy^2 = 0$
(d) None of the above

24. The value of $\sum_{n=2}^{5} \frac{f_{n+2}(x, y)}{f_n(x, y)}$ is
(a) 14 (b) 4
(c) 54 (d) 6

Paragraph III

(Q. Nos. 25 to 27)

Consider a pair of perpendicular straight lines $2x^2 + 3xy + by^2 - 11x + 13y + c = 0$

25. The value of c is
(a) -2 (b) 2
(c) -3 (d) 3

26. The value of $|b + 2c|$ is
(a) 4 (b) 6
(c) 8 (d) 10

27. If point of intersection of lines is C and points of intersection of the lines with the X-axis are A and B, if distance between the orthocentre and the circumcentre of ΔABC is λ, then $[\lambda]$ is (where $[.]$ denotes the greatest integer function
(a) 2 (b) 3
(c) 4 (d) 5

Pair of Straight Lines Exercise 4 :
Single Integer Answer Type Questions

- This section contains **5 questions**. The answer to each question is **a single digit integer**, ranging from 0 to 9 (both inclusive).

28. Equation $\lambda x^3 - 10x^2y - xy^2 + 4y^3 = 0$ represented three straight lines, out of these three, two lines makes equal angle with $y = x$ and $\lambda > 0$, then the value of λ is

29. Area enclosed by curves $y^2 - 5xy + 6x^2 + 3x - y = 0$ and $y^2 - 5xy + 6x^2 + 2x - y = 0$ is λ sq units, then the value of λ is

30. The lines represented by $x^2 + 2\lambda xy + 2y^2 = 0$ and $(\lambda + 1)$ $x^2 - 8xy + y^2 = 0$ are equally inclined, then the value of $|\lambda|$ is

31. If the lines joining the origin to the intersection of the line $y = nx + 2$ and the curve $x^2 + y^2 = 1$ are at right angles, then the value of n^2 is

32. If area of the triangle formed by the line $x + y = 3$ and the angle bisectors of the pair of straight lines $x^2 - y^2 + 2y = 1$ is λ sq units, then the value of λ is

Pair of Straight Lines Exercise 5 :
Matching Type Questions

- This section contains **one question.** This question has four statements (A,B,C and D) given in **Column I** and four statements (p, q, r and s) in **Column II**. Any given statements in **Column I** can have correct matching with one or more statement(s) given in **Column II**.

33. Match the following

	Column I		Column II
(A)	The pair of lines joining the origin to the points of intersection of the curve $9x^2 + 16y^2 = 144$ by the line $2x + 2y + \lambda = 0$ are coincident, then $\|\lambda\|$ is divisible by	(p)	2
(B)	If the straight lines joining the origin to the points of intersection of the straight line $4x + 3y = 24$ and the curve $(x-3)^2 + (y-4)^2 = \lambda^2$, are at right angles, then $\|\lambda\|$ is divisible by	(q)	3
(C)	The two line pairs $y^2 - 4y + 3 = 0$ and $x^2 + 4xy + 4y^2 - 5x - 10y + 4 = 0$ enclose a 4 sided convex polygon, if area of polygon is λ sq units, then λ is divisible by	(r)	5
(D)	If the pairs of lines $3x^2 - 2pxy - 3y^2 = 0$ and $5x^2 - 2qxy - 5y^2 = 0$ are such that each pair bisects the angle between the other pair. If $\lambda = \|pq\|$, then λ is divisible by	(s)	6

Pair of Straight Lines Exercise 6 :
Statement I and II Types Questions

- **Directions** (Q. Nos. 34-37) are Assertion-Reason type questions. Each of these questions contains two statements:
  Statement I (Assertion) and **Statement II** (Reason)
  Each of these questions also has four alternative choices, only one of which is the correct answer. You have to select the correct choice as given below :
  (a) Statement I is true, Statement II is true; Statement II is a correct explanation for Statement I
  (b) Statement I is true, Statement II is true; Statement II is not a correct explanation for Statement I
  (c) Statement I is true, Statement II is false
  (d) Statement I is false, Statement II is true

34. **Statement I** The four straight lines given by $6x^2 + 5xy - 6y^2 = 0$ and $6x^2 + 5xy - 6y^2 - x + 5y - 1 = 0$ are the sides of a square.

Statement II The lines represented by general equation of second degree $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ are perpendicular if $a + b = 0$.

35. **Statement I** Two of the straight lines represented by $dx^3 + cx^2y + bxy^2 + ay^3 = 0$ will be at right angles if $d^2 + bd + bc + a^2 = 0$.

Statement II Product of the slopes of two perpendicular lines is -1.

36. **Statement I** If $\alpha\beta = -1$, then the pair of straight lines $x^2 - 2\alpha xy - y^2 = 0$ and $y^2 + 2\beta xy - x^2 = 0$ are the angle bisector of each other.

Statement II Pair of angle bisector lines of the pair of lines $ax^2 + 2hxy + by^2 = 0$ is $h(x^2 - y^2) = (a - b)xy$.

37. **Statement I** If $a + b = -2h$, then one line of the pair of lines $ax^2 + 2hxy + by^2 = 0$ bisects the angle between coordinate axes in positive quadrant.

Statement II If $ax + y(2h + a) = 0$ is a factor of $ax^2 + 2hxy + by^2 = 0$, then $b + 2h + a = 0$.

Pair of Straight Lines Exercise 7 :
Subjective Type Questions

- In this section, there are **7 subjective questions**.

38. Prove that the straight lines represented by $(y - mx)^2 = a^2(1 + m^2)$ and $(y - nx)^2 = a^2(1 + n^2)$ form a rhombus.

39. Prove that the equation $m(x^3 - 3xy^2) + y^3 - 3x^2y = 0$ represents three straight lines equally inclined to each other.

40. Show that the straight lines $(A^2 - 3B^2)x^2 + 8ABxy + (B^2 - 3A^2)y^2 = 0$ form with the line $Ax + By + C = 0$ an equilateral triangle whose area is $\frac{C^2}{\sqrt{3}(A^2 + B^2)}$

41. Find the equations of the diagonals of the parallelogram formed by the lines $L^2 - aL = 0$ and $L'^2 - aL' = 0$, where $L = x\cos\theta + y\sin\theta - p$ *and* $L' = x\cos\theta' + y\sin\theta' - p'$.

42. If $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ and $ax^2 + 2hxy + by^2 - 2gx - 2fy + c = 0$ each represents a pair of lines, then prove that the area of the parallelogram enclosed by them is $\frac{2|c|}{\sqrt{(h^2 - ab)}}$.

43. Prove that lines $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ are equidistant from the origin, if $f^4 - g^4 = c(bf^2 - ag^2)$. Also, find the product of their distances from the origin.

44. Prove that if two of the lines represented by $ax^4 + bx^3y + cx^2y^2 + dxy^3 + ay^4 = 0$ bisects the angle between the other two, then $c + 6a = 0$ and $b + d = 0$.

Pair of Straight Lines Exercise 8 : Question Asked in Previous 13 Years Exams

- This section contains questions asked in **IIT-JEE, AIEEE, JEE Main & JEE Advanced** from year **2005** to **2017**.

45. If the pair of lines $ax^2+2(a+b)xy+by^2=0$ lie long diameters of a circle and divide the circle into four sectors such that the area of one of the sector is thrice the area of the another sector, then **[AIEEE 2005, 3M]**

(a) $3a^2+2ab+3b^2=0$ (b) $3a^2+10ab+3b^2=0$

(c) $3a^2-2ab+3b^2=0$ (d) $3a^2-10ab+3b^2=0$

46. If one of the lines of $my^2+(1-m^2)xy-mx^2=0$ is a bisector of the angle between the lines $xy=0$, then m is **[AIEEE 2007, 3M]**

(a) $-\frac{1}{2}$ (b) -2

(c) 1 (d) 2

41. $\begin{cases} x(\cos\theta-\cos\theta')+y(\sin\theta-\sin\theta')-p+p'=0 \\ \text{and } x(\cos\theta+\cos\theta')+y(\sin\theta+\sin\theta')-p-p'-a=0 \end{cases}$

43. $\frac{|c|}{\sqrt{(a-b)^2+4h^2}}$

45. (a) **46.** (c)

Solutions

1. $\because m_1 + m_2 = m_1 m_2 \Rightarrow \dfrac{-2\lambda}{-7} = \dfrac{4}{-7}$

$\therefore \quad \lambda = -2$

2. For perpendicular lines

$3a + (a^2 - 2) = 0$

$\Rightarrow \quad a = \dfrac{-3 \pm \sqrt{(9+8)}}{6} = \dfrac{-3 \pm \sqrt{17}}{6}$

3. For mirror image with respect to $y = 0$ replace y by $-y$, then image of the pair of lines $ax^2 + 2hxy + by^2 = 0$ is

$$ax^2 + 2hx(-y) + b(-y)^2 = 0$$

or $$ax^2 - 2hxy + by^2 = 0$$

4. $\because \quad 15x^2 + 56xy + 48y^2 = 0$ ...(i)

$\Rightarrow \quad (3x + 4y)(5x + 12y) = 0$

Equation of lines represented by Eq. (i) are

$3x + 4y = 0$ and $5x + 12y = 0$

Let any point on $7x + 4y + 2 = 0$ is $\left(\lambda, \dfrac{-7\lambda - 2}{4}\right)$.

According to questions,

$$\left|\frac{3\lambda + 4\left(\frac{-7\lambda-2}{4}\right)}{5}\right| = \left|\frac{5\lambda + 12\left(\frac{-7\lambda-2}{4}\right)}{13}\right|$$

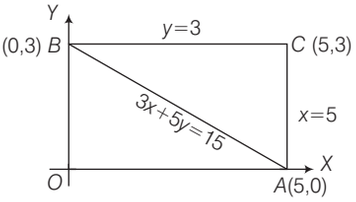
$$\Rightarrow \quad \frac{1}{5}|-4\lambda - 2| = \frac{1}{13}|-16\lambda - 6|$$

$$\Rightarrow \quad \frac{|2\lambda + 1|}{5} = \frac{|8\lambda + 3|}{13}$$

$$\Rightarrow \quad 13(2\lambda + 1) = \pm 5(8\lambda + 3)$$

$$\therefore \quad \lambda = -\frac{1}{7}, -\frac{14}{33}$$

5. Given lines are $xy - 3x - 5y + 15 = 0$



$\Rightarrow \quad (x - 5)(y - 3) = 0$

$\therefore \quad x = 5$ and $y = 3$

Hence, orthocentre is (5, 3).

6. $3x^3 + 3x^2y - 3xy^2 + dy^3 = (x^2 + pxy - y^2)(3x - dy)$

On comparing coefficients of x^2y and xy^2, we get

$$3p - d = 3$$

and $$-3 - pd = -3$$

$\therefore \quad p = 0, \ d = -3$

7. $\because \quad (x - 2y)^2 + \lambda(x - 2y) = 0$

$\Rightarrow \quad (x - 2y)(x - 2y + \lambda) = 0$

$\therefore$ Lines are $x - 2y = 0$ and $x - 2y + \lambda = 0$

Distance between lines = 3 (given)

$\Rightarrow \quad \dfrac{|\lambda - 0|}{\sqrt{(1+4)}} = 3$

$\therefore \quad |\lambda| = 3\sqrt{5}$

8. $\therefore \quad 12x^2 + 7xy - 12y^2 = 0$ ...(i)

$\Rightarrow \quad (3x + 4y)(4x - 3y) = 0$

$\therefore$ Lines represented by Eq. (i) are

$3x + 4y = 0$ and $4x - 3y = 0$

and $12x^2 + 7xy - 12y^2 - x + 7y - 1 = 0$ ...(ii)

$\Rightarrow \quad (3x + 4y - 1)(4x - 3y + 1) = 0$

$\therefore$ Lines represented by Eq. (ii) are

$3x + 4y - 1 = 0$ and $4x - 3y + 1 = 0$

Distance between parallel lines $3x + 4y = 0$ and

$3x + 4y - 1 = 0$ is $\dfrac{1}{5}$.

And distance between parallel lines $4x - 3y = 0$ and

$4x - 3y + 1 = 0$ is $\dfrac{1}{5}$.

Hence, all sides along a square.

9. Given,

$$4x^2 + 20xy + 25y^2 + 2x + 5y - 12 = 0 \quad \text{...(i)}$$

$$\Rightarrow \quad (2x + 5y)^2 + (2x + 5y) - 12 = 0$$

$$\Rightarrow \quad (2x + 5y + 4)(2x + 5y - 3) = 0$$

$\therefore$ Lines represented by Eq. (i) are

$2x + 5y + 4 = 0$ and $2x + 5y - 3 = 0$

Hence, distance between parallel lines $= \dfrac{|4 - (-3)|}{\sqrt{4 + 25}} = \dfrac{7}{\sqrt{29}}$.

10. Let $f(x, y) \equiv 2x^2 - 5xy + 2y^2 + 3x + 3y + 1 = 0$

$\therefore \quad \dfrac{\partial f}{\partial x} = 4x - 5y + 3$ and $\dfrac{\partial f}{\partial y} = -5x + 4y + 3$

For point of intersection $\dfrac{\partial f}{\partial x} = 0$ and $\dfrac{\partial f}{\partial y} = 0$

$\Rightarrow \ 4x - 5y + 3 = 0$ and $-5x + 4y + 3 = 0$, we get

$x = 3, y = 3$

$\therefore$ Point of intersection is (3, 3).

11. $\alpha x^2 + 4\gamma\, xy + \beta y^2 + 4p(x + y + 1) = 0$

represents a pair of straight lines.

$\therefore \ \Delta = 0$

$\Rightarrow 4\alpha\beta p + 16p^2\gamma - 4p^2\alpha - 4p^2\beta - 16\gamma^2 p = 0$

$\Rightarrow \quad (16p)\gamma^2 - 16p^2\gamma + 4p(p\alpha + p\beta - \alpha\beta) = 0$

$\therefore \quad B^2 - 4AC \geq 0$

$\Rightarrow \quad (16p^2)^2 - 4 \cdot (16p) \cdot 4p\,(p\alpha + p\beta - \alpha\beta) \geq 0$

$\Rightarrow \quad p^2(p^2 - p\alpha - p\beta + \alpha\beta) \geq 0$

$\Rightarrow \quad (p - \alpha)(p - \beta) \geq 0$

$\therefore \quad p \leq \alpha$ or $p \geq \beta \quad [\because \alpha < \beta]$

12. Equation of first line is $y-1=\tan\theta(x-1)$

Equation of second line is $y-1=\cot\theta(x-1)$

So, their joint equation is

$$[(y-1)-\tan\theta(x-1)][(y-1)-\cot\theta(x-1)]=0$$

$$\Rightarrow (y-1)^2-(x-1)(y-1)(\tan\theta+\cot\theta)+(x-1)^2=0$$

$$x^2-(\tan\theta+\cot\theta)xy+y^2+(\tan\theta+\cot\theta-2)(x+y-1)=0$$

On comparing with the given equation, we get

$$\tan\theta+\cot\theta=a+2$$

or $$\frac{1}{\sin\theta\cos\theta}=a+2$$

or $$\sin 2\theta=\frac{2}{(a+2)}$$

13. For image w.r.t., Y-axis replace x by $-x$, then required image of lines is

$$y=|-x-1| \text{ or } y=|x+1|$$

and on squaring both sides, then

$$y^2=x^2+2x+1$$

$$\Rightarrow x^2-y^2+2x+1=0$$

14. Given equation is

$$ax^2+by^2+cx+cy=0 \quad ...(i)$$

Eq. (i) represents a pair of straight lines.

$$\therefore \Delta=0$$

$$\Rightarrow 0+2\cdot 0-a\times\frac{c^2}{4}-b\times\frac{c^2}{4}=0$$

or $$c^2(a+b)=0$$

$$\therefore c=0 \text{ or } a+b=0$$

15. Given, equation is

$$x^2+\alpha y^2+2\beta y-a^2=0 \quad ...(i)$$

Equation (i) represents a pair of perpendicular straight lines

$\therefore \Delta=0$ and coefficient of x^2 + coefficient of $y^2=0$

$$\Rightarrow -a^2\alpha-\beta^2=0 \text{ and } 1+\alpha=0$$

$$\therefore \alpha=-1 \text{ and } \beta=\pm a$$

16. Given pair of lines is

$$ax^2+2hxy+by^2+2gx+2fy+c=0 \quad ...(i)$$

$\because$ Point of intersection of lines represented by (i) is

$$\left(\frac{hf-bg}{ab-h^2},\frac{gh-af}{ab-h^2}\right) \text{ or } \left(\sqrt{\left(\frac{f^2-bc}{h^2-ab}\right)},\sqrt{\left(\frac{g^2-ac}{h^2-ab}\right)}\right)$$

For Y-axis put $x=0$

$\therefore$ $hf=bg$, $f^2=bc$ and $h^2\neq ab$

Also, $\Delta=0$

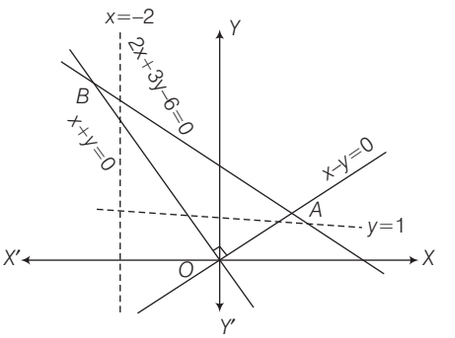
$\therefore$ $abc+2fgh-af^2-bg^2-ch^2=0$

For $$f^2=bc, 2fgh=bg^2+ch^2$$

17. Let $y=mx$ be the common line, then $m^2+m-12=0$ and $bm^2+2hm+a=0$, then from first equation $m=-4, 3$

Substitute $m=-4$ in second equation, then $a=8(h-2b)$ and substitute $m=3$ in second equation, then $a=-3(2h+3b)$.

18. The separate equations of the sides are $x+y=0$, $x-y=0$ and $\frac{x}{3}+\frac{y}{2}=1$.



Intersection of $x=-2$ with $y=-x$ and $2x+3y-6=0$ gives the range of values of a.

$$\therefore 2<a<\frac{10}{3}$$

and intersection of $y=1$ with $y=x$ and $2x+3y-6=0$ given the range of values of b

$$-1<b<1 \quad [\because (b,1) \text{ is exterior point}]$$

Sol. (Q. Nos. 19 to 21)

Given equation is $x^2-3xy+\lambda y^2+3x-5y+2=0$

Here, $a=1, b=\lambda, c=2,$

$$f=-\frac{5}{2}, g=\frac{3}{2} \text{ and } h=-\frac{3}{2}.$$

19. $\Delta=0$

$$1\times\lambda\times 2+2\times-\frac{5}{2}\times\frac{3}{2}\times-\frac{3}{2}-1\times\frac{25}{4}-\lambda\times\frac{9}{4}-2\times\frac{9}{4}=0$$

$$\Rightarrow 2\lambda+\frac{45}{4}-\frac{25}{4}-\frac{9\lambda}{4}-\frac{9}{2}=0$$

$$\Rightarrow -\frac{\lambda}{4}+\frac{1}{2}=0$$

$$\therefore \lambda=2$$

20. Let $f(x,y)=x^2-3xy+2y^2+3x-5y+2$ $[\because \lambda=2]$

$$\therefore \frac{\partial f}{\partial x}=2x-3y+3, \frac{\partial f}{\partial y}=-3x+4y-5$$

For point of intersection $\frac{\partial f}{\partial x}=0$ and $\frac{\partial f}{\partial y}=0$, we get

$$x=-3, y=-1$$

$$\therefore \alpha=-3 \text{ and } \beta=-1$$

$\therefore$ The value of $\alpha^2+\beta^2$ is 10.

21. $$\tan\theta=\frac{2\sqrt{(h^2-ab)}}{(a+b)}=\frac{2\sqrt{\left(\frac{9}{4}-2\right)}}{1+2}=\frac{1}{3}$$

$$\therefore \cos 2\theta=\frac{1-\tan^2\theta}{1+\tan^2\theta}=\frac{1-\frac{1}{9}}{1+\frac{1}{9}}=\frac{4}{5}$$

Solutions (Q. Nos. 22 to 24)

22. $\because \quad f_1(x, y) \equiv ax^2 + 2hxy + by^2 = 0$ ...(i)

bisectors of $f_1(x, y)$ is $f_2(x, y)$

$\therefore$ Equation of bisectors of (i) is $\dfrac{x^2 - y^2}{a - b} = \dfrac{xy}{h}$

$\Rightarrow \quad hx^2 - (a - b)xy - hy^2 = 0$

$\therefore \quad f_2(x, y) \equiv hx^2 - (a - b)xy - hy^2 = 0$ ...(ii)

Now, equation of bisectors of (ii) is

$$\frac{x^2 - y^2}{h - (-h)} = \frac{xy}{-\dfrac{(a - b)}{2}}$$

$\Rightarrow \quad \dfrac{x^2 - y^2}{2h} = -\dfrac{2xy}{(a - b)}$

$\Rightarrow \quad (a - b)x^2 + 4hxy - (a - b)y^2 = 0$

$\therefore \quad f_3(x, y) \equiv (a - b)x^2 + 4hxy - (a - b)y^2 = 0$

23. $f_2(x, y) \equiv bx^2 - 2hxy + ay^2 = 0$

and $f_3(x, y) \equiv ax^2 + 2hxy + by^2 = 0$

is same as $f_1(x, y) = 0$

24. For all $n \geq 2$

$$f_{n+2}(x, y) = f_n(x, y)$$

$\therefore \quad \dfrac{f_{n+2}(x, y)}{f_n(x, y)} = 1$

Now, $\displaystyle\sum_{n=2}^{5} \frac{f_{n+2}(x, y)}{f_n(x, y)} = \sum_{n=2}^{5} 1 = 1 + 1 + 1 + 1 = 4$

Sol. (Q. Nos. 25 to 27)

For perpendicular straight lines, then
coefficient of x^2 + coefficient of $y^2 = 0$

$\Rightarrow \quad 2 + b = 0$

$\therefore \quad b = -2$

25. $2x^2 + 3xy - 2y^2 - 11x + 13y + c = 0$

represents a pair of straight lines, then we have

$$2 \times -2 \times c + 2 \times \frac{13}{2} \times -\frac{11}{2} \times \frac{3}{2} - 2 \times \frac{169}{4} + 2 \times \frac{121}{4} - c \times \frac{9}{4} = 0$$

$\Rightarrow \quad -4c - \dfrac{429}{4} - \dfrac{169}{2} + \dfrac{121}{2} - \dfrac{9c}{4} = 0$

$\Rightarrow \quad c = -2$

26. $|b + 2c| = |-2 - 4| = 6$

27. Now, pair of lines is $2x^2 + 3xy - 2y^2 - 11x + 13y - 2 = 0$

Let $f(x, y) \equiv 2x^2 + 3xy - 2y^2 - 11x + 13y - 2 = 0$

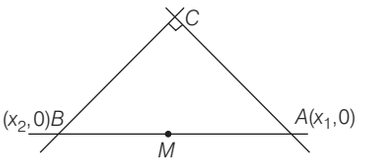
$\therefore \quad \dfrac{\partial f}{\partial x} = 4x + 3y - 11$ and $\dfrac{\partial f}{\partial y} = 3x - 4y + 13$

For point of intersection, $\dfrac{\partial f}{dx} = 0$ and $\dfrac{\partial f}{\partial y} = 0$

$\Rightarrow \quad 4x + 3y - 11 = 0$ and $3x - 4y + 13 = 0$

$\therefore \quad C \equiv \left(\dfrac{1}{5}, \dfrac{19}{5}\right)$

Also, intersection on X-axis put $y = 0$.



$\therefore \quad 2x^2 - 11x + 2 = 0 \Rightarrow x_1 + x_2 = \dfrac{11}{2}$

$\therefore$ Circumcentre of $\Delta ABC \Rightarrow M\left(\dfrac{x_1 + x_2}{2}, 0\right)$

$\therefore \quad M \equiv \left(\dfrac{11}{4}, 0\right)$

and orthocentre is $C \equiv \left(\dfrac{1}{5}, \dfrac{19}{5}\right)$

$\therefore$ Required distance $= \sqrt{\left(\dfrac{11}{4} - \dfrac{1}{5}\right)^2 + \left(0 - \dfrac{19}{5}\right)^2}$

$\therefore \quad \lambda = \sqrt{\dfrac{8377}{400}} = \sqrt{20.94} = 4.57$

$$[\lambda] = [4.57] = 4$$

28. Given, $4y^3 - xy^2 - 10x^2y + \lambda x^3 = 0$

$\Rightarrow \quad 4\left(\dfrac{y}{x}\right)^3 - \left(\dfrac{y}{x}\right)^2 - 10\left(\dfrac{y}{x}\right) + \lambda = 0$

Let $y = mx$, then

$$4m^3 - m^2 - 10m + \lambda = 0$$

and let m_1, m_2, m_3 be the slopes of three lines, then

$$m_1 + m_2 + m_3 = \frac{1}{4} \quad \text{...(i)}$$

$$m_1m_2 + m_2m_3 + m_3m_1 = -\frac{10}{4} \quad \text{...(ii)}$$

$$m_1m_2m_3 = -\frac{\lambda}{4} \quad \text{...(iii)}$$

Since, two lines are equally inclined with $y = x$, so let $m_2m_3 = 1$

From Eq. (iii), $m_1 = -\dfrac{\lambda}{4}$

From Eq. (i), $m_2 + m_3 = \dfrac{\lambda + 1}{4}$ ...(iv)

and from Eq. (ii), $1 + \left(-\dfrac{\lambda}{4}\right)\left(\dfrac{\lambda + 1}{4}\right) = -\dfrac{10}{4}$

$\Rightarrow \quad 16 - \lambda^2 - \lambda = -40$

$\Rightarrow \quad \lambda^2 + \lambda - 56 = 0$

$\Rightarrow \quad (\lambda + 8)(\lambda - 7) = 0$

$\lambda = -8, 7$

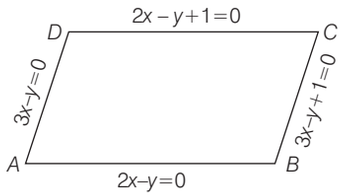
Hence, $\lambda = 7 \quad [\because \lambda > 0]$

29. $\because y^2 - 5xy + 6x^2 + 3x - y = 0$

$\Rightarrow \quad (3x - y)(2x - y + 1) = 0$

and $y^2 - 5xy + 6x^2 + 2x - y = 0$

$\Rightarrow \quad (3x - y + 1)(2x - y) = 0$



$\therefore$ Required Area $= \dfrac{(1-0)(1-0)}{\begin{vmatrix} 3 & -1 \\ 2 & -1 \end{vmatrix}} = 1$ sq unit

$\therefore \quad \lambda = 1$

30. Given pairs are

$$x^2 + 2\lambda xy + 2y^2 = 0 \quad \text{...(i)}$$

and $$(\lambda + 1)x^2 - 8xy + y^2 = 0 \quad \text{...(ii)}$$

$\because$ Equations of angle bisectors of (i) and (ii) are equal

$\Rightarrow \dfrac{x^2 - y^2}{1 - 2} = \dfrac{xy}{\lambda}$ and $\dfrac{x^2 - y^2}{(\lambda + 1) - 1} = \dfrac{xy}{-4}$ must be same

$\Rightarrow \quad \dfrac{\lambda}{-1} = -\dfrac{4}{\lambda} \Rightarrow \lambda^2 = 4 \Rightarrow \lambda = \pm 2$

$\therefore \quad |\lambda| = 2$

31. Given, $$\frac{y - nx}{2} = 1 \quad \text{...(i)}$$

and $$x^2 + y^2 = 1 \quad \text{...(ii)}$$

Homogenising Eq. (ii) with Eq. (i), we get

$$x^2 + y^2 = \left(\frac{y - nx}{2}\right)^2$$

$$\Rightarrow \quad \left(\frac{n^2}{4} - 1\right)x^2 - nxy + \left(\frac{1}{4} - 1\right)y^2 = 0$$

or $$(n^2 - 4)x^2 - 4nxy - 3y^2 = 0$$

The lines will be at right angles, when

$$(n^2 - 4) + (-3) = 0 \Rightarrow n^2 = 7$$

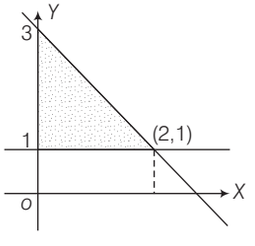
32. $\because \quad x^2 - y^2 + 2y = 1$

$$\Rightarrow \quad x^2 = (y^2 - 2y + 1) = (y - 1)^2$$

$$\Rightarrow \quad x = \pm (y - 1)$$

i.e. $\quad x - y + 1 = 0$ and $x + y - 1 = 0$

$\therefore$ Bisectors are $y = 1$ and $x = 0$



So, area between $x = 0$, $y = 1$ and $x + y = 3$ is given by

$$\frac{1}{2} \times 2 \times 2 = 2 \text{ sq units}$$

$\therefore \quad \lambda = 2$

33. (A) $\rightarrow$ (p, r); (B) $\rightarrow$ (r); (C) $\rightarrow$ (p, q, s); (D) $\rightarrow$ (q, r)

(A) Given $$\frac{2x + 2y}{-\lambda} = 1 \quad \text{...(i)}$$

and $$9x^2 + 16y^2 = 144 \quad \text{...(ii)}$$

Homogenising Eq. (ii) with Eq. (i), we get

$$9x^2 + 16y^2 = 144\left(\frac{2x + 2y}{-\lambda}\right)^2$$

$$\Rightarrow \quad (9\lambda^2 - 576)x^2 - 1152xy + (16\lambda^2 - 576)y^2 = 0$$

The lines are coincident, then

$$(-576)^2 = (9\lambda^2 - 576)(16\lambda^2 - 576)$$

$$\Rightarrow \quad 144\lambda^4 - 576\lambda^2(25) = 0$$

or $$\lambda^2 = 100$$

$\therefore \quad |\lambda| = 10$

(B) Given, $$\frac{4x + 3y}{24} = 1 \quad \text{...(i)}$$

and $$(x - 3)^2 + (y - 4)^2 = \lambda^2$$

or $$x^2 + y^2 - (6x + 8y) + 25 - \lambda^2 = 0 \quad \text{...(ii)}$$

Homogenising Eq. (ii) with Eq. (i), we get

$$x^2 + y^2 - (6x + 8y)\frac{(4x + 3y)}{24} + (25 - \lambda^2)\left(\frac{4x + 3y}{24}\right)^2 = 0$$

$$\Rightarrow \quad 16(25 - \lambda^2)x^2 + 9(25 - \lambda^2)y^2 + (-600 - 24\lambda^2)xy = 0$$

The lines will be at right angles, when

$$16(25 - \lambda^2) + 9(25 - \lambda^2) = 0$$

$$\Rightarrow \quad 625 - 25\lambda^2 = 0$$

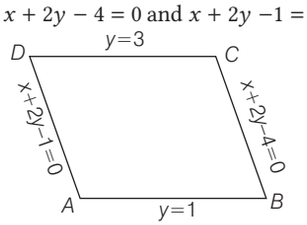
$$\Rightarrow \quad \lambda^2 = 25$$

$\therefore \quad |\lambda| = 5$

(C) The lines pairs are $(y - 1)(y - 3) = 0$ i.e. $y = 1$ and $y = 3$
the other line pair is $x^2 + 4xy + 4y^2 - 5x - 10y + 4 = 0$

i.e. $\quad (x + 2y - 4)(x + 2y - 1) = 0$

or $\quad x + 2y - 4 = 0$ and $x + 2y - 1 = 0$



Required area $= \dfrac{(3-1)(4-1)}{\begin{vmatrix} 1 & 2 \\ 0 & 1 \end{vmatrix}} = 6$ sq units

$\therefore \quad \lambda = 6$

(D) Equation of the bisectors of $3x^2 - 2pxy - 3y^2 = 0$ is

$$\frac{x^2 - y^2}{3 - (-3)} = \frac{xy}{-p} \Rightarrow px^2 + 6xy - py^2 = 0$$

Which is same as $5x^2 - 2qxy - 5y^2 = 0$

i.e. $$\frac{p}{5} = \frac{6}{-2q} = \frac{-p}{-5} \Rightarrow pq = -15$$

$\therefore \quad \lambda = |pq| = |-15| = 15$

34. $\because$ Lines represented by $6x^2 + 5xy - 6y^2 = 0$ are $l_1 : 2x + 3y = 0$, $l_2 : 3x - 2y = 0$

and lines represented by

$$6x^2 + 5xy - 6y^2 - x + 5y - 1 = 0$$

are $l_3 : 2x + 3y - 1 = 0$

$l_4 : 3x - 2y + 1 = 0$

$\because$ $l_1 \perp l_2, l_2 \perp l_3, l_3 \perp l_4$ and $l_4 \perp l_1$.

Also, l_1, l_2 intersect at $(0, 0)$ and $(0, 0)$ is equidistant from l_3 and l_4. These lines form sides of square.

$\therefore$ Statement I is true.

Statement II is true but Statement II is not a correct explanation for Statement I.

35. $dx^3 + cx^2y + bxy^2 + ay^3 = (x^2 + pxy - y^2)(dx - ay)$

On comparing, we get

$$c = -a + pd \implies p = \frac{c + a}{d} \quad \text{...(i)}$$

and $$b = -ap - d \implies p = \frac{-b - d}{a} \quad \text{...(ii)}$$

From Eq. (i) and Eq. (ii),

$$\frac{c + a}{d} = \frac{-b - d}{a}$$

$$\Rightarrow \quad d^2 + bd + ac + a^2 = 0$$

$\therefore$ Statement I is true.

Hence, both statements are true but Statement II is not correct explanation for Statement I.

36. Pair of bisectors between the lines $x^2 - 2\alpha xy - y^2 = 0$ is

$$\frac{x^2 - y^2}{1 - (-1)} = \frac{xy}{-\alpha}$$

$$\Rightarrow \quad \alpha x^2 + 2xy - \alpha y^2 = 0 \quad \text{...(i)}$$

Comparing it with $y^2 + 2\beta xy - x^2 = 0$, then

$$-\frac{\alpha}{1} = \frac{1}{\beta} = \frac{\lambda}{-1}$$

$$\Rightarrow \quad \alpha\beta = -1$$

Hence, both statements are true and Statement II is correct explanation for Statement I.

37. Put $2h = -(a + b)$ in $ax^2 + 2hxy + by^2 = 0$

$$\Rightarrow \quad ax^2 - (a + b)xy + by^2 = 0$$

$$\Rightarrow \quad (x - y)(ax - by) = 0$$

$\Rightarrow$ One of the line bisects the angle between coordinate axes in positive quadrant.

Also, put $b = -2h - a$ in $ax - by$, we have

$$ax - by = ax - (-2h - a)y$$
$$= ax + (2h + a)y$$

Hence, $ax + (2h + a)y$ is a factor of

$$ax^2 + 2hyx + by^2 = 0$$

$\therefore$ Both statements are true but Statement II is not correct explanation for Statement I.

38. From $(y - mx)^2 = a^2(1 + m^2)$

$$\Rightarrow \quad y - mx = \pm a\sqrt{(1 + m^2)}$$

$\therefore$ Lines $\quad y - mx = a\sqrt{1 + m^2}$ ...(i)

and $\quad y - mx = -a\sqrt{1 + m^2}$ ...(ii)

and from $\quad (y - nx)^2 = a^2(1 + n^2)$

$$\Rightarrow \quad y - nx = \pm a\sqrt{(1 + n^2)}$$

$\therefore$ Lines $\quad y - nx = a\sqrt{1 + n^2}$ ...(iii)

and $\quad y - nx = -a\sqrt{1 + n^2}$ ...(iv)

Since, lines (i) and (ii) are parallel, the distance between lines (i) and (ii) is

$$\frac{|a\sqrt{1 + m^2} + a\sqrt{1 + m^2}|}{\sqrt{1 + m^2}} = |2a|$$

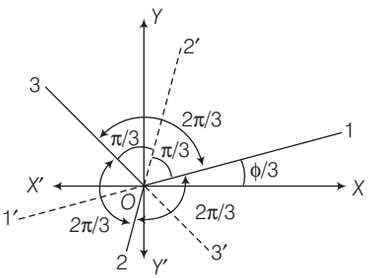
Similarly, (iii) and (iv) are parallel lines and the distance between them $= |2a|$. Therefore, distance between parallel lines are same.

Hence, lines (i), (ii), (iii) and (iv) form a rhombus.

39. Dividing by x^3, the given equation can be written as

$$m\left(1 - 3\left(\frac{y}{x}\right)^2\right) + \left(\frac{y}{x}\right)^3 - 3\left(\frac{y}{x}\right) = 0$$

writing $\frac{y}{x} = \tan\theta$, we have



$$m(1 - 3\tan^2\theta) + \tan^3\theta - 3\tan\theta = 0$$

$$\therefore \quad m = \frac{3\tan\theta - \tan^3\theta}{1 - 3\tan^2\theta} = \tan 3\theta$$

Let $\quad m = \tan\phi$,

then $\quad \tan 3\theta = \tan\phi$

$$\therefore \quad 3\theta = \phi, \quad \phi + \pi, \quad \phi + 2\pi$$

$$\Rightarrow \quad \theta = \frac{\phi}{3}, \quad \frac{\phi}{3} + \frac{\pi}{3}, \quad \frac{\phi}{3} + \frac{2\pi}{3}$$

Thus, the given equation represents three lines through the origin and they are inclined at angles $\frac{\phi}{3}, \frac{\phi}{3} + \frac{\pi}{3}, \frac{\phi}{3} + \frac{2\pi}{3}$ with the X-axis. Clearly, they are equally inclined to each other.

40. Given pair of lines is

$$(A^2 - 3B^2)x^2 + 8ABxy + (B^2 - 3A^2)y^2 = 0 \quad \ldots(i)$$

Given line is $Ax + By + C = 0$ ...(ii)

Comparing Eq. (i) with $ax^2 + 2hxy + by^2 = 0$

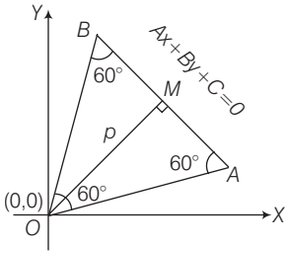
$$a = A^2 - 3B^2,\ h = 4AB,\ b = B^2 - 3A^2$$

If θ be the acute angle between the lines represented by Eq. (i), then

$$\tan\theta = \frac{2\sqrt{(h^2 - ab)}}{|a + b|} = \frac{2\sqrt{16A^2B^2 - (A^2 - 3B^2)(B^2 - 3A^2)}}{|(A^2 - 3B^2 + B^2 - 3A^2)|}$$

$$= \frac{2\sqrt{(3A^4 + 3B^4 + 6A^2B^2)}}{|-2(A^2 + B^2)|} = \frac{\sqrt{3}(A^2 + B^2)}{(A^2 + B^2)} = \sqrt{3}$$

$\therefore \quad \theta = 60°$



Eq. (i) can be written as

$$(B^2 - 3A^2)\left(\frac{y}{x}\right)^2 + 8AB\left(\frac{y}{x}\right) + (A^2 - 3B^2) = 0$$

Solving for y/x, we have

$$\frac{y}{x} = \frac{-8AB \pm \sqrt{64A^2B^2 - 4(B^2 - 3A^2)(A^2 - 3B^2)}}{2(B^2 - 3A^2)}$$

$$= \frac{-4AB \pm \sqrt{16A^2B^2 - (A^2B^2 - 3B^4 - 3A^4 + 9A^2B^2)}}{(B^2 - 3A^2)}$$

$$\Rightarrow \quad \frac{y}{x} = \frac{-4AB \pm \sqrt{3}(A^2 + B^2)}{(B^2 - 3A^2)}$$

$$\Rightarrow \quad y = \left\{\frac{-4AB \pm \sqrt{3}\,(A^2 + B^2)}{B^2 - 3A^2}\right\}x$$

Taking the positive sign, slope of one of the lines

$$= \frac{\sqrt{3}\,(A^2 + B^2) - 4AB}{B^2 - 3A^2}$$

and slope of the line $Ax + By + C = 0$ is $-A/B$.

Acute angle between these lines

$$= \tan^{-1}\left|\frac{\dfrac{\sqrt{3}(A^2 + B^2) - 4AB}{B^2 - 3A^2} + \dfrac{A}{B}}{1 - \left(\dfrac{A}{B}\right)\left[\dfrac{\sqrt{3}(A^2 + B^2) - 4AB}{B^2 - 3A^2}\right]}\right|$$

$$= \tan^{-1}\left|\frac{-3A^2 + \sqrt{3}\,A^2B - 3AB^2 + \sqrt{3}B^3}{-\sqrt{3}A^3 + A^2B - \sqrt{3}AB^2 + B^3}\right|$$

$$= \tan^{-1}(\sqrt{3}) = 60°$$

then remaining third angle is $180° - (60° + 60°) = 60°$.

$\therefore$ The ΔAOB is equilateral.

In ΔOAB,

Length of $\perp$ from O on AB $= p = OM = \dfrac{|0 + 0 + C|}{\sqrt{(A^2 + B^2)}}$

$$p = \frac{|C|}{\sqrt{(A^2 + B^2)}}$$

and in ΔOAM,

$$\sin 60° = \frac{p}{OA} \quad \Rightarrow \quad OA = \frac{2p}{\sqrt{3}}$$

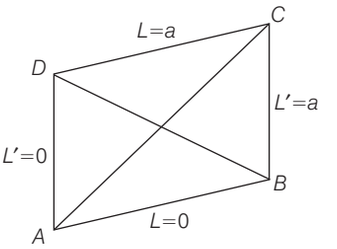
$$\therefore \qquad OA = \frac{2|C|}{\sqrt{3}\sqrt{(A^2 + B^2)}}$$

$\therefore$ Area of the equilateral triangle $= \dfrac{\sqrt{3}}{4}(\text{side})^2 = \dfrac{\sqrt{3}}{4}(OA)^2$

$$= \frac{\sqrt{3}}{4} \times \frac{4|C|^2}{3 \times (A^2 + B^2)} = \frac{C^2}{\sqrt{3}(A^2 + B^2)}$$

41. Lines of parallelogram are

$$L = 0,\ L = a$$
$$L' = 0,\ L' = a$$



where, $L = x\cos\theta + y\sin\theta - p$

$$L' = x\cos\theta' + y\sin\theta' - p'$$

Equation of the line AC, through the point of intersection of $L = 0$ and $L' = 0$ is

$$L + \lambda L' = 0$$

It also passes through

$$L = a \text{ and } L' = a, \quad \ldots(i)$$

then, $\quad a + \lambda a = 0$

$\therefore \qquad \lambda = -1$

Hence, diagonal of AC is $L - L' = 0$

i.e. $\quad x(\cos\theta - \cos\theta') + y(\sin\theta - \sin\theta') - p + p' = 0$

Equation of the line BD through point of intersection of $L = 0$ and $L' = a$ is

$$L + \lambda(L' - a) = 0$$

it also passes through $L = a$ and $L' = 0$.

$\therefore \quad a + \lambda(0 - a) = 0$

$\therefore \quad \lambda = 1$

Equation of diagonal BD is $L + L' - a = 0$

$\Rightarrow x(\cos\theta + \cos\theta') + y(\sin\theta + \sin\theta') - p - p' - a = 0$

42. Let the first equation represents lines

$$(lx + my + n)(l_1x + m_1y + n_1) = 0$$

then the second equation represents lines

$$(lx + my - n)(l_1x + m_1y - n_1) = 0$$

On comparing coefficients, $ll_1 = a, mm_1 = b, nn_1 = c$

$$mn_1 + m_1n = 2f, nl_1 + n_1l = 2g, \; lm_1 + l_1 m = 2h.$$

Let the angle between two non-parallel lines be θ, then

$$\tan\theta = \frac{2\sqrt{(h^2 - ab)}}{|a + b|}$$

$$\therefore \quad \sin\theta = \frac{2\sqrt{(h^2 - ab)}}{\sqrt{(a - b)^2 + 4h^2}}$$

$\therefore$ Area of parallelogram $= \dfrac{p_1p_2}{\sin\theta}$,

where, p_1 and p_2 are distance between two parallel sides.

$$\therefore \quad p_1 = \frac{|n - (-n)|}{\sqrt{l^2 + m^2}} \text{ and } p_2 = \frac{|n_1 - (-n_1)|}{\sqrt{l_1^2 + m_1^2}}$$

$$\therefore \quad p_1p_2 = \frac{|4nn_1|}{\sqrt{(l^2l_1^2 + l^2m_1^2 + m^2l_1^2 + m^2m_1^2)}}$$

$$= \frac{4|nn_1|}{\sqrt{\{l^2l_1^2 + m^2m_1^2 + (lm_1 + l_1m)^2 - 4ll_1mm_1\}}}$$

$$= \frac{4|c|}{\sqrt{a^2 + b^2 + 4h^2 - 2ab}} = \frac{4|c|}{\sqrt{(a - b)^2 + 4h^2}}$$

$$\therefore \quad \text{Area} = \frac{p_1p_2}{\sin\theta}$$

$$= \frac{4|c|}{(\sqrt{(a - b)^2 + 4h^2})\left(\dfrac{2\sqrt{h^2 - ab}}{\sqrt{(a - b)^2 + 4h^2}}\right)}$$

$$= \frac{2|c|}{\sqrt{(h^2 - ab)}}$$

43. Given, equation

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

represents two lines

$$lx + my + n = 0 \quad \text{and} \quad l_1x + m_1y + n_1 = 0$$

then, $ax^2 + 2hxy + by^2 + 2gx + 2fy + c$

$$= (lx + my + n)(l_1x + m_1y + n_1)$$

Comparing the coefficients of similar terms, we get

$$\left.\begin{aligned} &ll_1 = a, mm_1 = b, nn_1 = c \\ &lm_1 + ml_1 = 2h, n_1l + nl_1 = 2g, nm_1 + n_1m = 2f \end{aligned}\right\} \quad \ldots(\text{i})$$

Since, the lines $lx + my + n = 0$ and $l_1x + m_1y + n_1 = 0$ are equidistant from the origin, then

$$\frac{|n|}{\sqrt{l^2 + m^2}} = \frac{|n_1|}{\sqrt{l_1^2 + m_1^2}}$$

$$\Rightarrow \quad n^2l_1^2 + n^2m_1^2 = n_1^2l^2 + n_1^2m^2$$

$$\Rightarrow \quad n^2l_1^2 - n_1^2l^2 = n_1^2m^2 - n^2m_1^2$$

$$\Rightarrow (nl_1 - n_1l)(nl_1 + n_1l) = (n_1m - nm_1)(n_1m + nm_1)$$

On squaring both sides, we get

$$(nl_1 - n_1l)^2 (nl_1 + n_1l)^2 = (n_1m - nm_1)^2(n_1m + nm_1)^2$$

$$\Rightarrow \quad [(nl_1 + n_1l)^2 - 4ll_1nn_1][nl_1 + n_1l]^2$$

$$= [(n_1m + nm_1)^2 - 4mm_1nn_1][n_1m + nm_1]^2$$

$$\Rightarrow \quad (4g^2 - 4ac)(4g^2) = (4f^2 - 4bc)(4f^2)$$

[using the six relations]

$$\Rightarrow \quad (g^2 - ac)g^2 = (f^2 - bc)f^2 \qquad \text{[from Eq. (i)]}$$

$$\Rightarrow \quad f^4 - g^4 = c(bf^2 - ag^2)$$

Also, product of distances from origin to the lines represented by

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$

is $\dfrac{|n|}{\sqrt{(l^2 + m^2)}} \cdot \dfrac{|n_1|}{\sqrt{(l_1^2 + m_1^2)}}$

$$= \frac{|nn_1|}{\sqrt{(l^2l_1^2 + l^2m_1^2 + m^2l_1^2 + m^2m_1^2)}}$$

$$= \frac{|nn_1|}{\sqrt{(l^2l_1^2 + l^2m_1^2 + m^2l_1^2 + m^2m_1^2)}}$$

$$= \frac{|nn_1|}{\sqrt{(l^2l_1^2 + m^2m_1^2 + (lm_1 + ml_1)^2 - 2ll_1mm_1)}}$$

$$= \frac{|c|}{\sqrt{(a^2 + b^2 + 4h^2 - 2ab)}} \qquad \text{[from Eq. (i)]}$$

$$= \frac{|c|}{\sqrt{(a - b)^2 + 4h^2}}$$

44. We know that bisectors are mutually perpendicular to each other, then

$$ax^4 + bx^3y + cx^2y^2 + dxy^3 + ay^4 = 0$$

represents two pairs of mutually perpendicular lines.

Let $ax^4 + bx^3y + cx^2y^2 + dxy^3 + ay^4$

$$= (ax^2 + pxy - ay^2)(x^2 + qxy - y^2)$$

where, p and q are constants.

Comparing the coefficients of similar terms, we get

$$b = aq + p \qquad \ldots(\text{i})$$

$$c = pq - 2a \qquad \ldots(\text{ii})$$

$$d = -p - aq \qquad \ldots(\text{iii})$$

On adding Eqs. (i) and (iii), we have

$$b + d = 0$$

From Eq. (ii), $pq = c + 2a$ ...(iv)

But given that bisectors of one pair are given by the other, i.e.

$$\frac{x^2 - y^2}{a - (-a)} = \frac{xy}{(p/2)}$$

$$\Rightarrow \quad \frac{x^2 - y^2}{4xy} = \frac{a}{p} \qquad \text{...(v)}$$

is the same as the other pair.

$$x^2 + qxy - y^2 = 0$$

or $$\frac{x^2 - y^2}{4xy} = -\frac{q}{4} \qquad \text{...(vi)}$$

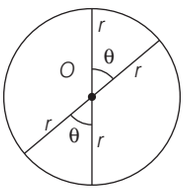
From Eqs. (v) and (vi), $\frac{a}{p} = -\frac{q}{4}$

$$\therefore \quad pq = -4a$$

Again from Eq. (iv), $-4a = c + 2a$

$$\therefore \quad c + 6a = 0$$

45. Let A be the area of small sector, then area of major sector is $3A$.



$$\therefore \quad A + 3A + A + 3A = \pi r^2$$

$$\Rightarrow \quad A = \frac{\pi}{8} r^2$$

$$\Rightarrow \quad \frac{1}{2} r^2\theta = \frac{\pi}{8} r^2 \quad [\because \text{area of sector} = \frac{1}{2} r^2\theta]$$

$$\therefore \quad \theta = \frac{\pi}{4}$$

$\therefore$ Angle between lines represented by

$ax^2 + 2(a + b)xy + by^2 = 0$ is $\frac{\pi}{4}$.

$$\Rightarrow \quad \tan\frac{\pi}{4} = \frac{2\sqrt{(a+b)^2 - ab}}{|a + b|}$$

$$\Rightarrow \quad 1 = \frac{2\sqrt{(a+b)^2 - ab}}{|a + b|}$$

$$\Rightarrow \quad (a + b)^2 = 4(a + b)^2 - 4ab$$

$$\therefore \quad 3a^2 + 2ab + 3b^2 = 0$$

46. The equation of the bisectors of the lines $xy = 0$ are $y = \pm x$.

Putting $y = \pm x$ in

$my^2 + (1 - m^2)xy - mx^2 = 0$, we get

$$\pm (1 - m^2)x^2 = 0$$

$$\Rightarrow \quad m^2 = 1$$

$\therefore$

Session 1

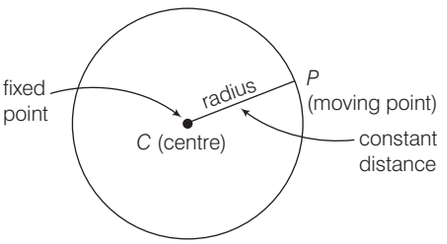
Definition, Equation of Circle in Different Forms, Locus of the Mid-point of the Chords of the Circle that Subtends an Angle of 2θ at its Centre

Definition

A circle is the locus of a point which moves in a plane, so that its distance from a *fixed point* in the plane is always *constant*.

The fixed point is called the *centre* of the circle and the constant distance is called its *radius*.



i.e. CP = constant distance = Radius

Equation of a Circle : The curve traced by the moving point is called its *circumference*. i.e. the equation of any circle is satisfied by co-ordinates of all points on its circumference.

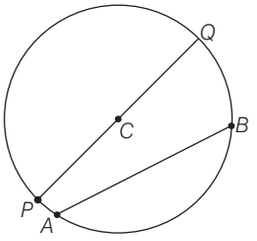
OR

The equation of the circle is meant the equation of the circumference.

OR

It is the set of all points lying on the circumference of the circle.

Chord and Diameter : The line joining any two points on the circumference is called a chord. If any chord passing through its centre is called its diameter.



AB = Chord, PQ = Diameter

where, C is centre of the circle.

Equation of Circle in Different Forms

1. Centre-radius form

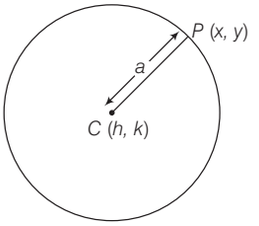
Let a be the *radius* and $C(h, k)$ be the *centre* of any circle.

If $P(x, y)$ be any point on the circumference.

Then, $CP = a \Rightarrow (CP)^2 = a^2$

$\Rightarrow$ $(x-h)^2 + (y-k)^2 = a^2$

This equation is known as the central form of the equation of a circle.



Remark

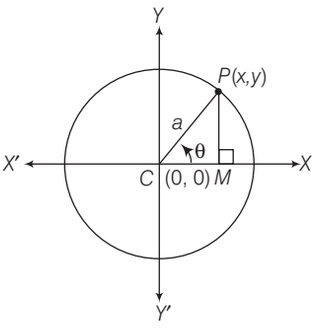
When, $C(h, k) = C(0, 0)$, then equation of circle becomes $x^2 + y^2 = a^2$ which is known as **standard form** of the circle.

2. Parametric form

If the radius of a circle whose centre is at $C(0, 0)$ makes an angle θ with the positive direction of X-axis, then θ is called the parameter.

Let $CP = a$

$\therefore$ $CM = x, PM = y \Rightarrow x = a\cos\theta, y = a\sin\theta$



Hence, $(a\cos\theta, a\sin\theta)$ or 'θ' are the parametric coordinates of the circle $x^2 + y^2 = a^2$ and $x = a\cos\theta$ and $y = a\sin\theta$ are called parametric equations of the circle $x^2 + y^2 = a^2$ with parameters a and θ. $(0 \le \theta < 2\pi)$.

Remarks

1. The parametric coordinates of any point on the circle $(x-h)^2 + (y-k)^2 = a^2$ are given by $(h + a\cos\theta, k + a\sin\theta)$ $(0 \le \theta < 2\pi)$ and parametric equations of the circle $(x-h)^2 + (y-k)^2 = a^2$ are $x = h + a\cos\theta$, $y = k + a\sin\theta$.
2. Equation of the chord of the circle $x^2 + y^2 = a^2$ joining $(a\cos\alpha, a\sin\alpha)$ and $(a\cos\beta, a\sin\beta)$ is
$$x\cos\left(\frac{\alpha+\beta}{2}\right) + y\sin\left(\frac{\alpha+\beta}{2}\right) = a\cos\left(\frac{\alpha-\beta}{2}\right).$$

General form The equation of the circle with centre (h, k) and radius a is $(x-h)^2 + (y-k)^2 = a^2$

or $$x^2 + y^2 - 2hx - 2ky + h^2 + k^2 - a^2 = 0 \quad \text{...(i)}$$

which is of the form

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(ii)}$$

This is known as the **general equation** of a circle comparing Eqs. (i) and (ii), we get

$$h = -g, k = -f \quad \text{and} \quad a = \sqrt{(g^2 + f^2 - c)}$$

$\therefore$ Coordinates of the centre are $(-g, -f)$ and

$$\text{Radius} = \sqrt{(g^2 + f^2 - c)}\ (g^2 + f^2 \ge c)$$

Remarks

1. **Rule for finding the centre and radius of a circle**
   (i) Make the coefficients of x^2 and y^2 equal to 1 and right hand side equal to zero.
   (ii) Then, coordinates of centre will be (α, β), where, $\alpha = -\frac{1}{2}$ (coefficient of x) and $\beta = -\frac{1}{2}$ (coefficient of y)
   (iii) Radius $= \sqrt{\alpha^2 + \beta^2 - (\text{constant term})}$
2. **Conditions for a circle** A general equation of second degree
   $$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$$
   in x, y represent a circle, if
   (i) coefficient of x^2 = coefficient of y^2
   i.e. $a = b$
   (ii) coefficient of xy is zero
   i.e. $h = 0$
3. **Nature of the circle** Radius of the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is $\sqrt{(g^2 + f^2 - c)}$
   Now, the following cases are possible :
   (i) If $g^2 + f^2 - c > 0$, then the radius of circle will be real. Hence in this case, real circle is possible.
   (ii) If $g^2 + f^2 - c = 0$, then the radius of circle will be real. Hence in this case, circle is called a point circle.
   (iii) If $g^2 + f^2 - c < 0$, then the radius of circle will be imaginary number. Hence in this case, circle is called a virtual circle or imaginary circle.
4. **Concentric circle** Two circles having the same centre $C(h, k)$ but different radii r_1 and r_2 respectively are called concentric circles. Thus, the circles $(x-h)^2 + (y-k)^2 = r_1^2$ and $(x-h)^2 + (y-k)^2 = r_2^2, r_1 \ne r_2$ are concentric circles. Therefore, the equations of concentric circles differ only in constant terms.

Example 1. Find the centre and radius of the circle
$$2x^2 + 2y^2 = 3x - 5y + 7$$

Sol. The given equation of circle is
$$2x^2 + 2y^2 = 3x - 5y + 7$$
or $$x^2 + y^2 - \frac{3}{2}x + \frac{5}{2}y - \frac{7}{2} = 0$$
If centre is (α, β), then
$$\alpha = -\frac{1}{2}\left(-\frac{3}{2}\right) = \frac{3}{4}$$
and $$\beta = -\frac{1}{2}\left(\frac{5}{2}\right) = -\frac{5}{4}$$
$\therefore$ Centre of circle is (α, β) i.e. $\left(\frac{3}{4}, -\frac{5}{4}\right)$
and radius of the circle
$$= \sqrt{\alpha^2 + \beta^2 - (\text{constant term})}$$
$$= \sqrt{\frac{9}{16} + \frac{25}{16} + \frac{7}{2}} = \sqrt{\frac{9 + 25 + 56}{16}} = \frac{3\sqrt{10}}{4}$$

Example 2. ***Prove that the radii of the circles*** $x^2 + y^2 = 1, x^2 + y^2 - 2x - 6y = 6$ and $x^2 + y^2 - 4x - 12y = 9$ ***are in AP.***

Sol. Given circles are $$x^2 + y^2 = 1 \quad \text{...(i)}$$
$$x^2 + y^2 - 2x - 6y - 6 = 0 \quad \text{...(ii)}$$
and $$x^2 + y^2 - 4x - 12y - 9 = 0 \quad \text{...(iii)}$$
Let r_1, r_2 and r_3 be the radii of the circles Eqs. (i), (ii) and (iii), respectively.
Then, $r_1 = 1$
$$r_2 = \sqrt{(-1)^2 + (-3)^2 + 6} = 4$$
and $$r_3 = \sqrt{(-2)^2 + (-6)^2 + 9} = 7$$
Clearly, $r_2 - r_1 = 4 - 1 = 3 = r_3 - r_2$
Hence, r_1, r_2, r_3 are in AP.

Example 3. ***Find the equation of the circle whose centre is the point of intersection of the lines*** $2x - 3y + 4 = 0$ ***and*** $3x + 4y - 5 = 0$ ***and passes through the origin.***

Sol. The point of intersection of the lines $2x - 3y + 4 = 0$ and $3x + 4y - 5 = 0$ is $\left(-\frac{1}{17}, \frac{22}{17}\right)$.

Therefore, the centre of the circle is at $\left(-\frac{1}{17}, \frac{22}{17}\right)$.

Since, the origin lies on the circle, its distance from the centre of the circle is radius of the circle, therefore,

$$r = \sqrt{\left(-\frac{1}{17} - 0\right)^2 + \left(\frac{22}{17} - 0\right)^2} = \sqrt{\frac{485}{289}}$$

$\therefore$ The equation of the circle becomes

$$\left(x + \frac{1}{17}\right)^2 + \left(y - \frac{22}{17}\right)^2 = \frac{485}{289}$$

or $\quad 17\,(x^2 + y^2) + 2x - 44y = 0$

Aliter : $\because$ Point of intersection of the lines $2x - 3y + 4 = 0$ and $3x + 4y - 5 = 0$ is $\left(-\frac{1}{17}, \frac{22}{17}\right)$.

Therefore, the centre of the circle is at $\left(-\frac{1}{17}, \frac{22}{17}\right)$

Let required circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0 \qquad \ldots(i)$$

Here, $-g = -\frac{1}{17}, -f = \frac{22}{17}, c = 0$

[$\because$ Circle passes through origin]

From Eq. (i), $\quad x^2 + y^2 + \frac{2x}{17} - \frac{44}{17}y = 0$

or $\quad 17(x^2 + y^2) + 2x - 44y = 0$

Example 4. *Find the equation of the circle concentric with the circle* $x^2 + y^2 - 8x + 6y - 5 = 0$ *and passing through the point* $(-2, -7)$ *.*

Sol. The given equation of circle is

$$x^2 + y^2 - 8x + 6y - 5 = 0$$

Therefore, the centre of the circle is at $(4, -3)$. Since, the required circle is concentric with this circle, therefore, the centre of the required circle is also at $(4, -3)$. Since, the point $(-2, -7)$ lies on the circle, the distance of the centre from this point is the radius of the circle. Therefore, we get

$$r = \sqrt{(4 + 2)^2 + (-3 + 7)^2} = \sqrt{52}$$

Hence, the equation of the circle becomes

$$(x - 4)^2 + (y + 3)^2 = 52$$

or $\quad x^2 + y^2 - 8x + 6y - 27 = 0$

Aliter : Equation of concentric circle is

$$x^2 + y^2 - 8x + 6y + \lambda = 0 \qquad \ldots(i)$$

which pass through $(-2, -7)$, then

$$4 + 49 + 16 - 42 + \lambda = 0$$

$\therefore \quad \lambda = -27$

From Eq. (i), required circle is

$$x^2 + y^2 - 8x + 6y - 27 = 0$$

Example 5. A circle has radius 3 units and its centre lies on the line $y = x - 1$. Find the equation of the circle if it passes through (7, 3).

Sol. Let the centre of the circle be (h, k). Since, the centre lies on $y = x - 1$, we get

$$k = h - 1 \qquad \ldots(i)$$

Since, the circle passes through the point $(7, 3)$, therefore the distance of the centre from this point is the radius r of the circle. We have,

$$r = \sqrt{(h - 7)^2 + (k - 3)^2}$$

or $\quad 3 = \sqrt{(h - 7)^2 + (h - 1 - 3)^2}$ [from Eq. (i)]

$\Rightarrow \quad 9 = (h - 7)^2 + (h - 4)^2$

$\Rightarrow \quad h^2 - 11h + 28 = 0$

or $\quad (h - 7)(h - 4) = 0$

or $\quad h = 7 \quad$ and $\quad h = 4$

For $h = 7$, we get $k = 6$ from Eq. (i)

and for $h = 4$, we get $k = 3$, from Eq. (i).

Hence, there are two circles which satisfy the given conditions. They are

$$(x - 7)^2 + (y - 6)^2 = 9$$

or $\quad x^2 + y^2 - 14x - 12y + 76 = 0$

and $\quad (x - 4)^2 + (y - 3)^2 = 9$

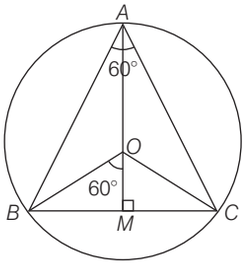
or $\quad x^2 + y^2 - 8x - 6y + 16 = 0$

Example 6. Find the area of an equilateral triangle inscribed in the circle $x^2 + y^2 + 2gx + 2fy + c = 0$.

Sol. Given circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0 \qquad \ldots(i)$$

Let O be the centre and ABC be an equilateral triangle inscribed in the circle Eq. (i).



$$O \equiv (-g, -f)$$

and $\quad OA = OB = OC = \sqrt{g^2 + f^2 - c} \qquad \ldots(ii)$

In ΔBOM, $\sin 60° = \frac{BM}{OB}$

$\Rightarrow$ $BM = OB \sin 60° = (OB)\frac{\sqrt{3}}{2}$

$\therefore$ $BC = 2BM = \sqrt{3}\,(OB)$ ...(iii)

$\therefore$ Area of $\Delta ABC = \frac{\sqrt{3}}{4}(BC)^2$

$= \frac{\sqrt{3}}{4} 3\,(OB)^2$ [from Eq. (iii)]

$= \frac{3\sqrt{3}}{4}(g^2 + f^2 - c)$ sq units.

Example 7. Find the parametric form of the equation of the circle

$$x^2 + y^2 + px + py = 0.$$

Sol. Equation of the circle can be re-written in the form

$$\left(x + \frac{p}{2}\right)^2 + \left(y + \frac{p}{2}\right)^2 = \frac{p^2}{2}$$

Therefore, the parametric form of the equation of the given circle is

$$x = -\frac{p}{2} + \frac{p}{\sqrt{2}}\cos\theta = \frac{p}{2}(-1 + \sqrt{2}\cos\theta)$$

and $$y = -\frac{p}{2} + \frac{p}{\sqrt{2}}\sin\theta = \frac{p}{2}(-1 + \sqrt{2}\sin\theta)$$

where, $0 \le \theta < 2\pi$.

Example 8. If the parametric of form of a circle is given by

(a) $x = -4 + 5\cos\theta$ and $y = -3 + 5\sin\theta$

(b) $x = a\cos\alpha + b\sin\alpha$ and $y = a\sin\alpha - b\cos\alpha$

find its cartesian form.

Sol. (a) The given equations are

$$x = -4 + 5\cos\theta$$

and $$y = -3 + 5\sin\theta$$

or $$(x + 4) = 5\cos\theta$$ ...(i)

and $$(y + 3) = 5\sin\theta$$ ...(ii)

Squaring and adding Eqs. (i) and (ii), then

$$(x + 4)^2 + (y + 3)^2 = 5^2$$

or $$(x + 4)^2 + (y + 3)^2 = 25$$

(b) The given equations are

$$x = a\cos\alpha + b\sin\alpha$$ ...(iii)

$$y = a\sin\alpha - b\cos\alpha$$ ...(iv)

Squaring and adding Eqs. (iii) and (iv), then

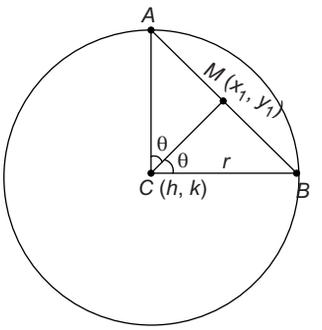
$$x^2 + y^2 = (a\cos\alpha + b\sin\alpha)^2 + (a\sin\alpha - b\cos\alpha)^2$$

$\Rightarrow$ $x^2 + y^2 = a^2 + b^2$

Locus of the Mid-point of the Chords of the Circle that Subtends an Angle of 2θ at its Centre

Let mid-point $M(x_1, y_1)$ and centre, radius of circle are (h,k), r respectively, then

$$\cos\theta = \frac{CM}{r} = \frac{\sqrt{(x_1 - h)^2 + (y_1 - k)^2}}{r}$$



$\therefore$ Required locus is $\frac{(x-h)^2 + (y-k)^2 - r^2}{r^2} = -\sin^2\theta$

Remembering Method :

First make coefficient of x^2 = coefficient of $y^2 = 1$

and RHS of circle is zero, then $\frac{\text{LHS of circle}}{(\text{radius})^2} = -\sin^2\theta$

Example 9. Find the locus of mid-points of the chords of the circle $4x^2 + 4y^2 - 12x + 4y + 1 = 0$ that subtend an angle of $\frac{2\pi}{3}$ at its centre.

Sol. Here, $2\theta = \frac{2\pi}{3} \Rightarrow \theta = \frac{\pi}{3}$

Equation of circle can be written as

$$x^2 + y^2 - 3x + y + \frac{1}{4} = 0$$

$\therefore$ Required locus is

$$\frac{x^2 + y^2 - 3x + y + \frac{1}{4}}{\left(\sqrt{\frac{9}{4} + \frac{1}{4} - \frac{1}{4}}\right)^2} = -\sin^2\left(\frac{\pi}{3}\right) = -\frac{3}{4}$$

$\Rightarrow$ $$x^2 + y^2 - 3x + y + \frac{1}{4} = -\frac{27}{16}$$

or $$16(x^2 + y^2) - 48x + 16y + 31 = 0$$

Exercise for Session 1

1. If $x^2 + y^2 - 2x + 2ay + a + 3 = 0$ represents a real circle with non-zero radius, then most appropriate is

(a) $a \in (-\infty, -1)$ (b) $a \in (-1, 2)$

(c) $a \in (2, \infty)$ (d) $a \in (-\infty, -1) \cup (2, \infty)$

2. If the equation $ax^2 + (2-b)xy + 3y^2 - 6bx + 30y + 6b = 0$ represents a circle, then $a^2 + b^2$ is

(a) 5 (b) 13

(c) 25 (d) 41

3. The equation of the circle passing through $(4, 5)$ having the centre at $(2, 2)$ is

(a) $x^2 + y^2 + 4x + 4y - 5 = 0$ (b) $x^2 + y^2 - 4x - 4y - 5 = 0$

(c) $x^2 + y^2 - 4x - 13 = 0$ (d) $x^2 + y^2 - 4x - 4y + 5 = 0$

4. Equation of the diameter of the circle is given by $x^2 + y^2 - 12x + 4y + 6 = 0$ is given by

(a) $x + y = 0$ (b) $x + 3y = 0$

(c) $x = y$ (d) $3x + 2y = 0$

5. If the lines $3x - 4y + 4 = 0$ and $6x - 8y - 7 = 0$ are tangents to a circle, then the diameter of the circle is

(a) $\frac{3}{2}$ (b) 3

(c) $\frac{5}{2}$ (d) 5

6. Area of a circle in which a chord of length $\sqrt{2}$ makes an angle $\frac{\pi}{2}$ at the centre is

(a) $\frac{\pi}{4}$ (b) $\frac{\pi}{2}$

(c) π (d) 2π

7. The lines $2x - 3y - 5 = 0$ and $3x - 4y = 7$ are diameters of a circle of area 154 sq units, then the equation of the circle is :

(a) $x^2 + y^2 + 2x - 2y - 62 = 0$ (b) $x^2 + y^2 + 2x - 2y - 47 = 0$

(c) $x^2 + y^2 - 2x + 2y - 62 = 0$ (d) $x^2 + y^2 - 2x + 2y - 47 = 0$

8. If the lines $2x + 3y + 1 = 0$ and $3x - y - 4 = 0$ lie along diameters of a circle of circumference 10π, then the equation of the circle is

(a) $x^2 + y^2 - 2x + 2y - 23 = 0$ (b) $x^2 + y^2 - 2x - 2y - 23 = 0$

(c) $x^2 + y^2 + 2x + 2y - 23 = 0$ (d) $x^2 + y^2 + 2x - 2y - 23 = 0$

9. The triangle PQR is inscribed in the circle $x^2 + y^2 = 25$. If Q and R have coordinates $(3, 4)$ and $(-4, 3)$ respectively, then $\angle QPR$ is equal to

(a) $\frac{\pi}{2}$ (b) $\frac{\pi}{3}$

(c) $\frac{\pi}{4}$ (d) $\frac{\pi}{6}$

10. If a circle is concentric with the circle $x^2 + y^2 - 4x - 6y + 9 = 0$ and passes through the point $(-4, -5)$, then its equation is

(a) $x^2 + y^2 + 4x + 6y - 87 = 0$ (b) $x^2 + y^2 - 4x + 6y + 87 = 0$

(c) $x^2 + y^2 - 4x - 6y - 87 = 0$ (d) $x^2 + y^2 + 4x + 6y + 87 = 0$

11. Let AB be a chord of the circle $x^2 + y^2 = r^2$ subtending a right angle at the centre. Then, the locus of the centroid of the ΔPAB as P moves on the circle is

(a) a parabola (b) a circle

(c) an ellipse (d) a pair of straight lines

12. Let PQ and RS be tangents extremities of the diameter PR of a circle of radius r. If PS and RQ intersect at a point X on the circumference of the circle, then $2r$ equals

(a) $\sqrt{PQ \cdot RS}$ (b) $\dfrac{PQ + RS}{2}$

(c) $\dfrac{2PQ.RS}{PQ + RS}$ (d) $\sqrt{\dfrac{(PQ)^2 + (RS)^2}{2}}$

13. Find the centre and radius of the circle $5x^2 + 5y^2 + 4x - 8y = 16$.

14. Prove that the centres of the circles $x^2 + y^2 = 1, x^2 + y^2 + 6x - 2y - 1 = 0$ and $x^2 + y^2 - 12x + 4y = 1$ are collinear.

15. Find the equation of the circle whose centre is $(1, 2)$ and which passes through the point of intersection of $3x + y = 14$ and $2x + 5y = 18$.

16. Find the equation of the circle passing through the centre of the circle $x^2 + y^2 - 4x - 6y = 8$ and being concentric with the circle $x^2 + y^2 - 2x - 8y = 5$.

17. Prove that the locus of the centre of the circle $\dfrac{1}{2}(x^2 + y^2) + x\cos\theta + y\sin\theta - 4 = 0$ is $x^2 + y^2 = 1$.

18. Find the equation of the following curves in cartesian form. If the curve is a circle, then find its centre and radius

$x = -1 + 2\cos\alpha,\ y = 3 + 2\sin\alpha \qquad (0 \le \alpha < 2\pi)$

Session 2

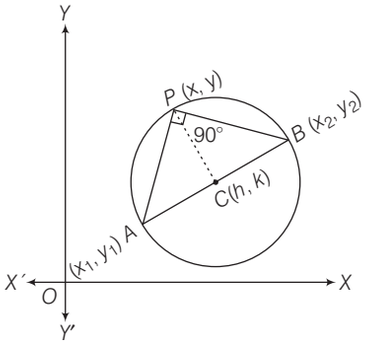
Diametric Form of a Circle, Equation of Circle Passing Through Three Non-Collinear Points

Diametric Form of a Circle

Theorem : The equation of the circle on the line segment joining (x_1, y_1) and (x_2, y_2) as diameter is

$$(x - x_1)(x - x_2) + (y - y_1)(y - y_2) = 0.$$

Proof : Let $A(x_1, y_1)$ and $B(x_2, y_2)$ be the end points of a diameter and let $P(x, y)$ be any point on the circle



Now, $\quad$ Slope of $AP = \dfrac{y - y_1}{x - x_1}$

and $\quad$ Slope of $BP = \dfrac{y - y_2}{x - x_2}$

Since, $\angle APB = 90°$

$\therefore$ Slope of $AP \times$ Slope of $BP = -1$

$$\Rightarrow \quad \frac{(y - y_1)}{(x - x_1)} \times \frac{(y - y_2)}{(x - x_2)} = -1$$

$$\Rightarrow \quad (x - x_1)(x - x_2) + (y - y_1)(y - y_2) = 0$$

Remark

The diameteric form of a circle can also be written as

$$x^2 + y^2 - x(x_1 + x_2) - y(y_1 + y_2) + x_1x_2 + y_1y_2 = 0$$

or $\quad x^2 + y^2 - x$ (sum of abscissae) $- y$ (sum of ordinates) + product of abscissae + product of ordinates $= 0$

Example 10. Find the equation of the circle the end points of whose diameter are the centres of the circles $x^2 + y^2 + 6x - 14y = 1$ and $x^2 + y^2 - 4x + 10y = 2$.

Sol. The centres of the given circles

$$x^2 + y^2 + 6x - 14y - 1 = 0$$

and $x^2 + y^2 - 4x + 10y - 2 = 0$ are $(-3, 7)$ and $(2, -5)$, respectively.

According to the question, the points $(-3, 7)$ and $(2, -5)$ are the extremities of the diameter of required circle.

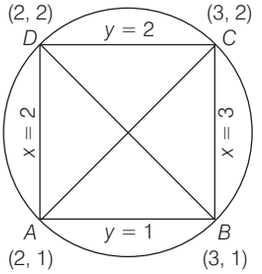
Hence, equation of circle is

$$(x + 3)(x - 2) + (y - 7)(y + 5) = 0$$

$$\Rightarrow \quad x^2 + y^2 + x - 2y - 41 = 0$$

Example 11. The sides of a square are $x = 2, x = 3, y = 1$ and $y = 2$. Find the equation of the circle drawn on the diagonals of the square as its diameter.

Sol. Let $ABCD$ be a square and equation of its sides AB, BC, CD and DA are $y = 1$, $x = 3$, $y = 2$, and $x = 2$, respectively.



Then, $A \equiv (2, 1)$, $B \equiv (3, 1)$, $C \equiv (3, 2)$ and $D \equiv (2, 2)$

Since, diagonals of squares are the diameters of the circle, then equation of circle is

$$(x - 2)(x - 3) + (y - 1)(y - 2) = 0$$

$$\Rightarrow \quad x^2 + y^2 - 5x - 3y + 8 = 0 \text{ (If } AC \text{ as diameter).}$$

Example 12. ***The abscissae of two points*** A ***and*** B ***are the roots of the equation*** $x^2 + 2ax - b^2 = 0$ ***and their ordinates are the roots of the equation*** $x^2 + 2px - q^2 = 0$***. Find the equation and the radius of the circle with*** AB ***as diameter.***

Sol. Given equations are

$$x^2 + 2ax - b^2 = 0 \qquad \text{...(i)}$$

and $x^2 + 2px - q^2 = 0$ ...(ii)

Let the roots of the Eq. (i) be α and β and those of Eq. (ii) be γ and δ. Then,

$$\left.\begin{aligned}\alpha + \beta &= -2a\\ \alpha\beta &= -b^2\end{aligned}\right\} \text{ and } \left.\begin{aligned}\gamma + \delta &= -2p\\ \gamma\delta &= -q^2\end{aligned}\right\}$$

Let $A \equiv (\alpha, \gamma)$ and $B \equiv (\beta, \delta)$.

Now, equation of circle whose diameter is AB will be

$$(x-\alpha)(x-\beta) + (y-\gamma)(y-\delta) = 0$$

$\Rightarrow$ $x^2 + y^2 - (\alpha+\beta)x - (\gamma+\delta)y + \alpha\beta + \gamma\delta = 0$

$\Rightarrow$ $x^2 + y^2 + 2ax + 2py - b^2 - q^2 = 0$

and radius $= \sqrt{(a^2 + p^2 + b^2 + q^2)}$

Equation of Circle Passing Through Three Non-Collinear Points

Let the equation of circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad ...(i)$$

If three points $(x_1, y_1), (x_2, y_2), (x_3, y_3)$ lie on the circle Eq. (i), their coordinates must satisfy its equation. Hence, solving equations

$$x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0, \quad ...(ii)$$

$$x_2^2 + y_2^2 + 2gx_2 + 2fy_2 + c = 0, \quad ...(iii)$$

and $$x_3^2 + y_3^2 + 2gx_3 + 2fy_3 + c = 0, \quad ...(iv)$$

g, f, c are obtained from Eqs. (ii), (iii) and (iv). Then, to find the circle Eq. (i).

Aliter : Eliminate g, f, c from Eqs. (i), (ii), (iii) and (iv) with the help of determinant

$$\begin{vmatrix} x^2+y^2 & x & y & 1\\ x_1^2+y_1^2 & x_1 & y_1 & 1\\ x_2^2+y_2^2 & x_2 & y_2 & 1\\ x_3^2+y_3^2 & x_3 & y_3 & 1\end{vmatrix} = 0$$

which is the required equation of circle

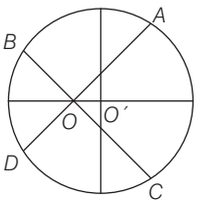
Applying $R_1 \to R_1 - R_4$, $R_2 \to R_2 - R_4$ and $R_3 \to R_3 - R_4$ then, we get

$$\begin{vmatrix} x^2+y^2-x_3^2-y_3^2 & x-x_3 & y-y_3 & 0\\ x_1^2+y_1^2-x_3^2-y_3^2 & x_1-x_3 & y_1-y_3 & 0\\ x_2^2+y_2^2-x_3^2-y_3^2 & x_2-x_3 & y_2-y_3 & 0\\ x_3^2+y_3^2 & x_3 & y_3 & 1\end{vmatrix} = 0$$

i.e. $$\begin{vmatrix} x^2+y^2-x_3^2-y_3^2 & x-x_3 & y-y_3\\ x_1^2+y_1^2-x_3^2-y_3^2 & x_1-x_3 & y_1-y_3\\ x_2^2+y_2^2-x_3^2-y_3^2 & x_2-x_3 & y_2-y_3\end{vmatrix} = 0$$

Remarks

1. **Cyclic quadrilateral** If all four vertices of a quadrilateral lie on a circle, then the quadrilateral is called a cyclic quadrilateral. The four vertices are said to be concyclic.
2. **Concyclic points** If A, B, C, D are concyclic, then
$$OA \cdot OD = OB \cdot OC$$
where, O' be the centre of the circle.



Example 13. Find the equation of the circle which passes through the points $(4, 1), (6, 5)$ and has its centre on the line $4x + y = 16$.

Sol. Let the equation of circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad ...(i)$$

Since, the centre of Eq. (i) i.e. $(-g, -f)$ lies on $4x + y = 16$

then, $-4g - f = 16$

or $4g + f + 16 = 0$ ...(ii)

Since, the points $(4, 1)$ and $(6, 5)$ lie on circle $x^2 + y^2 + 2gx + 2fy + c = 0$, we get the equations

$$16 + 1 + 8g + 2f + c = 0$$

or $17 + 8g + 2f + c = 0$ ...(iii)

and $36 + 25 + 12g + 10f + c = 0$

or $61 + 12g + 10f + c = 0$ ...(iv)

Subtracting Eq. (iii) from Eq. (iv), then

$$44 + 4g + 8f = 0 \quad ...(v)$$

Solving Eqs. (ii) and (v), we get

$$f = -4 \quad \text{and} \quad g = -3$$

Now, from Eq. (iii), $17 - 24 - 8 + c = 0$

$\Rightarrow$ $c = 15$

Hence, the equation of circle becomes

$$x^2 + y^2 - 6x - 8y + 15 = 0$$

Example 14. Find the equation of the circle passing through the three non-collinear points $(1, 1), (2, -1)$ and $(3, 2)$.

Sol. Let the equation of circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad ...(i)$$

Since, the three given points lie on circle Eq. (i), we get

$$1 + 1 + 2g + 2f + c = 0$$

or $2g + 2f + c + 2 = 0$ ...(ii)

$\Rightarrow$ $4 + 1 + 4g - 2f + c = 0$

or $4g - 2f + c + 5 = 0$ ...(iii)

$\Rightarrow$ $9 + 4 + 6g + 4f + c = 0$

or $6g + 4f + c + 13 = 0$ ...(iv)

Subtracting Eq. (ii) from Eq. (iii) and subtracting Eq. (iii) from Eq. (iv), then

$2g - 4f + 3 = 0$ ...(v)

and $2g + 6f + 8 = 0$ ...(vi)

Solving Eq. (v) and Eq. (vi), we get

$$f = -\frac{1}{2} \quad \text{and} \quad g = -\frac{5}{2}$$

Now, from Eq. (ii), $-5 - 1 + c + 2 = 0$

$\therefore$ $c = 4$

Hence, from Eq. (i), equation of circle is

$$x^2 + y^2 - 5x - y + 4 = 0$$

Aliter I Equation of circle passing through three points $(1, 1), (2, -1)$ and $(3, 2)$ is

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ 1^2 + 1^2 & 1 & 1 & 1 \\ 2^2 + (-1)^2 & 2 & -1 & 1 \\ 3^2 + 2^2 & 3 & 2 & 1 \end{vmatrix} = 0$$

$$\Rightarrow \quad \begin{vmatrix} x^2 + y^2 & x & y & 1 \\ 2 & 1 & 1 & 1 \\ 5 & 2 & -1 & 1 \\ 13 & 3 & 2 & 1 \end{vmatrix} = 0$$

Applying $R_1 \to R_1 - R_2, R_3 \to R_3 - R_2$ and $R_4 \to R_4 - R_2$, then

$$\Rightarrow \quad \begin{vmatrix} x^2 + y^2 - 2 & x - 1 & y - 1 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 2 & \ldots\ 1 & \ldots\ 1 & \ldots\ 1 \\ \vdots & \vdots & \vdots & \vdots \\ 3 & 1 & -2 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 11 & 2 & 1 & 0 \end{vmatrix} = 0$$

Expand with respect to fourth column, then

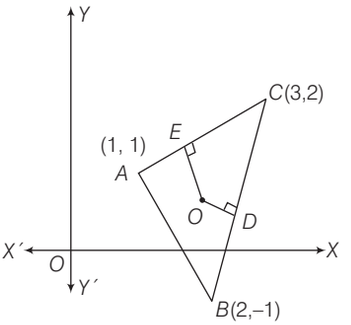
$$\begin{vmatrix} x^2 + y^2 - 2 & x - 1 & y - 1 \\ 3 & 1 & -2 \\ 11 & 2 & 1 \end{vmatrix} = 0$$

Expand with respect to first now, then

$$(x^2 + y^2 - 2)(5) - (x - 1)(25) + (y - 1)(-5) = 0$$

or $x^2 + y^2 - 5x - y + 4 = 0$

Aliter II The centre of the circumcircle is the point of intersection of the right bisectors of the sides of the triangle and the radius is the distance of the circumcentre from any of the vertices of the triangle.



Let D and E are the mid-points of BC and CA, then

$$D \equiv \left(\frac{5}{2}, \frac{1}{2}\right) \quad \text{and} \quad E \equiv \left(2, \frac{3}{2}\right)$$

Slope of $BC = \dfrac{2 - (-1)}{3 - 2} = 3$

$\therefore$ Slope of $OD = -\dfrac{1}{3}$

$\therefore$ Equation of OD, $y - \dfrac{1}{2} = -\dfrac{1}{3}\left(x - \dfrac{5}{2}\right)$

$\Rightarrow$ $6y - 3 = -2x + 5$

$\therefore$ $2x + 6y - 8 = 0$ ...(i)

or $x + 3y - 4 = 0$

and Slope of $CA = \dfrac{1 - 2}{1 - 3} = \dfrac{1}{2}$

$\therefore$ Slope of $OE = -2$

$\therefore$ Equation of OE,

$$y - \frac{3}{2} = -2(x - 2)$$

$\Rightarrow$ $2y - 3 = -4x + 8$

$\Rightarrow$ $4x + 2y - 11 = 0$ ...(ii)

Solving Eq. (i) and Eq. (ii), we get $x = \dfrac{5}{2}$ and $y = \dfrac{1}{2}$

$\therefore$ Circumcentre is $\left(\dfrac{5}{2}, \dfrac{1}{2}\right)$ and radius

$$OC = \sqrt{\left(3 - \frac{5}{2}\right)^2 + \left(2 - \frac{1}{2}\right)^2} = \sqrt{\frac{5}{2}}$$

$\therefore$ Equation of circle is

$$(x - 5/2)^2 + (y - 1/2)^2 = 5/2$$

$\Rightarrow$ $x^2 + y^2 - 5x - y + 4 = 0$

Example 15. Show that the four points $(1, 0), (2, -7), (8, 1)$ and $(9, -6)$ are concyclic.

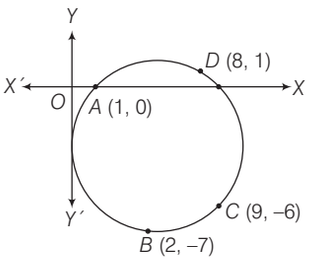
Sol. Since, the given four points are concyclic, we are to show that they lie on a circle. Let the general equation of circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0$$ ...(i)

has three parameters, it is sufficient to obtain the equation of the circle passing through any three of these points. For concyclic, the fourth point should lie on this circle.

Let three points $A(1, 0)$, $B(2, -7)$ and $D(8, 1)$ lie on Eq. (i), then

$$1 + 0 + 2g + 0 + c = 0 \quad \text{or} \quad 1 + 2g + c = 0 \qquad \text{...(ii)}$$



$$(2)^2 + (-7)^2 + 2g(2) + 2f(-7) + c = 0$$

or $$53 + 4g - 14f + c = 0 \qquad \text{...(iii)}$$

and $$(8)^2 + (1)^2 + 2g(8) + 2f(1) + c = 0$$

$$\Rightarrow \quad 65 + 16g + 2f + c = 0 \qquad \text{...(iv)}$$

Now, subtracting Eq. (ii) from Eq. (iii), we get

$$52 + 2g - 14f = 0$$

or $$26 + g - 7f = 0 \qquad \text{...(v)}$$

and subtracting Eq. (iii) from Eq. (iv), we get

$$12 + 12g + 16f = 0$$

$$\Rightarrow \quad 3 + 3g + 4f = 0 \qquad \text{...(vi)}$$

Solving Eq. (v) and Eq. (vi), we get

$$g = -5 \quad \text{and} \quad f = 3$$

From Eq. (ii), $1 - 10 + c = 0$

$$\therefore \quad c = 9$$

Therefore, equation of circle passing through these points is

$$x^2 + y^2 - 10x + 6y + 9 = 0$$

Substituting the fourth point in the equation of this circle, we get

$$(9)^2 + (-6)^2 - 10(9) + 6(-6) + 9 = 0$$

Hence, the point $C(9, -6)$ lies on the circle, that is, the four points are concyclic.

Exercise for Session 2

1. If the line $x + 2\lambda y + 7 = 0$ is a diameter of the circle $x^2 + y^2 - 6x + 2y = 0$, then the value of λ is

(a) 1 (b) 3
(c) 5 (d) 7

2. If one end of a diameter of the circle $2x^2 + 2y^2 - 4x - 8y + 2 = 0$ is $(-1, 2)$, then the other end of the diameter is

(a) (2, 1) (b) (3, 2)
(c) (4, 3) (d) (5, 4)

3. If a circle passes through the points (0,0), $(a, 0)$ and $(0, b)$, then centre of the circle is

(a) (a, b) (b) $\left(\frac{a}{2}, \frac{b}{2}\right)$
(c) $\left(\frac{a}{2}, \frac{b}{4}\right)$ (d) $\left(\frac{a}{4}, \frac{b}{2}\right)$

4. A circle passes through the points $(-1, 3)$ and $(5, 11)$ and its radius is 5. Then, its centre is

(a) $(-5, 0)$ (b) $(-5, 7)$
(c) $(2, 7)$ (d) $(5, 0)$

5. The radius of the circle, having centre at $(2, 1)$ whose one of the chord is a diameter of the circle $x^2 + y^2 - 2x - 6y + 6 = 0$ is

(a) 3 (b) 2
(c) 1 (d) $\sqrt{3}$

6. The centre of the circle inscribed in the square formed by the lines $x^2 - 8x + 12 = 0$ and $y^2 - 14y + 45 = 0$ is

(a) (4, 7) (b) (7, 4)
(c) (9, 4) (d) (4, 9)

7. $ABCD$ is a square whose side is a. The equation of the circle circumscribing the square, taking AB and AD as the axes of reference is

(a) $x^2 + y^2 + ax + ay = 0$ (b) $x^2 + y^2 - ax + ay = 0$

(c) $x^2 + y^2 - ax - ay = 0$ (d) $x^2 + y^2 + ax - ay = 0$

8. The locus of the centre of the circle for which one end of the diameter is (3, 3) while the other end lies on the line $x + y = 4$ is

(a) $x + y = 3$ (b) $x + y = 5$

(c) $x + y = 7$ (d) $x + y = 9$

9. The equation of the circle which passes through (1, 0) and (0, 1) and has its radius as small as possible is

(a) $x^2 + y^2 + x + y = 0$ (b) $x^2 + y^2 - x + y = 0$

(c) $x^2 + y^2 + x - y = 0$ (d) $x^2 + y^2 - x - y = 0$

10. If the points $(2, 0), (0, 1), (4,5)$ and $(0, c)$ are concyclic, then the value of c is

(a) 1 (b) -1

(c) $\frac{14}{3}$ (d) $-\frac{14}{3}$

11. The point on a circle nearest to the point $P(2,1)$ is at a distance of 4 units and farthest point is (6, 5), then the centre of the circle is

(a) $(3+\sqrt{2}, 2+\sqrt{2})$ (b) $(2+\sqrt{2}, 3+\sqrt{2})$

(c) $(4+\sqrt{2}, 3+\sqrt{2})$ (d) $(3+\sqrt{2}, 4+\sqrt{2})$

12. The intercept on the line $y = x$ by the circle $x^2 + y^2 - 2x = 0$ is AB. Equation of the circle on AB as a diameter is

(a) $x^2 + y^2 - x - y = 0$ (b) $x^2 + y^2 - x + y = 0$

(c) $x^2 + y^2 + x + y = 0$ (d) $x^2 + y^2 + x - y = 0$

13. Find the equation of the circle, the end points of whose diameter are $(2, -3)$ and $(-2, 4)$. Find the centre and radius.

14. If (4, 1) be an extremity of a diameter of the circle $x^2 + y^2 - 2x + 6y - 15 = 0$, find the coordinates of the other extremity of the diameter.

15. Find the equation of the circle drawn on the diagonal of the rectangle as its diameter whose sides are $x = 4, x = -2, y = 5$ and $y = -2$.

16. Find the equation of the circle which passes through the points $(1, 1), (2, 2)$ and whose radius is 1.

17. Find the equation of the circle which passes through the points $(3, 4), (3, -6)$ and $(1, 2)$.

Session 3

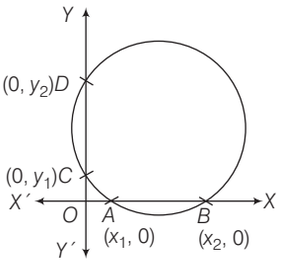
Intercepts Made on the Axes by a Circle, Different Forms of the Equations of a Circle, Position of a Point with Respect to Circle, Maximum and Minimum Distance of a Point from the Circle

Intercepts Made on the Axes by a Circle

Let the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ ...(i)

Length of intercepts on X-axis and Y-axis are

$|AB| = |x_2 - x_1|$ and $|CD| = |y_2 - y_1|$ respectively.



The circle intersects the X-axis, when $y = 0$

then $x^2 + 2gx + c = 0$

Since, the circle intersects the X-axis at $A(x_1, 0)$ and $B(x_2, 0)$

then, $x_1 + x_2 = -2g, x_1 x_2 = c$

$\therefore \quad |AB| = |x_2 - x_1| = \sqrt{(x_2 + x_1)^2 - 4x_1 x_2}$

$= 2\sqrt{(g^2 - c)}$

and the circle intersects the Y-axis, when $x = 0$, then

$y^2 + 2fy + c = 0$

Since, the circle intersects the Y-axis at $C(0, y_1)$ and $D(0, y_2)$

then, $y_1 + y_2 = -2f, y_1 y_2 = c$

$\therefore \quad |CD| = |y_2 - y_1| = \sqrt{(y_2 + y_1)^2 - 4y_2 y_1}$

$= 2\sqrt{(f^2 - c)}$

Remarks

1. Intercepts are always positive.
2. If circle touches X-axis, then $|AB| = 0$

   $\therefore \quad c = g^2$

   and if circle touches Y-axis, then $|CD| = 0$

   $\therefore \quad c = f^2$
3. If circle touches both axes, then $|AB| = 0 = |CD|$

   $\therefore \quad c = g^2 = f^2$

Example 16. Find the equation of the circle whose diameter is the line joining the points $(-4, 3)$ and $(12, -1)$. Find also the intercept made by it on Y-axis.

Sol. Equation of circle having $(-4, 3)$ and $(12, -1)$ as the ends of a diameter is

$(x + 4)(x - 12) + (y - 3)(y + 1) = 0$

$\Rightarrow \quad x^2 + y^2 - 8x - 2y - 51 = 0$ ...(i)

Comparing Eq. (i) with standard equation of circle

$x^2 + y^2 + 2gx + 2fy + c = 0$

then, $g = -4, f = -1, c = -51$

$\therefore$ Intercept on Y-axis $= 2\sqrt{(f^2 - c)} = 2\sqrt{(1 + 51)} = 4\sqrt{13}$.

Different Forms of the Equations of a Circle

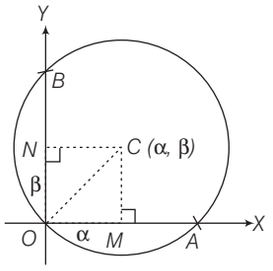
(i) When the circle passes through the origin (0, 0) and has intercepts 2α and 2β on the X-axis and Y-axis, respectively

Here, $OA = 2\alpha, OB = 2\beta$

then, $OM = \alpha$ and $ON = \beta$

Centre of the circle is $C(\alpha, \beta)$ and radius

$OC = \sqrt{(\alpha^2 + \beta^2)}$



then, equation of circle is

$$(x-\alpha)^2+(y-\beta)^2=\alpha^2+\beta^2$$

or $$x^2+y^2-2\alpha x-2\beta y=0$$

Remark

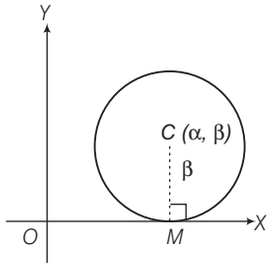
If a circle is passing through origin, then constant term is absent i.e. $x^2+y^2+2gx+2fy=0$

(ii) When the circle touches *X*-axis

Let (α,β) be the centre of the circle, then radius $=|\beta|$

$\therefore$ Equation of circle is

$$(x-\alpha)^2+(y-\beta)^2=\beta^2$$



$$\Rightarrow \quad x^2+y^2-2\alpha x-2\beta y+\alpha^2=0$$

Remark

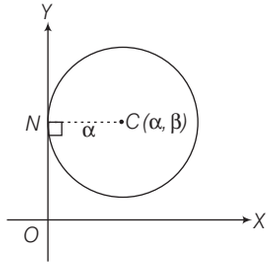
If the circle $x^2+y^2+2gx+2fy+c=0$ touches the *X*-axis, then

$$|-f|=\sqrt{g^2+f^2-c} \quad \text{or} \quad c=g^2$$

(iii) When the circle touches *Y*-axis

Let (α,β) be the centre of the circle, then

$$\text{radius}=|\alpha|$$



$\therefore$ Equation of circle is

$$(x-\alpha)^2+(y-\beta)^2=\alpha^2$$

$$\Rightarrow \quad x^2+y^2-2\alpha x-2\beta y+\beta^2=0$$

Remark

If the circle $x^2+y^2+2gx+2fy+c=0$ touches the *Y*-axis, then

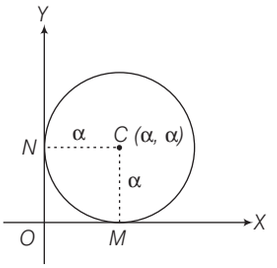
$$|-g|=\sqrt{g^2+f^2-c}$$

or $$c=f^2$$

(iv) When the circle touches both axes

Here, $$|OM|=|ON|$$

Since, length of tangents are equal from any point on circle.



$\therefore$ Let centre is (α,α) also radius $=\alpha$

$\therefore$ Equation of circle is $(x-\alpha)^2+(y-\alpha)^2=\alpha^2$

$$\Rightarrow \quad x^2+y^2-2\alpha x-2\alpha y+\alpha^2=0$$

Remarks

1. If the circle $x^2+y^2+2gx+2fy+c=0$ touches both the axes, then $|-g|=|-f|=\sqrt{g^2+f^2-c}$

$\therefore \quad c=g^2=f^2$

$\therefore \quad g=f=\pm\sqrt{c}$

$\therefore$ Equation of circle is

$$x^2+y^2\pm2\sqrt{c}\,x\pm2\sqrt{c}\,y+c=0$$

$$\Rightarrow \quad (x\pm\sqrt{c})^2+(y\pm\sqrt{c})^2=c^2$$

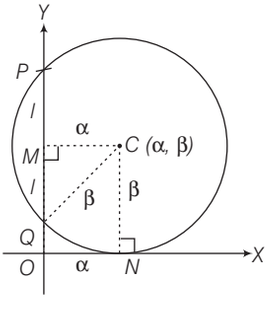
2. If $\alpha>0$, then centres for I, II, III and IV quadrants are $(\alpha,\alpha),(-\alpha,\alpha),(-\alpha,-\alpha)$ and $(\alpha,-\alpha)$, respectively. Then, equation of circles in these quadrants are

$$(x-\alpha)^2+(y-\alpha)^2=\alpha^2,(x+\alpha)^2+(y-\alpha)^2=\alpha^2,$$

$(x+\alpha)^2+(y+\alpha)^2=\alpha^2$ and $(x-\alpha)^2+(y+\alpha)^2=\alpha^2$, respectively.

(v) When the circle touches *X*-axis and cut-off intercepts on *Y*-axis of length 2*l*

Let centre be (α,β)



$\therefore$ radius $= \beta$

$CQ = CN = \beta$

In $\Delta CMQ, \beta^2 = \alpha^2 + l^2, \alpha = \sqrt{(\beta^2 - l^2)}$ (for I quadrant)

$\therefore$ Equation of circle is

$$[x - \sqrt{(\beta^2 - l^2)}]^2 + (y - \beta)^2 = \beta^2$$

Remark

$\because$ Length of intercepts on Y-axis of the circle

$x^2 + y^2 + 2gx + 2fy + c = 0$ is $2l = 2\sqrt{(f^2 - c)}$

i.e. $l^2 = f^2 - c$

and also circle touches X-axis

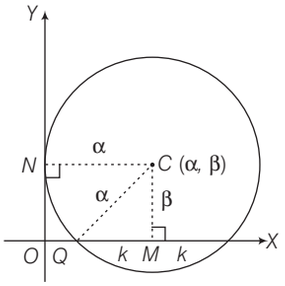
then, $c = g^2$

$\therefore$ $l^2 = f^2 - g^2$ or $l^2 = (-f)^2 - (-g)^2$

$\therefore$ Locus of centre is $y^2 - x^2 = l^2$ (rectangular hyperbola)

(vi) When the circle touches *Y*-axis and cut-off intercept on *X*-axis of length $2k$

Let centre be (α, β)



$\therefore$ radius $= \alpha$

$CN = CQ = \alpha$

In ΔCMQ, $\alpha^2 = \beta^2 + k^2$

$\beta = \sqrt{(\alpha^2 - k^2)}$ (for I quadrant)

$\therefore$ Equation of circle is

$$(x - \alpha)^2 + (y - \sqrt{\alpha^2 - k^2})^2 = \alpha^2$$

Remarks

$\because$ Length of intercept on X-axis of the circle

$x^2 + y^2 + 2gx + 2fy + c = 0$ is $2k = 2\sqrt{(g^2 - c)}$

i.e. $k^2 = g^2 - c$

and also circle touches Y-axis

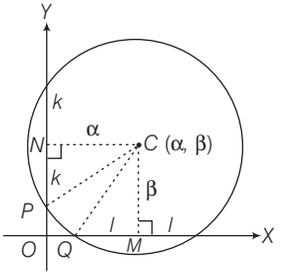
then, $c = f^2$

$\therefore$ $k^2 = g^2 - f^2 = (-g)^2 - (-f)^2$

$\therefore$ Locus of centre is $x^2 - y^2 = k^2$ (rectangular hyperbola)

(vii) When the circle cut-off intercepts on *X*-axis and *Y*-axis of lengths $2l$ and $2k$ and not passing through origin

Let centre be (α, β)



$\therefore$ radius $= CP = CQ = \lambda$ (say)

$(CP)^2 = (CQ)^2 = \lambda^2$

$\alpha^2 + k^2 = \beta^2 + l^2 = \lambda^2$

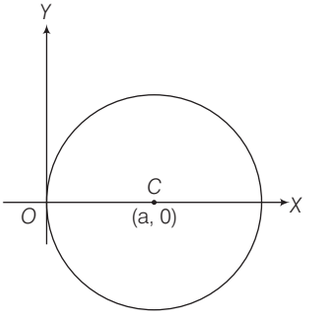
$\therefore$ $\alpha = \sqrt{\lambda^2 - k^2}$ and $\beta = \sqrt{\lambda^2 - l^2}$

$\therefore$ Equation of circle is (for I quadrant)

$$(x - \sqrt{\lambda^2 - k^2})^2 + (y - \sqrt{\lambda^2 - l^2})^2 = \lambda^2$$

(viii) When the circle passes through the origin and centre lies on *X*-axis

Let centre of circle be $C(a, 0)$



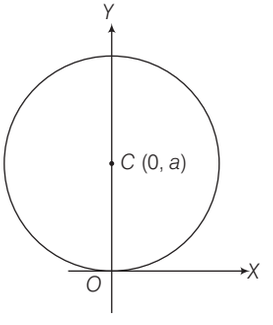
$\therefore$ radius $= a$

$\therefore$ Equation of circle is

$$(x - a)^2 + (y - 0)^2 = a^2 \text{ or } x^2 + y^2 - 2ax = 0$$

(ix) When the circle passes through origin and centre lies on *Y*-axis

Let centre of circle be $C(0, a)$



$\therefore$ radius $= a$

$\therefore$ Equation of circle is

$$(x-0)^2 + (y-a)^2 = a^2$$

or $$x^2 + y^2 - 2ay = 0$$

Example 17. Find the equation of the circle which touches the axis of y at a distance of 4 units from the origin and cuts the intercept of 6 units from the axis of x.

Sol. $\because$ $CM = NO = 4$

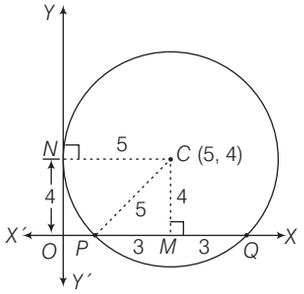
In ΔPCM, $(PC)^2 = (3)^2 + (4)^2$

$\therefore$ $PC = 5$

radius of circle $= 5$

$\therefore$ $NC = 5$

Centre of circle is (5, 4).



$\therefore$ Equation of circle, if centre in I quadrant

$$(x-5)^2 + (y-4)^2 = 25$$

If centre in II, III and IV quadrant, then equations are

$$(x+5)^2 + (y-4)^2 = 25,$$

$$(x+5)^2 + (y+4)^2 = 25$$

and $$(x-5)^2 + (y+4)^2 = 25$$

Hence, there are 4 circles which satisfy the given conditions. They are

$$(x \pm 5)^2 + (y \pm 4)^2 = 25$$

or $$x^2 + y^2 \pm 10x \pm 8y + 16 = 0$$

Aliter : Let the equation of the circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(i)}$$

Since, the circle touches the Y-axis

$\therefore$ $c = f^2$

or $f = \pm\sqrt{c}$

Also given the circle makes an intercept of 6 units along X-axis. Therefore,

$$2\sqrt{g^2 - c} = 6$$

or $$g^2 - c = 9$$

or $$g = \pm\sqrt{(c+9)}$$

From Eq. (i), the equation of circle can be written as

$$x^2 + y^2 \pm 2\sqrt{(c+9)}\, x \pm 2\sqrt{c}y + c = 0$$

The circle touches the Y-axis

$\therefore$ $x = 0$

$\therefore$ $y^2 \pm 2\sqrt{c}y + c = 0$

or $(y \pm \sqrt{c})^2 = 0$

$\therefore$ $y \pm \sqrt{c} = 0$

$$y = \mp\sqrt{c}$$

Since, the circle touches the Y-axis at a distance of 4 units from the origin, we have

$$y = \mp\sqrt{c} = 4$$

or $c = 16$

therefore, $f = \pm\sqrt{c} = \pm 4$

and $g = \pm\sqrt{c+9} = \pm\sqrt{16+9} = \pm 5$

Hence, there are 4 circles which satisfy the given conditions. They are

$$x^2 + y^2 \pm 10x \pm 8y + 16 = 0$$

Example 18. Find the equation of the circle which passes through the origin and makes intercepts of length a and b on the X and Y axes, respectively.

Sol. Let the equation of the circle be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(i)}$$

Since, the circle passes through the origin, we get $c = 0$ and given the intercepts on X and Y axes are a and b

then, $2\sqrt{(g^2 - c)} = a$

or $2\sqrt{(g^2 - 0)} = a$

$\therefore$ $g = \pm a/2$

and $2\sqrt{(f^2 - c)} = b$

or $2\sqrt{(f^2 - 0)} = b$

$\therefore$ $f = \pm b/2$

Hence, the equation of circle from Eq. (i) becomes

$$x^2 + y^2 \pm ax \pm by = 0$$

Example 19. Find the equation of the circle which touches the axes and whose centre lies on the line $x - 2y = 3$.

Sol. Since, the circle touches both the axes, let the radius of the circle by a, then

Case I If centre (a, a) but given centre lies on

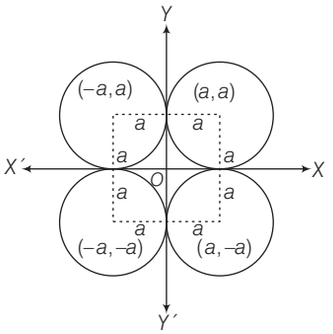
$$x - 2y = 3$$

$\therefore$ $a - 2a = 3$

$\therefore$ $a = -3$

$\therefore$ Centre $= (-3, -3)$

and radius = $|-3| = 3$



∴ Equation of circle is

$$(x+3)^2 + (y+3)^2 = 3^2$$

and $x^2 + y^2 + 6x + 6y + 9 = 0$

Case II If centre $(-a, a)$ but centre lies on $x - 2y = 3$

∴ $-a - 2a = 3$

∴ $a = -1$

then, centre $= (1, -1)$ and radius $= |-1| = 1$

∴ Equation of circle is $(x-1)^2 + (y+1)^2 = 1$

or $x^2 + y^2 - 2x + 2y + 1 = 0$

Case III If the centre $= (-a, -a)$

but centre lies on $x - 2y = 3$

∴ $-a + 2a = 3$

∴ $a = 3$

then centre $(-3, -3)$ and radius $= |3| = 3$

∴ Equation of circle is

$$(x+3)^2 + (y+3)^2 = 3^2$$

or $x^2 + y^2 + 6x + 6y + 9 = 0$

Case IV If centre $= (a, -a)$ but centre lies on $x - 2y = 3$

or $a + 2a = 3$

∴ $a = 1$

then centre $= (1, -1)$ and radius $= 1$

∴ Equation of circle is

$$(x-1)^2 + (y+1)^2 = 1$$

or $x^2 + y^2 - 2x + 2y + 1 = 0$

Aliter I : Since, the circle touches both the axes, therefore its centre will be $(a, \pm a)$ and radius will be $|a|$, where a is positive or negative number.

Case I If centre $= (a, a)$

Since, centre lies on $x - 2y = 3$

∴ $a - 2a = 3$

$a = -3$

∴ Centre of circle is $(-3, -3)$ and radius $= |-3| = 3$.

Hence, equation of circle will be

$$(x+3)^2 + (y+3)^2 = 3^2$$

or $x^2 + y^2 + 6x + 6y + 9 = 0$

Case II If centre $= (a, -a)$

Since, centre lies on $x - 2y = 3$

∴ $a + 2a = 3$

∴ $a = 1$

∴ Centre of circle is $(1, -1)$ and radius $= |1| = 1$

Hence, equation of circle will be

$$(x-1)^2 + (y+1)^2 = 1$$

or $x^2 + y^2 - 2x + 2y + 1 = 0$

Aliter II : Let the equation of circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(i)}$$

centre $= (-g, -f)$

Since, centre $(-g, -f)$ lies on $x - 2y = 3$

or $-g + 2f = 3$ ...(ii)

Since, circle touches both axes

∴ $g^2 = f^2 = c$ or $g = \pm f$

if $g = f$, then from Eq. (ii), $-f + 2f = 3$

∴ $f = 3$ and $g = 3$

but $c = f^2 = g^2 = 9$

∴ Equation of circle from Eq. (i) is

$$x^2 + y^2 + 6x + 6y + 9 = 0$$

and if $g = -f$, then from Eq. (ii)

$$f + 2f = 3$$

∴ $f = 1$ and $g = -1$

but $c = g^2 = f^2 = 1$

∴ Equation of circle from Eq. (i) is

$$x^2 + y^2 - 2x + 2y + 1 = 0$$

Aliter III : Since, centre of circle lies on $x - 2y = 3$, also since circle touches the axes, therefore, its centre will lie on the line $y = x$ or $y = -x$

Case I When the centre lies on the line $y = x$

but $x - 2y = 3$

or $x - 2x = 3$

∴ $x = -3 = y$

Hence, the centre $= (-3, -3)$ and radius $= |-3| = 3$

Therefore, the equation of circle in this case will be

$$(x+3)^2 + (y+3)^2 = 3^2$$

or $x^2 + y^2 + 6x + 6y + 9 = 0$

Case II When the centre lies on the line $y = -x$

but $x - 2y = 3$

or $x + 2x = 3$

∴ $x = 1$ then $y = -1$

∴ Centre of circle $(1, -1)$ and radius is $|1| = 1$

Hence, equation of circle will be

$$(x-1)^2 + (y+1)^2 = 1$$

or $x^2 + y^2 - 2x + 2y + 1 = 0$

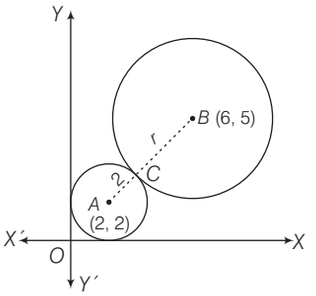
Example 20. A circle of radius 2 lies in the first quadrant and touches both the axes of coordinates. Find the equation of the circle with centre at (6, 5) and touching the above circle externally.

Sol. Given, $AC = 2$ units

and $A \equiv (2, 2), B \equiv (6, 5)$

then $AB = \sqrt{(2-6)^2 + (2-5)^2}$

$= \sqrt{16+9} = 5$



Since $AC + CB = AB$

$\therefore \quad 2 + CB = 5$

$\therefore \quad CB = 3$

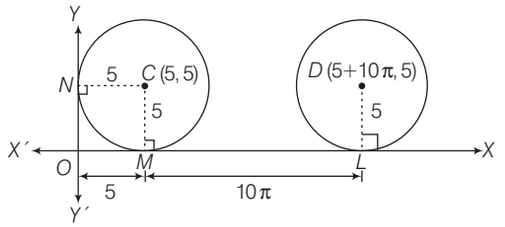
Hence, equation of required circle with centre at (6, 5) and radius 3 is

$$(x-6)^2 + (y-5)^2 = 3^2$$

or $x^2 + y^2 - 12x - 10y + 52 = 0$

Example 21. A circle of radius 5 units touches the coordinate axes in first quadrant. If the circle makes one complete roll on X-axis along the positive direction of X-axis, find its equation in the new position.

Sol. Let C be the centre of the circle in its initial position and D be its centre in the new position.



Since, the circle touches the coordinates axes in first quadrant and the radius of circle be 5 units.

$\therefore$ Centre of circle is (5, 5)

Moving length of circle = circumference of the circle

$$= 2\pi r = 2\pi(5) = 10\pi$$

Now, centre of circle in new position is $(5 + 10\pi, 5)$ and radius is 5 units, therefore, its equation will be

$$(x - 5 - 10\pi)^2 + (y-5)^2 = 5^2$$

or $x^2 + y^2 - 10(1 + 2\pi)x - 10y + 100\pi^2 + 100\pi + 25 = 0$

Position of a Point with Respect to Circle

Theorem : A point (x_1, y_1) lies outside, on or inside a circle

$$S \equiv x^2 + y^2 + 2gx + 2fy + c = 0$$

according as $S_1 >, =, \text{or} < 0$

where, $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c.$

Proof : Let $P(x_1, y_1)$ be the given point and let C be the centre of the circle

Then, $C \equiv (-g, -f)$

$\therefore \quad CP = \sqrt{(x_1+g)^2 + (y_1+f)^2}$

If r be the radius of the circle, then

$$r = \sqrt{(g^2 + f^2 - c)}$$

The point P lies outside, on or inside the circle according as

$CP >, =, \quad \text{or} \quad < r$

$\Rightarrow \quad (CP)^2 >, =, \quad \text{or} \quad < r^2$

$\Rightarrow \quad (x_1+g)^2 + (y_1+f)^2 >, =, \quad \text{or} \quad < g^2 + f^2 - c$

$\Rightarrow \quad x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c >, =, \quad \text{or} \quad < 0$

$\Rightarrow \quad S_1 >, =, \quad \text{or} \quad < 0$

where, $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c.$

Example 22. Discuss the position of the points (1, 2) and (6, 0) with respect to the circle

$$x^2 + y^2 - 4x + 2y - 11 = 0.$$

Sol. Let $S \equiv x^2 + y^2 - 4x + 2y - 11 = 0$ for the point (1, 2)

$$S_1 = 1^2 + 2^2 - 4 \cdot 1 + 2 \cdot 2 - 11 = -6$$

$\therefore \quad S_1 < 0$

and for the point (6, 0)

$$S_2 = 6^2 + 0 - 4 \cdot 6 + 2 \cdot 0 - 11$$

$$= 36 - 24 - 11$$

$$= 36 - 35 = 1$$

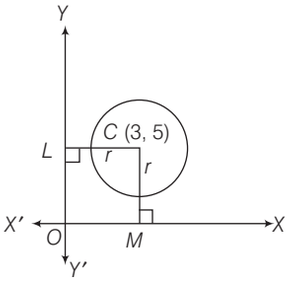
$\therefore \quad S_2 > 0$

Hence, the point (1, 2) lies inside the circle and the point (6, 0) lies outside the circle.

Example 23. The circle $x^2 + y^2 - 6x - 10y + \lambda = 0$ does not touch or intersect the coordinate axes and the point (1, 4) is inside the circle. Find the range of values of λ.

Sol. Let $S \equiv x^2 + y^2 - 6x - 10y + \lambda = 0$

$\because$ Point (1, 4) is inside the circle, then $S_1 < 0$



$$1 + 16 - 6 - 40 + \lambda < 0$$

$$\Rightarrow \quad \lambda < 29 \qquad \text{...(i)}$$

Centre and radius of the circle are (3, 5) and $\sqrt{(34 - \lambda)}$, respectively.

$\because$ Circle does not touch or intersect the coordinate axes.

$\therefore \quad 5 > r$ and $3 > r$

or $\quad 5 > \sqrt{(34 - \lambda)}$ and $3 > \sqrt{(34 - \lambda)}$

$\Rightarrow \quad 25 > 34 - \lambda$ and $9 > 34 - \lambda$

$\Rightarrow \quad \lambda > 9$ and $\lambda > 25$

$\therefore \quad \lambda > 25 \qquad \text{...(ii)}$

Also, $\quad 34 - \lambda > 0$

$\therefore \quad \lambda < 34 \qquad \text{...(iii)}$

From Eqs. (i), (ii) and (iii), we get $25 < \lambda < 29$

Maximum and Minimum Distance of a Point from the Circle

Let any point $P(x_1, y_1)$ and circle

$$S \equiv x^2 + y^2 + 2gx + 2fy + c = 0 \qquad \text{...(i)}$$

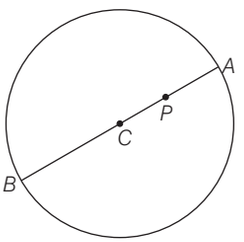
The centre and radius of the circle are

$$C(-g, -f) \quad \text{and} \quad \sqrt{(g^2 + f^2 - c)} \text{ respectively}$$

Case I If *P* inside the circle

In this case $S_1 < 0$

$\because \quad r = \sqrt{(g^2 + f^2 - c)} = CA = CB$



The **minimum distance** of P from circle $= PA = CA - CP$

$$= r - CP$$

and the **maximum distance** of P from circle $= PB$

$$= CB + CP = r + CP$$

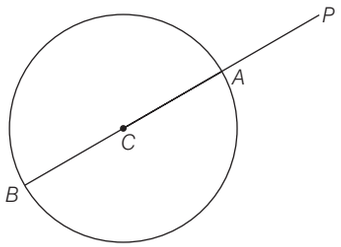
Case II If *P* outside the circle

In this case $S_1 > 0$ the **minimum distance** of P from circle

$$= PA = CP - CA = CP - r$$

and the **maximum distance** of P from the circle

$$= PB = CP + CB = r + CP$$



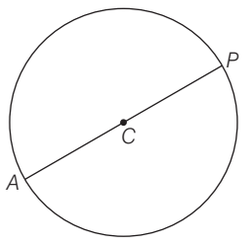
Case III If *P* on the circle

In this case $S_1 = 0$

the **minimum distance** of P from the circle $= 0$

and the **maximum distance** of P from the circle

$$= PA = 2r$$



Remark

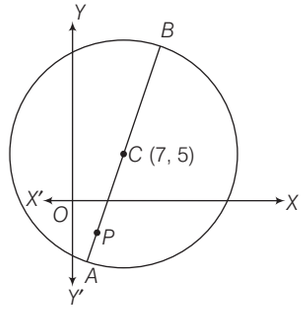
If point P inside or outside or on the circle and centre of circle at C and radius r, then minimum distance of P from the circle $= |CP - r|$ and maximum distance of P from the circle $= CP + r$

Example 24. *Find the shortest and largest distance from the point* $(2, -7)$ *to the circle*

$$x^2 + y^2 - 14x - 10y - 151 = 0$$

Sol. Let $\quad S \equiv x^2 + y^2 - 14x - 10y - 151 = 0$

$\therefore \quad S_1 = (2)^2 + (-7)^2 - 14(2) - 10(-7) - 151 = -56 < 0$



$\therefore$ $P(2,-7)$ inside the circle

radius of the circle, $r = \sqrt{(-7)^2 + (-5)^2 + 151} = 15$

$\because$ Centre of circle $C \equiv (7,5)$

$\therefore$ $CP = \sqrt{(7-2)^2 + (5+7)^2} = 13$

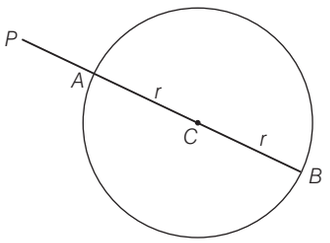
$\therefore$ **Shortest distance** $= PA = r - CP = 15 - 13 = 2$

and **Largest distance** $= PB = r + CP = 15 + 13 = 28$

Example 25. Find the points on the circle $x^2 + y^2 - 2x + 4y - 20 = 0$ which are farthest and nearest to the point $(-5,6)$.

Sol. The given circle is $S \equiv x^2 + y^2 - 2x + 4y - 20 = 0$

Let $P \equiv (-5,6)$



For the point P

$S_1 = 25 + 36 + 10 + 24 - 20$

$= 75 > 0$

$\therefore$ Point $P(-5,6)$ lies outside the circle.

The centre and radius of the circle are $(1,-2)$ and 5, respectively.

$\because$ $CP = \sqrt{(1+5)^2 + (-2-6)^2} = 10$

Now, point A divides CP in the ratio

$$\frac{AP}{AC} = \frac{CP - r}{r} = \frac{10-5}{5} = 1$$

$\therefore$ A is mid-point of CP.

$\therefore$ $A \equiv \left(\frac{1-5}{2}, \frac{-2+6}{2}\right)$

or $A \equiv (-2,2)$

and C is the mid-point of AB.

$\therefore$ $B \equiv (2\times 1 - (-2), 2\times -2 - 2)$

or $B \equiv (4,-6)$

Hence, point $A(-2,2)$ is nearest to P and $B(4,-6)$ is farthest from P.

Exercise for Session 3

1. The length of intercept, the circle $x^2 + y^2 + 10x - 6y + 9 = 0$ makes on the X-axis is

(a) 2 (b) 4 (c) 6 (d) 8

2. The circle $x^2 + y^2 + 4x - 7y + 12 = 0$ cuts an intercept on Y-axis is of length

(a) 1 (b) 3 (c) 5 (d) 7

3. The locus of the centre of a circle which passes through the origin and cuts-off a length $2b$ from the line $x = c$ is

(a) $y^2 + 2cx = b^2 + c^2$ (b) $x^2 + cx = b^2 + c^2$ (c) $y^2 + 2cy = b^2 + c^2$ (d) $x^2 + cy = b^2 + c^2$

4. If a straight line through $C(-\sqrt{8}, \sqrt{8})$ making an angle of 135° with the X-axis cuts the circle $x = 5\cos\theta$, $y = 5\sin\theta$ at points A and B, then the length of AB is

(a) 3 (b) 5 (c) 8 (d) 10

5. If a circle of constant radius $3k$ passes through the origin and meets the axes at A and B, the locus of the centroid of ΔOAB is

(a) $x^2 + y^2 = k^2$ (b) $x^2 + y^2 = 2k^2$ (c) $x^2 + y^2 = 3k^2$ (d) $x^2 + y^2 = 4k^2$

6. The centre of the circle touching Y-axis at $(0,3)$ and making an intercept of 2 units on positive X-axis is

(a) $(10, \sqrt{3})$ (b) $(\sqrt{3}, 10)$ (c) $(\sqrt{10}, 3)$ (d) $(3, \sqrt{10})$

7. A circle passes through the points $A(1,0)$ and $B(5,0)$ and touches the Y-axis at $C(0,\lambda)$. If $\angle ACB$ is maximum, then

(a) $|\lambda| = \sqrt{5}$ (b) $|\lambda| = 2\sqrt{5}$ (c) $|\lambda| = 3\sqrt{5}$ (d) $|\lambda| = 4\sqrt{5}$

8. The equation of a circle whose centre is $(3, -1)$ and which intercept chord of 6 units length on straight line $2x - 5y + 18 = 0$ is

(a) $x^2 + y^2 - 6x + 2y - 28 = 0$ (b) $x^2 + y^2 + 6x - 2y - 28 = 0$

(c) $x^2 + y^2 + 4x - 2y + 24 = 0$ (d) $x^2 + y^2 + 2x - 2y - 12 = 0$

9. The locus of the centre of a circle which touches externally the circle $x^2 + y^2 - 6x - 6y + 14 = 0$ and also touches the *Y*-axis, is given by the equation

(a) $x^2 - 6x - 10y + 14 = 0$ (b) $x^2 - 10x - 6y + 14 = 0$

(c) $y^2 - 6x - 10y + 14 = 0$ (d) $y^2 - 10x - 6y + 14 = 0$

10. The locus of the centre of a circle of radius 2 which rolls on the outside of circle $x^2 + y^2 + 3x - 6y - 9 = 0$ is

(a) $x^2 + y^2 + 3x - 6y + 5 = 0$ (b) $x^2 + y^2 + 3x - 6y - 31 = 0$

(c) $x^2 + y^2 + 3x - 6y + 11 = 0$ (d) $x^2 + y^2 + 3x - 6y - 36 = 0$

11. The point $([\lambda + 1], [\lambda])$ is lying inside the circle $x^2 + y^2 - 2x - 15 = 0$. Then, the set of all values of λ is (where [.] represents the greatest integer function)

(a) $[-2, 3]$ (b) $(-2, 3)$ (c) $[-2, 0) \cup (0, 3)$ (d) $[0, 3)$

12. The greatest distance of the point $(10, 7)$ from the circle $x^2 + y^2 - 4x - 2y - 20 = 0$ is

(a) 5 (b) 10 (c) 15 (d) 20

13. Find equations to the circles touching *Y*-axis at $(0, 3)$ and making intercept of 8 units on the *X*-axis.

14. Show that the circle $x^2 + y^2 - 2ax - 2ay + a^2 = 0$ touches both the coordinate axes.

15. If the point $(\lambda, -\lambda)$ lies inside the circle $x^2 + y^2 - 4x + 2y - 8 = 0$, then find range of λ.

16. Find the equation of the circle which passes through the origin and cuts-off chords of lengths 4 and 6 on the positive side of the *X*-axis and *Y*-axis, respectively.

Session 4

Intersection of a Line and a Circle, Product of the Algebraical Distances *PA* and *PB* is Constant when from *P*, *A* Secant be Drawn to Cut the Circle in the Points *A* and *B*, The Length of Intercept Cut-off from a Line by a Circle, Tangent to a Circle at a Given Point, Normal to a Circle at a Given Point

Intersection of a Line and a Circle

Let the equation of the circle be

$$x^2 + y^2 = a^2 \quad \text{...(i)}$$

and the equation of the line be

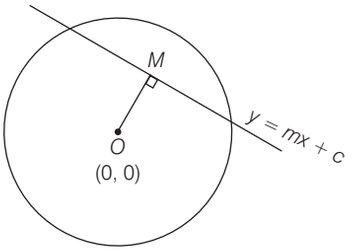
$$y = mx + c \quad \text{...(ii)}$$

From Eq. (i) and Eq. (ii)

$$x^2 + (mx + c)^2 = a^2$$

or $$(1 + m^2)\, x^2 + 2mcx + c^2 - a^2 = 0 \quad \text{...(iii)}$$

Case I When points of intersection are real and distinct, then Eq. (iii) has two distinct roots.



$$\therefore \quad B^2 - 4AC > 0$$

or $$4m^2c^2 - 4(1 + m^2)(c^2 - a^2) > 0$$

or $$a^2 > \frac{c^2}{1 + m^2}$$

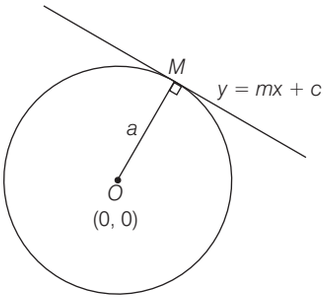
or $$a > \frac{|c|}{\sqrt{(1 + m^2)}} = \text{length of perpendicular}$$

from $(0, 0)$ to $y = mx + c$

$\Rightarrow$ $a >$ length of perpendicular from $(0, 0)$ to $y = mx + c$

Thus, a line intersects a given circle at two distinct points if radius of circle is greater than the length of perpendicular from centre of the circle to the line.

Case II When the points of intersection are coincident, then Eq. (iii) has two equal roots



$$\therefore \quad B^2 - 4AC = 0$$

$$\Rightarrow \quad 4m^2c^2 - 4(1 + m^2)(c^2 - a^2) = 0$$

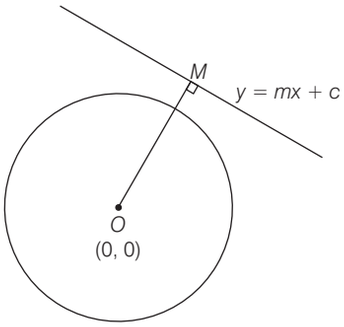
$$\therefore \quad a^2 = \frac{c^2}{(1 + m^2)}$$

or $$a = \frac{|c|}{\sqrt{(1 + m^2)}}$$

$a =$ length of the perpendicular from the point $(0, 0)$ to $y = mx + c$

Thus, a line touches the circle if radius of circle is equal to the length of perpendicular from centre of the circle to the line.

Case III When the points of intersection are imaginary. In this case (iii) has imaginary roots



$$\therefore \quad B^2 - 4AC < 0$$

$$4m^2c^2 - 4(1+m^2)(c^2 - a^2) = 0$$

$$\therefore \quad a^2 < \frac{c^2}{1+m^2}$$

or $a < \dfrac{|c|}{\sqrt{1+m^2}}$ = length of perpendicular from $(0,0)$ to $y = mx + c$

or $a <$ length of perpendicular from $(0,0)$ to $y = mx + c$

Thus, a line does not intersect a circle if the radius of circle is less than the length of perpendicular from centre of the circle to the line.

Example 26. *Find the points of intersection of the line* $2x + 3y = 18$ *and the circle* $x^2 + y^2 = 25$.

Sol. We have, $2x + 3y = 18$ ....(i)

and $x^2 + y^2 = 25$ ...(ii)

From Eq. (i), $y = \dfrac{18 - 2x}{3}$

Substituting in Eq. (ii), then $x^2 + \left(\dfrac{18-2x}{3}\right)^2 = 25$

$\Rightarrow \quad 9x^2 + 4(9 - x)^2 = 225$

$\Rightarrow \quad 9x^2 + 4(81 - 18x + x^2) = 225$

$\Rightarrow \quad 13x^2 - 72x + 324 - 225 = 0$

$\Rightarrow \quad 13x^2 - 72x + 99 = 0$

$\Rightarrow \quad (x - 3)(13x - 33) = 0$

$\Rightarrow \quad x = 3 \quad \text{or} \quad x = \dfrac{33}{13}$

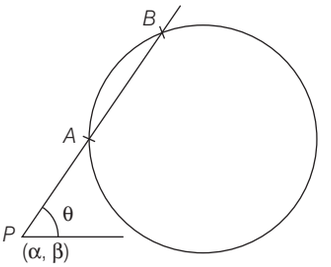
From Eq. (i), $y = 4 \quad \text{or} \quad y = \dfrac{56}{13}$

Hence, the points of intersection of the given line and the given circle are $(3,4)$ and $\left(\dfrac{33}{13}, \dfrac{56}{13}\right)$.

Product of the Algebraical Distances *PA* and *PB* is Constant when from *P*, A Secant be Drawn to Cut the Circle in the Points *A* and *B*

If a straight line through $P(\alpha, \beta)$ makes an angle θ with the positive direction of X-axis, then its equation is

$$\frac{x - \alpha}{\cos\theta} = \frac{y - \beta}{\sin\theta} = r$$



where, r is the algebraical distance of the point (x, y) from the point $P(\alpha, \beta)$.

$\therefore \quad (x, y) = (\alpha + r\cos\theta, \beta + r\sin\theta)$

If this point lies on the circle $x^2 + y^2 + 2gx + 2fy + c = 0$

or $(\alpha + r\cos\theta)^2 + (\beta + r\sin\theta)^2 + 2g(\alpha + r\cos\theta) + 2f(\beta + r\sin\theta) + c = 0$

$\Rightarrow \quad r^2 + 2r(\alpha\cos\theta + \beta\sin\theta + g\cos\theta + f\sin\theta) + (\alpha^2 + \beta^2 + 2g\alpha + 2f\beta + c) = 0$

This is quadratic equation in r, then PA and PB are the roots of this equation.

$\therefore \quad PA \cdot PB = \alpha^2 + \beta^2 + 2g\alpha + 2f\beta + c = \text{constant}$

Since, RHS is independent of θ.

Remark

Secants are drawn from a given point A to cut a given circle at the pairs of points P_1, Q_1 ; P_2, Q_2;...; P_n, Q_n, then

$$AP_1 \cdot AQ_1 = AP_2 \cdot AQ_2 = \ldots = AP_n \cdot AQ_n$$

The Length of Intercept Cut-off from a Line by a Circle

Theorem : The length of the intercept cut-off from the line $y = mx + c$ by the circle $x^2 + y^2 = a^2$ is

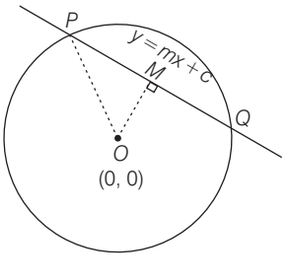
$$2\sqrt{\left\{\frac{a^2(1+m^2) - c^2}{(1+m^2)}\right\}}$$

Proof : Draw OM perpendicular to PQ

Now, OM = length of perpendicular from $O(0,0)$ to

$$(y = mx + c) = \frac{|c|}{\sqrt{(1+m^2)}}$$

and OP = radius of the circle = a



In ΔOPM, $PM = \sqrt{(OP)^2 - (OM)^2}$

$$= \sqrt{a^2 - \frac{c^2}{(1+m^2)}} = \sqrt{\left\{\frac{a^2(1+m^2) - c^2}{1+m^2}\right\}}$$

$$\therefore \quad PQ = 2PM = 2\sqrt{\left\{\frac{a^2(1+m^2) - c^2}{1+m^2}\right\}}$$

Remarks

1. If the line $y = mx + c$ touches the circle $x^2 + y^2 = a^2$, then intercepted length is zero

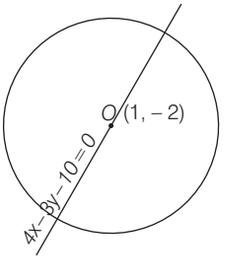
   i.e. $PQ = 0 \Rightarrow 2\sqrt{\left\{\frac{a^2(1+m^2) - c^2}{1+m^2}\right\}} = 0$

   $\therefore \quad c^2 = a^2(1+m^2)$

   which is the required condition for tangency.
2. If a line touches the circle, then length of perpendicular from the centre upon the line is equal to the radius of the circle.

Example 27. *Find the length of the intercept on the straight line* $4x - 3y - 10 = 0$ *by the circle* $x^2 + y^2 - 2x + 4y - 20 = 0$.

Sol. Centre and radius of the circle $x^2 + y^2 - 2x + 4y - 20 = 0$ are $(1, -2)$ and $\sqrt{1 + 4 + 20} = 5$ respectively.



Let OM be the perpendicular from O on the line

$$4x - 3y - 10 = 0$$

then $$OM = \frac{|4 \times 1 - 3 \times (-2) - 10|}{\sqrt{4^2 + (-3)^2}} = 0$$

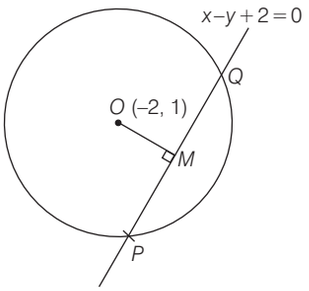
Hence, line $4x - 3y - 10 = 0$ passes through the centre of the circle.

Hence, intercepted length = diameter of the circle

$$= 2 \times 5 = 10$$

Example 28. Find the coordinates of the middle point of the chord which the circle $x^2 + y^2 + 4x - 2y - 3 = 0$ cuts-off the line $x - y + 2 = 0$.

Sol. Centre and radius of the circle $x^2 + y^2 + 4x - 2y - 3 = 0$ are $(-2, 1)$ and $\sqrt{4 + 1 + 3} = 2\sqrt{2}$ respectively.



Draw perpendicular from O upon $x - y + 2 = 0$ is OM.

Equation of OM which is perpendicular to $x - y + 2 = 0$ is $x + y = \lambda$, it passes through $(-2, 1)$

Then, $-2 + 1 = \lambda$

$\therefore \quad \lambda = -1$

then equation of OM is $x + y + 1 = 0$

Since, M is the mid-point of PQ which is point of intersection of $x - y + 2 = 0$ and $x + y + 1 = 0$, coordinates of M is $\left(-\frac{3}{2}, \frac{1}{2}\right)$.

Aliter : Let $M \equiv (\alpha, \beta)$, then

$$\frac{\alpha + 2}{1} = \frac{\beta - 1}{-1} = -\frac{(-2 - 1 + 2)}{1 + 1}$$

(Here, M is foot of perpendicular)

$$\Rightarrow \quad \frac{\alpha + 2}{1} = \frac{\beta - 1}{-1} = \frac{1}{2}$$

or $$\alpha = -\frac{3}{2} \text{ and } \beta = \frac{1}{2}$$

$$\therefore \quad M \equiv \left(-\frac{3}{2}, \frac{1}{2}\right)$$

Example 29. For what value of λ will the line $y = 2x + \lambda$ be a tangent to the circle $x^2 + y^2 = 5$?

Sol. Comparing the given line with $y = mx + c$, we get

$m = 2$, $c = \lambda$ and given circle with $x^2 + y^2 = a^2$

then $$a^2 = 5$$

$\because$ Condition for tangency is

$$c^2 = a^2(1 + m^2)$$

$\Rightarrow$ $\lambda^2 = 5(1 + 4)$

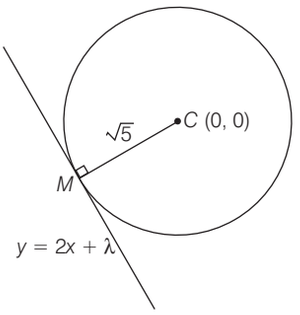
$\lambda^2 = 25$

$\therefore$ $\lambda = \pm 5$

Aliter : Since, line $y = 2x + \lambda$

or $2x - y + \lambda = 0$

is the tangent to the circle $x^2 + y^2 = 5$ then length of perpendicular from centre upon the line is equal to the radius of the circle



$\therefore$ $|CM| = \sqrt{5}$

or $\dfrac{|0 - 0 + \lambda|}{\sqrt{4 + 1}} = \sqrt{5}$

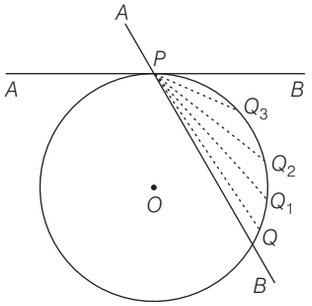
$\Rightarrow$ $\dfrac{|\lambda|}{\sqrt{5}} = \sqrt{5}$

$\Rightarrow$ $|\lambda| = 5$

or $\lambda = \pm 5$

Tangent to a Circle at a Given Point

Let PQ be a chord and AB be a secant passing through P. Let P be the fixed point and move along the circle towards P, then the secant PQ turns about P. In the limit, when Q coincides with P, then the secant AB becomes a tangent to the circle at the point P.



Different forms of the equations of tangents

1. Point form :

Theorem : The equation of tangent at the point $P(x_1, y_1)$ to a circle

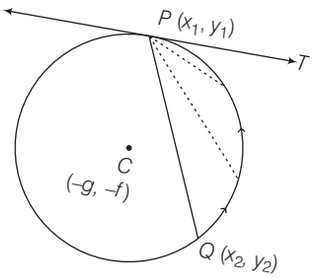
$$x^2 + y^2 + 2gx + 2fy + c = 0 \text{ is}$$

$$xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c = 0$$

Proof : Since, $P(x_1, y_1)$ be a point on the circle

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(i)}$$

Let $Q(x_2, y_2)$ be any other point on the circle Eq. (i). Since, points $P(x_1, y_1)$ and $Q(x_2, y_2)$ lie on the circle, therefore



$$x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0 \quad \text{...(ii)}$$

and $$x_2^2 + y_2^2 + 2gx_2 + 2fy_2 + c = 0 \quad \text{...(iii)}$$

On subtracting Eq. (ii) from Eq. (iii), we have

$$(x_2^2 - x_1^2) + (y_2^2 - y_1^2) + 2g$$

$$(x_2 - x_1) + 2f(y_2 - y_1) = 0$$

$\Rightarrow$ $(x_2 - x_1)(x_2 + x_1 + 2g) + (y_2 - y_1)$

$$(y_2 + y_1 + 2f) = 0$$

$\Rightarrow$ $$\left(\frac{y_2 - y_1}{x_2 - x_1}\right) = -\left(\frac{x_1 + x_2 + 2g}{y_1 + y_2 + 2f}\right) \quad \text{...(iv)}$$

Now, the equation of the chord PQ is

$$y - y_1 = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)(x - x_1) \quad \text{...(v)}$$

Putting the value of $\left(\dfrac{y_2 - y_1}{x_2 - x_1}\right)$ from Eq. (iv) in Eq. (v), then equation PQ becomes

$$y - y_1 = -\left(\frac{x_1 + x_2 + 2g}{y_1 + y_2 + 2f}\right)(x - x_1) \quad \text{...(vi)}$$

Now, when $Q \to P$ (along the circle), line PQ becomes tangent at P, we have $x_2 \to x_1, y_2 \to y_1$. So, the equation of tangent at $P(x_1, y_1)$ is :

$$y - y_1 = -\left(\frac{x_1 + x_1 + 2g}{y_1 + y_1 + 2f}\right)(x - x_1)$$

$$\Rightarrow \quad y - y_1 = -\left(\frac{x_1 + g}{y_1 + f}\right)(x - x_1)$$

$$\Rightarrow \quad (y - y_1)(y_1 + f) + (x - x_1)(x_1 + g) = 0$$

$$\Rightarrow \quad xx_1 + yy_1 + gx + fy = x_1^2 + y_1^2 + gx_1 + fy_1$$

On adding $gx_1 + fy_1 + c$ to both sides, we get

$$xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c$$
$$= x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0 \qquad \text{[from Eq. (ii)]}$$

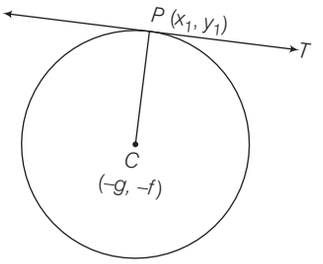
$$\Rightarrow \quad xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c = 0$$

This is the required equation of the tangent PT to the circle at the point (x_1, y_1).

Aliter : Since, circle is $x^2 + y^2 + 2gx + 2fy + c = 0$

$P(x_1, y_1)$ lie on the circle

$$\therefore \quad x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0 \qquad \text{...(i)}$$



Its centre is $C(-g, -f)$

$$\therefore \quad \text{Slope of } CP = \frac{y_1 - (-f)}{x_1 - (-g)} = \frac{y_1 + f}{x_1 + g}$$

Since, tangent PT is perpendicular to CP.

$$\therefore \quad \text{Slope of tangent} = -\left(\frac{x_1 + g}{y_1 + f}\right)$$

$\therefore$ Equation of tangent at $P(x_1, y_1)$ is

$$y - y_1 = -\left(\frac{x_1 + g}{y_1 + f}\right)(x - x_1)$$

$$\Rightarrow \quad (y - y_1)(y_1 + f) + (x_1 + g)(x - x_1) = 0$$

$$\Rightarrow \quad xx_1 + yy_1 + gx + fy = x_1^2 + y_1^2 + gx_1 + fy_1$$

On adding $gx_1 + fy_1 + c$ to both sides, we get

$$xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c$$
$$= x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0 \qquad \text{[from Eq. (i)]}$$

or $\quad xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c = 0$

This is the required equation of the tangent PT to the circle at the point $P(x_1, y_1)$.

Remarks

1. For equation of tangent of circle at (x_1, y_1), substitute xx_1 for x^2, yy_1 for y^2, $\frac{x + x_1}{2}$ for x, $\frac{y + y_1}{2}$ for y and $\frac{xy_1 + x_1y}{2}$ for xy and keep the constant as such.
2. This method of tangent at (x_1, y_1) is applied only for any conics of second degree. i.e. equation of tangent of $ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0$ at (x_1, y_1) is $axx_1 + h(xy_1 + x_1y) + byy_1 + g(x + x_1) + f(y + y_1) + c = 0$

Wrong process : Mostly students use wrong process

Suppose any curve

$$ax^3 + by^3 = c$$

or $\quad a(x)(x^2) + b(y)(y^2) = c$

Equation of tangent at (x_1, y_1)

$$\Rightarrow \quad a\left(\frac{x + x_1}{2}\right)xx_1 + b\left(\frac{y + y_1}{2}\right)yy_1 = c^2$$

which is a second degree conic not the equation of tangent.

Reason : This method is applicable only for second degree conic, its a third degree conic. (find its tangent only by calculus)

Example 30. *Prove that the tangents to the circle $x^2 + y^2 = 25$ at $(3, 4)$ and $(4, -3)$ are perpendicular to each other.*

Sol. The equations of tangents to $x^2 + y^2 = 25$ at $(3, 4)$ and $(4, -3)$ are

$$3x + 4y = 25 \qquad \text{...(i)}$$

and $\quad 4x - 3y = 25 \qquad \text{...(ii)}$

respectively.

Now, $\quad$ slope of Eq. (i) $= -\frac{3}{4} = m_1$ (say)

and $\quad$ slope of Eq. (ii) $= \frac{4}{3} = m_2$ (say)

Clearly, $\quad m_1 m_2 = -1$

Hence, Eq. (i) and Eq. (ii) are perpendicular to each other.

Example 31. Find the equation of tangent to the circle $x^2 + y^2 - 2ax = 0$ at the point $[a(1 + \cos\alpha), a\sin\alpha]$.

Sol. The equation of tangent of $x^2 + y^2 - 2ax = 0$ at $[a(1 + \cos\alpha), a\sin\alpha]$ is

$$x \cdot a(1 + \cos\alpha) + y \cdot a\sin\alpha - a[x + a(1 + \cos\alpha)] = 0$$

$$\Rightarrow \quad ax\cos\alpha + ay\sin\alpha - a^2(1 + \cos\alpha) = 0$$

or $\quad x\cos\alpha + y\sin\alpha = a(1 + \cos\alpha)$

Example 32. Show that the circles $x^2 + y^2 - 4x + 6y + 8 = 0$ and $x^2 + y^2 - 10x - 6y + 14 = 0$ touch at $(3, -1)$.

Sol. Equation of tangent at $(3, -1)$ of the circle $x^2 + y^2 - 4x + 6y + 8 = 0$ is

$$3x + (-1)\,y - 2(x + 3) + 3(y - 1) + 8 = 0$$

or $$x + 2y - 1 = 0 \quad \text{...(i)}$$

and equation of tangent at $(3, -1)$ of the circle $x^2 + y^2 - 10x - 6y + 14 = 0$ is

$$3 \cdot x + (-1) \cdot y - 5(x + 3) - 3(y - 1) + 14 = 0$$

or $$-2x - 4y + 2 = 0$$

or $$x + 2y - 1 = 0 \quad \text{...(ii)}$$

which is the same as Eq (i).

Hence, the given circles touch at $(3, -1)$.

2. Parametric form :

Theorem : The equation of tangent to the circle $x^2 + y^2 = a^2$ at the point $(a\cos\theta, a\sin\theta)$ is $x\cos\theta + y\sin\theta = a$

Proof : The equation of tangent of $x^2 + y^2 = a^2$ at (x_1, y_1) is $xx_1 + yy_1 = a^2$ (using point form of the tangent)

Putting $x_1 = a\cos\theta, y_1 = a\sin\theta$

then, we get $x\cos\theta + y\sin\theta = a$

***Corollary* 1 :** Equation of chord joining $(a\cos\theta, a\sin\theta)$ and $(a\cos\phi, a\sin\phi)$ is

$$x\cos\left(\frac{\theta+\phi}{2}\right) + y\sin\left(\frac{\theta+\phi}{2}\right) = a\cos\left(\frac{\theta-\phi}{2}\right)$$

***Corollary* 2 :** Point of intersection of tangents at $(a\cos\theta, a\sin\theta)$ and $(a\cos\phi, a\sin\phi)$ is

$$\left(\frac{a\cos\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}, \frac{a\sin\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}\right)$$

Remembering method :

$$\because \quad x\cos\left(\frac{\theta+\phi}{2}\right) + y\sin\left(\frac{\theta+\phi}{2}\right) = a\cos\left(\frac{\theta-\phi}{2}\right)$$

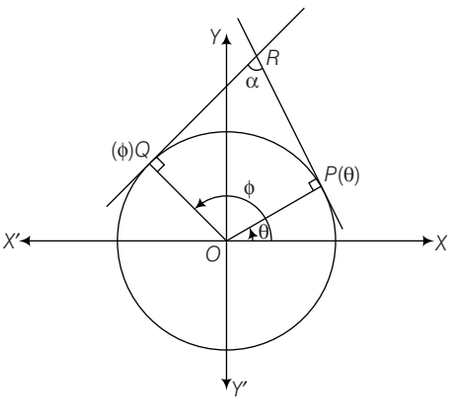
or $$x\left\{\frac{a\cos\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}\right\} + y\left\{\frac{a\sin\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}\right\} = a^2$$

We get $$\left(\frac{a\cos\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}, \frac{a\sin\left(\frac{\theta+\phi}{2}\right)}{\cos\left(\frac{\theta-\phi}{2}\right)}\right)$$

***Corollary* 3 :** The angle between a pair of tangents from a point P to the circle $x^2 + y^2 = a^2$ is α. Then, the locus of the point P is

$$x^2 + y^2 = \frac{a^2}{\sin^2\left(\frac{\alpha}{2}\right)}$$

Proof



$$\because \quad \phi - \theta + \alpha = 180^\circ$$

$$\therefore \quad \frac{\theta - \phi}{2} = -\left(90^\circ - \frac{\alpha}{2}\right)$$

or $$\cos\left(\frac{\theta-\phi}{2}\right) = \sin\left(\frac{\alpha}{2}\right)$$

Now, point of intersection is

$$\left(\frac{a\cos\left(\frac{\theta+\phi}{2}\right)}{\sin\left(\frac{\alpha}{2}\right)}, \frac{a\sin\left(\frac{\theta+\phi}{2}\right)}{\sin\left(\frac{\alpha}{2}\right)}\right)$$

Let $$x = \frac{a\cos\left(\frac{\theta+\phi}{2}\right)}{\sin\left(\frac{\alpha}{2}\right)} \text{ and } y = \frac{a\sin\left(\frac{\theta+\phi}{2}\right)}{\sin\left(\frac{\alpha}{2}\right)}$$

$$\therefore \quad x^2 + y^2 = \frac{a^2}{\sin^2\left(\frac{\alpha}{2}\right)}$$

Remarks

1. The angle between a pair of tangents from a point P to the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is 2θ, then the locus of P is $x^2 + y^2 + 2gx + 2fy + c = (g^2 + f^2 - c)\cot^2\theta$
2. If angle between a pair of tangents from a point P to the circle $x^2 + y^2 = a^2$ is $\frac{\pi}{2}$, then the locus of P is
$$x^2 + y^2 = 2a^2 \qquad \left(\text{Here, } \alpha = \frac{\pi}{2}\right)$$
which is **director circle** of $x^2 + y^2 = a^2$.
($\because$ locus of point of intersection of perpendicular tangents is **director circle**)
3. The equation of the tangent to the circle $(x-a)^2 + (y-b)^2 = r^2$ at the point $(a + r\cos\theta, b + r\sin\theta)$ is
$$(x-a)\cos\theta + (y-b)\sin\theta = r.$$

Example 33. ***The angle between a pair of tangents from a point P to the circle $x^2 + y^2 = 25$ is $\frac{\pi}{3}$. Find the equation of the locus of the point P.***

Sol. Here, $\alpha = \frac{\pi}{3}$

$\therefore$ Required locus is $x^2 + y^2 = \frac{25}{\sin^2\left(\frac{\pi}{6}\right)} = 100$

Example 34. ***The angle between a pair of tangents from a point P to the circle $x^2 + y^2 - 6x - 8y + 9 = 0$ is $\frac{\pi}{3}$. Find the equation of the locus of the point P.***

Sol. Here, $2\theta = \frac{\pi}{3}$ or $\theta = \frac{\pi}{6}$

$\therefore$ Required locus is

$$x^2 + y^2 - 6x - 8y + 9 = (9 + 16 - 9)\cot^2\frac{\pi}{6}$$

or $\quad x^2 + y^2 - 6x - 8y + 9 = 16 \times 3$

or $\quad x^2 + y^2 - 6x - 8y - 39 = 0$

3. Slope form :

Theorem : The equation of a tangent of slope m to the circle $x^2 + y^2 = a^2$ is $y = mx \pm a\sqrt{(1+m^2)}$ and the coordinates of the point of contact are

$$\left(\pm\frac{am}{\sqrt{(1+m^2)}}, \mp\frac{a}{\sqrt{(1+m^2)}}\right)$$

Proof : Let $y = mx + c$ is the tangent of the circle $x^2 + y^2 = a^2$.

$\therefore$ Length of perpendicular from centre of circle $(0,0)$ on $(y = mx + c)$ = radius of circle

$$\therefore \quad \frac{|c|}{\sqrt{(1+m^2)}} = a \quad \Rightarrow \quad c = \pm a\sqrt{(1+m^2)}$$

On substituting this value of c in $y = mx + c$, we get

$$y = mx \pm a\sqrt{(1+m^2)} \qquad \ldots(i)$$

which are the required equations of tangents.

Also, let (x_1, y_1) be the point of contact, then equation of tangent at (x_1, y_1) to the circle $x^2 + y^2 = a^2$ is

$$xx_1 + yy_1 = a^2 \qquad \ldots(ii)$$

On comparing Eq. (i) and Eq. (ii), we get

$$\frac{x_1}{m} = \frac{y_1}{-1} = \frac{a^2}{\pm a\sqrt{(1+m^2)}}$$

$$\Rightarrow \quad \frac{x_1}{m} = -\frac{y_1}{1} = \pm\frac{a}{\sqrt{(1+m^2)}}$$

$$\Rightarrow \quad x_1 = \pm\frac{am}{\sqrt{1+m^2}} \quad \text{and} \quad y_1 = \mp\frac{a}{\sqrt{(1+m^2)}}$$

Hence, $(x_1, y_1) = \left(\pm\frac{am}{\sqrt{(1+m^2)}}, \mp\frac{a}{\sqrt{(1+m^2)}}\right)$

Corollary : It also follows that $y = mx + c$ is a tangent to $x^2 + y^2 = a^2$, if $c^2 = a^2(1+m^2)$ which is condition of tangency.

Remarks

1. The reason why there are two equations $y = mx \pm a\sqrt{1+m^2}$, there are two tangents, both are parallel and at the ends of diameter.
2. The line $ax + by + c = 0$ is tangent to the circle $x^2 + y^2 = r^2$ if and only if $c^2 = r^2(a^2 + b^2)$.
3. If the line $y = mx + c$ is the tangent to the circle $x^2 + y^2 = r^2$, then point of contact is given by $\left(-\frac{mr^2}{c}, \frac{r^2}{c}\right)$
4. If the line $ax + by + c = 0$ is the tangent to the circle $x^2 + y^2 = r^2$, then point of contact is given by $\left(-\frac{ar^2}{c}, -\frac{br^2}{c}\right)$.
5. The condition that the line $lx + my + n = 0$ touches the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is $(lg + mf - n)^2 = (l^2 + m^2)(g^2 + f^2 - c)$.
6. Equation of tangent of the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ in terms of slope is $y + f = m(x + g) \pm \sqrt{(g^2 + f^2 - c)(1 + m^2)}$
7. The equation of tangents of slope m to the circle $(x-a)^2 + (y-b)^2 = r^2$ are given by $(y-b) = m(x-a) \pm r\sqrt{(1+m^2)}$
and the coordinates of the points of contact are $\left(a \pm \frac{mr}{\sqrt{(1+m^2)}}, b \mp \frac{r}{\sqrt{(1+m^2)}}\right)$

Example 35. Find the equations of the tangents to the circle $x^2 + y^2 = 9$, which

(i) are parallel to the line $3x + 4y - 5 = 0$

(ii) are perpendicular to the line $2x + 3y + 7 = 0$

(iii) make an angle of 60^o with the X-axis

Sol. (i) Slope of $3x + 4y - 5 = 0$ is $-\frac{3}{4}$

Let $m = -\frac{3}{4}$

and equation of circle is $x^2 + y^2 = 9$

$\therefore$ Equations of tangents

$$y = -\frac{3}{4}x \pm 3\sqrt{\left(1 + \left(-\frac{3}{4}\right)^2\right)}$$

$\Rightarrow \quad 4y = -3x \pm 15$ or $3x + 4y \pm 15 = 0$

(ii) Slope of $2x + 3y + 7 = 0$ is $-\frac{2}{3}$

$\therefore$ Slope of perpendicular to $2x + 3y + 7 = 0$ is $\frac{3}{2} = m$ (say)

and given circle is $x^2 + y^2 = 9$

$\therefore$ Equations of tangents perpendicular to $2x + 3y + 7 = 0$ is

$$y = \frac{3}{2}x \pm 3\sqrt{1 + \left(\frac{3}{2}\right)^2}$$

$\Rightarrow \quad 2y = 3x \pm 3\sqrt{13}$

or $\quad 3x - 2y \pm 3\sqrt{13} = 0$

(iii) Since, tangent make an angle $60°$ with the X-axis

$\therefore \quad m = \tan 60° = \sqrt{3}$

and given circle $\quad x^2 + y^2 = 9$

$\therefore$ Equation of tangents $y = \sqrt{3}x \pm 3\sqrt{1 + (\sqrt{3})^2}$

or $\quad \sqrt{3}\,x - y \pm 6 = 0$

Aliter :

(i) Let tangent parallel to $3x + 4y - 5 = 0$ is

$$3x + 4y + \lambda = 0 \qquad \ldots(i)$$

and circle $\quad x^2 + y^2 = 9$

then perpendicular distance from $(0, 0)$ on Eq. (i) = radius

$$\frac{|\lambda|}{\sqrt{(3^2 + 4^2)}} = 3$$

or $\quad |\lambda| = 15$

$\therefore \quad \lambda = \pm 15$

From Eq. (i), equations of tangents are

$$3x + 4y \pm 15 = 0$$

(ii) Let tangent perpendicular to $2x + 3y + 7 = 0$ is

$$3x - 2y + \lambda = 0 \qquad \ldots(ii)$$

and circle $\quad x^2 + y^2 = 9$

then, perpendicular distance from $(0, 0)$ on Eq. (ii) = radius

$$\frac{|\lambda|}{\sqrt{3^2 + (-2)^2}} = 3$$

or $\quad |\lambda| = 3\sqrt{13}$

or $\quad \lambda = \pm 3\sqrt{13}$

From Eq. (ii), equations of tangents are

$$3x - 2y \pm 3\sqrt{13} = 0$$

(iii) Let equation of tangent which makes an angle of $60°$ with the X-axis is

$$y = \sqrt{3}x + c \qquad \ldots(iii)$$

or $\quad \sqrt{3}x - y + c = 0$

and circle $\quad x^2 + y^2 = 9$

then, perpendicular distance from $(0, 0)$ to Eq. (iii) = radius

$$\frac{|c|}{\sqrt{(\sqrt{3})^2 + (-1)^2}} = 3$$

or $\quad |c| = 6$

or $\quad c = \pm 6$

From Eq. (iii), equations of tangents are

$$\sqrt{3}x - y \pm 6 = 0$$

Example 36. Prove that the line $lx + my + n = 0$ touches the circle $(x - a)^2 + (y - b)^2 = r^2$ if $(al + bm + n)^2 = r^2(l^2 + m^2)$.

Sol. If the line $lx + my + n = 0$ touches the circle $(x - a)^2 + (y - b)^2 = r^2$, then length of the perpendicular from the centre = radius

$$\frac{|la + mb + n|}{\sqrt{(l^2 + m^2)}} = r$$

$\Rightarrow \quad (la + mb + n)^2 = r^2(l^2 + m^2)$

Aliter :

Here, line is $lx + my + n = 0$ and circle is $(x - a)^2 + (y - b)^2 = r^2$. Here, centre of circle (a, b) shift at $(0, 0)$, then replacing x by $x + a$ and y by $y + b$ in the equation of straight line $lx + my + n = 0$ and circle $(x - a)^2 + (y - b)^2 = r^2$, the new form of straight line and circle are

$$l(x + a) + m(y + b) + n = 0$$

or $\quad lx + my + (al + mb + n) = 0 \qquad \ldots(i)$

and $\quad x^2 + y^2 = r^2 \qquad \ldots(ii)$

respectively.

On comparing Eq. (i) with $y = Mx + C$

then $\quad M = -\frac{l}{m}$

and $\quad C = -\frac{(al + bm + n)}{m}$

Since, Eq. (i) is the tangent of Eq. (ii), then

$$C^2 = r^2 (1 + M^2)$$

or $$\frac{(al + bm + n)^2}{m^2} = r^2 \left(1 + \frac{l^2}{m^2}\right)$$

or $$(al + bm + n)^2 = r^2 (l^2 + m^2)$$

Example 37. Show that the line $3x - 4y = 1$ touches the circle $x^2 + y^2 - 2x + 4y + 1 = 0$. Find the coordinates of the point of contact.

Sol. The centre and radius of the circle

$$x^2 + y^2 - 2x + 4y + 1 = 0 \text{ are } (1, -2)$$

and $\sqrt{(-1) + (2)^2 - 1} = 2$ respectively.

Since, length of perpendicular from centre $(1, -2)$ on $3x - 4y = 1$ is

$$\frac{|3 \times 1 - 4 \times (-2) - 1|}{\sqrt{(3)^2 + (-4)^2}} = \frac{10}{5}$$

$$= 2 = \text{radius of the circle}$$

Hence, $3x - 4y = 1$ touches the circle

$$x^2 + y^2 - 2x + 4y + 1 = 0$$

Second part : Let point of contact is (x_1, y_1), then tangent at (x_1, y_1) on $x^2 + y^2 - 2x + 4y + 1 = 0$ is

$$xx_1 + yy_1 - (x + x_1) + 2(y + y_1) + 1 = 0$$

$$\Rightarrow \quad x(x_1 - 1) + y(y_1 + 2) - x_1 + 2y_1 + 1 = 0 \quad \text{...(i)}$$

and given line $\quad 3x - 4y - 1 = 0 \quad$ ...(ii)

Since, Eq. (i) and Eq. (ii) are identical, then comparing Eq. (i) and Eq. (ii), we get

$$\frac{x_1 - 1}{3} = \frac{y_1 + 2}{-4} = \frac{-x_1 + 2y_1 + 1}{-1}$$

or $$x_1 = -\frac{1}{5} \quad \text{and} \quad y_1 = -\frac{2}{5}$$

$\therefore$ Point of contact is $\left(-\frac{1}{5}, -\frac{2}{5}\right)$.

Aliter for second part : Since, perpendicular line to tangent always passes through the centre of the circle, perpendicular line to

$$3x - 4y = 1 \quad \text{...(i)}$$

is $$4x + 3y = \lambda \quad \text{...(ii)}$$

which passes through $(1, -2)$, then

$$4 - 6 = \lambda$$

$\therefore$ $$\lambda = -2$$

From Eq. (ii), $\quad 4x + 3y = -2 \quad$ ...(iii)

Solving Eq. (i) and Eq. (iii), we get the point of contact i.e. $x = -\frac{1}{5}$ and $y = -\frac{2}{5}$

Hence, point of contact is $\left(-\frac{1}{5}, -\frac{2}{5}\right)$.

Example 38. If $lx + my = 1$ touches the circle $x^2 + y^2 = a^2$, prove that the point (l, m) lies on the circle $x^2 + y^2 = a^{-2}$.

Sol. Since, $lx + my = 1$ touches the circle $x^2 + y^2 = a^2$.

Then, length of perpendicular from $(0, 0)$ on $lx + my = 1$ is equal to radius

then, $\frac{|-1|}{\sqrt{l^2 + m^2}} = a$ or $l^2 + m^2 = a^{-2}$

Hence, locus of (l, m) is $x^2 + y^2 = a^{-2}$

Aliter : Let the point of contact of line $lx + my = 1$ and circle $x^2 + y^2 = a^2$ is (x_1, y_1), then tangent of circle at (x_1, y_1) is $xx_1 + yy_1 = a^2$

Since, $\quad xx_1 + yy_1 = a^2 \quad$ and $\quad lx + my = 1$

are identical, then $\frac{x_1}{l} = \frac{y_1}{m} = \frac{a^2}{1}$

$\therefore$ $$x_1 = la^2, y_1 = ma^2$$

but (x_1, y_1) lie on $x^2 + y^2 = a^2$

then, $$l^2a^4 + m^2a^4 = a^2$$

$\therefore$ $$l^2 + m^2 = a^{-2}$$

$\therefore$ Locus of (l, m) is $x^2 + y^2 = a^{-2}$

Example 39. Show that the line $(x - 2)\cos\theta + (y - 2)\sin\theta = 1$ touches a circle for all values of θ. Find the circle.

Sol. Given line is $(x - 2)\cos\theta + (y - 2)\sin\theta$

$$1 = \cos^2\theta + \sin^2\theta$$

On comparing

$$x - 2 = \cos\theta \quad \text{...(i)}$$

and $$y - 2 = \sin\theta \quad \text{...(ii)}$$

Squaring and adding Eq. (i) and Eq. (ii), then

$$(x - 2)^2 + (y - 2)^2 = \cos^2\theta + \sin^2\theta$$

$$\Rightarrow \quad (x - 2)^2 + (y - 2)^2 = 1$$

or $$x^2 + y^2 - 4x - 4y + 7 = 0$$

Aliter : Since, tangent at $(\cos\theta, \sin\theta)$ of

$$x^2 + y^2 = 1 \quad \text{...(i)}$$

is $$x\cos\theta + y\sin\theta = 1 \quad \text{...(ii)}$$

replacing x by $x - 2$ and y by $y - 2$ in Eqs. (i) and (ii), then

$$(x - 2)^2 + (y - 2)^2 = 1 \quad \text{...(iii)}$$

$$(x - 2)\cos\theta + (y - 2)\sin\theta = 1 \quad \text{...(iv)}$$

Hence, Eq. (iv) touches the circle Eq. (iii).

$\therefore$ Equation of circle is

$$(x - 2)^2 + (y - 2)^2 = 1$$

or $$x^2 + y^2 - 4x - 4y + 7 = 0$$

Normal to a Circle at a Given Point

The normal of a circle at any point is a straight line which is perpendicular to the tangent at the point and always passes through the centre of the circle.

Different form of the Equation of Normals

1. Point form :

Theorem : The equation of normal at the point $P(x_1, y_1)$ to the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is

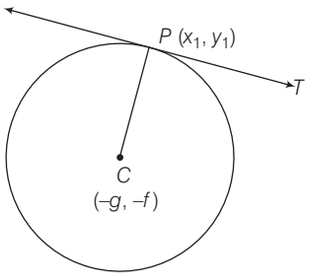
$$\frac{x - x_1}{x_1 + g} = \frac{y - y_1}{y_1 + f}$$

Proof :

Equation of the given circle is

$$x^2 + y^2 + 2gx + 2fy + c = 0 \qquad ...(i)$$

Its centre C is $(-g, -f)$



Let $P(x_1, y_1)$ be the given point.

$\because$ Normal of the circle at $P(x_1, y_1)$ passes through centre $C(-g, -f)$ of the circle.

Then, equation of normal CP passes through the points $C(-g, -f)$ and $P(x_1, y_1)$ is

$$y - y_1 = \frac{(y_1 + f)}{(x_1 + g)}(x - x_1)$$

or $$\frac{x - x_1}{x_1 + g} = \frac{y - y_1}{y_1 + f}$$

This is the required equation of normal at $P(x_1, y_1)$ of the given circle.

Remark

Easy method to find normal at (x_1, y_1) of second degree conics

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \qquad ...(i)$$

then, according to determinant $\begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix}$

write first two rows as $ax_1 + hy_1 + g$ and $hx_1 + by_1 + f$

Then, normal at (x_1, y_1) of conic (i)

$$\frac{x - x_1}{ax_1 + hy_1 + g} = \frac{y - y_1}{hx_1 + by_1 + f}$$

***Corollary* 1 :** Equation of normal of $x^2 + y^2 = a^2$ at (x_1, y_1) is

$$\frac{x - x_1}{1 \cdot x_1 + 0 + 0} = \frac{y - y_1}{0 + 1 \cdot y_1 + 0}$$

(Here, $g, f = 0$ and $a = b = 1$)

$\Rightarrow$ $$\frac{x - x_1}{x_1} = \frac{y - y_1}{y_1}$$

or $$\frac{x}{x_1} = \frac{y}{y_1}$$

***Corollary* 2 :** Equation of normal of $x^2 + y^2 + 2gx + 2fy + c = 0$ at (x_1, y_1) is

$$\frac{x - x_1}{x_1 + g} = \frac{y - y_1}{y_1 + f}$$ (Here, $a = b = 1$ and $h = 0$)

Remarks

1. Normal always passes through the centre of the circle. Just write the equation of the line joining (x_1, y_1) and the centre of the circle.
2. The equations of the normals show that they pass through the centre i.e. the normals are the radii which we know from *Euclidean geometry*.

Example 40. ***Find the equation of the normal to the circle*** $x^2 + y^2 = 2x$***, which is parallel to the line*** $x + 2y = 3$.

Sol. Given circle is $x^2 + y^2 - 2x = 0$

Centre of given circle is $(1, 0)$

Since, normal is parallel to $x + 2y = 3$

let the equation of normal is $x + 2y = \lambda$

Since, normal passes through the centre of the circle i.e. $(1, 0)$

then $1 + 0 = \lambda$

$\therefore$ $\lambda = 1$

then, equation of normal is $x + 2y = 1$

or $x + 2y - 1 = 0$

Aliter Equation of normal at (x_1, y_1) of $x^2 + y^2 - 2x = 0$ is

$$\frac{x - x_1}{x_1 - 1} = \frac{y - y_1}{y_1 - 0}$$

or $$\text{Slope} = \frac{y_1}{x_1 - 1} = m_1 \qquad \text{(say)}$$

Since normal is parallel to $x + 2y = 3$

$\therefore$ Slope $= -\frac{1}{2} = m_2$ (say)

but given $m_1 = m_2$

$$\frac{y_1}{x_1 - 1} = -\frac{1}{2} \text{ or } x_1 + 2y_1 - 1 = 0$$

$\therefore$ Locus of (x_1, y_1) is $x + 2y - 1 = 0$

Example 41. Find the equation of the normal to the circle $x^2 + y^2 - 5x + 2y - 48 = 0$ at the point $(5, 6)$.

Sol. Equation of the normal at $(5, 6)$ is

$$\frac{x-5}{5-\frac{5}{2}} = \frac{y-6}{6+1} \Rightarrow \frac{x-5}{\frac{5}{2}} = \frac{y-6}{7} \Rightarrow \frac{2x-10}{5} = \frac{y-6}{7}$$

$\Rightarrow$ $14x - 70 = 5y - 30$

$\therefore$ $14x - 5y - 40 = 0$

Aliter I : Since, centre of the circle $x^2 + y^2 - 5x + 2y - 48 = 0$ is $\left(\frac{5}{2}, -1\right)$, normal at (5,6) is the equation of a line, which passes through $\left(\frac{5}{2}, -1\right)$ and (5, 6) is

$$y + 1 = \frac{6+1}{5-\frac{5}{2}}\left(x - \frac{5}{2}\right) \Rightarrow y + 1 = \frac{14}{5}\left(x - \frac{5}{2}\right)$$

$\Rightarrow$ $y + 1 = \frac{7}{5}(2x - 5)$

$\Rightarrow$ $5y + 5 = 14x - 35$ or $14x - 5y - 40 = 0$

Aliter II : Equation of tangent at (5, 6) is

$$5 \cdot x + 6 \cdot y - \frac{5}{2}(x + 5) + (y + 6) - 48 = 0$$

$\Rightarrow$ $10x + 12y - 5x - 25 + 2y + 12 - 96 = 0$

$\Rightarrow$ $5x + 14y - 109 = 0$

Slope of tangent $= -\frac{5}{14}$

$\therefore$ Slope of normal $= \frac{14}{5}$

$\therefore$ Equation of normal at (5, 6) with slope $\frac{14}{5}$ is

$$y - 6 = \frac{14}{5}(x - 5)$$

$\Rightarrow$ $5y - 30 = 14x - 70$

or $14x - 5y - 40 = 0$

2. Parametric form

Since, parametric coordinates of circle $x^2 + y^2 = a^2$ is $(a\cos\theta, a\sin\theta)$.

$\therefore$ Equation of normal at $(a\cos\theta, a\sin\theta)$ is

$$\frac{x}{a\cos\theta} = \frac{y}{a\sin\theta}$$

or $$\frac{x}{\cos\theta} = \frac{y}{\sin\theta} \text{ or } y = x\tan\theta$$

or $y = mx$, where $m = \tan\theta$

which is slope form of normal.

Exercise for Session 4

1. The length of the chord cut-off by $y = 2x + 1$ from the circle $x^2 + y^2 = 2$ is

(a) $\frac{5}{6}$ (b) $\frac{6}{5}$ (c) $\frac{6}{\sqrt{5}}$ (d) $\frac{\sqrt{5}}{6}$

2. Circle $x^2 + y^2 - 4x - 8y - 5 = 0$ will intersect the line $3x - 4y = \lambda$ in two distinct points, if

(a) $-10 < \lambda < 5$ (b) $9 < \lambda < 20$ (c) $-35 < \lambda < 15$ (d) $-16 < \lambda < 30$

3. If the line $3x - 4y + \lambda = 0$, $(\lambda > 0)$ touches the circle $x^2 + y^2 - 4x - 8y - 5 = 0$ at (a, b), then $\lambda + a + b$ is equal to

(a) -22 (b) -20 (c) 20 (d) 22

4. Tangent which is parallel to the line $x - 3y - 2 = 0$ of the circle $x^2 + y^2 - 4x + 2y - 5 = 0$, has point/points of contact

(a) (1, – 2) (b) (–1, 2) (c) (3, 4) (d) (3, – 4)

5. If a circle, whose centre is $(-1,1)$ touches the straight line $x + 2y = 12$, then the co-ordinates of the point of contact are

(a) $\left(-\frac{7}{2}, -4\right)$ (b) $\left(-\frac{18}{5}, -\frac{21}{5}\right)$ (c) $(2, -7)$ (d) $(-2, -5)$

6. The area of the triangle formed by the tangent at the point (a, b) to the circle $x^2 + y^2 = r^2$ and the coordinate axes is

(a) $\frac{r^4}{2ab}$ (b) $\frac{r^4}{2|ab|}$ (c) $\frac{r^4}{ab}$ (d) $\frac{r^4}{|ab|}$

7. The equation of the tangent to the circle $x^2 + y^2 + 4x - 4y + 4 = 0$ which make equal intercepts on the positive coordinate axes is

(a) $x + y = 2$ (b) $x + y = 2\sqrt{2}$ (c) $x + y = 4$ (d) $x + y = 8$

8. If $a > 2b > 0$, then the positive value of m for which $y = mx - b\sqrt{(1+m^2)}$ is a common tangent to $x^2 + y^2 = b^2$ and $(x-a)^2 + y^2 = b^2$ is

(a) $\frac{2b}{\sqrt{(a^2-4b^2)}}$ (b) $\frac{\sqrt{(a^2-4b^2)}}{2b}$ (c) $\frac{2b}{a-2b}$ (d) $\frac{b}{a-2b}$

9. The angle between a pair of tangents from a point P to the circle $x^2 + y^2 = 16$ is $\frac{\pi}{3}$ and locus of P is $x^2 + y^2 = r^2$, then value of r is

(a) 5 (b) 6 (c) 7 (d) 8

10. The normal at the point $(3, 4)$ on a circle cuts the circle at the point $(-1, -2)$. Then, the equation of the circle is

(a) $x^2 + y^2 + 2x - 2y - 13 = 0$ (b) $x^2 + y^2 - 2x - 2y - 11 = 0$

(c) $x^2 + y^2 - 2x + 2y + 12 = 0$ (d) $x^2 + y^2 - 2x - 2y + 14 = 0$

11. The line $ax + by + c = 0$ is a normal to the circle $x^2 + y^2 = r^2$. The portion of the line $ax + by + c = 0$ intercepted by this circle is of length

(a) $\sqrt{r}$ (b) r (c) r^2 (d) $2r$

12. If the line $ax + by + c = 0$ touches the circle $x^2 + y^2 - 2x = \frac{3}{5}$ and is normal to the circle $x^2 + y^2 + 2x - 4y + 1 = 0$, then (a, b) are

(a) (1, 3) (b) (3, 1) (c) (1, 2) (d) (2, 1)

13. Show that for all values of θ, $x \sin\theta - y \cos\theta = a$ touches the circle $x^2 + y^2 = a^2$.

14. Find the equation of the tangents to the circle $x^2 + y^2 - 2x - 4y - 4 = 0$ which are (i) parallel (ii) perpendicular to the line $3x - 4y - 1 = 0$.

15. Find the equation of the family of circle which touch the pair of straight lines $x^2 - y^2 + 2y - 1 = 0$.

16. Find the value of λ so that the line $3x - 4y = \lambda$ may touch the circle $x^2 + y^2 - 4x - 8y - 5 = 0$.

17. Show that the area of the triangle formed by the positive X-axis, the normal and tangent to the circle $x^2 + y^2 = 4$ at $(1, \sqrt{3})$ is $2\sqrt{3}$.

Session 5

Tangents from a Point to the Circle, Length of the Tangent from a Point to a Circle, Power of a Point with Respect to a Circle, Chord of Contact, Chord Bisected at a Given Point, Pair of Tangents, Director Circle

Tangent from a Point to the Circle

Theorem : From a given point two tangents can be drawn to a circle which are real, coincident or imaginary according as the given point lies outside,on or inside the circle .

Proof : If circle is $x^2 + y^2 = a^2$ ...(i)

any tangent to the circle Eq. (i) is

$$y = mx + a\sqrt{(1+m^2)} \quad \text{...(ii)}$$

If outside point is (x_1, y_1)

then, $y_1 = mx_1 + a\sqrt{1+m^2}$

or $(y_1 - mx_1)^2 = a^2(1+m^2)$

or $y_1^2 + m^2x_1^2 - 2mx_1y_1 = a^2 + a^2m^2$

$\Rightarrow$ $m^2(x_1^2 - a^2) - 2mx_1y_1 + y_1^2 - a^2 = 0$ ...(iii)

which is quadratic in m which gives two values of m.

(real coincident or imaginary) corresponding to any value of x_1 and y_1.

The tangents are real, coincident or imaginary according as the values of m obtained from Eq. (iii) are real, coincident or imaginary.

or Discriminant $>, =,$ or <0

$\Rightarrow$ $4x_1^2y_1^2 - 4(x_1^2 - a^2)(y_1^2 - a^2) >, =, \text{or} < 0$

$\Rightarrow$ $(x_1^2 + y_1^2 - a^2) >, = \text{or} < 0$

i.e. $P(x_1, y_1)$ lies outside, on or inside the circle $x^2 + y^2 = a^2$.

If P outside the circle, then substituting these values of m in Eq. (ii), we get the equation of tangents.

Aliter :

First write equation of line through (x_1, y_1) say

$$y - y_1 = m(x - x_1) \quad \text{...(i)}$$

which is tangent of the circle $x^2 + y^2 = a^2$, then

length of perpendicular from centre $(0, 0)$ to Eq. (i) = radius of the circle

then, $\dfrac{|mx_1 - y_1|}{\sqrt{(1+m^2)}} = a$

or $(mx_1 - y_1)^2 = a^2(1+m^2)$

or $m^2x_1^2 - 2mx_1y_1 + y_1^2 = a^2 + a^2m^2$

$\Rightarrow$ $m^2(x_1^2 - a^2) - 2mx_1y_1 + y_1^2 - a^2 = 0$

which is quadratic in m which gives two values of m.

Example 42. Find the equations of the tangents to the circle $x^2 + y^2 = 16$ drawn from the point $(1, 4)$.

Sol. Given circle is

$$x^2 + y^2 = 16 \quad \text{...(i)}$$

Any tangent of Eq. (i) in terms of slope is

$$y = mx + 4\sqrt{(1+m^2)} \quad \text{...(ii)}$$

which passes through $(1, 4)$

then, $4 = m + 4\sqrt{(1+m^2)}$

$\Rightarrow$ $(4 - m)^2 = 16(1 + m^2)$

$\Rightarrow$ $15m^2 + 8m = 0$

$\therefore$ $m = 0, -\dfrac{8}{15}$

From Eq. (ii), equations of tangents drawn from (1, 4) are

$$y = 4$$

and $$y = -\frac{8}{15}x + 4\sqrt{\left(1 + \frac{64}{225}\right)}$$

or $8x + 15y = 68$ respectively.

Aliter : Equation of line through (1, 4) is $y - 4 = m(x - 1)$

$\Rightarrow$ $$mx - y + 4 - m = 0 \quad ...(i)$$

Then, perpendicular length from centre (0, 0) to $mx - y + 4 - m = 0$ is equal to radius

then, $$\frac{|4 - m|}{\sqrt{m^2 + 1}} = 4$$

or $$(4 - m)^2 = 16(m^2 + 1)$$

$\Rightarrow$ $$15m^2 + 8m = 0$$

$\therefore$ $$m = 0, -\frac{8}{15}$$

From Eq. (i), equation of tangents from (1, 4) are $y = 4$ and $8x + 15y = 68$, respectively.

Example 43. The angle between a pair of tangents from a point P to the circle $x^2 + y^2 + 4x - 6y + 9\sin^2\alpha + 13\cos^2\alpha = 0$ is 2α. Find the equation of the locus of the point P.

Sol. Let coordinates of P be (x_1, y_1) and given circle is

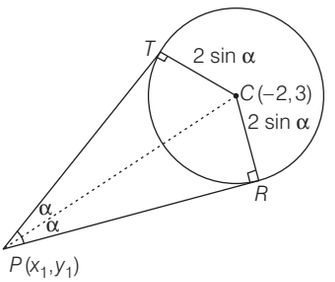
$$x^2 + y^2 + 4x - 6y + 9\sin^2\alpha + 13\cos^2\alpha = 0$$

or $$(x + 2)^2 + (y - 3)^2 - 4 - 9 + 9\sin^2\alpha + 13\cos^2\alpha = 0$$

$\Rightarrow$ $$(x + 2)^2 + (y - 3)^2 + 9\sin^2\alpha - 13(1 - \cos^2\alpha) = 0$$

$\Rightarrow$ $$(x + 2)^2 + (y - 3)^2 = 4\sin^2\alpha$$

$\therefore$ Centre and radius are $(-2, 3)$ and $2\sin\alpha$, respectively.



Distance between $P(x_1, y_1)$ and centre of circle $C(-2, 3)$ is

$$CP = \sqrt{(x_1 + 2)^2 + (y_1 - 3)^2}$$

In ΔPCT, $$\sin\alpha = \frac{CT}{CP} = \frac{2\sin\alpha}{\sqrt{(x_1 + 2)^2 + (y_1 - 3)^2}}$$

or $$\sqrt{(x_1 + 2)^2 + (y_1 - 3)^2} = 2$$

or $$(x_1 + 2)^2 + (y_1 - 3)^2 = 4$$

The required locus of $P(x_1, y_1)$ is

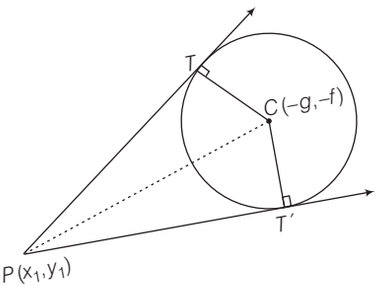
$$(x + 2)^2 + (y - 3)^2 = 4$$

Length of the Tangent from a Point to a Circle

Theorem : The length of tangent from the point $P(x_1, y_1)$ to the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is

$$\sqrt{(x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c)} = \sqrt{S_1}$$

Proof : Let PT and PT' be two tangents from the given point $P(x_1, y_1)$ to the circle $x^2 + y^2 + 2gx + 2fy + c = 0$. Then, the centre and radius are $C(-g, -f)$ and $\sqrt{(g^2 + f^2 - c)}$ $(= CT = CT')$ respectively.



In ΔPCT,

$$PT = \sqrt{(PC)^2 - (CT)^2}$$

$$= \sqrt{(x_1 + g)^2 + (y_1 + f)^2 - g^2 - f^2 + c}$$

$$= \sqrt{(x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c)} = \sqrt{S_1} = PT'$$

where, $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$

Remarks

1. To find length of tangent
   let $S = x^2 + y^2 + 2gx + 2fy + c$
   then, $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$
   where, $P(x_1, y_1)$
   $\therefore$ length of tangent $= \sqrt{S_1}$
2. For S_1 first write the equation of circle in general form i.e. coefficient of x^2 = coefficient of $y^2 = 1$ and making RHS of circle is zero, then let LHS by S.

Example 44. ***Find the length of tangents drawn from the point*** $(3, -4)$ ***to the circle*** $2x^2 + 2y^2 - 7x - 9y - 13 = 0$.

Sol. The equation of the given circle is

$$2x^2 + 2y^2 - 7x - 9y - 13 = 0$$

Re-writing the given equation of the circle

i.e. $$x^2 + y^2 - \frac{7}{2}x - \frac{9}{2}y - \frac{13}{2} = 0$$

Let $S = x^2 + y^2 - \frac{7}{2}x - \frac{9}{2}y - \frac{13}{2}$

$\therefore \quad S_1 = (3)^2 + (-4)^2 - \frac{7}{2}\times 3 - \frac{9}{2}\times(-4) - \frac{13}{2}$

$= 25 - \frac{21}{2} + 18 - \frac{13}{2} = 43 - 17 = 26$

$\therefore$ Length of tangent $= \sqrt{S_1} = \sqrt{26}$

Example 45. If the length of tangent from (f, g) to the circle $x^2 + y^2 = 6$ be twice the length of the tangent from (f, g) to circle $x^2 + y^2 + 3x + 3y = 0$, then find the value of $f^2 + g^2 + 4f + 4g$.

Sol. According to the question

$$\sqrt{(g^2 + f^2 - 6)} = 2\sqrt{(f^2 + g^2 + 3f + 3g)}$$

On squaring $g^2 + f^2 - 6 = 4f^2 + 4g^2 + 12f + 12g$

or $3f^2 + 3g^2 + 12f + 12g + 6 = 0$

or $f^2 + g^2 + 4f + 4g + 2 = 0$

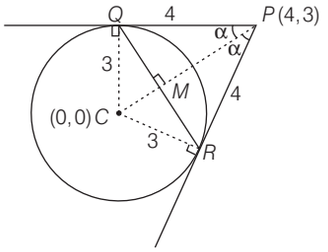
or $f^2 + g^2 + 4f + 4g = -2$

Example 46. Show that the area of the triangle formed by tangents from the point (4, 3) to the circle $x^2 + y^2 = 9$ and the line segment joining their points of contact is $7\frac{17}{25}$ square units in length.

Sol. Since, $PQ = PR = \sqrt{4^2 + 3^2 - 9} = 4$ units

$\therefore \quad \angle CPQ = \angle CPR = \alpha$ (let)

$\therefore \quad PC = \sqrt{(4-0)^2 + (3-0)^2} = 5$ units



$\therefore$ In $\Delta PQC, \quad \tan\alpha = \frac{3}{4},$

$\therefore \quad \sin\alpha = \frac{3}{5}$

and $\cos\alpha = \frac{4}{5}$

In $\Delta PMQ, \quad \cos\alpha = \frac{PM}{4} = \frac{4}{5}$

$\therefore \quad PM = \frac{16}{5}$

and $\sin\alpha = \frac{QM}{4} = \frac{3}{5}$

$\therefore \quad QM = \frac{12}{5}$

$\therefore$ Area of $\Delta PQR = \frac{1}{2}\cdot QR \cdot PM$

$= \frac{1}{2}(2QM)\cdot PM = (QM)(PM)$

$= \left(\frac{12}{5}\right)\left(\frac{16}{5}\right) = \frac{192}{25}$

$= 7\frac{17}{25}$ sq units

Example 47. Show that the length of the tangent from any point on the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ to the circle $x^2 + y^2 + 2gx + 2fy + c_1 = 0$ is $\sqrt{(c_1 - c)}$.

Sol. Let (x_1, y_1) be any point on

$$x^2 + y^2 + 2gx + 2fy + c = 0$$

then $x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = 0$ ...(i)

$\therefore$ Length of tangent from (x_1, y_1) to the circle

$x^2 + y^2 + 2gx + 2fy + c_1 = 0$ is

$\sqrt{x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c_1}$

$= \sqrt{(-c + c_1)} = \sqrt{(c_1 - c)}$ [From Eq. (i)]

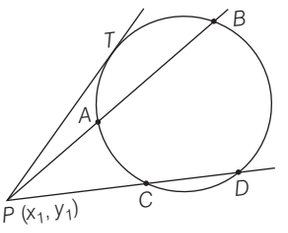
Power of a Point With Respect to a Circle

Theorem : The power of a point $P(x_1, y_1)$ with respect to the circle

$$x^2 + y^2 + 2gx + 2fy + c = 0 \text{ is } S_1$$

where, $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$

Proof : Let $P(x_1, y_1)$ be a point outside the circle and PAB and PCD drawn two secants. The power of $P(x_1, y_1)$ with respect to



$$S \equiv x^2 + y^2 + 2gx + 2fy + c = 0$$

is equal to $PA \cdot PB$ which is

$$x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c = S_1$$

$\therefore$ Power remains constant for the circle

i.e. independent of A and B.

$\therefore\ PA \cdot PB = PC \cdot PD = (PT)^2 = S_1 = (\sqrt{S_1})^2$

$\therefore\ PA \cdot PB = (\sqrt{S_1})^2$ = square of the length of tangent.

Remark

If P outside, inside or on the circle, then $PA \cdot PB$ is + ve, − ve or zero, respectively.

Example 48. ***Find the power of point*** $(2, 4)$ ***with respect to the circle*** $x^2 + y^2 - 6x + 4y - 8 = 0$

Sol. The power of the point $(2, 4)$ with respect to the circle

$$x^2 + y^2 - 6x + 4y - 8 = 0 \text{ is } (\sqrt{S_1})^2 \text{ or } S_1$$

where, $S = x^2 + y^2 - 6x + 4y - 8$

$$\therefore \quad S_1 = (2)^2 + (4)^2 - 6 \times 2 + 4 \times 4 - 8$$
$$= 4 + 16 - 12 + 16 - 8 = 16$$

[$\because (2, 4)$ is outside from the circle $x^2 + y^2 - 6x + 4y - 8 = 0$]

Example 49. ***Show that the locus of the point, the powers of which with respect to two given circles are equal, is a straight line.***

Sol. Let the given circles be

$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad \text{...(i)}$$

and $$x^2 + y^2 + 2g_1x + 2f_1y + c_1 = 0 \quad \text{...(ii)}$$

Let $P(x_1, y_1)$ be a point, the powers of which with respect to the circles Eqs. (i) and (ii) are equal. Then,

$$\therefore \quad [\sqrt{(x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c)}]^2$$
$$= [\sqrt{(x_1^2 + y_1^2 + 2g_1x_1 + 2f_1y_1 + c_1)}]^2$$

or $$x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$$
$$= x_1^2 + y_1^2 + 2g_1x_1 + 2f_1y_1 + c_1$$

$$\Rightarrow \quad 2(g - g_1)x_1 + 2(f - f_1)y_1 + c - c_1 = 0$$

then, locus of $P(x_1, y_1)$ is

$$2(g - g_1)x + 2(f - f_1)y + c - c_1 = 0$$

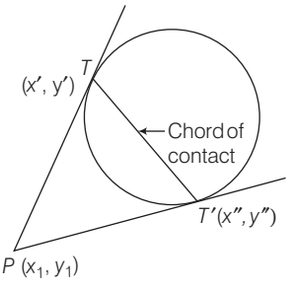
which is a straight line.

Chord of Contact

From any external point, two tangents can be drawn to a given circle. The chord joining the points of contact of the two tangents is called the chord of contact of tangents.

Theorem : The equation of the chord of contact of tangents drawn from a point (x_1, y_1) to the circle $x^2 + y^2 = a^2$ is $xx_1 + yy_1 = a^2$.

Sol. Let $T(x', y')$ and $T'(x'', y'')$ be the points of contact of tangents drawn from $P(x_1, y_1)$ to $x^2 + y^2 = a^2$.



Then, equations of tangents PT and PT' are

$$xx' + yy' = a^2 \text{ and } xx'' + yy'' = a^2 \text{ respectively.}$$

Since, both tangents pass through $P(x_1, y_1)$, then

$$x_1x' + y_1y' = a^2$$

and $$x_1x'' + y_1y'' = a^2$$

$\because$ Points $T(x', y')$ and $T'(x'', y'')$ lie on

$$xx_1 + yy_1 = a^2$$

$\therefore$ Equation of **chord of contact** TT' is $xx_1 + yy_1 = a^2$

Remark

Equation of chord of contact like as equation of tangent at that point but point different.

Now, for chord of contact at (x_1, y_1), replacing x^2 by xx_1, y^2 by yy_1, x by $\frac{x + x_1}{2}$, y by $\frac{y + y_1}{2}$

and xy by $\frac{xy_1 + x_1y}{2}$.

Corollary 1 : If R is the radius of the circle and L is the length of the tangent from $P(x_1, y_1)$ on $S = 0$.

Here, $L = \sqrt{S_1}$, then

(a) Length of chord of contact $TT' = \dfrac{2LR}{\sqrt{(R^2 + L^2)}}$

(b) Area of triangle formed by the pair of tangents and its chord of contact $= \dfrac{RL^3}{R^2 + L^2}$

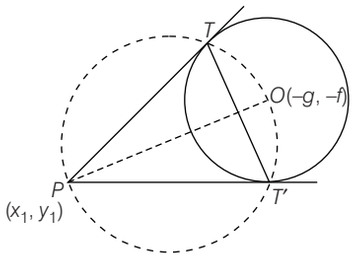
(c) Angle between the pair of tangents from $P(x_1, y_1)$ $= \tan^{-1}\left(\dfrac{2RL}{L^2 - R^2}\right)$

Corollary 2 : Equation of the circle circumscribing the triangle PTT' is

$$(x - x_1)(x + g) + (y - y_1)(y + f) = 0,$$

where, $O(-g, -f)$ is the centre of the circle

$$x^2 + y^2 + 2gx + 2fx + c = 0$$



i.e. Required circle always passes through the centre of the given circle (Here, OP is the diameter of the required circle).

Example 50. If the pair of tangents are drawn from the point $(4,5)$ to the circle $x^2+y^2-4x-2y-11=0$, then,

(i) Find the length of chord of contact.

(ii) Find the area of the triangle formed by a pair of tangents and their chord of contact.

(iii) Find the angle between the pair of tangents.

Sol. Here, $P \equiv (4,5)$,

$$R = \sqrt{((2)^2+(1)^2+11)} = 4$$

and $L = \sqrt{S_1} = \sqrt{((4)^2+(5)^2-4\times4-2\times5-11)} = 2$

(i) Length of chord of contact

$$= \frac{2LR}{\sqrt{(R^2+L^2)}} = \frac{2\times2\times4}{\sqrt{(4)^2+(2)^2}} = \frac{8}{\sqrt{5}} \text{ unit}$$

(ii) Area of triangle $= \frac{RL^3}{R^2+L^2} = \frac{4\times8}{16+4} = \frac{8}{5}$ sq units

(iii) Angle between the pair of tangents

$$= \pi + \tan^{-1}\left(\frac{2\times4\times2}{2^2-4^2}\right)$$

$$= \pi - \tan^{-1}\left(\frac{4}{3}\right) \qquad (\because L < R)$$

Example 51. Tangents PQ, PR are drawn to the circle $x^2+y^2=36$ from the point $P(-8,2)$ touching the circle at Q, R respectively. Find the equation of the circumcircle of ΔPQR.

Sol. Here, $P \equiv (-8,2)$ and $O \equiv (0,0)$

$\therefore$ Equation of the required circle is

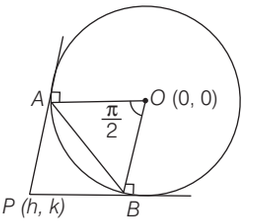
$$(x-(-8))(x-0)+(y-2)(y-0)=0$$

or $x^2+y^2+8x-2y=0$ ($\because OP$ is the diameter)

Example 52. Find the condition that chord of contact of any external point (h,k) to the circle $x^2+y^2=a^2$ should subtend right angle at the centre of the circle .

Sol. Equation of chord of contact AB is $hx+ky=a^2$

For equation of pair of tangents of OA and OB, make homogeneous $x^2+y^2=a^2$ with the help of $hx+ky=a^2$ or $\frac{hx+ky}{a^2}=1$



then, $$x^2+y^2 = a^2\left(\frac{hx+ky}{a^2}\right)^2$$

or $$a^2(x^2+y^2) = (hx+ky)^2$$

or $$x^2(a^2-h^2) - 2hkxy + y^2(a^2-k^2) = 0$$

but $$\angle AOB = \frac{\pi}{2}$$

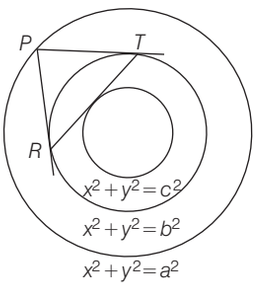
$\therefore$ Coefficient of x^2 + Coefficient of $y^2 = 0$

$\Rightarrow$ $a^2-h^2+a^2-k^2=0$ or $h^2+k^2=2a^2$

Example 53. The chord of contact of tangents drawn from a point on the circle $x^2+y^2=a^2$ to the circle $x^2+y^2=b^2$ touches the circle $x^2+y^2=c^2$. Show that a,b,c are in GP.

Sol. Let $P(a\cos\theta, a\sin\theta)$ be a point on the circle $x^2+y^2=a^2$.

Then, equation of chord of contact of tangents drawn from $P(a\cos\theta, a\sin\theta)$ to the circle $x^2+y^2=b^2$ is



$$ax\cos\theta + ay\sin\theta = b^2 \qquad \text{...(i)}$$

This touches the circle $x^2+y^2=c^2$ ...(ii)

$\therefore$ Length of perpendicular from $(0,0)$ to Eq. (i) = radius of Eq. (ii)

$\therefore$ $$\frac{|0+0-b^2|}{\sqrt{(a^2\cos^2\theta + a^2\sin^2\theta)}} = c$$

or $$b^2 = ac$$

$\Rightarrow$ a, b, c are in GP.

Chord Bisected at a Given Point

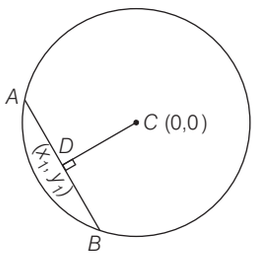
Theorem : The equation of the chord of the circle $x^2 + y^2 = a^2$ bisected at the point (x_1, y_1) is given by

$$xx_1 + yy_1 - a^2 = x_1^2 + y_1^2 - a^2$$

or $$T = S_1$$

Proof : Let any chord AB of the circle $x^2 + y^2 = a^2$ be bisected at $D(x_1, y_1)$.

If centre of circle is represented by C



then, slope of $DC = \dfrac{0 - y_1}{0 - x_1} = \dfrac{y_1}{x_1}$

$\therefore$ Slope of the chord AB is $-\dfrac{x_1}{y_1}$

then, equation of AB is $y - y_1 = -\dfrac{x_1}{y_1}(x - x_1)$

or $$yy_1 - y_1^2 = -xx_1 + x_1^2$$

or $$xx_1 + yy_1 = x_1^2 + y_1^2$$

or $$\boldsymbol{xx_1 + yy_1 - a^2 = x_1^2 + y_1^2 - a^2} \text{ or } \boldsymbol{T = S_1}$$

Remarks

1. The equation of chord of the circle $x^2 + y^2 + 2gx + 2fy + c = 0$, which is bisected at (x_1, y_1) ; is $T = S_1$
   where, $T = xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c$
   and $S_1 = x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$
2. The chord bisected at point (x_1, y_1) is the farthest from the centre among all the chords passing through the point (x_1, y_1). Also, for such chord, the length of the chord is minimum.

Example 54. ***Find the equation of the chord of*** $x^2 + y^2 - 6x + 10y - 9 = 0$ ***which is bisected at*** $(-2, 4)$.

Sol. The equation of the required chord is

$$-2x + 4y - 3(x - 2) + 5(y + 4) - 9 = 4 + 16 + 12 + 40 - 9$$

$\Rightarrow$ $$-5x + 9y - 46 = 0$$

or $$5x - 9y + 46 = 0$$

Example 55. Find the middle point of the chord intercepted on line $lx + my + n = 0$ by the circle $x^2 + y^2 = a^2$.

Sol. Let (x_1, y_1) be the middle point of the chord intercepted by the circle $x^2 + y^2 = a^2$ on the line $lx + my + n = 0$.

Then, equation of the chord of the circle $x^2 + y^2 = a^2$, whose middle points is (x_1, y_1), is

$$xx_1 + yy_1 - a^2 = x_1^2 + y_1^2 - a^2$$

or $$xx_1 + yy_1 = x_1^2 + y_1^2 \quad \text{...(i)}$$

Clearly, $lx + my + n = 0$ and Eq. (i) represented the same line,

$$\frac{x_1}{l} = \frac{y_1}{m} = \frac{x_1^2 + y_1^2}{-n} = \lambda \quad \text{(say)}$$

$\therefore$ $$\left.\begin{aligned} x_1 &= l\lambda \\ y_1 &= m\lambda \end{aligned}\right\} \quad \text{...(ii)}$$

and $$x_1^2 + y_1^2 = -n\lambda$$

or $$l^2\lambda^2 + m^2\lambda^2 = -n\lambda \quad \text{[from (ii)]}$$

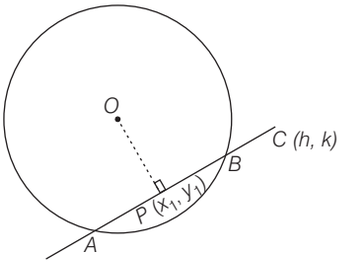
$\therefore$ $$\lambda = -\frac{n}{l^2 + m^2}$$

So, from Eq. (ii), $$x_1 = -\frac{nl}{l^2 + m^2}, y_1 = -\frac{mn}{l^2 + m^2}$$

Hence, the required point is $\left(-\dfrac{nl}{l^2 + m^2}, -\dfrac{nm}{l^2 + m^2}\right)$.

Example 56. Through a fixed point (h, k), secants are drawn to the circle $x^2 + y^2 = r^2$. Show that the locus of mid-point of the portions of secants intercepted by the circle is $x^2 + y^2 = hx + ky$.

Sol. Let $P(x_1, y_1)$ be the middle point of any chord AB, which passes through the point $C(h, k)$.



Equation of chord AB is $T = S_1$

$\therefore$ $$xx_1 + yy_1 - r^2 = x_1^2 + y_1^2 - r^2$$

or $$x_1^2 + y_1^2 = xx_1 + yy_1$$

But since AB passes through $C(h, k)$, then

$$x_1^2 + y_1^2 = hx_1 + ky_1$$

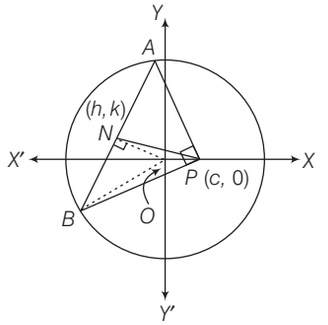
$\therefore$ Locus of $P(x_1, y_1)$ is $x^2 + y^2 = hx + ky$

Example 57. Find the locus of middle points of chords of the circle $x^2 + y^2 = a^2$, which subtend right angle at the point $(c, 0)$.

Sol. Let $N(h, k)$ be the middle point of any chord AB, which subtend a right angle at $P(c, 0)$.

Since, $\angle APB = 90°$

$\therefore$ $NA = NB = NP$



(since distance of the vertices from middle point of the hypotenuse are equal)

or $(NA)^2 = (NB)^2 = (h - c)^2 + (k - 0)^2$ ...(i)

But also $\angle BNO = 90°$

$\therefore$ $(OB)^2 = (ON)^2 + (NB)^2$

$\Rightarrow$ $-(NB)^2 = (ON)^2 - (OB)^2$

$\Rightarrow$ $-[(h - c)^2 + (k - 0)^2] = (h^2 + k^2) - a^2$

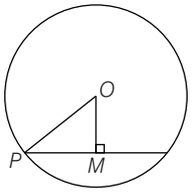
or $2(h^2 + k^2) - 2ch + c^2 - a^2 = 0$

$\therefore$ Locus of $N(h, k)$ is

$$2(x^2 + y^2) - 2cx + c^2 - a^2 = 0$$

Example 58. Find the equation of the chord of the circle $x^2 + y^2 = r^2$ passing through the point $(2,3)$ farthest from the centre.

Sol. Let $P \equiv (2,3)$ be the given point and M be the middle point of chord of circle $x^2 + y^2 = r^2$ through P.



Then, $(OM)^2 = (OP)^2 - (PM)^2$

If OM maximum, then PM is minimum. i.e. P coincides with M, which is middle point of the chord.

Hence, the equation of the chord is

$$T = S_1$$

i.e. $2x + 3y - r^2 = 2^2 + 3^2 - r^2$

or $2x + 3y = 13$

Pair of Tangents

Theorem : The combined equation of the pair of tangents drawn from a point $P(x_1, y_1)$ to the circle $x^2 + y^2 = a^2$ is

$$(x^2 + y^2 - a^2)(x_1^2 + y_1^2 - a^2) = (xx_1 + yy_1 - a^2)^2$$

or $SS_1 = T^2$

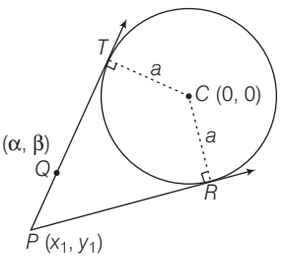
where, $S = x^2 + y^2 - a^2, S_1 = x_1^2 + y_1^2 - a^2$

and $T = xx_1 + yy_1 - a^2$

Proof : The given circle is $x^2 + y^2 = a^2$

Its centre and radius are $C(0, 0)$ and a respectively . Given external point be $P(x_1, y_1)$.

From point $P(x_1, y_1)$ two tangents PT and PR be drawn to the circle, touching circle at T and R respectively.



Let $Q(\alpha, \beta)$ on PT, then equation of PQ is

$$y - y_1 = \frac{\beta - y_1}{\alpha - x_1}(x - x_1)$$

or $y(\alpha - x_1) - x(\beta - y_1) - \alpha y_1 + \beta x_1 = 0$

Length of perpendicular from $C(0, 0)$ on $PT = a$ (radius)

$$\Rightarrow \quad \frac{|\beta x_1 - \alpha y_1|}{\sqrt{(\alpha - x_1)^2 + (\beta - y_1)^2}} = a$$

or $(\beta x_1 - \alpha y_1)^2 = a^2\{(\alpha - x_1)^2 + (\beta - y_1)^2\}$

$\therefore$ Locus of $Q(\alpha, \beta)$ is

$$(yx_1 - xy_1)^2 = a^2\{(x - x_1)^2 + (y - y_1)^2\}$$

$\Rightarrow$ $y^2x_1^2 + x^2y_1^2 - 2xy\,x_1y_1 = a^2$

$$\{x^2 + x_1^2 - 2xx_1 + y^2 + y_1^2 - 2yy_1\}$$

$\Rightarrow y^2(x_1^2 - a^2) + x^2(y_1^2 - a^2) - a^2(x_1^2 + y_1^2)$

$$= 2xyx_1y_1 - 2a^2xx_1 - 2a^2yy_1$$

On adding both sides, $(x^2x_1^2 + y^2y_1^2 + a^4)$, then

$y^2(x_1^2 + y_1^2 - a^2) + x^2(x_1^2 + y_1^2 - a^2) - a^2(x_1^2 + y_1^2 - a^2)$

$$= (xx_1 + yy_1 - a^2)^2$$

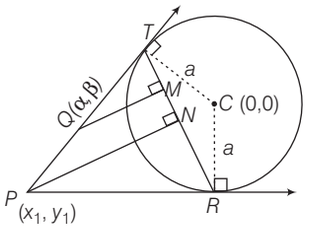
$$\Rightarrow \quad (x^2 + y^2 - a^2)(x_1^2 + y_1^2 - a^2) = (xx_1 + yy_1 - a^2)^2$$

This is the required equation of pair of tangents drawn from (x_1, y_1) to circle $x^2 + y^2 = a^2$.

Aliter : Let circle be $x^2 + y^2 = a^2$ with centre $C(0, 0)$ and radius a. Length of tangents from $P(x_1, y_1)$ and $Q(\alpha, \beta)$ are

$$PT = \sqrt{x_1^2 + y_1^2 - a^2}$$

and $$QT = \sqrt{\alpha^2 + \beta^2 - a^2}$$



Now, equation of TR (chord of contact is)

$$xx_1 + yy_1 - a^2 = 0$$

$$\therefore \quad PN = \frac{|x_1^2 + y_1^2 - a^2|}{\sqrt{(x_1^2 + y_1^2)}} \text{ and } QM = \frac{|\alpha x_1 + \beta y_1 - a^2|}{\sqrt{(x_1^2 + y_1^2)}}$$

But from similar Δ^s PNT and QMT,

$$\frac{PN}{QM} = \frac{PT}{QT} \Rightarrow \frac{(PN)^2}{(QM)^2} = \frac{(PT)^2}{(QT)^2}$$

$$\Rightarrow \quad \frac{\dfrac{(x_1^2 + y_1^2 - a^2)^2}{(x_1^2 + y_1^2)}}{\dfrac{(\alpha x_1 + \beta y_1 - a^2)^2}{(x_1^2 + y_1^2)}} = \frac{x_1^2 + y_1^2 - a^2}{\alpha^2 + \beta^2 - a^2}$$

$$\Rightarrow \quad (x_1^2 + y_1^2 - a^2)(\alpha^2 + \beta^2 - a^2) = (\alpha x_1 + \beta y_1 - a^2)^2$$

$\therefore$ Locus of $Q(\alpha, \beta)$ is

$$(x^2 + y^2 - a^2)(x_1^2 + y_1^2 - a^2)$$
$$= (xx_1 + yy_1 - a^2)^2$$

This is the required equation of pair of tangents drawn from (x_1, y_1) to circle $x^2 + y^2 = a^2$.

Corollary **:** The angle between the two tangents from (x_1, y_1) to the circle $x^2 + y^2 = a^2$ is $2\tan^{-1}\left(\dfrac{a}{\sqrt{S_1}}\right)$, where $S_1 = x_1^2 + y_1^2 - a^2$.

Remarks

1. Equation of pair of tangents in notation form is $SS_1 = T^2$
   where, $S \equiv x^2 + y^2 - a^2$
   $S_1 \equiv x_1^2 + y_1^2 - a^2, T \equiv xx_1 + yy_1 - a^2$
2. When circle is $x^2 + y^2 + 2gx + 2fy + c = 0$ and tangents are drawn from (x_1, y_1), then pair of tangents is
   $(x^2 + y^2 + 2gx + 2fy + c)(x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c)$
   $= [xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c]^2$
   where, $S \equiv x^2 + y^2 + 2gx + 2fy + c$,
   $S_1 \equiv x_1^2 + y_1^2 + 2gx_1 + 2fy_1 + c$,
   and $T \equiv xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c$

Advised for Students

Students are advised that, if they do not want to use the formula $(SS_1 = T^2)$, then use the following method :

Let $y - y_1 = m(x - x_1)$ be any line through $P(x_1, y_1)$.

Then, use condition of tangency $p = r$ i.e.

Length of perpendicular from the centre of circle or this line = radius of the circle.

Gives the values of m. In such away, we can find the equations of tangents from P.

Example 59. Find the equations of the tangents from the point $A(3, 2)$ to the circle $x^2 + y^2 + 4x + 6y + 8 = 0$.

Sol. Combined equation of the pair of tangents drawn from $A(3, 2)$ to the given circle $x^2 + y^2 + 4x + 6y + 8 = 0$ can be written in the usual notation.

$$T^2 = SS_1 \text{ namely}$$

$$\Rightarrow \quad [3x + 2y + 2(x + 3) + 3(y + 2) + 8]^2$$
$$= [x^2 + y^2 + 4x + 6y + 8][9 + 4 + 12 + 12 + 8]$$

$$\Rightarrow \quad (5x + 5y + 20)^2 = 45(x^2 + y^2 + 4x + 6y + 8)$$

$$\Rightarrow \quad 5(x + y + 4)^2 = 9(x^2 + y^2 + 4x + 6y + 8)$$

$$\Rightarrow \quad 5(x^2 + y^2 + 2xy + 8x + 8y + 16)$$
$$= 9(x^2 + y^2 + 4x + 6y + 8)$$

$$\Rightarrow \quad 4x^2 + 4y^2 - 10xy - 4x + 14y - 8 = 0$$

or $$2x^2 + 2y^2 - 5xy - 2x + 7y - 4 = 0$$

or $$(2x - y - 4)(x - 2y + 1) = 0$$

Hence, the required tangents to the circle from $A(3, 2)$ are

$$2x - y - 4 = 0 \quad \text{and} \quad x - 2y + 1 = 0$$

Aliter : Let $S \equiv x^2 + y^2 + 4x + 6y + 8 = 0$

Centre $C(-2, -3)$ and radius $= \sqrt{5}$

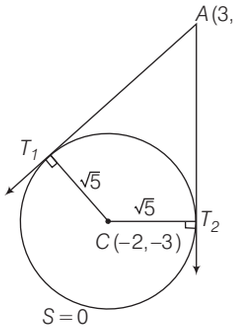
Let the slope of a tangent from A to '$S=0$' be m, then equation of tangent is

$$y-2=m(x-3)$$

or $$mx-y+2-3m=0 \quad \ldots(i)$$

Length of perpendicular from $C(-2,-3)$ on Eq. (i)

= radius of circle.



$$\Rightarrow \quad \frac{|-2m+3+2-3m|}{\sqrt{(m^2+1)}}=\sqrt{5}$$

or $$(5m-5)^2=5(m^2+1)$$

$$\Rightarrow \quad 25m^2-50m+25=5m^2+5$$

$$\Rightarrow \quad 20m^2-50m+20=0$$

or $$2m^2-5m+2=0$$

or $$(2m-1)(m-2)=0$$

$$\therefore \quad m=\frac{1}{2} \text{ or } m=2$$

Substituting these values of m in Eq. (i), we get the equations of two tangents are $x-2y+1=0$ and $2x-y-4=0$.

Director Circle

Director circle : The locus of the point of intersection of two perpendicular tangents to a given circle is known as its director circle.

Theorem : The equation of the director circle of the circle $x^2+y^2=a^2$ is

$$x^2+y^2=2a^2$$

Proof : The equation of any tangent to the circle $x^2+y^2=a^2$

is $$y=mx+a\sqrt{(1+m^2)} \quad \ldots(i)$$

Let $P(h,k)$ be the point of intersection of tangents, then $P(h,k)$ lies on Eq. (i)

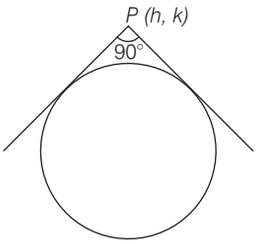
$$\therefore \quad k=mh+a\sqrt{(1+m^2)}$$

or $$(k-mh)^2=a^2(1+m^2)q$$

or $$m^2(h^2-a^2)-2mkh+k^2-a^2=0$$

This is quadratic equation in m, let two roots are m_1 and m_2.

But tangents are perpendiculars, then



$$m_1m_2=-1$$

$$\Rightarrow \quad \frac{k^2-a^2}{h^2-a^2}=-1 \text{ or } k^2-a^2=-h^2+a^2$$

or $$h^2+k^2=2a^2$$

Hence, locus of $P(h,k)$ is $\boldsymbol{x^2+y^2=2a^2}$

Aliter : The combined equation of the pair of tangents drawn from (h,k) to $x^2+y^2=a^2$ is

$$SS_1=T^2$$

where, $$S=x^2+y^2-a^2$$

$$S_1=h^2+k^2-a^2$$

and $$T=hx+ky-a^2$$

$$\therefore \quad (x^2+y^2-a^2)(h^2+k^2-a^2)=(hx+ky-a^2)^2$$

This equation will represent a pair of perpendicular lines if, coefficient of x^2 + coefficient of $y^2=0$

$$\Rightarrow \quad h^2+k^2-a^2-h^2+h^2+k^2-a^2-k^2=0$$

$$\Rightarrow \quad h^2+k^2-2a^2=0 \text{ or } h^2+k^2=2a^2$$

Hence, the locus of (h,k) is $\boldsymbol{x^2+y^2=2a^2}$

Remarks

1. The equation of the director circle of the circle $(x-h)^2+(y-k)^2=a^2$ is $(x-h)^2+(y-k)^2=2a^2$
2. The equation of the director circle of the circle $x^2+y^2+2gx+2fy+c=0$ is $x^2+y^2+2gx+2fy+c=g^2+f^2-c$
3. If two tangents are drawn from a point on the director circle to the circle, then angle between tangents is 90°.

Example 60. If two tangents are drawn from a point on the circle $x^2+y^2=50$ to the circle $x^2+y^2=25$, then find the angle between the tangents.

Sol. $\because x^2+y^2=50$ is the director circle of $x^2+y^2=25$

Hence, angle between tangents = 90°

Exercise for Session 5

1. If the tangent at the point P on the circle $x^2 + y^2 + 6x + 6y = 2$ meets the straight line $5x - 2y + 6 = 0$ at a point Q on the Y-axis, then the length PQ is

(a) 4 (b) $2\sqrt{5}$ (c) 5 (d) $3\sqrt{5}$

2. If the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is touched by $y = x$ at P such that $OP = 6\sqrt{2}$, where O is origin, then the value of c is

(a) 36 (b) 72 (c) 144 (d) 288

3. The chord of contact of tangents from a point P to a circle passes through Q. If l_1 and l_2 are the lengths of tangents from P and Q to the circle, then PQ is equal to

(a) $\frac{l_1 + l_2}{2}$ (b) $\frac{l_1 - l_2}{2}$ (c) $\sqrt{(l_1^2 + l_2^2)}$ (d) $\sqrt{(l_1^2 - l_2^2)}$

4. If the chord of contact of tangents from a point (x_1, y_1) to the circle $x^2 + y^2 = a^2$ touches the circle $(x - a)^2 + y^2 = a^2$, then the locus of (x_1, y_1) is

(a) a circle (b) a parabola (c) an ellipse (d) a hyperbola

5. The locus of the mid-points of a chord of the circle $x^2 + y^2 = 4$, which subtends a right angle at the origin is

(a) $x + y = 1$ (b) $x^2 + y^2 = 1$ (c) $x + y = 2$ (d) $x^2 + y^2 = 2$

6. The length of tangents from $P(1,-1)$ and $Q(3,3)$ to a circle are $\sqrt{2}$ and $\sqrt{6}$ respectively, then the length of tangent from $R(-2,-7)$ to the same circle is

(a) $\sqrt{41}$ (b) $\sqrt{51}$ (c) $\sqrt{61}$ (d) $\sqrt{71}$

7. If the angle between the tangents drawn to $x^2 + y^2 + 2gx + 2fy + c = 0$ from $(0,0)$ is $\frac{\pi}{2}$, then

(a) $g^2 + f^2 = 3c$ (b) $g^2 + f^2 = 2c$ (c) $g^2 + f^2 = 5c$ (d) $g^2 + f^2 = 4c$

8. The chords of contact of the pair of tangents drawn from each point on the line $2x + y = 4$ to the circle $x^2 + y^2 = 1$ pass through a fixed point

(a) (2, 4) (b) $\left(-\frac{1}{2}, -\frac{1}{4}\right)$ (c) $\left(\frac{1}{2}, \frac{1}{4}\right)$ (d) (–2, – 4)

9. The length of tangent from (0, 0) to the circle $2(x^2 + y^2) + x - y + 5 = 0$ is

(a) $\sqrt{5}$ (b) $\sqrt{\left(\frac{5}{2}\right)}$ (c) $\frac{\sqrt{5}}{2}$ (d) $\sqrt{2}$

10. The perpendicular tangents to the circle $x^2 + y^2 = a^2$ meet at P. Then, the locus of P has the equation

(a) $x^2 + y^2 = 2a^2$ (b) $x^2 + y^2 = 3a^2$ (c) $x^2 + y^2 = 4a^2$ (d) $x^2 + y^2 = 5a^2$

11. The tangents to $x^2 + y^2 = a^2$ having inclinations α and β intersect at P. If $\cot\alpha + \cot\beta = 0$, then the locus of P is

(a) $x + y = 0$ (b) $x - y = 0$ (c) $xy = 0$ (d) $xy = 1$

12. The exhaustive range of values of a such that the angle between the pair of tangents drawn from (a,a) to the circle $x^2 + y^2 - 2x - 2y - 6 = 0$ lies in the range $\left(\frac{\pi}{3}, \pi\right)$ is

(a) (–1, 3) (b) $(-5,-3) \cup (3, 5)$ (c) (–3, 5) (d) $(-3,-1) \cup (3, 5)$

13. Distances from the origin to the centres of the three circles $x^2 + y^2 - 2\lambda x = c^2$, where c is a constant and λ is available, are in GP. Prove that the lengths of tangents drawn from any point on the circle $x^2 + y^2 = c^2$ to the three circles are also in GP.

14. Find the area of the quadrilateral formed by a pair of tangents from the point $(4, 5)$ to the circle $x^2 + y^2 - 4x - 2y - 11 = 0$ and a pair of its radii.

15. If the length of the tangent from a point (f, g) to the circle $x^2 + y^2 = 4$ be four times the length of the tangent from it to the circle $x^2 + y^2 = 4x$, show that $15f^2 + 15g^2 - 64f + 4 = 0$.

16. Find the equation of that chord of the circle $x^2 + y^2 = 15$ which is bisected at $(3, 2)$.

17. The chords of contact of the pair of tangents to the circle $x^2 + y^2 = 1$ drawn from any point on the line $2x + y = 4$ pass through the point (α, β), then find $\alpha^2 + \beta^2$.

Session 6

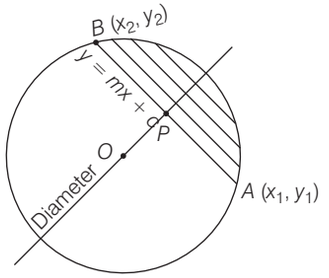
Diameter of a Circle, Two Circles Touching Each Other, Common Tangents to Two Circles, Common Chord of Two Circles, Family of Circles

Diameter of a Circle

The locus of the middle points of a system of parallel chords of a circle is called a diameter of the circle.

Let the circle be $x^2 + y^2 = a^2$ and equation of parallel chord is

$$y = mx + c$$



Let $P(h, k)$ be the middle point of the chord $y = mx + c$.
Since, P is the mid-point of $A(x_1\ y_1)$ and $B(x_2, y_2)$, then

$$\frac{x_1 + x_2}{2} = h \quad \text{and} \quad \frac{y_1 + y_2}{2} = k$$

or $x_1 + x_2 = 2h$ and $y_1 + y_2 = 2k$ ...(i)

$\because$ $P(h, k)$ lie on $y = mx + c$

then, $k = mh + c$

or $k - mh = c$ ...(ii)

Substituting $y = mx + c$ in $x^2 + y^2 = a^2$

then, $x^2 + (mx + c)^2 = a^2$

or $(1 + m^2)\, x^2 + 2mcx + c^2 - a^2 = 0$ ...(iii)

Let x_1, x_2 are roots of Eq. (iii), then

$$x_1 + x_2 = -\frac{2mc}{1 + m^2}$$

$\Rightarrow$ $2h = -\frac{2m}{(1 + m^2)}(k - mh)$ [from Eq. (i) and Eq. (ii)]

$\Rightarrow$ $h + m^2 h = -mk + m^2 h \quad \Rightarrow \quad h + mk = 0$

Hence, locus of (h, k) is $x + my = 0$

Aliter : Let (h, k) be the middle point of the chord $y = mx + c$ of the circle $x^2 + y^2 = a^2$

then, $T = S_1 \quad \Rightarrow \quad xh + ky = h^2 + k^2$

$$\text{slope} = -\frac{h}{k} = m \quad \Rightarrow \quad h + mk = 0$$

Hence, locus of mid-point is $x + my = 0$.

Remark

The diameter of circle always passes through the centre of the circle and perpendicular to the parallel chords.

Let circle is $x^2 + y^2 = a^2$ and parallel chord be $y = mx + c$, then equation of line $\perp$ to $y = mx + c$ is

$$my + x + \lambda = 0 \qquad \ldots(i)$$

which passes through origin (centre)

then, $0 + 0 + \lambda = 0 \quad \therefore \quad \lambda = 0$

Then, equation of diameter from Eq. (i) is $x + my = 0$.

Example 61. Find the equation of the diameter of the circle $x^2 + y^2 + 2gx + 2fy + c = 0$ which corresponds to the chord $ax + by + d = 0$.

Sol. The diameter of circle passes through the centre of the circle and perpendicular to the chord $ax + by + d = 0$ is

$$bx - ay + \lambda = 0 \qquad \ldots(i)$$

which passes through centre of circle i.e. $(-g, -f)$

Then, $-bg + af + \lambda = 0$

$\therefore$ $\lambda = bg - af$

From Eq. (i), the equation of the diameter is

$$bx - ay + bg - af = 0$$

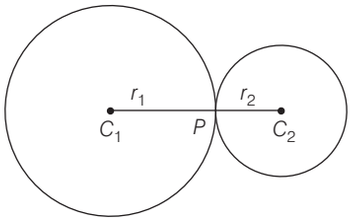
Two Circles Touching Each Other

1. When two circles touch each other externally

Then, distance between their centres = sum of their radii

i.e. $|C_1C_2| = r_1 + r_2$

In such cases, the point of contact P divides the line joining C_1 and C_2 internally in the ratio $r_1 : r_2$



$$\Rightarrow \qquad \frac{C_1P}{C_2P} = \frac{r_1}{r_2}$$

If $C_1 \equiv (x_1, y_1)$ and $C_2 \equiv (x_2, y_2)$

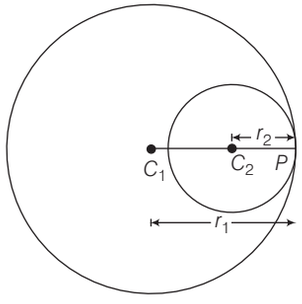
then, coordinate of P is $\left(\frac{r_1x_2 + r_2x_1}{r_1 + r_2}, \frac{r_1y_2 + r_2y_1}{r_1 + r_2} \right)$

2. When two Circles Touch each other Internally

Then, distance between their centres =Difference of their radii

i.e. $|C_1C_2| = |r_1 - r_2|$

In such cases, the point of contact P divides the line joining C_1 and C_2 externally in the ratio $r_1 : r_2$



$$\Rightarrow \qquad \frac{C_1P}{C_2P} = \frac{r_1}{r_2}$$

If $C_1 \equiv (x_1, y_1)$ and $C_2 \equiv (x_2, y_2)$

then, coordinates of P is $\left(\frac{r_1x_2 - r_2x_1}{r_1 - r_2}, \frac{r_1y_2 - r_2y_1}{r_1 - r_2} \right)$

Example 62. ***Examine if the two circles*** $x^2 + y^2 - 2x - 4y = 0$ ***and*** $x^2 + y^2 - 8y - 4 = 0$ ***touch each other externally or internally.***

Sol. Given circles are

$$x^2 + y^2 - 2x - 4y = 0 \qquad \text{...(i)}$$

and $$x^2 + y^2 - 8y - 4 = 0 \qquad \text{...(ii)}$$

Let centres and radii of circles Eqs. (i) and (ii) are represented by C_1, r_1 and C_2, r_2, respectively.

$\therefore$ $C_1 \equiv (1, 2), r_1 = \sqrt{(1 + 4)}$ or $r_1 = \sqrt{5}$

and $C_2 \equiv (0, 4), r_2 = \sqrt{0 + 16 + 4}$ or $r_2 = 2\sqrt{5}$

Now, $C_1C_2 = \sqrt{(1 - 0)^2 + (2 - 4)^2}$

$C_1C_2 = \sqrt{5} = r_2 - r_1$

Hence, the two circles touch each other internally.

Example 63. ***Prove that the circles*** $x^2 + y^2 + 2ax + c^2 = 0$ ***and*** $x^2 + y^2 + 2by + c^2 = 0$ ***touch each other, if*** $\frac{1}{a^2} + \frac{1}{b^2} = \frac{1}{c^2}$.

Sol. Given circles are

$$x^2 + y^2 + 2ax + c^2 = 0 \qquad \text{...(i)}$$

and $$x^2 + y^2 + 2by + c^2 = 0 \qquad \text{...(ii)}$$

Let C_1 and C_2 be the centres of circles Eqs. (i) and (ii), respectively and r_1 and r_2 be their radii, then

$C_1 = (-a, 0), C_2 = (0, -b)$,

$r_1 = \sqrt{(a^2 - c^2)}$, $r_2 = \sqrt{(b^2 - c^2)}$

Here, we do not find the two circles touch each other internally or externally.

For touch, $|C_1C_2| = |r_1 \pm r_2|$

or $\sqrt{(a^2 + b^2)} = |\sqrt{(a^2 - c^2)} \pm \sqrt{(b^2 - c^2)}|$

On squaring

$$a^2 + b^2 = a^2 - c^2 + b^2 - c^2 \pm 2\sqrt{(a^2 - c^2)}\sqrt{(b^2 - c^2)}$$

or $$c^2 = \pm \sqrt{a^2b^2 - c^2(a^2 + b^2) + c^4}$$

Again, squaring,

$$c^4 = a^2b^2 - c^2(a^2 + b^2) + c^4$$

or $c^2(a^2 + b^2) = a^2b^2$ or $\frac{1}{a^2} + \frac{1}{b^2} = \frac{1}{c^2}$

Common Tangents to Two Circles

Different Cases of Intersection of Two Circles :

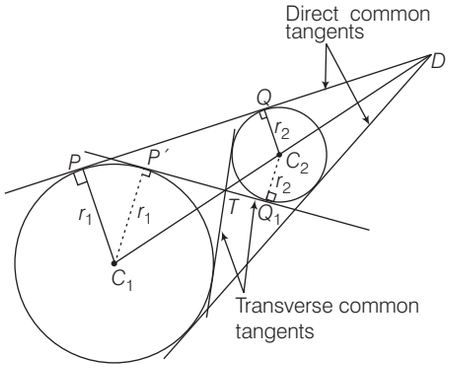
Let the two circles be

$$(x - x_1)^2 + (y - y_1)^2 = r_1^2 \qquad \text{...(i)}$$

and $$(x - x_2)^2 + (y - y_2)^2 = r_2^2 \qquad \text{...(ii)}$$

with centres $C_1(x_1, y_1)$ and $C_2(x_2, y_2)$ and radii r_1 and r_2 respectively. Then following cases may arise :

Case I : When $|C_1C_2| > r_1 + r_2$ i.e. the distance between the centres is greater than the sum of their radii.



$\because$ $C_1 \equiv (x_1, y_1)$, $C_2 \equiv (x_2, y_2)$

$\therefore$ $D \equiv \left(\dfrac{r_1x_2 - r_2x_1}{r_1 - r_2}, \dfrac{r_1y_2 - r_2y_1}{r_1 - r_2} \right) \equiv (\alpha, \beta)$ (say)

and $T \equiv \left(\dfrac{r_1x_2 + r_2x_1}{r_1 + r_2}, \dfrac{r_1y_2 + r_2y_1}{r_1 + r_2} \right)$

$\equiv (\gamma, \delta)$ (say)

How to find direct common tangents Let equation of common tangent through $D(\alpha, \beta)$ is

$$y - \beta = m(x - \alpha) \quad \text{...(i)}$$

Now, length of $\perp$ from C_1 or C_2 on Eq. (i) $= r_1$ or r_2

Then, we get two values of m.

Substituting the values of m in Eq. (i), we get two direct common tangents.

How to find transverse common tangents Let equation of common tangent through $T(\gamma, \delta)$ is

$$y - \delta = M(x - \gamma) \quad \text{...(ii)}$$

Now, length of $\perp$ from C_1 or C_2 on Eq. (i) $= r_1$ or r_2

then, we get two values of M.

Substituting the values of M in Eq. (i), we get two transverse common tangents.

Remark

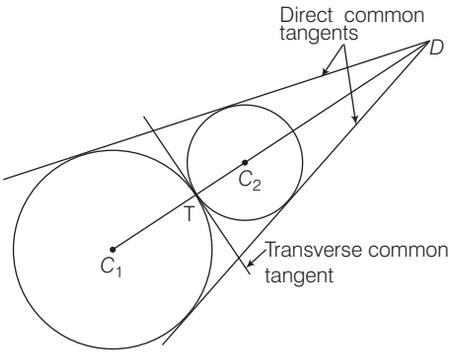
In this case circles neither cut nor touch i.e. Number of solutions of two circles is zero.

Case II : When $|C_1C_2| = r_1 + r_2$

i.e. the distance between the centres is equal to the sum of their radii.

In this case two direct common tangents are real and distinct while the transverse tangents are coincident.

How to find transverse common tangent



$\because$ Equation of circles are

$$S_1 \equiv (x - x_1)^2 + (y - y_1)^2 - r_1^2 = 0$$

and $S_2 \equiv (x - x_2)^2 + (y - y_2)^2 - r_2^2 = 0$

then, equation of common tangent is

$$S_1 - S_2 = 0$$

which is same as equation of common chord.

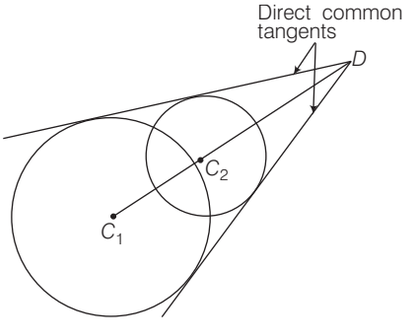
Remark

In this case circles touch at one point i.e. Number of solutions of two circles is one.

Case III : When $|r_1 - r_2| < |C_1C_2| < r_1 + r_2$

i.e. the distance between the centres is less than sum of their radii and greater than difference of their radii.

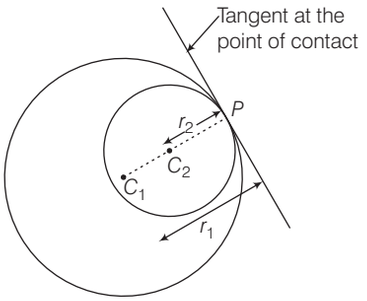
In this case two direct common tangents are real and distinct while the transverse tangents are imaginary.



Remark

In this case circles cuts at two points i.e. Number of solutions of two circles is two.

Case IV : When $|C_1C_2| = |r_1 - r_2|$, i.e. the distance between the centres is equal to the difference of their radii.



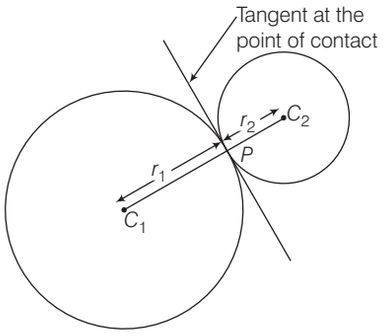
In this case two tangents are real and coincident while the other two tangents are imaginary.

If circles are represented by $S_1 = 0$ and $S_2 = 0$, then equation of common tangent is $S_1 - S_2 = 0$.

Remark

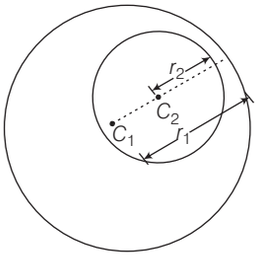
If circles touch each other externally, i.e. $|C_1C_2| = r_1 + r_2$, then equation of tangent at the point of contact is

$$S_1 - S_2 = 0$$



In this case circles touch at one point.
i.e. Number of solutions of two circles is one.

Case V : When $|C_1C_2| < |r_1 - r_2|$, i.e. the distance between the centres is less than the difference of their radii.



In this case, all the four common tangents are imaginary.

Remark

In this case circles neither cut nor touch each other i.e. Number of solution of two circles is zero.

Common Tangents to two Circles

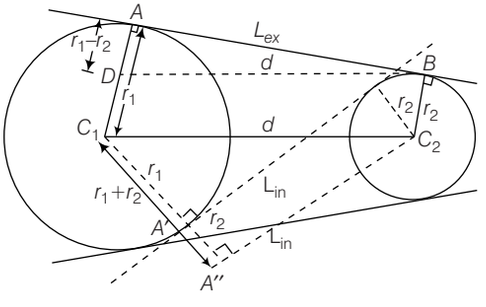
If two circles with centres C_1 and C_2 and their radii are r_1 and r_2, then

	Condition	Figure	Number of common tangents
(i)	$\|C_1C_2\| > r_1 + r_2$		4
(ii)	$\|C_1C_2\| = r_1 + r_2$		3
(iii)	$\|r_1 - r_2\| < \|C_1C_2\| < r_1 + r_2$		2
(iv)	$\|C_1C_2\| = \|r_1 - r_2\|$		1
(v)	$\|C_1C_2\| < \|r_1 - r_2\|$		0

Length of External Common Tangent and Internal Common Tangent to Two Circles

Length of external common tangent $L_{ex} = \sqrt{d^2 - (r_1 - r_2)^2}$

and length of internal common tangent



$L_{in} = \sqrt{d^2 - (r_1 + r_2)^2}$ (Applicable only when $d > r_1 + r_2$)

where, d is the distance between the centres of two circles and r_1, r_2 are the radii of two circles, when $|C_1C_2| = d$.

Angle between Direct Common Tangents (DCT) and Transverse Common Tangents (TCT)

Case I : If $d > r_1 + r_2$, then

Angle between DCT $= 2\sin^{-1}\left(\frac{|r_1 - r_2|}{d}\right)$

And angle between TCT $= 2\sin^{-1}\left(\frac{r_1 + r_2}{d}\right)$

Case II : If $d = r_1 + r_2$, then

angle between DCT $= 2\sin^{-1}\left(\frac{|r_1 - r_2|}{r_1 + r_2}\right)$

and angle between TCT $= \pi$

Case III : If $|r_1 - r_2| < d < r_1 + r_2$, then

angle between DCT $= 2\sin^{-1}\left(\frac{|r_1 - r_2|}{d}\right)$

Here, transverse common tangents are not possible .

Case IV : If $d = |r_1 - r_2|$

Angle between DCT $= \pi$

Here, transverse common tangents are not possible.

Case V : If $d < |r_1 - r_2|$

Here, tangents are not possible.

Example 64. Find all the common tangents to the circles

$x^2 + y^2 - 2x - 6y + 9 = 0$ and $x^2 + y^2 + 6x - 2y + 1 = 0$.

Sol. The given circles are

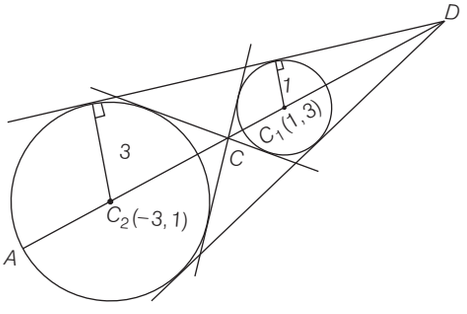
$$x^2 + y^2 - 2x - 6x + 9 = 0$$

$$\Rightarrow \quad (x-1)^2 + (y-3)^2 = 1 \qquad \ldots(i)$$

and $\quad x^2 + y^2 + 6x - 2y + 1 = 0$

$$\Rightarrow \quad (x+3)^2 + (y-1)^2 = 9 \qquad \ldots(ii)$$

Centres and radii of circles Eq. (i) and Eq. (ii) are



$C_1(1, 3), r_1 = 1$

and $C_2(-3, 1), r_2 = 3$ respectively.

$\therefore \quad C_1C_2 = \sqrt{(16 + 4)} = 2\sqrt{5}$

$\therefore \quad C_1C_2 > r_1 + r_2$

Hence, the circles do not intersect to each other.

The direct common tangents meet AB produced at D, then point D will divide C_2C_1 in the ratio 3 : 1 (externally).

Coordinates of D are $\left(\frac{3(1) - 1(-3)}{3 - 1}, \frac{3(3) - 1(1)}{3 - 1}\right)$ or (3, 4)

and the point C divide C_2C_1 in the ratio 3 : 1 (internally)

then coordinates of C are $\left(\frac{3(1) + 1(-3)}{3 + 1}, \frac{3(3) + 1(1)}{3 + 1}\right)$ or

(0, 5/2)

Direct tangents : Any line through (3, 4) is

$$y - 4 = m(x - 3)$$

$$\Rightarrow \quad mx - y + 4 - 3m = 0 \qquad \ldots(i)$$

Apply the usual condition of tangency to any of the circle

$$\frac{m - 3 + 4 - 3m}{\sqrt{m^2 + 1}} = \pm 1$$

$$\Rightarrow \quad (-2m + 1)^2 = m^2 + 1$$

$$\Rightarrow \quad 3m^2 - 4m = 0$$

$$\Rightarrow \quad m = 0, m = 4/3$$

$\therefore$ Equations of direct common tangents are

$$y = 4 \quad \text{and} \quad 4x - 3y = 0$$

Transverse tangents : Any line through $C\ (0,\ 5/2)$ is

$$y - 5/2 = mx$$

or $\quad mx - y + 5/2 = 0 \qquad \ldots(ii)$

Apply the usual condition of tangency to any of the circle

$$\therefore \quad \frac{m \cdot 1 - 3 + 5/2}{\sqrt{m^2 + 1}} = \pm 1$$

$$\Rightarrow \quad m^2 + \frac{1}{4} - m = m^2 + 1$$

$$\Rightarrow \quad 0 \cdot m^2 - m - \frac{3}{4} = 0$$

$$\therefore \quad m = \infty \quad \text{and} \quad m = -3/4$$

Hence, equations of transverse tangents are

$$x = 0 \quad \text{and} \quad 3x + 4y - 10 = 0$$

Example 65. Show that the common tangents to the circles $x^2 + y^2 - 6x = 0$ and $x^2 + y^2 + 2x = 0$ form an equilateral triangle.

Sol. The given circles are

$$x^2 + y^2 - 6x = 0$$

or $\quad (x-3)^2 + (y-0)^2 = 9 \qquad \ldots(i)$

and $\quad x^2 + y^2 + 2x = 0$

or $\quad (x+1)^2 + (y-0)^2 = 1 \qquad \ldots(ii)$

Centres and radii of circles Eqs. (i) and (ii) are $C_1(3, 0), r_1 = 3$ and $C_2(-1, 0), r_2 = 1$, respectively.

$\because \quad C_1C_2 = \sqrt{[3 - (-1)]^2 + 0} = 4$

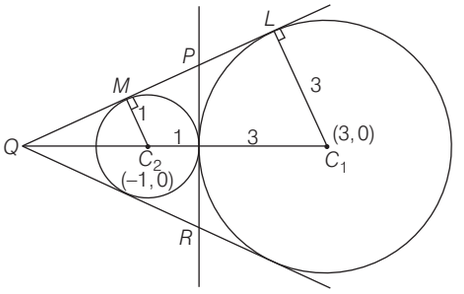
$\therefore \quad C_1C_2 = r_1 + r_2$

Hence, the two circles touch each other externally, therefore, there will be three common tangents. Equation of the common tangent at the point of contact is $S_1 - S_2 = 0$

$\Rightarrow \quad (x^2 + y^2 - 6x) - (x^2 + y^2 + 2x) = 0$

$\Rightarrow \quad -8x = 0$

$\therefore \quad x = 0$



Let the coordinates of Q be (h, k), then

$$\frac{QC_2}{QC_1} = \frac{C_2M}{C_1L} = \frac{1}{3}$$

$\therefore \quad QC_2 : QC_1 = 1 : 3$

$\therefore \quad h = \dfrac{1\cdot(3) - 3\cdot(-1)}{1-3} = -3 \quad \text{and} \quad k = 0$

$\therefore \quad Q \equiv (-3, 0)$

Equation of line passing through $Q(-3, 0)$ is

$$y - 0 = m(x + 3)$$

or $\quad mx - y + 3m = 0 \quad \ldots(iii)$

where, m is the slope of direct tangents since Eq. (iii) is the common tangent (direct) of the circles Eqs. (i) and (ii), then Length of perpendicular from centre of Eq. (ii) i.e. $(-1, 0)$ to the Eq. (iii) = radius of circle Eq. (ii)

$$\Rightarrow \quad \frac{|-m - 0 + 3m|}{\sqrt{m^2 + 1}} = 1 \quad \text{or} \quad 4m^2 = m^2 + 1$$

$$\Rightarrow \quad 3m^2 = 1$$

$$\therefore \quad m = \pm \frac{1}{\sqrt{3}}$$

From Eq. (iii), common tangents are (direct)

$$y = \frac{x}{\sqrt{3}} + \sqrt{3} \quad \text{and} \quad y = -\frac{x}{\sqrt{3}} - \sqrt{3}$$

Hence, all common tangents are $\quad x = 0 \quad \ldots(iv)$

$$y = \frac{x}{\sqrt{3}} + \sqrt{3} \quad \ldots(v)$$

and $\quad y = -\dfrac{x}{\sqrt{3}} - \sqrt{3} \quad \ldots(vi)$

Let P,Q,R be the point of intersection of lines Eqs.(iv), (v); (v), (vi) and (iv), (vi) respectively, then

$$P \equiv (0, \sqrt{3}); Q \equiv (-3, 0) \quad \text{and} \quad R \equiv (0, -\sqrt{3})$$

Now, $\quad PQ = QR = RP = 2\sqrt{3}$

Hence, ΔPQR is an equilateral triangle thus common tangents form an equilateral triangle.

Example 66. Find the number of common tangents to the circles $x^2 + y^2 - 8x + 2y + 8 = 0$ and $x^2 + y^2 - 2x - 6y - 15 = 0$.

Sol. For $x^2 + y^2 - 8x + 2y + 8 = 0$

$$C_1 \equiv (4, -1), r_1 = \sqrt{(16 + 1 - 8)} = 3$$

and for $x^2 + y^2 - 2x - 6y - 15 = 0$

$$C_2 \equiv (1, 3), r_2 = \sqrt{(1 + 9 + 15)} = 5$$

Now, $\quad |C_1C_2|$ = Distance between centres

$$= \sqrt{(4-1)^2 + (-1-3)^2} = 5$$

and $\quad r_1 + r_2 = 3 + 5 = 8$

$$|r_1 - r_2| = |3 - 5| = 2$$

or $\quad |r_1 - r_2| < |C_1C_2| < r_1 + r_2$

Hence, the two circles intersect at two distinct points. Therefore, two tangents can be drawn.

Example 67. Find the lengths of external and internal common tangents and also find the angle between external common tangents and internal common tangents of the circles $x^2 + y^2 + 2x - 8y + 13 = 0$ and $x^2 + y^2 - 8x - 2y + 8 = 0$.

Sol. The given circles are $x^2 + y^2 + 2x - 8y + 13 = 0$

$$\Rightarrow \quad (x+1)^2 + (y-4)^2 = 2^2 \quad \ldots(i)$$

and $\quad x^2 + y^2 - 8x - 2y + 8 = 0$

$$\Rightarrow \quad (x-4)^2 + (y-1)^2 = 3^2 \quad \ldots(ii)$$

Centres and radii of circles Eqs. (i) and (ii) are $C_1(-1, 4)$, $r_1 = 2$ and $C_2(4, 1)$, $r_2 = 3$ respectively.

$\therefore \quad |C_1C_2| = d = \sqrt{(25 + 9)} = \sqrt{34}$

$\Rightarrow \quad d > r_1 + r_2$

Hence, the circles do not intersect to each other.

$\therefore \quad L_{ex} = \sqrt{d^2 - (r_1 - r_2)^2} = \sqrt{34 - 1} = \sqrt{33}$

and $\quad L_{in} = \sqrt{d^2 - (r_1 + r_2)^2} = \sqrt{(34 - 25)} = 3$

Angle between external common tangents

$$= 2\sin^{-1}\left(\frac{|r_1 - r_2|}{d}\right) = 2\sin^{-1}\left(\frac{1}{\sqrt{33}}\right)$$

and angle between internal common tangent

$$= 2\sin^{-1}\left(\frac{r_1 + r_2}{d}\right) = 2\sin^{-1}\left(\frac{5}{\sqrt{33}}\right)$$

Common Chord of Two Circles

The chord joining the points of intersection of two given circles is called their common chord.

Theorem : The equation of common chord of two circles

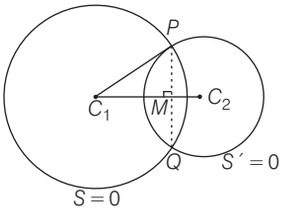
$$S \equiv x^2 + y^2 + 2gx + 2fy + c = 0$$

and $S' \equiv x^2 + y^2 + 2g'x + 2f'y + c' = 0$

is $2x(g - g') + 2y(f - f') + c - c' = 0$

i.e. $S - S' = 0$

Proof : $\because$ $S = 0$ and $S' = 0$ be two intersecting circles.



Then, $S - S' = 0$ or

$2x(g - g') + 2y(f - f') + c - c' = 0$

is a first degree equation in x and y.

So, it represent a straight line. Also, this equation satisfied by the intersecting points of two given circles $S = 0$ and $S' = 0$.

Hence, $S - S' = 0$ represents the common chord of circles $S = 0$ and $S' = 0$

Length of common chord :

We have, $PQ = 2(PM)$ ($\because M$ is mid-point of PQ)

$$= 2\sqrt{\{(C_1P)^2 - (C_1M)^2\}}$$

where, C_1P = radius of the circle ($S = 0$)

and $C_1M =$ length of perpendicular from C_1 on common chord PQ.

Corollary 1 : The common chord PQ of two circles becomes of the maximum length when it is a diameter of the smaller one between them.

Corollary 2 : Circle on the common chord a diameter, then centre of the circle passing through P and Q lie on the common chord of two circles i.e.

$$S - S' = 0$$

Corollary 3 : If the length of common chord is zero, then the two circles touch each other and the common chord becomes the common tangent to the two circles at the common point of contact.

Example 68. *Prove that the length of the common chord of the two circles :*

$(x-a)^2 + (y-b)^2 = c^2$

and $(x-b)^2 + (y-a)^2 = c^2$ is $\sqrt{4c^2 - 2(a-b)^2}$.

Find also the condition when the given circles touch.

Sol. The equation of circles are

$$S_1 \equiv (x-a)^2 + (y-b)^2 - c^2 = 0 \quad \text{...(i)}$$

and $$S_2 \equiv (x-b)^2 + (y-a)^2 - c^2 = 0 \quad \text{...(ii)}$$

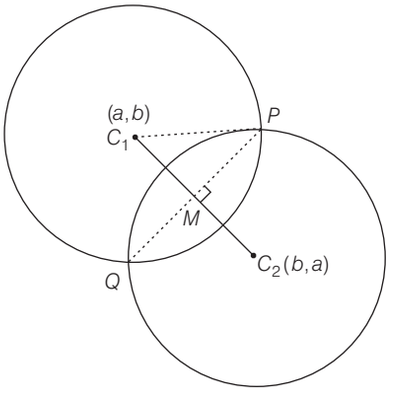
then equation of common chord is $S_1 - S_2 = 0$

$\Rightarrow$ $(x-a)^2 - (x-b)^2 + (y-b)^2 - (y-a)^2 = 0$

or $(2x - a - b)(-a + b) + (2y - b - a)(-b + a) = 0$

$\Rightarrow$ $2x - a - b - 2y + b + a = 0$

$\Rightarrow$ $x - y = 0$



Now, C_1M = Length of perpendicular from C_1 (a, b) on $PQ(x - y = 0) = \dfrac{|a-b|}{\sqrt{2}}$

and C_1P = radius of the circle Eq. (i) = c

$\therefore$ In ΔPC_1M, $PM = \sqrt{(PC_1)^2 - (C_1M)^2}$

$$= \sqrt{c^2 - \frac{(a-b)^2}{2}}$$

$\therefore$ $$PQ = 2PM = 2\sqrt{c^2 - \frac{(a-b)^2}{2}}$$

$$= \sqrt{4c^2 - 2(a-b)^2}$$

Also, when the circles touch, then chord PQ becomes the tangent and $PQ = 0$.

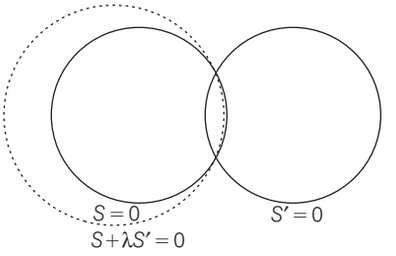
$\therefore$ The condition of tangency is $4c^2 - 2(a-b)^2 = 0$.

i.e. $2c^2 = (a-b)^2$

Family of Circles

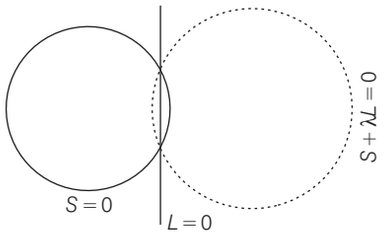
1. The equation of the family of circles passing through the point of intersection of two given circles $S = 0$ and $S' = 0$ is given as

$$S + \lambda S' = 0 \quad (\text{where, } \lambda \text{ is a parameter, } \lambda \neq -1)$$



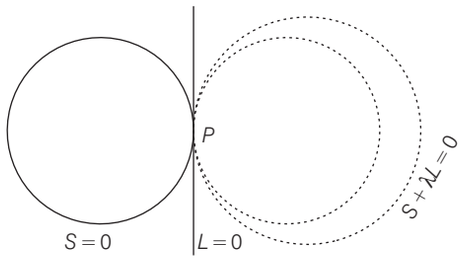
2. The equation of the family of circles passing through the point of intersection of circle $S=0$ and a line $L=0$ is given as

$$S+\lambda L=0 \qquad \text{(where, } \lambda \text{ is a parameter)}$$

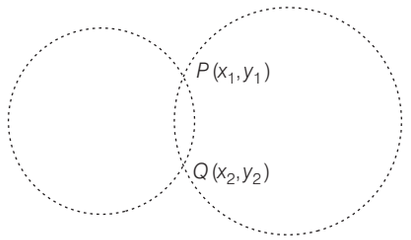


3. The equation of the family of circles touching the circle $S=0$ and the line $L=0$ at their point of contact P is

$$S+\lambda L=0 \qquad \text{(where, } \lambda \text{ is a parameter)}$$



4. The equation of a family of circles passing through two given points $P(x_1, y_1)$ and $Q(x_2, y_2)$ can be written in the form



$$(x-x_1)(x-x_2)+(y-y_1)(y-y_2)+\lambda\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix}=0$$

(where, λ is a parameter)

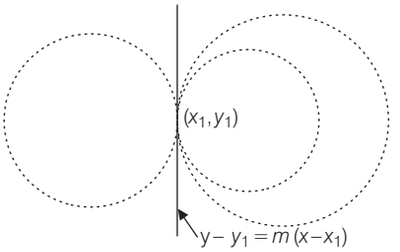
5. The equation of family of circles which touch $y-y_1=m(x-x_1)$ at (x_1, y_1) for any finite m is

$$(x-x_1)^2+(y-y_1)^2+\lambda\{(y-y_1)-m(x-x_1)\}=0$$

and if m is infinite, the family of circles is

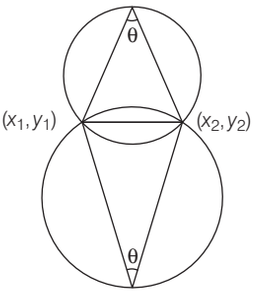
$$(x-x_1)^2+(y-y_1)^2+\lambda(x-x_1)=0$$

(where, λ is a parameter)



6. Equation of the circles given in diagram are

$$(x-x_1)(x-x_2)+(y-y_1)(y-y_2)\pm\cot\theta\{(x-x_1)(y-y_2)-(x-x_2)(y-y_1)\}=0$$



Example 69. ***Find the equation of the circle passing through*** (1, 1) ***and the points of intersection of the circles***

$x^2+y^2+13x-3y=0$ and $2x^2+2y^2+4x-7y-25=0$.

Sol. The given circles are

$$x^2+y^2+13x-3y=0 \qquad \text{...(i)}$$

and $2x^2+2y^2+4x-7y-25=0$

or $$x^2+y^2+2x-\frac{7}{2}y-\frac{25}{2}=0 \qquad \text{...(ii)}$$

Equation of any circle passing through the point of intersection of the circles Eqs. (i) and (ii) is

$$(x^2+y^2+13x-3y)+\lambda\left(x^2+y^2+2x-\frac{7}{2}y-\frac{25}{2}\right)=0 \quad \text{...(iii)}$$

Its passes through (1, 1), then

$$(1+1+13-3)+\lambda\left(1+1+2-\frac{7}{2}-\frac{25}{2}\right)=0$$

$\Rightarrow \quad 12+\lambda(-12)=0 \ \therefore \ \lambda=1$

Substituting the value of λ in Eq. (iii), the required equation is

$$x^2+y^2+13x-3y+x^2+y^2+2x-\frac{7}{2}y-\frac{25}{2}=0$$

$\Rightarrow \quad 2x^2+2y^2+15x-\frac{13}{2}y-\frac{25}{2}=0$

$\Rightarrow \quad 4x^2+4y^2+30x-13y-25=0$

Example 70. Find the equation of the circle passing through the point of intersection of the circles $x^2 + y^2 - 6x + 2y + 4 = 0$, $x^2 + y^2 + 2x - 4y - 6 = 0$ and with its centre on the line $y = x$.

Sol. Equation of any circle through the points of intersection of given circles is

$$(x^2 + y^2 - 6x + 2y + 4) + \lambda (x^2 + y^2 + 2x - 4y - 6) = 0$$

$$\Rightarrow \quad x^2(1 + \lambda) + y^2 (1 + \lambda) - 2x (3 - \lambda) + 2y (1 - 2\lambda) + (4 - 6\lambda) = 0$$

$$\text{or} \quad x^2 + y^2 - \frac{2x(3 - \lambda)}{(1 + \lambda)} + \frac{2y(1 - 2\lambda)}{(1 + \lambda)} + \frac{(4 - 6\lambda)}{(1 + \lambda)} = 0 \qquad ...(i)$$

Its centre $\left\{\frac{3 - \lambda}{1 + \lambda}, \frac{2\lambda - 1}{1 + \lambda}\right\}$ lies on the line $y = x$

$$\text{then} \quad \frac{2\lambda - 1}{1 + \lambda} = \frac{3 - \lambda}{1 + \lambda} \Rightarrow \lambda \neq -1$$

$$\therefore \quad 2\lambda - 1 = 3 - \lambda \text{ or } 3\lambda = 4$$

$$\therefore \quad \lambda = 4/3$$

$\therefore$ Substituting the value of $\lambda = 4/3$ in Eq. (i), we get the required equation is

$$7x^2 + 7y^2 - 10x - 10y - 12 = 0$$

Example 71. ***Find the equation of the circle passing through the points of intersection of the circles*** $x^2 + y^2 - 2x - 4y - 4 = 0$ ***and*** $x^2 + y^2 - 10x - 12y + 40 = 0$ ***and whose radius is 4.***

Sol. Equation of the any circle through the points of intersection of given circles is

$$(x^2 + y^2 - 2x - 4y - 4) + \lambda(x^2 + y^2 - 10x - 12y + 40) = 0$$

$$\Rightarrow \quad x^2(1 + \lambda) + y^2(1 + \lambda) - 2x(1 + 5\lambda) - 2y(2 + 6\lambda) - 4 + 40\lambda = 0$$

$$\text{or} \quad x^2 + y^2 - 2x\frac{(1 + 5\lambda)}{(1 + \lambda)} - 2y\frac{(2 + 6\lambda)}{(1 + \lambda)} + \frac{(40\lambda - 4)}{(1 + \lambda)} = 0 \qquad ...(i)$$

Its radius

$$\sqrt{\left(\frac{1 + 5\lambda}{1 + \lambda}\right)^2 + \left(\frac{2 + 6\lambda}{1 + \lambda}\right)^2 - \left(\frac{40\lambda - 4}{1 + \lambda}\right)} = 4 \qquad \text{(given)}$$

$$\Rightarrow \quad \frac{(1 + 5\lambda)^2 + (2 + 6\lambda)^2 - (40\lambda - 4)(1 + \lambda)}{(1 + \lambda)^2} = 16$$

$$\Rightarrow \quad 5\lambda^2 - 34\lambda - 7 = 0$$

$$\text{or} \quad (\lambda - 7)(5\lambda + 1) = 0$$

$$\therefore \quad \lambda = 7 \quad \text{or} \quad \lambda = -\frac{1}{5}$$

Substituting the values of λ in Eq. (i), the required circles are

$$2x^2 + 2y^2 - 18x - 22y + 69 = 0$$

and

$$x^2 + y^2 - 2y - 15 = 0$$

Example 72. Find the equation of the circle passing through points of intersection of the circle $x^2 + y^2 - 2x - 4y + 4 = 0$ and the line $x + 2y = 4$ which touches the line $x + 2y = 0$.

Sol. Equation of any circle through points of intersection of the given circle and the line is

$$(x^2 + y^2 - 2x - 4y + 4) + \lambda(x + 2y - 4) = 0$$

$$\text{or} \quad x^2 + y^2 + (\lambda - 2)x + (2\lambda - 4)y + 4(1 - \lambda) = 0 \qquad ...(i)$$

It will touch the line $x + 2y = 0$, then solution of Eq. (i) and $x = -2y$ be unique.

Hence, the roots of the equation

$$(-2y)^2 + y^2 + (\lambda - 2)(-2y) + (2\lambda - 4)y + 4(1 - \lambda) = 0$$

$$\text{or} \quad 5y^2 + 4(1 - \lambda) = 0$$

must be equal.

Then, $0 - 4 \cdot 5 \cdot 4(1 - \lambda) = 0$ or $1 - \lambda = 0$ or $\lambda = 1$

From Eq. (i), the required circle is $x^2 + y^2 - x - 2y = 0$

Example 73. Find the circle whose diameter is the common chord of the circles $x^2 + y^2 + 2x + 3y + 1 = 0$ and $x^2 + y^2 + 4x + 3y + 2 = 0$.

Sol. Given circles are

$$S \equiv x^2 + y^2 + 2x + 3y + 1 = 0$$

and

$$S' \equiv x^2 + y^2 + 4x + 3y + 2 = 0$$

Hence, their common chord is $S - S' = 0$

$$\Rightarrow \quad -2x - 1 = 0 \quad \text{or} \quad 2x + 1 = 0 \qquad ...(i)$$

Now, the required circle must pass through the point of intersection of S and S'.

Hence, its equation is $S + \lambda S' = 0$

$$\Rightarrow \quad (x^2 + y^2 + 2x + 3y + 1) + \lambda (x^2 + y^2 + 4x + 3y + 2) = 0$$

$$\Rightarrow \quad x^2 (1 + \lambda) + y^2 (1 + \lambda) + 2x (1 + 2\lambda) + 3y (1 + \lambda) + (1 + 2\lambda) = 0$$

$$\text{or} \quad x^2 + y^2 + 2x \frac{(1 + 2\lambda)}{(1 + \lambda)} + 3y + \frac{(1 + 2\lambda)}{(1 + \lambda)} = 0 \qquad ...(ii)$$

Its centre is $\left(-\frac{1 + 2\lambda}{1 + \lambda}, -\frac{3}{2}\right)$

But from Eq. (i), $2x + 1 = 0$ is a diameter of this circle.

Hence, its centre must lie on this line

$$\therefore \quad -2\left(\frac{1 + 2\lambda}{1 + \lambda}\right) + 1 = 0$$

$$\Rightarrow \quad -2 - 4\lambda + 1 + \lambda = 0$$

$$\Rightarrow \quad -1 - 3\lambda = 0$$

$$\therefore \quad \lambda = -\frac{1}{3}$$

Hence, from Eq. (ii), the required circle is

$$2x^2 + 2y^2 + 2x + 6y + 1 = 0$$

Example 74. If two curves, whose equations are $ax^2+2hxy+by^2+2gx+2fy+c=0$ and $a'x^2+2h'xy+b'y^2+2g'x+2f'y+c'=0$ intersect in four concyclic points, prove that $\frac{a-b}{h}=\frac{a'-b'}{h'}$

Sol. The equation of family of curves passing through the points of intersection of two curves is

$$(ax^2+2hxy+by^2+2gx+2fy+c)+\lambda(a'x^2+2h'xy+b'y^2+2g'x+2f'y+c')=0$$

or $$(a+\lambda a')x^2+2xy(h+h'\lambda)+(b+\lambda b')y^2+2x(g+\lambda g')+2y(f+\lambda f')+(c+\lambda c')=0 \quad ...(i)$$

Four concyclic points lie on a circle, then Eq. (i) represents a circle. Then,

coefficient of x^2 = coefficient of y^2 and coefficient of $xy=0$

$\Rightarrow$ $a+\lambda a'=b+\lambda b'$

or $(a-b)=-\lambda(a'-b')$ ...(ii)

and $2(h+h'\lambda)=0$

or $\lambda=-\frac{h}{h'}$ ...(iii)

Substituting the value of λ from Eq. (iii) in Eq. (ii), then

$$\frac{a-b}{h}=\frac{a'-b'}{h'}$$

Exercise for Session 6

1. Circles $x^2+y^2-2x-4y=0$ and $x^2+y^2-8y-4=0$

(a) touch each other internally
(b) touch each other externally
(c) cuts each other at two points
(d) None of these

2. The number of common tangents that can be drawn to the circles $x^2+y^2-4x-6y-3=0$ and $x^2+y^2+2x+2y+1=0$ is

(a) 1 (b) 2 (c) 3 (d) 4

3. If one of the circles $x^2+y^2+2ax+c=0$ and $x^2+y^2+2bx+c=0$ lies within the other, then

(a) $ab>0, c>0$
(b) $ab>0,\ c<0$
(c) $ab<0,\ c>0$
(d) $ab<0,\ c<0$

4. The condition that the circle $(x-3)^2+(y-4)^2=r^2$ lies entirely within the circle $x^2+y^2=R^2$ is

(a) $R+r\le 7$
(b) $R^2+r^2<49$
(c) $R^2-r^2<25$
(d) $R-r>5$

5. The circles whose equations are $x^2+y^2+c^2=2ax$ and $x^2+y^2+c^2-2by=0$ will touch one another externally, if

(a) $\frac{1}{b^2}+\frac{1}{c^2}=\frac{1}{a^2}$
(b) $\frac{1}{c^2}+\frac{1}{a^2}=\frac{1}{b^2}$
(c) $\frac{1}{a^2}+\frac{1}{b^2}=\frac{1}{c^2}$
(d) $\frac{1}{b^2}+\frac{1}{c^2}=\frac{2}{a^2}$

6. Two circles with radii r_1 and r_2, $r_1>r_2\ge 2$, touch each other externally. If θ be the angle between the direct common tangents, then

(a) $\theta=\sin^{-1}\left(\frac{r_1+r_2}{r_1-r_2}\right)$
(b) $\theta=2\sin^{-1}\left(\frac{r_1-r_2}{r_1+r_2}\right)$
(c) $\theta=\sin^{-1}\left(\frac{r_1-r_2}{r_1+r_2}\right)$
(d) None of these

7. The circles $x^2+y^2-10x+16=0$ and $x^2+y^2=r^2$ intersect each other in two distinct points if

(a) $r<2$ (b) $r>8$ (c) $2<r<8$ (d) $2\le r\le 8$

8. If the circle $x^2+y^2+4x+22y+c=0$ bisects the circumference of the circle $x^2+y^2-2x+8y-d=0$, then $c+d$ is equal to

(a) 40 (b) 50 (c) 60 (d) 70

9. Two circles $x^2 + y^2 = 6$ and $x^2 + y^2 - 6x + 8 = 0$ are given. Then, the equation of the circle through their points of intersection and the point (1, 1) is

(a) $x^2 + y^2 - 6x + 4 = 0$ (b) $x^2 + y^2 - 3x + 1 = 0$

(c) $x^2 + y^2 - 4x + 2 = 0$ (d) $x^2 + y^2 - 2x + 1 = 0$

10. The equation of the circle described on the common chord of the circles $x^2 + y^2 + 2x = 0$ and $x^2 + y^2 + 2y = 0$ as diameter is

(a) $x^2 + y^2 + x - y = 0$ (b) $x^2 + y^2 - x + y = 0$

(c) $x^2 + y^2 - x - y = 0$ (d) $x^2 + y^2 + x + y = 0$

11. The equation of the diameter of the circle $3(x^2 + y^2) - 2x + 6y - 9 = 0$ which is perpendicular to the line $2x + 3y = 12$ is

(a) $3x - 2y + 3 = 0$ (b) $3x - 2y - 3 = 0$

(c) $3x - 2y + 1 = 0$ (d) $3x - 2y - 1 = 0$

12. If the curves $ax^2 + 4xy + 2y^2 + x + y + 5 = 0$ and $ax^2 + 6xy + 5y^2 + 2x + 3y + 8 = 0$ intersect at four concyclic points, then the value of a is

(a) -6 (b) -4 (c) 4 (d) 6

13. Find the equation of the circle passing through the points of intersection of $x^2 + y^2 + 13x - 3y = 0$ and $2x^2 + 2y^2 + 4x - 7y - 25 = 0$ and the point (1, 1).

14. Show that the common chord of the circles $x^2 + y^2 - 6x - 4y + 9 = 0$ and $x^2 + y^2 - 8x - 6y + 23 = 0$ pass through the centre of the second circle and find its length.
